AMERICAN BEE JOURNAL.

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. X.

CHICAGO, JANUARY, 1874.

No. 1.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

Translated for the American Bee Journal.

Bee-Keeping in the Valley of the Weser.

The valley of the Weser, in the neighborhood of Rinteln, is admitted by every stranger to be one of the most beautiful and favored spots in Germany, and yet bee culture, especially rational bee culture, is so much neglected, that an improvement is greatly to be desired.

In Rinteln, a town of over 5000 inhabitants, there are not, leaving out my apiary, fifteen swarms! That more bees are not kept here is to be wondered at, as nearly every house has a large garden attached, and most of the owners of houses are also farmers to a greater or less extent. And the open country could hardly be better adapted to bee culture. The largest apiaries are found five or six leagues from here, in the neighborhood of Stadhagen and Rodenberg. The bee-keepers of that locality wander about with the bees in the Heath. The Weser Valley here, however, having an early yield of honey which is unsurpassed, has for years been visited every Spring by bee-keepers with from 200 to 300 stocks in straw baskets. The apiarian remains here until the blossoming of the flowers in the Heath. The Spring honey harvest here is wonderful. Then comes the blossoming of the fruit trees, of which there are a great abundance in the gardens, and along the roadway, giving an abundance of honey and pollen; then follows the harvest from the seed fields, which is usually very abundant. Nowhere are there greater quantities of

rape raised than here. Along the Weser are found many meadows, rich in soil and producing much honey. Boundless fields are covered with the most beautiful flowers. On the heavy grounds beans are cultivated; and along the roadways, etc., millet grows and blossoms until late in Fall.

I can this year report the honey yield to have been very good, because in the Summer fruit fields there was a great quantity of wild heather, so that they appeared as yellow as if covered with rape blossoms. Thus, it is no wonder the bees had no more room in which to store their honey.* I observed that the queen stopped laying for upwards of three weeks since, just as soon as the cells were built, and filled with honey. In such years those stocks are of the greatest advantage, which are the most populous. It is true we receive somewhat later pasturage from the forests, yet our main dependence is upon the previously mentioned plants. This year I learned the difference between the German and Italian bees. The latter are much earlier with their brood, and are, therefore, best suited for localities like this. For many years I have observed that the German bees only become strong and populous when the honey harvest is on the decline, while the reverse is the case with the Italians.

I have the pleasure of being the first person in this neighborhood to adopt the movable comb system, and also to introduce Italian bees.

I secured the Italian race without much trouble. I engaged a queen in the Autumn of 1871, from Herr Henric of Nierburg, and received a beautiful specimen with a few worker bees. These I introduced in the usual way into a stock of German bees, which I had eight days previously unqueened. Before introducing

*Here was a chance to use the honey emptying machine.

the queen I carefully examined the hive, and destroyed the queen-cells that had been begun. The queen was warmly received, and in a few days the bees released her of their own accord. The stock wintered well, and was one of the best of my stocks. Towards Spring I found many young Italians. That Summer I made from it five new swarms. My greatest care was, to have these beautiful colored queens purely mated. I separated them half a league from the common bees, and attained my object. I could last Summer have raised a large number of queens, but I wished first to test the virtues of the race. I wintered six Italian stocks. As these made their appearance this Spring to my full satisfaction, towards June I made ten artificial swarms, some having most beautiful queens.

The mother swarm I divided three times, and yet it swarmed four times. Through these after swarms I received a number of queens which I substituted for common ones. I do not desire to remove all the common queens, yet it would be possible for me this Summer to have Italianized all my stocks.

It is with great sadness that I see B culture so much neglected in this favorable locality.

WILHELM BORNEMANN.

Rinteln, July 10, 1873.

For The American Bee Journal.

Bee Anomalies.

One pleasant afternoon last August, as I was standing near one of my nucleus hives, I observed a commotion at the entrance, and soon saw that the naughty little fellows had it in their heads to leave their home. I let them have their own way, contenting myself with observing their actions. They soon settled on a bush near by. After requesting my assistant to hive them in a small box, I went to the deserted hive and opened it, and found plenty of brood and honey, satisfying myself that they did not leave for the want of these. As the hive was well shaded, they did not desert because it was too hot.

I put them immediately back into the hive from which they came; but I had no sooner done this, than another nucleus quit its hive and settled on the same spot

that the first one did. This I also put back.

Having some curiosity as to how the "pesky chaps" in the first hive were behaving themselves, I opened it and found them engaged in killing their queen. As this queen had mis-mated with a black drone, I let them alone, and in an hour's time they had her carried out "a corpse."

From hive No. 1, I went to hive No. 2, and found them treating their queen in a similar manner. As the progeny of the queen was pure, I caged her, and kept her confined until their fiery ardor cooled down. She was then kindly received.

I can only account for the strange conduct of these bees, by supposing that the honey harvest at the time they became discouraged to leave; and as I put it to their will, they became angry with their queen, and determined to raise another.

Have of these cases any other similar cases?

In my colony of *Apis mellifera* I found a queen which I had taken from a colony, and which I found to be a usurper. I found her on the next day, in the act of laying. As my eye caught sight of her, I concluded at once that she was a usurper, and had displaced my old, familiar queen (sixteen months old, with one wing clipped). But on looking on the other side of the card of comb, I found my old queen, occupied with her usual pastime of laying, and looking as though she was perfectly at home. I caged the would-be usurper, and gave her to a colony from which I had taken a queen. My queen with the clipped wing seems to be as prolific as ever. As far as I can see, shows no signs of diminished vigor. This case, while it establishes no rule, proves that it is possible for two laying queens to be in one hive at the same time peaceably performing their functions.

J. P. H. E.

Augusta, Ga.

Prof. Gerstocker, of Berlin, Prussia, writes: "The Egyptian bee is nearly a third larger than the common bee. The abdomen resembles that of the Italian but the color is yellow, the downy hairs of the thorax are whitish."

The Honey Extractor.

AN ADDRESS BY A. I. ROOT, OF MEDINA, OHIO,
BEFORE THE MICHIGAN BEE-KEEPERS' ASSOCIATION.

Mr. President, Ladies and Gentlemen—
We have been requested to address you on the "Honey Extractor, its use and benefits," but before so doing would remark, that should we here repeat much that has been gone over before, we hope to be excused on the ground that much repetition seems to be necessary to induce bee-keepers to give the credit that is due to this implement of the apiary.

About the year 1856, we, as an experiment, moved a small colony from its stand in the month of June, and placed in its stead a hive containing only empty combs with a caged fertile queen. On releasing the queen, forty-eight hours afterward, we were so astonished at the appearance of things that we weighed the hive, bees and all, and found that it had gained in the interval, thirty pounds.

The question at once arose whether they would not go on increasing at the rate of fifteen pounds per day, for some days to come, were they furnished with facilities in the shape of empty combs as fast as they were filled, for none of our other colonies, though equally strong, had made any such increase in the same time.

Shortly afterward, E. Van Slyke, in the *Bee-keepers' Gazette*, solved the problem for us by his notice of the German Centrifugal Machine, and soon we had hastily extemporized a rude tin can with revolving frame inside, made of iron wire and hair-cloth. A brief trial of this rude machine, in a half finished state, convinced us that combs could be made empty in a twinkling and without injury, and before the season closed we had half a ton of nice honey put up in quart glass jars, neatly labelled, and these sold rapidly for a time at one dollar each.

After cold weather came on, the honey of course, candied, and our beautiful honey that had been so much admired for its transparency and purity, presented more the appearance of jars of lard than anything else, and in spite of the fair reputation that we had always borne, there began to be considerable "talk" that we had manufactured the honey, and our bees

didn't gather so much, for it was "actually turning back to sugar." However, the honey all went somewhere before another season, and we indulged through the Winter in "bright visions," and before "fruit blossoms" we had purchased one pound jars to hold a ton, and labels in two colors for all sources we could think of from which our bees might gather honey, so as to be all ready for the coming harvest. By the way, we have just been looking over our unused labels and find those printed for Fruit blossoms, Locust blossoms, Alsike Clover, (we had all of an eighth of an acre,) Buckwheat, and Autumn wild-flowers nearly all remain on hand. White clover and basswood being the principal well defined sources.

Well our jars to hold a ton were soon filled, and we need not tell here how we borrowed all the wash boilers in the neighborhood, and washing day *did* come, and our bottles *didn't* come; but it was all made "lovely" and we sold nearly three tons of honey in the one and two pound bottles. But cold weather came again, and again it looked like lard and wouldn't sell, and, "more too," in the candying process it pushed the corks out of the bottles, and some of the boxes had been left "wrong side up," and the labels were spoiled on those that weren't wrong side up, and as a last resort we poured or *tried to pour* the honey out those little bottles into barrels, and they had to be warmed, and if we hurried them to get through the "muss" they broke, and now we don't put our honey into glass jars until they are ordered in that shape. We use nothing smaller than quart fruit jars, and never try to hold honey with corks, but use those jars that have secure fastenings equal to all emergencies: those with glass covers and a metal clamp, called the Haines Fruit Jar, we like best.

Again, during a very rapid yield of honey, combs are sometimes filled before the honey has had time to ripen, and some that we bottled in that state came so near fermenting that it gave extracted honey rather a bad reputation, and justly so, for we were astonished at the contents of some of our own when picked out at random and brought to the table. At first the idea was quite romantic of bottling the "nectar" fresh from the flowers the same day it was gathered, but even our

favorite White Clover under such circumstances had a decidedly *green* taste, and, unless evaporated by setting the jars in an oven until the honey attained the desired consistency, would most assuredly encourage a preference for old-fashioned comb honey.

Honey when extracted from sealed combs, or at a time when the bees just begin to seal it, we think, however, is in no respect different from, or inferior to comb honey, and we think most people will, after a time decide that wax is not particularly desirable as an article of food.

Instructions for the use of the extractor we think are hardly needed now, for "Young America" very soon finds a way to get out the honey after he once gets an idea of the *modus operandi*.

Uncapping the combs, it is true, once seemed a formidable task, but just hand your honey knife (it must be very thin, very sharp, and of the finest steel), to some one of our bright, keen, go-ahead feminine friends, tell her what is to be done and after a little practice her knife will glide under the caps and roll them off in a sheet (no hot water is needed) at a rate that will convince any "lord of creation" that at least a *part* of bee culture is women's work.

Also in using the extractor, many have been led to think the operation a laborious task because their machines were heavy and cumbersome, with gearing like a fanning mill, and even yet we find it hard work to convince many that it is a great waste of strength and time to whirl a can. honey and all, at the speed necessary for the honey to fly out, when only the comb itself needs whirling.

It is for this reason that we so strongly urge that every apiarist should have but one sized frames in his apiary, and have his extractor made to fit them and *no others*; for to make a frame of wire cloth with the necessary supports and braces larger than the comb we use, to be constantly brought up to the proper speed and quickly stopped, simply because the manufacturer was obliged to make his machines large that they might fit all frames, it seems to us, is very poor economy.

The smallest frame generally in use is the Gallup frame, eleven and one-fourth inches square, and the largest is the Quin-

by, twelve by eighteen and one-half inches. Now to revolve the ponderous frame necessary to receive the latter in extracting combs of the former size would be a constant waste of strength; yet there is no objection to using the large frame and large extractor, for with all large frames work is pushed more rapidly to compensate for an increase of power being demanded. Also with the small extractor the small frames could be handled and extracted with much greater rapidity.

An extractor made expressly for the Langstroth frames may be made very light and work very easy, for if placed longest way up and down, the wire cloth may come within five inches of the shaft, and its length may just as well be two inches less than the length of the frame, for the attachment of the comb to the wood is ample support.

Now as the Langstroth frame is but ten and one-eighth inches broad, we cannot afford to make the extractor frame more than ten inches, and nine and one-half inches would be better economy for a very light running extractor; but this could not be used for the Gallup frame, unless increased to eleven and one-half inches or more. Then comes the American frame, twelve by twelve inches, or old style, twelve by sixteen inches, and perhaps we might as well use a Quinby extractor for all of the American frames, even at the expense of whirling some superfluous metals below the comb.

Strips of folded tin seem to combine more of the qualities of strength and lightness than any other material we know of for making the inside framework to an extractor, and a tin tube makes all the shaft that can be needed. We would always have both top and bottom bearings of tempered steel, and, to conclude, we know of no better winter amusement for the bee-keeper than to see how nice an extractor (*i. e.*, light, strong, and easy running) he can make, or at least can make with the assistance of his timer, and we would advise every bee keeper to get on friendly terms with his neighboring tinsmith by all means, for they are destined, it seems to us, to be our greatest allies.

As to the "use and benefits" of the extractor, really it seems to us that our friends need no remarks on this head. We have learned to build up colonies, rear

queens, increase the number of our stocks artificially, and we feel like adding, how to winter successfully, and with certainty also, but we should feel lost to attempt any of these without the extractor, most especially the latter. Before the advent of the extractor, even with movable combs, the progress in the interior of the hive was mostly guesswork, and only viewed at rare intervals and with the feeling that it was an intrusion.

Now we watch the progress of honey storing and comb building, even to seeing every comb that is built and whether it be worker comb, strait, etc.; our queens are seen, their fertility noted, progress of brood rearing, amount of pollen on hand, what becomes of it, etc. Swarming is kept under almost entirely by its use, and the disorderly work that follows almost always where natural swarming is allowed, is avoided.

Last and not least, without the use of the extractor we should be almost powerless to avert the consequences of Bee Malady in wintering. By removing natural stores entirely, and supplying them with food of *known* and *invariable* quality, we are no farther depending on the chance that may perhaps have provided wholesome food for Winter.

For The American Bee Journal.

How to Feed and Winter Bees.

Messrs. Editors: In response to many inquiries in regard to keeping and wintering bees, please give the following an insertion in the AMERICAN BEE JOURNAL if found worthy.

To each quart of sugar add one pint of hot water, heat to the boiling point and skim; or to every three pounds of sugar add two pounds of hot water, stir, heat, and skim as before directed. As soon as cool enough it is ready for the bees.

For feeding in the Spring, Summer or early in the Fall, a common grade of good sugar does very well; but for late Fall or Winter feeding, use the most refined grades. Feeding for Winter should be done during warm weather, soon after the first killing frosts and as fast as the bees can store away the syrup, and until the brood combs have been well filled. Molasses, sorghum, or the poorest grade of

sugar should never be used. Good sugar is the cheapest, and is also healthy for the bees. Honey from other hives often proves fatal to them while confined to their hives. When bees are fed late in the Fall, or during continued cold weather, place their hive at an open window in a room kept constantly warm, where the bees can crawl back into the hive after flying. Keep the room warm until they have stored, *evaporated*, and *sealed* over enough syrup to last them until Spring. With the Universal Hive, as patented Aug. 26, 1873, I accomplish the same thing without letting the bees out, by placing a screen in front of the hive, securing a space for the bees to fly in. A frame of empty comb filled with syrup, poured into the cells from a suitable height, may also be placed between the screen and the end of the hive, which, being exposed to the light and the open air, will cause the bees to remove the syrup to the interior. By this means the bees may be kept in a parlour, or any other suitable, warm room while being fed, and at any season of the year. When feeding bees in the Spring, or any other time, care should be taken not to give them much more syrup than they will consume in preparing food for the young.

In judicious feeding lies one of the great secrets of success. Plenty of flour also should be given to the bees as early and late in the Spring as they will use it. It may be protected from robber bees by means of the screen arranged as already pointed out. In the sunshine is the most favorable place for the flour, which may also be made of different kinds of grain.

A *cool, still, dry*, and perfectly *dark* place, with *thorough ventilation* to the hive, is the most favorable place and condition in which to winter bees. They should be kept as quiet and free from disturbance as possible. To prevent the accumulation and retention of dampness or water, the hive must be well ventilated, and should also be so arranged and protected that the bees can economize their animal heat to the best advantage. Proper conditions will ever secure success in wintering bees. The required conditions may be enumerated as follows: 1st. A productive queen, with bees enough to rear brood. 2d. Suitable combs stored with wholesome food. 3d. A pure atmosphere of a suitable tempera-

ture, about 40° or 50° above zero being the best. 4th. No disturbances of any kind, with a proper exclusion of light—total darkness and stillness being the best for keeping the bees quietly confined to their hives. A good method of out-door wintering is to set up and tie a shock of corn stalks around the hive, enough to break the winds and keep the hive dry, at the same time packing plenty of hay or straw around and over the frames, after properly ventilating and protecting the bees from the mice, and also securing the bees a small and suitable passage to and from the external atmosphere. The straw and fodder will absorb the moisture collecting around the bees, conveying it to the external atmosphere and also more fully protect them by confining their animal heat.

I hope the foregoing may enable some of my fellow bee-keepers to be more successful in feeding and wintering their bees than heretofore.

A. T. WRIGHT.

Chicago, Ill., Dec. 1, 1873.

For The American Bee Journal.

Adam Grimm's Bee-feeder and Smoker.

In the December JOURNAL Mrs. Lucinda W. Harrison wants to know why I did not describe Mr. Grimm's bee-feeder and smoker. I thought I would leave that for Mr. G. to do, but as he has not done so, I will do it now. Ladies are said to have a lively imagination, so, Mrs. H., please try and imagine this description.

BEE-FEEDER,—a tin can four and one fourth inches in diameter, and four inches high; a hole in the center of the end, one and one half inches in diameter, covered with perforated tin, soldered on; a small hole near the edge of the same end, on which is soldered a screw cap, the same as on kerosene cans, with the rim of the cap cut down so as not to project over five eighths of an inch from the can. A rim is soldered on to the end of the can, three fourths of an inch wide, so that when the can is turned with the hole downwards, there will be room for the bees to come up under it, and eat honey, syrup, or water through the perforated tin. Fill the can with a tunnel through the screw cap, turn the cap on tight, and with a quick motion turn the can bottom

up over the bees, when the atmospheric pressure will keep the liquid from running out, except at first, when a teaspoon-full or so will drop, which the bees will take care of. The hive should be as near level as possible. Sometimes when the bees do not care for the food, or the weather is too cool, drops of moisture will gather on the can, and form a draft for the syrup, which will act the same as a half dozen bees, and the feeder will leak a little. The can must be perfectly air-tight. I give mine a couple of coats of paint, outside, which keeps them from rusting.

SMOKER,—a tin tube, one and one-fourth by six inches, ends covered with perforated tin, pressed inwards; two mouth pieces fitting over the ends of the tube, removable, and tapering to a point, with a knob on each to hold between the teeth like the stem of a pipe. To use it, fill one of the mouth pieces with tobacco (I suppose fine rotten wood would do), light it, and crowd it on to the table, then blow through the other mouth-piece, and there is your smoke. For those who use the weed, it is very handy, for it can be held between the teeth, through a hole in the veil, and the smoke directed to different places, while both hands are at liberty to handle frames, etc. But for those who do not use tobacco, and certainly ladies, I think a piece of rotten wood is far preferable. A little cup with handle and perforated tin bottom, is a nice thing to lay the wood in, when the smoke can be blown down through it, and no danger from fire when it is set down. If Mrs. H. does not understand the description of the feeder, I will send her a sample by express for twenty-five cents, and her tinman can make them from it.

W. M. KELLOGG.

Oneida, Ill., Dec. 19, 1873.

Honey may be kept in perfect purity for years by boiling the strained or extracted article, then skim it carefully, and seal it up air tight, as fruit is canned, then keep it in a cool, dark place.

As a supply for the Winter, a strong stock should, on the first of November, contain at least one pound of honey for every thousand bees; and a weak stock should then have a pound and a half for every thousand bees.—*Hoffman*.

THE WINGS OF THE BEE.

Physiologically Considered as Organs of Flight and of Special Sensation.

The following paper was read before the Bee-keepers' Convention, by Gen. Adair:

To the novice the wings of a bee appear as a dry membrane or tissue of skin, stretched over a frame-work of as equally dry and lifeless ribs of hard, elastic, horny matter. He does not suspect that they have other than to enable the bees to fly, or that their loss or destruction does other injury than to disable them from flight. It is a common practice even among well informed apiarians to cut off the wings of the queen to prevent her going off with a swarm. A better acquaintance with the structure and uses of the wings would show that any such mutilation must be injurious.

Bees do not breathe through the mouth, neither do they have lungs, like the higher animals. Respiration is carried on through an intricate ramification of minute tubes called *trachea*, having their outlets or mouths as pores (called spiracles or *stigmata*) in the sides of their bodies, under and behind their wings. Through these breathing pores the air is led by those delicate tubes to every part of the body, even to the tips of their wings.

Bees have no heart as higher animals have. A tube, or as it is called, a "dorsal vessel," lying just beneath the middle line of the back, and extending from the head to the tip of the abdomen, performs that office. The blood is received into this tube, and, as bees have no veins proper, it escapes from all parts of the tube and traverses the body in currents, bathing all the organs, even to the extremities of the wings.

The nervous system of bees consists of a cord, or rather a double cord, commencing in a knot in the head, which is their so-called brain; from thence it extends throughout the whole length of the body under all the internal organs, resting on the "floor" of the body-walls. On this cord, at intervals, there are swellings (*ganglia*) from which fine filaments are sent out, which are special nerves for the various organs to which they lead; one branch passing to the wings is distributed through all parts of them.

The horny frame upon which the fine membrane of the wings is stretched, is all of it composed of hollow tubes of a hard substance called *chitine* (the same substance that constitutes the hard part of the organs and the crust of all insects). Those tubes are double, being one tube inside of another. The inner ones are extensions of the *trachea* through which the air circulates in breathing; between which and the other is a space through which the blood circulates, and is brought in contact with the air through the thin walls of the air tubes, just as the air and blood are brought together in the human lungs, and with the same effect.

Thus we see that the wings, besides being organs of flight, are in reality lungs. The blood in the wings, however, is not confined to those tubes, but circulates like the sap in the leaves of plants to all parts of them, and, it is likely, is thus also aerated.

The nervous filaments we have also seen pass to the wings. They follow these tubes, and all the fine venations, and terminate in every part of the wings in what are called nerve filaments (*papillæ*), which in all animals are vehicles through which all sensations are perceived; so that we may infer that the wings of bees, besides giving the power of flying and acting as lungs, are also organs of sensation of some kind. All parts of the human body have these nerve filaments on the surface, through which the sense of touch is exercised. The eye has them so modified that they give us sight. On the tongue they give us taste; in the nose, smell, and in the ear, hearing—in each case modified to give different perceptions. For what purpose the wings of bees are so supplied has not been determined. We would of course conclude that the wings were not organs of sight or taste.

In all the investigations of naturalists none of them have been able to locate the organ of smell, although the belief is that it is the most powerful of all their senses and the most necessary to them in searching for honey. By means of it, it is supposed that they recognize each other and distinguish between their fellows and strangers to the colony. Some have suggested the antennæ as the organs of smell, but as they appear to be poorly adapted to perform such an office, it is just about

as likely that they smell with them as that they see with them, which some have supposed they did. Invisible and subtle particles emanating from odorous bodies (often so fine that they elude all attempts to detect them by any other means), coming in contact with the olfactory nerve-fibers, produce the sense of smell. These atoms are mixed with and float in the air, and in order to collect them a considerable volume of air must be made to pass over the surface—a thing which the wings certainly accomplish in an eminent degree. It is highly probable that the sense of smell is lodged in the wings.

The sense of hearing in bees has never been located by naturalists, although that office has by some been attributed to the antennae also. Is it not more probable that the wings exercise it? The impression of sound is produced on the organs of hearing in all animals by vibrations of elastic bodies (commonly the air). A delicate, thin membrane stretched across what is called the drum of the ear, receives the impression, and communicates it by means of an intricate arrangement of parts to the auditory nerve-fibers, or *papillae*. What appendage of the bee would be more suited to receive such impressions than the thin, stiff membranes composing the wings?

But it is not intended in this article to discuss these questions. I only throw them out as suggestions. Whether the wings are the organs of smell or hearing, or not, does not materially affect the point I wished to make, *i. e.*, that the clipping of a queen's wings is an injury to her. We have seen that they perform the office of lungs, and that a queen with clipped wings is in the same condition that a man would be with part of his lungs gone. Those who have seen human beings in that condition need not be told how useless they are for the active duties of life. An insect like the bee, with a differently distributed vitality, may not be injured to the same extent, but that it is injurious no one certainly can doubt; and if by the mutilation, the sense of smell is destroyed, and the queen rendered deaf, her usefulness would certainly be impaired.

In the act of flying the bee makes another use of the tracheae. At the moment of elevating its wings it may be seen to increase in size suddenly, which is the ef-

fect of drawing in through the spiracles a quantity of air, which is distributed over the whole body, thus rendering it of less specific gravity; the air being further expanded by the warmth of the body acts like the heated air of a balloon, and enables the insect to rise easily and sustain a long flight, even when loaded with honey and pollen. In the act of alighting it expels the air with which it has been inflated, and falls suddenly to the alighting-board of the hive. If the landing place is narrow and elevated, and it misses reaching it, the bee will be sure to fall helplessly to the ground, and can only rise again by inflating its body. Bees with larger bodies than our honey-bee, the large bumble-bees have at the base of the abdomen, in addition to the ordinary air-vessels, two large sacs, called *air vesicles*, which are supposed to be used alone for inflation in flying, and some other insects have in the heavier parts of their bodies similar sacs.

For the American Bee Journal.

Italian Bees.—Their Worthlessness.

We give below, an extract from the discussion that took place at the meeting of the Bee-keepers' Association, of Ober Hess, in July last, by which it will be seen that there are some in Germany as well as this country, who have no faith in the Italian race of Bees.

The question before the Association for discussion was: What practical results have thus far been obtained by the introduction of the Heath bee as compared with that of the other imported races—Carnolian and Italian?

Herr Dorr, of Mettenheim, said: Gents, Since 1857 I have interested myself in imported races of bees, especially the Italian. I was their warm defender, and protected and guarded them as pet children, and thus became possessed of fine, pure colonies, and also some crosses in the first and second degree. But when I seek to find out what has been the practical result from 1857 to the present, what return I have had for my trouble, outlay of money, etc., in the introduction of different races of bees, I am forced to acknowledge that all the foreign races combined are not worth an iota. I will not include the list by foul-brood which was introduced into my apiary through these importations.

I, for my part lost 500 guilders through the foul brood introduced by the Italians, and on these grounds I warn all my Association friends. I must hence decidedly oppose any further importations.

Inestimable damage has been done to our neighborhood by the introduction of the Italian race. I could mention whole apiaries, containing upwards of forty stocks of movable comb hives, that were Italianized and have gone to total ruin. In 1868 I owned 100 movable comb hives; three fourths of which had pure Italian queens, and the other fourth were half-breeds. From that time on I began to Germanize my stocks, and from 100 have come down to 40 Italian stocks; and so perhaps it may be with other members of the Association. I could show you with statistics how great the loss has been to our Association alone. You would be amazed, and from this basis advise against every introduction of foreign races.

The Heath bee does not suit us, because it swarms too much, when it should be gathering honey. I have in my immediate neighborhood, a beginner, a man of good judgment, who, persuaded by the praises of Gravenhorst, procured 22 stocks of heather-bees. These cost, when they reached Alshiem, somewhat over 500 guilders. He built a house. To-day they are standing there without a half ounce of honey; they swarmed, however, in abundance. Thus are failures produced, and upon these grounds I hold it to be my duty to so work, that our Associations will take this matter decisively in hand.

Since 1868 I would not endure any Italian blood in my apiary. I have half-breeds who do very well. Last year I allowed myself to be again persuaded and engaged 4 very choice queens, and this spring three of them were proved to have foul brood. The entire stands were destroyed. This again cost me a fine sum of money. It would be far otherwise, if we would more closely watch our native bees, and from year to year note what stock distinguishes itself beyond the others, and make these the standards from which to rear our queens, and I believe we would improve our race of bees without costing us so much money.

President. It might, perhaps, be interesting should Mr. Dorr explain how the foul brood got into his hives, whether it

was imported with the Italian bees, or whether from a peculiar character of the Italian bee, which would in our climate produce foul brood.

Herr Dorr. From 1857 to 1863, as Secretary of this Association, I received from Dzierzon Italian Queens. The Association of the Palaterate received from me Queens. Yet not in one instance did foul brood appear. In 1863 after the meeting at Hanover occurred the discussion as to the difference between the queens raised by Dzierzon, and those imported.

In the spring of 1863 I received my first queens from Mora, and the following Fall foul brood made its appearance. At the time I ascribed the appearance of foul brood to a peculiar circumstance. A friend of mine had some Italian queens in a triple hive. He desired me to put it in order. I agreed to do it, and had the hives brought to my apiary. I then purchased some honey from the honey dealers, for feeding, and I believed that the foul brood was caused by this honey. But it so happened that others, who in 1863 and 1864 received queens were as unfortunate as myself. Last year I tried some from Uhle, but with the same result—foul brood.

Prof. Baest. At what time did foul brood appear most abundant?

Mr. Dorr. I have not yet concluded. From the hundred, yes, hundreds of queens, I have certain information of, I am convinced that the queens reared in May, June, and July are not foul-broody; while on the other hand, those raised in the Autumn months, and those raised in Canton Tessin and sent out by the farmers, are nine-tenths of them foul-broody. Of the former, hardly one fourth show themselves foul-broody. Hence let the importing of strange races of bees alone. If we had spent for the aid of natural bee-keeping in the Grand Duchy of Hesse, the amount of money expended for importing foreign bees, bee-keeping here would be in a very different stage.

President. Judging from the remarks of Mr. Dorr, it appears that foul brood is imported with the Italians, and not a peculiarity of that race.

Mr. Dorr. I have one more remark to make. I have, for example, often in Fall, in order to quickly accomplish my work, smoked the bees with a puff-ball, and in the evening I opened the hive and placed

all the combs over the stultified bees. This Fall I watched the operation carefully. Every swarm so treated became foul-broody. I do not know of a single exception, which I could say did not become foul-broody.

Did I cage the queen, foul brood did not make its appearance so readily. On a former occasion in order to introduce foreign queens, I stupified them with the smoke of a puff-ball, the most of them became foul broody. To another I gave a queen, and it also became foul-broody. I yesterday destroyed it, bees and hive. I can knowingly tell you of two incidents, where a queen was taken from a hive infected with foul-brood and put in a queen-cage, so that not a particle of foul-brood was present, and yet after a time it made its appearance. Dzierzon himself is unable to explain this.

Mr. Secretary Gros von Arnsburg. It appears to me that Mr. Dorr admits that Italian queens reared in the months of May, June, and July are free from foul brood, while those reared in September produce foul brood. Why not rear our queens in those months?

President. That is a very natural inference, but we must remember that queens reared in the Fall months are much cheaper, so that the largest number are sold at that period, while those sold in Spring cost double, yes, three times as much.

Mr. Gross. But sooner than obtain foul brood, I would willingly pay a larger sum of money.

President. What you say is very rational, but one comes in conflict with his purse. I think this question has been sufficiently discussed. Should I in a few words give you my practical experience, it would be, that crosses obtained by the union of a pure Italian queen with a common drone, or a queen of the Heath bees impregnated by an Italian drone, are the best bees I have in my apiary, and I invite all who wish to be convinced of this to visit my apiary. . . . We have been too long breeding in and in, and this phlegmatic German blood needs quickening. This is just what is done in improving our breeds of cattle, and why should we not adopt the same measures with our bees? I cannot entirely agree with Mr. Dorr.

Pastor Weber. Mr. Dorr told us that

he began Italianizing in 1857. He has been breeding queens, then, for 10 years, and only lately has he become satisfied with his bees—and now they are all crosses. If one procures queens in 100 or 1000 different ways, there will be no more of the pure German race. In Rheinisch Hesse this freshening of the blood has been carried on to a great extent. There is, there, no pure race, but everywhere are traces of foreign blood.

For the American Bee Journal.

The North American Bee Keepers' Association.

The Third Annual Session of this Association was held in the city of Louisville during the first week in December.

In the absence of the President, Vice President Hamlin, of Tennessee, took the chair and called the meeting to order, Gen. Adair acting as Secretary.

Owing to the inclement weather, and the sickness of some of the members, the attendance was not so large as could be wished, but the sessions were full of interest. The first morning was devoted to an informal meeting, and the afternoon to a free social conference. Letters were read from absent members. Several practical questions were discussed: viz., The size of brood laid by a prolific queen; The cause of foul brood; Why queens sometimes desert the hive, etc.

The propriety of clipping the wings of queens was talked over at length, disclosing quite a difference of opinion on this subject. The proper kind of food for bees was also discussed, after which the meeting adjourned until 7 p. m.

In the evening the respective value of the various honey plants was considered, and the Alsike clover was highly recommended.

The subject of introducing queens was also discussed, and the propriety of extracting honey freely commented upon. The members were largely in favor of extracted honey, as it leaves the comb intact, and ready to be refilled at once with honey, thereby saving to the bees more than half their labor. It is also claimed that it is better for the table, having been prepared for assimilation by the stock. It is asserted that the only thing which renders

honey injurious to invalids, is the indigestible *comb* that is taken with it.

MORNING SESSION.

The Convention met at half-past 9 o'clock this morning Mr. Hamlin in the chair.

General Adair stated that it was proposed to hold a Centennial Exposition in Philadelphia, and moved that a committee of three be appointed to correspond with the managers, and see what arrangements could be made for having the bee interests represented. The resolution was adopted, and subsequently the chair appointed a committee, and authorized them to appoint sub-committees in such states as they should deem proper.

The Society then proceeded to the

ELECTION OF OFFICERS.

Seth Hoagland, of Pennsylvania, and Dr. F. B. Hamlin, of Tennessee, were placed in nomination for President, and a ballot was taken, resulting in the election of Mr. Hoagland by one majority.

For Recording Secretary, Abner Pope, and for Corresponding Secretary, General Adair, were elected without opposition, as was also J. S. Hill, of Mt. Healthy, O., as Treasurer.

The following Vice-Presidents were then elected:

New York—J. E. Hetherington, Cherry Valley.

Pennsylvania—A. J. Hooker.

Kansas—L. J. Dallas, Baldwin City.

Michigan—A. J. Cook, Lansing.

Minnesota—J. W. Hosmer, Janesville.

Utah—W. D. Roberts, Provo City.

New Jersey—E. J. Peck, Linded.

Wisconsin—A. H. Hart, Appleton.

District of Columbia—Hugh Cameron, Washington.

Ontario—J. C. Thorn, Garafraxa.

Georgia—R. Peters, Atlanta.

Texas—J. W. Dum, Corpus Christi.

Arkansas—G. B. Peters, Council Bend.

Maine—Mrs. A. C. Hatch, Houston.

Connecticut—W. H. Kirk, West Cheshire.

Louisiana—T. J. Bert, Mansfield.

Alabama—Miss Fanny L. Morris, Shelby Springs.

Massachusetts—E. N. Dyer, Amherst.

West Virginia—A. Chapman, New Cumberland.

Nebraska—W. Young, Plattsmouth.

Tennessee—T. B. Hamlin, Edgefield Junction.

Florida—Mrs. C. Atkinson, Leesburg.

Ohio—Aaron Benedict, Bennington.

Kentucky—Major T. J. Key, Anchorage.

Indiana—A. T. Wright, Kokoma.

Illinois—J. L. Lucas, Peoria.

Iowa—Mrs. E. S. Tupper, Des Moines.

Colorado—T. J. Dorr, Colorado Springs.

The subject of wintering bees was then discussed; The moth and its troubles were also talked over, but it was claimed that with good hives and Italian bees, there was no danger to be apprehended from this quarter. Adjourned until 2 p. m.

AFTERNOON SESSION.

An interesting letter was read from the former Secretary, Mr. King, after which remedies for stings were considered. Colp water and wet cloths changed as often as necessary, or the compound tincture of Lobelia, were pronounced very effectual remedies. Mr Winder, however recommended sulphate of zinc dissolved in water, and Mr. Murray, supercarbonate of soda, used in the same way as an outward application.

The Corresponding Secretary then read a letter from Dr. Phillips, which was placed on file. On a motion the Doctor was elected as an honorary member of the Society.

The following resolutions were adopted:

RESOLVED, That the thanks of this society be tendered the city of Louisville for kindness and hospitality shown to the Association at this time.

RESOLVED, That the Treasurer pay to D. L. Adair, Corresponding Secretary, \$6, amount expended by him for envelopes and postage in distributing the proceedings of last year's transactions, out of the first funds in the treasury not otherwise appropriated.

RESOLVED, That the thanks of this society be tendered to the Louisville COURIER-JOURNAL, COMMERCIAL, and LEDGER, for their correct report of our proceedings.

RESOLVED, That the thanks of this society be tendered to the trustees of the Public Library Hall, for their fine hall and their kind attention to us, and the Treasurer pay to the same, \$32 for the two days' use of their hall, if the Treasurer cannot get it for reduced rates.

WHEREAS, We have no funds in Treasury to meet current expenses:

RESOLVED, That each member present pay one dollar additional, which shall be credited to them as one year's payment in advance as members of this society.

RESOLVED, That our Corresponding Secretary be allowed \$10 for making out the transactions of this meeting, out of any fund not appropriated otherwise; \$5.00 also appropriated for Dr. Hamlin, money spent for postage, &c., in arranging for this meeting.

RESOLVED, That as Mrs. E. S. Tupper is the only publisher who is here, the society request her to prepare a synopsis of the reports of this meeting and publish them in the December number of the NATIONAL BEE JOURNAL, and send a copy to each member who has paid the annual fee, and also to other Bee publications and agricultural journals, and that the Secretary make an official report in pamphlet form as soon as he has funds to do it and that the Secretary be paid a reasonable sum for performing the above services.

The question was asked, "Is artificial swarming as good or better than natural

swarming?" Adair moved that the Society answer the question in the affirmative, and gave substantial reasons therefor.

An able paper was then read on the wings of the bee, which will be found entire in the present number of the JOURNAL.

The meeting then adjourned to meet at Pittsburg, Pa., the second Wednesday in November, 1874.

For the American Bee Journal

Doolittle's Article.

DEAR JOURNAL: In the July number, page 7, we gave you under the above heading our experience with bees up to April 28th. We propose now to let the readers of the JOURNAL know what we have done since; and by the way, Mr. Editor, if more of your contributors would give their practical experience with bees instead of disputing so much with each other, and about hives, we think it would be of more benefit to beginners as well as more edifying to experienced bee-keepers. The cold weather which began April 17th, continued until May 1st, and upon examining we found that our bees had decreased one-half in number to each hive. We united the weakest swarms so that we had but twenty-nine to begin the season with, one of which lost its queen shortly after. On May 1st, we did not have a hive that contained a quart of bees, and not a hive that had ten square inches of brood. The majority of them occupied from two to four ranges of comb and had no brood at all. The first pollen gathered was on April 30th, which was very small pillets indeed, and that from skunk's cabbage. Bees began to rear brood again May 2nd, and raised sparingly until May 14th, when it became cold again and remained so until the 20th, at which time the larvæ was all destroyed again. May 21st, the hard maple threw out its thousands of blossoms and the bees, what were left of them, began in earnest to prepare for the summer; before that time we had spread the brood twice a week by putting empty frames or frames of honey in the center, and on the 30th, we never had so much brood according to the number of bees in our hives, five hundred bees covering five thousand of brood easily, and from

the 12th to the 18th of June we had multiplied their number by ten and were once more in a very prosperous condition. June 15, white and red clover began to bloom, and that with locust blossoms furnished our bees with an abundant supply of honey. June, 19, our first swarm came, Basswood commenced blossoming July 16 and lasted until August 2nd, which was the end of the honey season with us. We have at the present time fifty-four colonies in good condition for wintering, and four nuclei, so it will be seen that we have doubled our number counting the nuclei. We have sold surplus honey to the amount of 2350 pounds, 635 pounds of which was extracted and which we sold for fourteen cents per pound, the remainder was in two pound boxes which brought us twenty-seven cents per pound. On the whole we are satisfied with our season's work. We propose wintering the same as last year with the exception that we shall leave the straw out of our safes until spring for the reason that our bees were kept too warm during the winter. Keep hives banked with snow out of sight, and have all lower ventilation nearly or entirely closed with one of Novice's quilts over the frames, well tucked down at the sides, and we will bid adieu to cellar wintering, as we believe bees can be wintered in no better way. No lugging or lifting nor any mixing in the spring, but just a little pleasant exercise of sweeping the snow as it falls around the hives, and if it should come warm enough for them to fly, shovel it away in front and what a nice fly they will have. If it does not come quite warm enough they will keep quiet, as the snow keeps them at an even temperature, so there is no loss of bees from getting chilled in the snow every time the mercury rises to forty in the shade.

G. M. DOOLITTLE.

Boradino, N. Y., Dec. 6, 1873.

Italian bees are said to guard their hives against the moth-miller much better than the common black bees, and for this reason their combs are seldom injured by the moth.

The Alsike clover is equal if not superior to buckwheat as a honey plant, while the honey produced from it is fully equal to that made from white clover.

Do Bees Make Honey?

Do the bees simply gather the juice or secretion of the flowers and deposit it in the hive unchanged, does it undergo a change in their stomach, or is honey a secretion of the bees resembling that of milk in mammals?

This question was asked me lately by a reader of the *Dollar Monthly*. With your permission I will describe my views on this question, subject to the criticism of older heads.

When the bee visits the flowers it sucks the nectar with its proboscis and swallows it. The honey passes into what entomologists call the proventriculus, or first stomach, commonly called "honey sac." If a part of this honey is needed for the nourishment of the insect, it passes into the ventriculus, or true stomach, in which it is digested. When the honey-sac is full the bee returns to the hive, unloads himself by throwing the honey into the cells and again starts for the field. It is, therefore, quite plain that honey is not a secretion. Now, is honey changed in any way by passing in and out of the honey-sac of the bee? That is the question.

It has been found by chemical analysis that the nectar of the flowers is cane sugar and that the honey harvested by the bees from those flowers is grape sugar. This discovery would be sufficient to prove that the honey gathered by the bees undergoes a certain change in the honey-sac. On the other hand, W. W. Stoddard said, in a back number of *U. B. J.*, that the honey when in the honey-sac comes in contact with an acid, that proved to be identical with formic acid. He says: "This it is which doubtless causes the peculiar tingling sensation at the back of the throat when much honey has been swallowed."

Later we find in the *Apiculture* of Milan a definite account of the existence of secreting glands communicating with honey sac, and containing a saliva of a strong, peculiar odor that passes by means of contraction into the honey-sac.

These three glands were discovered by Prof. Von Siebold, the well known German entomologist. He claims the honor of having described them the first, as they had always been thought by others to be respiratory organs.

If the above discoveries are real and well understood, we shall have to conclude that honey does undergo a certain change in the stomach of the bee, and, therefore, cannot be made artificially. It does not exist in a natural state outside of the hive.

The change effected in the nectar of flowers by the stomach of the bee is not very great, however. The bee gives it a peculiar taste, but it cannot add anything to its quality or diminish it in any way.

Before I close, permit me to thank Mr. M. Quinby for his article on wintering, in the December number. I also wish to tell friend Kretchner that we agree perfectly together. Bees will not work as well in side boxes as in top boxes, although they *will* work in side boxes if they have no top boxes. But give them their choice and see what they will do.

D. P. DADANT.

Hamilton, Ill., Dec. 15, 1873.

Shaking Bees.

James Heddon at the Michigan Bee Keepers' Meeting, said, "I find that shaking deep combs to get off the bees, irritates them. Is there a remedy?"

There are several, a couple of which I will give. First, Use more care in subduing bees in long, deep, or large hives. It is generally best to manage hives of bees, extracting honey, making swarms, &c. during a yield of honey, and before it is sealed with wax, that all the bees may fill their sacs with honey; which they will do, if there is enough uncapped, and they are disturbed properly. If the honey is not in a condition, or of sufficient quantity, food may be given, to subdue the most vicious stock. The best brush is one or more grape or plantain leaves rolled loosely, sometimes the end trimmed. Weeds, grass, broom, feathers, or brushes may be used; and if the articles are scarce, or only one at hand, dip occasionally in water to wash off the odor which enrages badly managed bees.

Second, Use the old fashioned, native, or black bees with your deep frames, that drop off the comb like shot off a shingle, at the least handling. The stock is getting scarce. It can probably be obtained of our former President, as they are his pets.

St. Charles, Ill.

J. M. MARVIN.

American Bee Journal.

CHICAGO, ILL., JANUARY, 1874.

Business Notice.

The public are hereby informed that the proprietorship and management of the AMERICAN BEE JOURNAL have been transferred to the American Publishing Company, of Chicago, the undersigned retaining henceforward only an editorial connection therewith. By this arrangement additional security is given for the permanence, effective conduct and progressive improvement of this journal, inasmuch as the company into whose hands it has passed possess unusual facilities for carrying it on. They are already publishing *The Illustrated Journal*, with which has recently been incorporated *The Chicago Graphic and Illustrated American*, the announcement of which will be found in the advertising department of this number. They are also issuing other works of art. Having a corps of engravers connected with their establishment, they will be able from time to time to illustrate the pages of the JOURNAL, a desideratum long felt by its proprietors and friends. The new publishers are determined to spare neither cost nor pains in making this periodical worthy of the patronage of the bee-keepers of North America. The experience of a year in the business and editorial conduct of the AMERICAN BEE JOURNAL has convinced the undersigned that the apiculturists of this country need and are prepared to sustain a well-managed organ and exponent of their important industry. It has also convinced him that in order to the complete success of the JOURNAL, it is absolutely necessary that more capital, business ability and energy should be connected with it. These are now secured, and the new arrangement is announced in the fullest confidence that the results will be most satisfactory to all concerned.

W. F. CLARKE.

THE OUTLOOK FOR BEE-KEEPING.

Bee-keeping has come to take a high rank among the productive industries of the world. For want of statistics, which have never yet been faithfully collected, and which it is very difficult to get with any accuracy, only general terms can be employed in speaking of its condition and progress. A national census throws but little light on this subject, for census commissioners do not usually enquire about live-stock so insignificant as bees, and what information they get is drawn out of the people by questions. They have a printed catechism, which does not embrace the inquiries, "Any hives of bees?" "How many?" and hence the most profitable kind of live-stock in proportion to cost and value, finds no place in the record. Very much the same is true of the honey product of this and other countries. It is very imperfectly represented by figures, and is only found in commercial reports that are devoted to market prices. We are consequently quite in the dark as to the important items of consumption and demand.

But amid all this vagueness of knowledge about apiculture and honey, there are some things that stand out distinctly enough. One is the universality and abundance of honey. Everywhere in innermost hearts of myriad flowers, the Creator has garnered up stores of liquid sweet, which wait for collection and appropriation. Another thing we are perfectly sure of, viz., that this teeming and superabundant sweetness can only be made available through the good offices of the bee.

Whether the floral sweet is really honey as it lies treasured in the flower, or whether it undergoes a chemical change in the body of the bee, whereby common saccharine matter is transformed into honey, we need not now stop to enquire; but it is absolutely certain that if man is to have honey, the bee must collect and store it for him. Every schoolboy knows how to get at the drop of sweetness that lies hid in a head of red

clover, but there is no way of doing it on a large scale except by bringing the "little busy bee" into our service. We know, moreover, that the proportion of honey actually gathered and made available for human use, is very small compared with what might be got, if there were gatherers enough to do it. Further, it is quite certain, that there is no danger of the market being glutted with honey. It has never been abundant enough to cause a decline in the price, except as there has been doubt as to genuineness of quality. The best box honey never goes begging for purchasers, and the same would be true of extracted honey, but for a prejudice growing out of doubt as to its purity. Finally, we know that bee-keeping, though subject to fluctuation is no more so than most other sublunary things. Even the wheat crop sometimes fails, or when it does not fail, the demand slackens, and the price is low. In every line of business there is more or less of uncertainty, risk, and liability to sustain loss. This is no more true of bee-keeping than of other pursuits, and, therefore, it may fairly take rank among the safe and regular occupations of mankind.

So much being settled in regard to the present condition of bee-keeping, let us glance at its future. It is now reduced to a science, which, though in its infancy, has its main principles ascertained and fixed. It is also an art, whose essential manipulations have been reduced to a system. Only those will succeed in it who master the principles of the science, and learn the *modus operandi* of the art. It is passing out of the hands of unscientific and unskilled people, who are convinced that it is an unprofitable business, and better hands are taking hold of it. Our best bee-keepers make apiculture pay, and some of them are quickly amassing snug little fortunes out of the industry of the bee. As a higher class of bee-keepers get possession of the field, and apiculture acquires its true status among the indus-

tries of the world, many will be attracted to the pursuit, who, instead of rushing into it with ignorance and ardor as their only qualifications will first lay the foundation of success by thoroughly learning their business. We look for the springing up of a new generation of advanced bee-keepers—bee-keepers who will be free from prejudice against book-learning about rural matters, and who will believe in movable-comb hives, Italian bees, and honey extractors. The disasters of the last two years, which have fallen most heavily upon the ignorant class of bee-keepers, have had the effect of discouraging these, and leaving only those in the field of apiculture, who have science enough to account for failure, and faith enough to try again, and keep trying until they achieve success.

We believe, too, that the age of empiricism in bee-keeping is passing away. Impostures feed and live on ignorance. Worthless patents and clap-trap appendages, are thrown away so soon as the noviciate of bee-keeping is passed. What apiarian of any experience has not plenty of old lumber in the shape of abandoned hives and rejected "fixings?" We know now that with the movable frame, air-space, and the requisite room, bees will store honey in any sort of receptacle, and that the bee-keeper may suit his own taste and convenience in the matter of hives. Moth-traps, non-swarmers, and the endless little variations about frames and hives which have been made excuses for getting patents, are fast coming to be estimated at their real worthlessness.

An eager demand for trustworthy information and teaching on this subject, will manifest itself on every hand, and we shall soon have a race of studious, pains-taking, successful bee-keepers, whose influence will allure multitudes to this fascinating pursuit, and these in their turn will draw others into the apicultural ranks.

So important and growing an interest must have due representation in the press,

and will find it in such apiarian periodicals as make it their aim to advance apiculture, irrespective of all merely selfish interests. At the head of all these stands the AMERICAN BEE JOURNAL, and therefore all the auguries of success for intelligent bee-keeping are omens of prosperity for it. In this confidence it was removed to this city a year ago, and during a season of depression among bee-keepers, pushed with all the energy circumstances admitted. In this confidence, it is now laid hold of by the AMERICAN PUBLISHING CO., under whose auspices it enters on the year 1874 with every prospect of a growing circulation, and widening usefulness.

Knowing, as we do so well, the firm faith our most intelligent bee-keepers have in their business, and the high esteem in which they hold the AMERICAN BEE JOURNAL as the best exponent and organ of their special interests, we count most confidently on their continued co-operation. Their success is ours, and our success is theirs. In this community of interests and fellowship of labour for the general good, they have our best wishes, and we are certain that we have theirs. As we work on dilligently and hopefully, do we not hear merry voices ringing out the cheering refrain :

“There’s a good time coming, boys,
Wait a little longer.”

Hints to Correspondents.

Perhaps there is no way in which the science of bee-keeping can be better advanced than by comparing the experience of *practical men*. One *fact* is worth a dozen theories. Therefore we are grateful to our friends for giving their thoughts and the result of their efforts to the JOURNAL. But it must be borne in mind that our space is not equal to our good wishes in this matter, therefore it will be necessary for our friends to *condense* their thoughts as much as possible. Try and give us the “concentrated extract” of your experience in Bee Culture. We will publish

nearly all if possible, but if we have to cut and prune sometimes a little closely, please bear in mind that our space can only be filled, therefore we are sometimes obliged to publish only extracts, instead of whole letters. Another thing we would suggest is, that our correspondents avoid as far as possible, *all personalities*. These are hardly calculated to produce harmonious feelings in our families, and certainly not essential to the science of Apiculture.

Annual Meeting of the North American Bee-Keepers' Society.

Elsewhere in this number will be found a report of the above meeting, held at Louisville, Ky. The editor of this journal fully intended to have been present, alike in the interest of the JOURNAL and in the discharge of his duty as President of the Society. His intention was frustrated by the death of his father-in-law. The sad event took place too near the time of the meeting to arrange for the attendance of any other representative of the JOURNAL. It is hoped, however, that the report of the proceedings will be found accurate and satisfactory, and that this explanation of his non-attendance will be accepted by all concerned.

To Those Interested in Bee Culture.

At the sixth annual convention of the Michigan Bee-Keepers' Association, it was decided to hold a special meeting at Kalamazoo, to commence Wednesday, May 6th, 1874. It is especially desired that all members be present, and, in behalf of the Association, we urge every bee-keeper in Michigan to attend. A cordial invitation is also extended to all persons interested in the science of bee-culture, whether residing in this or other States. Surely much good may be derived from a comparison of experiences next Spring, and from the able papers that will then be presented. Timely notice will be given of all further arrangements. Address communications or inquiries concerning the subject to
FRANK BENTON,
Sec'y Mich. Bee-Keepers' Association.
Shelby, Oceana Co., Mich.

“Instead of complaining that the rose has thorns, I congratulate myself that the thorn is surmounted by roses.”

Sundry Items.

INTRODUCING QUEENS.—Having more experience in introducing queens as recommended by me in October JOURNAL, I would advise not to release *late* in the season, especially in cool weather.

PACKING HIVES FOR WINTER.—I have packed some hives to winter on summer stands, as follows: Of stuff inch wide by quarter inch thick, I cut off lengths so as to make frame, four pieces for a frame, the outside dimensions of which are same as the side walls and top of brood chamber. These skeletons were covered with coffee sacking, and when ready to pack, I removed the wooden sidewalls and top of brood chamber altogether, replacing with those just described, and then filled in all around and on top with straw. I am confident this will avoid all moisture, and be much warmer—the two most essential points to be gained, for successful out door wintering.

Now if any who chance to read these lines, have bees in single walls to winter on summer stands, having done *nothing* by way of protection, I would say, Try a few hives as follows: Make a frame and cover it with sacking as above described, that will fit snugly inside of cap, fill cap with straw and press the frame down upon it, having put the side to which the sacking is fastened to frame next to the straw. Remove the honey-board, and replace the cap on hive. Now set the hive one side, and place on the stand a dry goods box, several inches larger all round than the hive, with the open side facing the same way as the front of the hive. Fill in the back side of the box with straw, and set the hive in the box, and fill in both sides with straw. If your bees dont come out in Spring in better condition, *on less honey consumed*, tell us all about it in the JOURNAL.

This brings us to consider Novice's allusion to us in November JOURNAL, on "Out-door wintering," in regard to which he has heretofore expressed himself, as follows: "We should give them no protection whatever, unless it be from the wind; but should endeavour to have them receive all the *sun* possible." One of Novice's correspondents writes, "that in this climate, out door, without protection is very unsafe," to which Novice adds, "We have been obliged to come to the same conclusion in regard to out-door wintering." What conclusion,

Novice? Why, that out-door wintering, *without protection*, is very unsafe. That is plain enough without "pursuing our reading any farther," as we do not think the statement about the sunshine alters the meaning of the above at all.

In giving our views we have always confined ourself to the subject in hand, viz., "Wintering on Summer Stand," and not as Novice generally does, shift it to "Wintering in Special Depositories."

In the report of the Kansas State Beekeepers' Association, we find the following assertions by Mr. Meador: In speaking of the queen he says, "After impregnation *all* the eggs produce females, and that the male bees were *generally* produced by eggs from the *worker* bee, fed for the purpose."

That we have fertile "workers," I suppose every queen breeder has found out to his detriment; but the above assertions in regard to the same are at variance with all our reading or experience. I for one, and methinks a whole brigade of JOURNAL readers join in, would like his "proofs for the faith that is in him."

I removed a queen from a hive in May, from which drones were flying, and as I wanted drones from the queen that succeeded the one removed, I placed drone comb in the middle of the hive, which was filled with eggs, and cells sealed long before any worker progeny of the new queen hatched. So if that drone comb was filled with eggs by a fertile worker, it must have been one bred from the *old* queen, consequently there could be no *variation* in drones hatching from that brood, and those in the hive when the old queen was removed. There was, however a *great* difference in the markings, showing a different strain altogether.

J. E. MOORE.

Rochester, Pa., Nov. 28, 1873.

"Moon's Bee World," is the name of a new periodical published at Rome, Ga.—We wish the new magazine all success and may the South soon become "a land flowing with milk and honey."

Fruit may be preserved with honey by putting the fruit first in the can, then pouring honey over it, and seal air tight; when the honey is poured from the fruit it will have the flavor and appearance of jelly, making a delicious dessert.

For the American Bee Journal.

A New Repository for Bees.

MR. EDITOR: Of the great number who suffered from the loss of bees last Winter I am one. I lost all I had, forty-two stocks, leaving a large amount of honey. And now after sifting the matter down to a fine thing, I have concluded the cause was in a measure carelessness, in not protecting the bees and giving them sufficient ventilation. The Winter set in about Nov. 12th, 1872, and continued until about the last of March, 1873, too cold all that time for bees to be out, except one or two days in February, then but few made their appearance. The consequence was that the frost accumulated in the hive, and then a moderate day would come to melt the frost and make it run down over the combs and thin the honey, which caused dysentery. Nearly all in this section lost all the bees they had; the disease paid no respect to the pattern of hive but entered all alike.

Last Spring I procured two very weak stocks of black bees from a neighbor, the best that I could do here. I also procured a medium stock (five frames) of Italians from W. J. Davis, of Youngsville, Pa; this stock contained a beautiful queen, and as prolific a queen as I ever saw. In order to make a cross I procured a very beautiful queen from Mr. D. A. Pike, of Smithsburg, Md., and introduced her into one of the black stocks, then after a sufficient length of time formed nucleus, raised queens, which mated with Mr. Davis' stock of drones. No drone brood was allowed to hatch in the black stocks for six weeks after the Italian queens were introduced. I have increased to eleven good stocks with abundant stores for a long Winter, and the nicest, most robust and the best workers that I ever saw. The loss of last Winter is a dear lesson to most beekeepers—it has proved so to me at least.

I have built a repository, which I think is complete, as follows: I selected a dry spot which slopes a little to the north, then graded it to the south twelve feet, and ten feet the other way; then set two posts at north end, wide enough apart for a door, then four feet south two other posts, same distance apart, and eight feet farther south two posts, same distance, then pinned perlines on top of the posts, same as a barn, put stays across the top to keep the posts from leaning in toward each other, posts four feet high from

the floor; then set up two-inch plank of sufficient length to meet at the top, same as rafters, with one end on the ground, thus making a roof eight feet wide; then planking up the ends, all but the door four feet high and thirty inches wide, then planked up the remaining four feet perpendicular and out to the first two posts, then horizontal over the top, and then covered the whole over with dirt from twelve to fifteen inches deep, leaving another door at the north end, forming a hall, can open the first door, pass in and shut it, and open the next, this lets no light in nor sudden change of air. Have ventilated at the bottom with two inch pipe and at the top with six inch stove-pipe; put a roof of boards above the dirt, and kept a stove and fire in it about four weeks before putting in the bees. Have only the out-side door shut, it is warm enough up to this date. The bees are perfectly quiet with all the holes open in the honey-board. They were put in on the 13th of November. The weather has not been warm enough to fly since had they been out.

M. WILSON.

Meredith, Pa., Nov. 28, 1873.

Hints to Ladies.

Much has been said and done in relation to "Woman's Rights," but amid all the speeches, conventions and resolutions of the last few years, the most successful women have been those who have quietly gone to work, winning their own way to prosperity.

All the conventions this side of the garden of Eden will not help woman into a position of comparative independence unless she tries to help herself. Rosa Bonheur did not ask Congress to make her an artist—nature gave her the ability and she wrought out her own problems with patience and earnestness.

Harriet Hosmer sought no aid from conventions and by-laws when she began her life work, and Florence Nightingale did not care to vote before she went into the Crimea. But all women are not artists or sculptors. Their gifts vary as much as those of the other sex, and indeed like many of them, some of us seem to have received none at all, that is no bright particular talent, which, if cultivated, will bring wealth and fame.

To hundreds and thousands of brave-hearted women the serious question comes home "What can we do for a living." The endless round of domestic labor brings little or no reward, while the ranks of teachers and seamstresses are filled to overflowing. There are clerkships to be sure, and many of them are ably filled by ladies; but side by side with them, are stalwart men who *wear* themselves with handling ribbons and laces, while the soil waits for tilling and the harvest for reapers. In many departments of life man gets sadly "out of his sphere" by intruding upon women's legitimate domain. But we cannot straighten the world's machinery, though it sometimes gets badly out of gear, neither can we force the drones into their proper places. It therefore behooves us to find fields of labor where there is room enough and to spare, and perhaps the most tempting of these is the science of *Apiculture*.

Woman is particularly fitted for the handling of bees. Her perceptions are quick, her touch is delicate and her instincts are seldom at fault. Many of us can find time amid domestic cares to cultivate a few flowers and we do not feel that the time thus spent is wasted, even though it brings no financial reward. But the care of a few colonies of bees would require no more time than the same number of flower beds and the pursuit is even more fascinating; there is more pleasure in seeing the little workers build without a compass their geometrical cells than in watching the unfoldings of bud and blossom. The work is lighter and cleaner than Horticulture, besides yielding substantial returns. And however happily a woman may be situated in life there is a pleasure and independence derived from the use of money which she has *earned* that can be found in no other way. Then if she wishes to make her husband a holiday present, she can do so without feeling that it came from his own pocket. Many a worn out teacher and tired house-wife may find among their bees rest, health and a new interest in life. To women in feeble health bee-keeping offers many advantages. Let them be hers and let her take care of them, and she will feel an interest in the little creatures that can be awakened in no other way. Every pleasant day will find her more than once beside

the hives, and the fresh air and glad sunshine with the aid of light employment will give her a strong hold upon life. It opens a new world in natural history which proves to be one of absorbing interest. It has been demonstrated that some of the most successful Apianians in the country are ladies.

Says Mrs. E. S. Tupper: "In the summer of 1863 I had but two pure Italian stocks to commence with. One of these stored *one hundred and ten* pounds of honey besides giving three swarms. The other gave two swarms and stored ninety-six pounds of honey. All of the young swarms filled their hives and some of them stored honey in boxes. In the summer of 1864 I averaged from nine Italian colonies *one hundred and eighteen pounds each*."

A gentleman writes from Odell, Ill., that "Wife has managed the bees at home this summer. She had twelve swarms to start with, some of them very weak. Sold one hundred and thirty dollars worth of surplus bees and two hundred and fifty pounds of honey, which was doing pretty well, considering the *poor season* and the first attempt." Yet we will venture the assertion that this lady did not neglect her other duties or enjoy life any the less on account of the time spent in caring for her bees.

Ladies here is health, happiness and financial success for you. Do not say that you do not understand the business, that you cannot learn, that you are afraid of failures, &c. One year's subscription to the AMERICAN BEE JOURNAL will give you a whole volume of advice from the best practical Apianians in the country. It requires but little capital to begin with, hence the risk is very small and success is almost certain. Try the experiment next summer, and let us hear of your success in the fall through the columns of the JOURNAL.

MRS. H. V. REED.

Central Iowa Bee-Keepers' Association.

The next annual meeting of the Central Iowa Bee-Keepers' Association will be held at Cedar Rapids, Iowa, Jan. 21, 1874, and hold two or three days. It is expected that the usual reductions will be made in railroad and hotel fare.

A. B. MASON, Sec'y,
Waterloo, Iowa.

A large natural swarm of bees carries with it four or five pounds of honey when leaving.

Translated for the American Bee Journal.

Early and Full-developed Queens.

Whoever has, even superficially, examined the internal arrangements of the hive, can see readily how differently the development of the stock takes place under varying circumstances. You may have seen a swarm fill in three days an ordinary sized hive, while it would take, with other swarms, three years to accomplish the same.

Hanneman tells us that in Brazil young swarms after one month send out new swarms, while under other circumstances such a young swarm would not think of swarming under a year. As with the development of the whole hive, so it is in resemblance, if not in proportion, with the development of each individual under various circumstances and at different periods of the year. How marked the difference, we may see in the varying lengths of the life of the worker bee at different periods of the year. Of those bred in April or May, not one will be living six weeks afterward; or at least very few; while those born shortly before lived to hoary old age. Those hatched in August or September, appear six months afterwards, in Spring, as young and active as though just one day old. Such is the effect of the constant and incessant labor during the Summer, and the protracted rest in Winter.

Should we observe the queen, the most perfectly developed of all the bees, upon whom depends the development, populousness and profitableness of the hive, we would see that her activity differs greatly at different portions of the year. Normally her activity with us ceases entirely during the last three months of the year. Only in swarms which breed a queen late in the season, or which are for a long time queenless do we find any brood in the fall and winter months, which is owing to the fact that the bees have a desire for it, owing to their long queenlessness: having on hand in their cells a store of brood-food.

This untimely breeding, especially if it extends into the Winter, works to their injury, and is as undesirable as the, in other hives, too early and extensive breeding in Spring for fear of the cold. Also towards the close of the honey harvest, an earlier shrinking of the quantities of brood would be advantageous.

On the other hand, in the early months immediately preceding the honey harvest, in April, May, and June, the bee keeper desires to stimulate breeding to the utmost, and prevent any possible interruption. The more brood the hive now possesses, the more workers it will have to gather the harvest. At the first start young swarms are very industrious, but this gradually diminishes, owing to inevitable loss of workers, without any supply being furnished until three weeks later when the young brood begins to hatch out, and renew the life of the swarm. From a strong colony we can gradually remove great masses of bees, without any injury to its strength, either as regards its flight or building capacity; but should the queen depart, either by natural or artificial swarming, or by any other means, all building will at once cease, and how sadly the swarm falls gradually behind hand in its working capacities, all bee keepers well know.

The brood supply will disappear in a few weeks, in which time several strong swarms might have been reared, and perhaps at the height of the honey harvest, the hive will be almost empty of bees and will have no surplus for its winter support, if it even lives that long. Here becomes apparent the advantages of the movable comb hives and a rational system of bee-keeping. Here these dangers of queenlessness are so diminished as to be rendered almost harmless. The swarm can be readily supplied with brood from time to time, and more readily supplied with queen. While in other hives, eleven to thirteen days will elapse before a young queen will be hatched out, I can now remove a laying queen, and usually in two days after have a young queen hatched, which in eight days will begin to lay. From April, as soon as drone-brood is to be seen, I seek constantly to have a supply of queen-cells on hand.

I utilize the queen as soon as hatched; generally, however, use the queen-cells just before the queens hatch. To remove a fertile queen, and introduce a young one, or insert a queen-cell, will often miscarry. One must adopt many maneuvers to reach his object. To an unqueened stock, in the meantime, I give a comb of brood from another stock or nucleus, upon which are found queen-cells some days old, and give

to these latter an already hatched queen, or a queen-cell. It is not to be feared that these latter will destroy the cells, especially if they are young and were given to the hive with the bees on them.

The swarm will at once protect the cells and commence to complete them, and will thereby be favorably inclined on the following day to accept an older queen-cell or perhaps a recently hatched queen, and the comb containing the cells may be given to another recently unqueened swarm.

By mixing the bees of two swarms, either by interchanging combs, or by shaking the bees from them, a swarm may be prepared for accepting a young queen. Also a stupefying of the bees, with the smoke of a puff-ball, perfumery, etc., serves well.

When one has not a surplus of young queens, it is well to confine them in a cage until the bees become acquainted with her.

This introduction, however, is only complete when the young queen becomes fertile, which is sometimes very slow. The impregnating of young queens depends much on the weather, since it requires bright, pleasant weather with a temperature of upwards 77° F. in the shade. Here the bee-keeper can aid somewhat, that the young queen may become earlier capable of being impregnated, earlier capable of making her wedding flight, and, consequently, earlier capable of laying. That young queens will make their wedding flight at a certain specific time, as Herr Collen claims to have discovered, is opposed by theory and practice. Fourteen days in March will not advance a queen as far as seven days in May.

The queen of an after swarm will be laying before the queen of another stock, of like age, will hardly be thinking of making her wedding trip, perhaps not yet ruler of the hive. There is very good ground for this. To attain the capability of being impregnated the internal organs must be more developed, which require the building up of the muscles and nitrogenous nourishment. Such food the bees alone prepare when in full, active life, when building and brooding is going on. It is true that in after swarms there is no breeding going on, but there is great activity in building, and for this purpose a higher temperature is maintained; this stimulates in the young queen an earlier development, earlier flight and earlier laying. In the mother stock, however, there is neither breeding nor building going on, no

full active life rules the hive, hence the young queen remaining behind, in general, develops herself much more slowly. Many keepers of movable comb hives, or basket hives, cut away some portion of the comb near the entrance, in order by the filling of the vacancy, to test whether the hive was queenless or not. And by so doing they obtain, without thinking of it, an earlier impregnation of their queen, the increased activity in building bringing this about. In movable comb hives the activity of the bees is aroused and the development of the queen is hastened by placing in the hive a comb of young unsealed brood, or, if he does not wish to destroy fine empty combs, let him separate the combs and insert between them, near the fly hole, empty frames with simply foundations. Again, by feeding in the evening, and from time to time sprinkling with thinned honey, will the early and full development of the queen be not a little hastened. Yesterday, August 8, a hot, oppressive day, I entered my Apiary about three P. M. Hardly any bees were flying, since this one week of oppressive heat had parched all vegetation. Only the drones, where any were yet present, were hotly pursued. Their number becoming daily less, I sprinkled all my nuclei, containing young queens, with diluted honey. It was hardly a minute before I saw a young queen with her cluster of bees leave the hive; on opening the hive a quarter of an hour later, I found the plain signs of her copulation. Without the aid given by this sprinkling of thinned honey the queen would not have come out; and had the weather changed, days, yes weeks, might have elapsed before another favorable opportunity would have presented itself.

Moreover, the periods at which the impregnated queens begin to lay differ widely. Often in two days after copulation she has full laying powers, but with as thin a body as an unimpregnated queen. And then nothing is so stimulating as comb of young brood. The bees having then to prepare food for the brood, the queen will also be abundantly furnished with it, and thus begins to lay so much earlier. In this is also the advantage that in looking for the queen you will find her on the brood comb, and then one can readily see whether she is wanting in any particular.

DZIERZON.

Carlsmark, Aug. 9, 1873.

Voices from Among the Hives.

A. C. BALCH, Kalamazoo, Mich., writes:—I have put all my bees into the cellar for the winter, and have no fears of losing them, as I have no faith in dysentery or bad honey. I believe with Cromwell—'Put your faith in Providence and keep your powder dry.'—Have good hives, the tighter the better, and give very little ventilation. Put them in a good, warm, dark and dry cellar, with enough to eat, and they will come out all right; at least mine always have. I never give any top ventilation, and but small bottom, and thus have no circulation of air through the hive.

JOSEPH B. RAPP, Owensville, O., writes:—Some of us beginners would like to have communications from A. Grimm, M. Quinby, Capt. Hetherington and other Apianians, describing in detail their methods of managing apiaries. From what little knowledge I have been able to pick up about bees, I think that Mr. Faulkners, of Vevay, Ind., has the best way of managing bees for profit. Colonies in this country are almost all weak in numbers, and will necessarily have to be protected to winter surely.

W. J. MCKEE, Cedar Falls, Iowa, writes:—I consider the JOURNAL indispensable to every bee-keeper.

A. GREY, Reiley, Ohio, writes:—What few bees were alive last Spring have done fine this season, both in honey and in increase of stock. I do not fear the dysentery this Winter, as the honey is of the best quality and the stocks are in good condition for Winter. Success to the JOURNAL and all of its readers.

W. M. KELLOGG, Oneida, Ills., writes of Bee-stings and "Novice," as follows:—"Friend Argus thinks the lips the worst place on which to have a loving bee salute a person. Just let him get a good deep one on the inside of the nostril, as I have had twice, and he will own up that he had rather try the kiss on the lips, or take one on the tip end of the nose ker slap, with the bee coming like a ball from a rifle. As for me, I had rather be excused from any of them. Friend Chapman, I agree with you in regard to the abuse heaped upon "Novice," and I too enter my protest against having any such articles appear in the JOURNAL. And as to his opposition to patent hives, I think if a little more of it were done, bee-keepers in general would be the gainers. I bought the Right? of an Eastern hive, and it would have been a hundred dollars in my pocket had I never seen said hive; and now we all have the *right* to make as many of them as we (*don't*) want.

E. LISTON, Virgil City, Missouri, reports as follows: My bees are all in good order for wintering, and are on their summer stands. Winter is open and the bees

fly every few days. In this section of the country bees made us no surplus the past season on account of dry weather, and I fear many black bees in old box hives will starve to death before bloom comes next summer. Successful Apianians in this section are very scarce,⁶ because they have not the energy, industry and care that the calling requires.

J. F. LOVE, Cornersville, Tenn., writes:—Our bees are in the very best condition possible for wintering, and this has been a good season for honey in this part of the State. I do not expect to lose a single stock; our bees can fly every ten or fifteen days through the Winter generally; we keep them on the summer stand. I saved every full stock and all nuclei last Winter on the summer stands and with no sign of disease of any kind.

DR. E. G. DECKER, Fort Fairfield, Maine, says:—Being an Apianian, I do not know how to get along without the JOURNAL. Bees did well here the past season; my thirty hives paid me ten dollars apiece, besides increasing to seventy-five full stocks. My surplus was all boxes, price here, twenty cents, gross weight. I take no particular pains with them as I have a large country practice to attend to. Winter in the cellar, keep them in from November 25th to April 10th or 20th. I hope to see the JOURNAL semi-monthly before long.

J. HARPER, Mason, Mich., writes that bees have done well in his locality for the last three seasons and that the last year has been the best of all. He also mentions a fatal disease which has attacked his bees. Having found a goodly number dead, he inquired into the cause and found a maggot or crab, about the size of a horse-fly maggot, only they are wider between the eyes and very black. He states that he has put some of these in glass vials, and thinks they will hatch in the Spring; they are now in cocoon state. Some explanation is asked for from any one who has had any practical experience in that direction.

P. J. TALBOT, Viola, Iowa, says:—I deprecate all complicated hives, not because they are patented, but because they are very injurious to beginners—experienced apianians will not use them. . . . The frames should be high enough from the bottom of the hive to allow it to be easily cleaned out with a small scraper and slip board at the bottom and rear of the hive. That should be attended to often if the weather will permit.

MR. CAMPBELL of Tennessee, writes:—Three years ago I began with two stocks in box hives, one of which I transferred to the Langstroth hive, and the other to the Buckeye. Those in the Langstroth hive did well and increased rapidly, but the moths took charge of the other, and the bees refused to stay in it. I put them in three times, and the last time they

came out they took to the woods with a "whiz." I had no surplus honey this season. It has been a very poor year for honey in this locality.

S. J. FREEBORN, Ithaca, Wis., says: There is very little done in this section in scientific bee-keeping, but thanks to the JOURNAL, we hope to do a little in that line another Summer. What few bees there were left did very well in gathering honey last Summer. It was mostly collected from buckwheat, and was thicker than usual.

WM. MUTH RASMUSSEN, of El Monte, Los Angeles Co., Cal., writes: Last August a small number of bee-keepers of this county formed the Bee-keepers' Association of Los Angeles County. We do not yet count many members, but hope before long to have most of the bee-keepers of the county join us, and new members are coming in at each meeting. A committee appointed for the purpose, reported at the last meeting 3117 hives of bees in the county, and probably more which they had not been able to find. The yield of honey from these hives for the last season was estimated at 160,000 pounds.

THOS. H. HUNTER, Zanesville, Ohio, says:—This has been a poor season for gathering honey in this locality. From seven colonies I had only about a hundred pounds of box honey.

JOHN MIDDLEWORTH, Byron, Mich., writes:—The last two Winters will long be remembered by the bee-keepers in this vicinity. I lost in 1871, forty-three stocks out of forty-six, and in 1872, lost thirty-three out of thirty-six. There was only one stock besides mine wintered, making only four in the township. I now have nine colonies, and hope for better success.

WM. ASHCOME, Ligonier, Pa., writes:—Bees have done better here the last season, than they have for the past twenty years. I never had them in a better condition than now. I keep them on their summer stands, using the one story Langstroth hive. In the Fall I pack between the outside and the glass with dry leaves, and since doing this have had no moldy comb.

J. A. FOULSTON, of Farley, Iowa, says:—I had ten swarms last Spring in very poor condition. I Italianized all but two, and increased them to fifteen colonies, and took three hundred pounds of honey with the extractor.

JAMES SCOTT, Epworth, Iowa, reports as follows:—I went into winter quarters in 1872 with thirty-six stands: lost one in the cellar by starvation with plenty of honey in the hive. It was a two story hive, and I had neglected to remove the upper story. I lost seven in all, in the Spring sold two, leaving twenty-six, most of them in poor condition; but I obtained 1900 pounds of extracted honey and increased my stock to thirty-six.

MRS. V. C. CONDIT, of Howard Springs, Tenn. states:—Bees did poorly here until the 1st. of July, on account of wet weather. After that they did very well: but we had no increase.

W. J. DAVIS, Youngsville, Pa., says:—I prize the AMERICAN BEE JOURNAL very highly, and consider it worth more than all the other Bee magazines combined.

JAMES M. LAY, of Madison, Wis., writes:—In relation to the bee plant, *Monarda Punctata*, I think it grows best when sown in the Fall or in the Spring before the snow goes off. I sowed some last May that did not come up, but expect so see it next Spring. Lost all our bees last Winter: bought one swarm last Spring, and it increased to fourteen, besides giving 190 pounds of honey.

JOHN A. BUCHANAN, of Wintersville, Ohio, writes as follows:—Our experience in this locality is, that our gains are doubled by the use of the Extractor and more than doubled by reading and practicing upon the many valuable suggestions found in the columns of THE AMERICAN BEE JOURNAL.

H. ROOT, Otisco Valley, N. Y., states:—Out of ninety-nine swarms last year, only thirty-three survived, and most of them in a very weak condition. I increased them to only forty-one, my object being honey, and they gave me 1800 pounds of nice honey, which I sold in New York for thirty-six cents a pound. This was done by the black bee in the Langstroth hive. If any have done better, let us hear from them through the JOURNAL. You may consider me a subscriber for life.

J. T. WATKINS, of Sparta, Ind., asks several questions, which he will find fully answered in this number and the next.

ANNA SAUNDERS, of Woodville, Miss., writes that there are very few bees in that locality, but that the few are prosperous, there being no bee disease in that vicinity. She says farther:—I enclose you a few seeds of the Sage tree, which is as large as the medium sized Larch, and when in bloom is alive with bees. Will take pleasure in sending the seed to any one. In reply to her questions about the sale of queens, apiarian supplies, etc., we would refer her to our advertising columns. We shall take pleasure in testing the seeds sent.

A. B. MASON, of Waterloo, Iowa, called on us a few days ago. Mr. M. reports that Italian bees did not do well in his section of Iowa, on account of the severe drought in the early part of the season.

Mr. Lee, of Peatonica, Ill., brought to our market 1400 pounds of comb honey in December. It was very choice indeed. We did not learn to whom it was sold. His bees were very successful during last season. He commenced the season with forty colonies, and now has over one hundred, and has sold over 3000 pounds, comb and extracted.

MR. JAMES J. H. GREGORY of Marblehead, Mass., aims to supply one great want, which many a good farmer, when too late, has felt to his keen sorrow: Garden seeds that know how to come up, and when the crop is gathered prove to be just the kind the label said they were. Mr. Gregory is one of the few seedsmen in the United States who grows a large portion of the seed he sells, and he gets out a live Catalogue, as would be expected of the original introducer of the Hubbard Squash. His advertisement will be found in this number. His Illustrated Catalogue will be sent FREE to applicants.

Michigan Bee-Keepers' Convention.

The following report of the proceedings of that body is just received from the Secretary. He makes an apology for the delay upon the ground that he has been getting married, and, therefore, had no time to attend to matters of minor importance. We accept his excuse as being perfectly valid:

GRAND RAPIDS, MICH., Sep. 17, 1873.

7:30 P. M.—The sixth annual convention of the Michigan Bee-Keepers Association met, pursuant to notice, in the Court-House, at Grand Rapids, Vice-President A. C. Balch, of Kalamazoo, in the chair.

The minutes of the previous meeting were read and approved.

A number of those announced for papers not being present, the Secretary proposed that extemporaneous remarks upon some subject of present interest to bee-keepers be made.

The subject of Hives was decided upon. The point contended was for the most part the relative merits of one and two story hives.

Mr. H. A. Burch, of South Haven, claimed that in his experience the hive with a single story had proved the most successful.

Mr. James Heddon, of Dowagiac, defended hives of two or more stories. He piled his hives one upon another to the height of two or three stories, and said by changing the frames from one part to another part of the sections, he had induced the queen to go into all parts of the hive and deposit her eggs, thus filling every part with brood.

Mr. Tomlinson, of Allegan, used a hive of one story, and very shallow frames, only six inches in width. He had, during the Summer just passed, increased his swarms from five to twenty in number, and had taken four hundred pounds of box-honey.

The meeting was rather informal, and considerable digression from the main subject was indulged in.

Adjourned until to-morrow 9 A. M.

THURSDAY MORNING SESSION.

The President still being absent, the chair was filled by Vice-President Balch. The order of business was announced to be the consideration of Artificial Swarming and the Honey Extractor.

The subject of artificial swarming was discussed and the various methods stated by Messrs. A. C. Balch, C. I. Balch, Heddon, Everard and Porter.

The Secretary then read an interesting paper by A. I. Root, of Medina, Ohio, upon "The Honey Extractor, its Uses and Benefits."

After the experience of some of the members present with the Honey Extractor was given, the meeting adjourned till evening.

THURSDAY EVENING SESSION.

The meeting was called to order by the President, T. F. Bingham, of Allegan, who had arrived during the day.

To the great satisfaction of all present, Prof. A. J. Cook, of Lansing, formerly Secretary of the Association, put in an appearance at the opening of the meeting.

The topic for the evening, as announced at the previous meeting, was the all important subject of Wintering Bees.

Upon this subject Prof. Cook had prepared a somewhat lengthy, able and scientific paper, which he read to the convention. The paper drew out a most hearty vote of thanks to Prof. Cook. Some remarks were made, and the experience of members stated on the subject under consideration.

Mr. A. C. Balch stated that according to his experience very little ventilation was needed in Winter, and gave his reason for such a position. He stated that with much ventilation there was a constant escape of heat, and that the temperature inside the hive would be more variable.

After a very interesting evening, the meeting adjourned until to-morrow morning at eight o'clock.

FRIDAY MORNING SESSION.

Meeting called to order by President Bingham. Minutes of last meeting read and approved. The convention then proceeded to transact miscellaneous business.

Motion made and carried that the Society hold a special meeting at Kalamazoo, the first Wednesday in May of 1874.

Motion made and carried to empower the special meeting at Kalamazoo to appoint the time and place of holding the next annual meeting.

The election of officers was then proceeded with, the following being the result: President, A. C. Balch, Kalamazoo; Vice-President, H. A. Burch, South Haven; Secretary, Frank Benton, Shelby, Oceana Co; Treasurer, T. F. Bingham, Allegan.

Motion made and carried that the retiring President and Secretary receive a vote of thanks from the Society for the faithful manner in which they have performed their respective duties.

A resolution was then introduced relative to amending the constitution so that instead of the former number of officers, there should be in addition a Vice-President for each of the several counties of the State, so far as represented in the Association. Adopted.

The convention proceeded to appoint Vice-Presidents for all the counties represented in the Society.

The meeting then adjourned until the first Wednesday in May, 1874.

J. W. PORTER,
Sec'y Mich. Bee-Keepers' Association.

T. F. BINGHAM, President.

To Bee-Keepers.

The North Eastern Bee-Keepers' Association will hold its fourth annual meeting at the Butterfield House, Utica, N. Y., on the 4th. and 5th. of February, 1874.

Questions of importance will be discussed. Bee-keepers are most urgently requested to attend and take part in the proceedings. In union there is strength. Please respond.

M. QUINBY, Pres.

The *National Bee Journal*, Mrs. E. S. Tupper, Publisher, has recently been improved in its appearance by the addition of a neat cover. The *Journal* is well executed, and promises to be a success in the hands of the present Publisher.

CHICAGO, FEBRUARY, 1874.

No. 2.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

For the American Bee Journal.

Gallup's Corn as a Honey-plant.

In reply to persons who have made application for corn, we will say that it is climatic or atmospheric influence that causes a plant to produce Bee-forage in one locality, and not in another. For example, Mr. Adair and others say that buckwheat never produces anything in the shape of Bee-forage in their climate, while in my climate, both here and in Canada, it never fails to produce an abundance in ordinary seasons. The partridge pea is highly esteemed around Washington, while here Bees did not visit it at all. Timothy or herds' grass produces large quantities of pollen while in bloom here and elsewhere. We have seen fields of it literally covered with Bees while in bloom, yet we have never seen it mentioned as a Bee-plant. In 1870-71 our fields or patches of pop corn, smelt corn, or flint corn, were alive with the hum of the "little busy Bee," while it was in bloom. They seemed to gather pollen from the blossoms and honey from the silk at the same time. Then the corn silk glistened with sweet, yet in 1872 not a single Bee did I see visit it; and in fact white clover produced nothing in my vicinity in 1872.

Our old stand-by, the basswood, only produced forage for eight days in 1872, while in 1870, it lasted twenty days; and in 1871, it lasted in all, nearly thirty days; all owing to climatic and at-

mospheric influences. If the atmosphere is moist and warm, and well charged with electricity, then is the time our flowers produce the most forage. On the contrary, the atmosphere may be dry and warm, or hot, and flowers produce nothing. But by heavily manuring a piece of land for white clover or buckwheat, we can cause it to produce honey in a dry or cool season. Manure warms up the land, and it also causes a vapor or moisture to arise from the soil, which does not arise from an impoverished soil. We have noticed this repeatedly. We have seen a row of current bushes alive with Bees, that had been heavily manured the season previous, while a row that was not manured was not visited by the Bees. We have seen a four-acre patch of white clover that had been heavily manured the season previous, covered with Bees, while the clover field by the side of it was not visited by a single Bee. We have had some buckwheat on poor land, and on rich land at the same time.—That on the poor land was not visited, while that on the rich land was alive with Bees, and fairly scented the atmosphere with sweet around it. White clover on warm sandy land, produced abundance of forage the past season, while on clay soil it produced nothing.

Now, Brother Bee-Keepers, you can easily see from the above why you do not want my kind of corn, or my kind of hay, &c., for Bees. E. GALLUP.

Orchard, Iowa.

DZIERZON watched a queen Bee when laying, and noticed that she laid eighteen worker eggs in three minutes. She appeared to dispatch business still more expeditiously when laying drone eggs.

For the American Bee Journal.

A Letter from Kansas.

EDITOR JOURNAL: The past season has been to the Apiarist the poorest for years in this section of the State. The causes to which the general failure is attributed, are many; among the most prominent that might be mentioned were the cold Winter and backward Spring we passed through, which had the tendency to reduce the colonies to a few handfuls of bees (as a general thing), and the negligence on the part of many to stimulate and build them up early in the season. Consequently, when the early blossoms came there were no Bees to gather the honey. Most of the stocks, however, were pretty strong by the 20th of June, and in fair condition for the basswood harvest; but unfortunately the blossoms failed to secrete any of the sweet fluid. From the 1st of July to the 24th of September, we were subjected to drought, with very warm, sultry weather, causing a complete failure in the Fall flowers. It is very easy to perceive that we are not placed in an enviable position so far as the profits of apiculture are concerned. I was informed last week by a gentleman who has been in the business fifteen years, that out of sixty colonies with which he started last Spring, he has made no increase in his number during the season, and, unfortunately, has not obtained one pound of surplus honey. He farther states that two-thirds of his stocks do not weigh as much now as they did last March. You can draw your own conclusions. I have mine, which are, that in the Spring of seventy-four there will either be quite a demand for Bees, or there will be a large number of disgusted Apiarians.

As for myself, I do not profess to be anything but a beginner at the business; and I do not keep them for the profit, but for the pleasure derived from obtaining knowledge under difficulties. I started with one colony last year, I increased that one to five, and obtained about thirty pounds of surplus honey; lost one during the Winter. From four, have increased during the past season to eight; but have obtained no surplus honey. This is not a bad beginning.

considering the disadvantage of residing in the heart of a city of twenty-seven-thousand inhabitants.

I have all my colonies in good condition, by feeding sugar syrup in November—six in the cellar, and two in an experimental hive outside. If this should prove a success, I will, in the Spring, furnish your readers with a full description of the method, and give them the benefit of it. Lou.

Leavenworth, Kan.

For the American Bee Journal.

Pollen.

In Vol. 9, page 28, I made the assertion that brood could not be raised without pollen. On page 27 J. Butler experimented in this direction, and declares that his Bees did raise brood without pollen.

Now, I must confess this somewhat astonished me, for it was contrary to all our knowledge and practice. I however believed Mr. Butler in his public statement, but still I thought there must be a great mistake somewhere. It however stimulated to further investigation, and I have come to the conclusion that he was right in his observation, but wrong in his conclusion, and in order to establish this I will quote high authority, but before doing so permit me to remark that it is admitted by all distinguished apiarists, both in Europe and America, that brood has been raised (to a limited extent, however,) without pollen *being visible*, as in Mr. Butler's case.

In Vol. 1, page 253, of the AMERICAN BEE JOURNAL, Dr. Donhoff, in analyzing the excreta of Bees, says: "What was left after again filtering could, from its insolubility, be only the remains of pollen. It appeared under the microscope like an indistinctly granular mass." When I first saw the above, I at once came to the conclusion that pollen was retained in the bodies of the Bees for sometime, and the following further convinced me, as well as solved the mystery.

Baron Berlepsch, on page 230, Vol. 1, says: "It has been demonstrated that common workers are produced in colonies which have not a particle of pollen

in their hives, and at a time when the Bees could not gather any. * * * But it is by no means easy to determine when there is an entire absence of pollen, or its essential equivalent in the hive."

There may not be a particle of it discoverable in the cells, and yet a store of it amply sufficient for the needs of the larvæ may be deposited in the stomachs of the workers, or their general organism. I hope, from the above, Mr. Butler will see that his Bees had some pollen. ARGUS.

For the American Bee Journal.

Good Bee Location—Rape Seed.

MR. EDITOR:—It is with a great deal of hesitation and a troubling of conscience, that I again ask for a corner in the JOURNAL, for I have already had rather more than my share of "space." But there are a few words that I would like to say.

Mr. Colburn, in the December Number, would like to know where he can find a good place to start an apiary, not too far from Chicago. Now, I don't wish to boast of *my* locality, nor would I like to coax any one here, lest he should afterwards be discontented and then blame me for so doing. Therefore, I would say, that he could find many such places as he mentions, between here (Berlin) and Milwaukee,—there is plenty of Basswood; and the country is old enough so that white clover has well set in, wherever it has an opportunity to grow. In addition to this, we have plenty of buckwheat—at least in this vicinity—and also many cranberry marshes, which were referred to as being of value, by the editor, in the November Number of the AMERICAN BEE JOURNAL.

Berlin is about 180 miles from Chicago, and can now be reached without change of cars, *via* Milwaukee, which is 90 miles from Chicago.

If the gentleman wishes further information I shall be glad to answer his questions through the mails. The best way, however, to ascertain the truth, would be to pay us, or this part of the country, a visit.

Mr. Frank W. Chapman gives a report from his rape seed. I am sorry he is so sensitive as to give up its culture, because his neighbors make fun of him about his "turnip patch." But I don't see any fun in it. Mr. Dadant and my brother, in Illinois, planted turnips *expressly* for Bees; and I can't see where the laugh comes in. But some people are, perhaps, more easily amused than your humble servant. He further states that he thinks it was too dry. Well, from what I have learned about the weather in Illinois last Summer, I should think it *was* too dry. Mr. Dadant reports nearly an entire failure, 1,000 lbs. only, from 230 stocks, I think, because of the severe drought.

Rape seed should be planted on good, rich soil—soil where wheat or other grain has been raised, will be good, because grain will leave that portion of nutriment in the soil which rape requires—and, of course, the weather must be favorable for it, as well as for other farm products. Lastly, the time for harvesting must be well watched; as soon as the kernel is filled and turns, cut it; and as soon as sufficiently dry, haul it in.

Mr. Editor, the December issue is, in my judgment, of extraordinary interest. Long live the AMERICAN BEE JOURNAL! for it is the "right bower" in the pack of different Bee journals that adorn our shelf.

Chips from Sweet Home.

Two years ago I lost six hives by disease, and last winter I lost fifty-five hives, being all I had. They were left on their summer stand. This Winter I put ninety-five hives in my cellar during the first cold snap, all but seven were put in three days after they flew, the seven two days later, Nov. 28th. I now have four cases of the disease out of the seven. They have been very uneasy ever since taken in. My cellar is 20x24, the sides and bottom are cemented, a chimney built on the bottom of the cellar, with an opening at the bottom in which there is a continual draft, besides four windows which I open nights to cool

the cellar and close daytimes. I have never given my opinion as to the cause of the disease, for I had none. I noticed Bees which were housed *early* escaped the disease.

I will now give what I suppose to be the *cause of the disease*, and if there are any exceptions we shall be pleased to hear them.

All Bees which have died of the disease have been exposed to a *week or more* of cold weather, during which time they *gorge* themselves with honey, if then they are moved into cellars or Bee houses, or are kept confined by cold weather so that they are unable to empty themselves, dysentery will be the effect every time.

Will "Novice," or others who have fed sugar syrup, try an experiment as follows? Leave a hive out during a week or more of cold weather, then, without allowing them to discharge, take them in a Bee house or cellar, and report the result.

To-day I set the four ill-fated hives out and let them fly.

D. D. PALMER.

Eliza, Mercer Co., Ill.

Bee Notes from Darwin.

Bees have solved a recondite problem. They have made their cells of a proper shape to hold the greatest possible amount of honey, with the least possible consumption of precious wax, in their construction.

No human workman is skilful enough to do what a crowd of Bees can do—working in a dark hive—make cells of wax of the true form.

The number of humble Bees in the country will depend upon the number of cats! How can that be? Because the number of Bees is dependent upon the number of field mice, which eat the Bees. Hence the more cats, the fewer mice; and the fewer mice, the more Bees.

If the whole germs of Humble-Bees became extinct, or very rare, the heart's ease and red clover would become rare or wholly disappear. How is that? Because Bees promote the growth of those flowers. The visits of Bees are necessary to the fertilization of some kinds of

clover, and almost indispensable to the fertilization of the heart's ease, for these Bees do not visit this flower. Humble-Bees alone visit red clover as other Bees cannot reach the nectar.

In a word—no Bees, no seed; no seed, no increase of the flower. The more visits from Bees, the more seeds from the flower; the more seeds from the flower, the more flowers from the seeds.

Nearly all our orchidaceous plants absolutely require the visits of insects to remove their pollen-masses and thus to fertilize them.

Twenty heads of unprotected Dutch clover yields 2,990 seeds. The same number protected from Bees produced not one seed; 100 heads of unprotected red clover yielded 2,700, and the same number protected from Bees not a seed.

Pruning Broods.

Pruning brood combs is generally quite unnecessary, in fact is more often injurious than otherwise. If they ever require excision, it can only be when they are so overcharged with pollen as to render breeding impossible, in which case the operation should be performed in the Spring. Pruning them after the Bees have swarmed and cast, is very unwise for several reasons. First, there is a possibility that during a glut of honey, the Bees would build an excess of drone comb, or supposing their queen to be lost, that they would build drone comb exclusively, if any; second, that having to replace the excised comb, they would be less likely to yield a surplus in their super; and, third, there is the undoubted fact that Bees winter much better in old combs than in new ones, because being coated with so much silky fibre, they are the warmer of the two, and again there is the chance that in an unfavorable season they may be unable to build any comb at all.—*British Bee Journal*.

A person who has familiarized himself to Bees, can by means of the passion of fear impressed upon them, and by that dexterity in the management of them, which can only be acquired by practice, manage Bees as he pleases.—*Wildman*.

Bee Keeping for Farmers.

Some have adopted Bee keeping as the business of life; and these have mostly attained a flattering success. Others engage in it as a pastime and amusement chiefly.

Apiculture has made great advances of late years. The intelligent Bee-keeper no longer consigns his favorites to a hollow log, or rude box, nor what is even worse, to any of those absurd contrivances which have proved the ruin of thousands of happy colonies of Bees, and provoked the disgust of their unfortunate owners. But providing himself with some form of movable comb hive, well constructed, and having a sufficiently capacious brood chamber (or main apartment) and suitable arrangement for surplus honey, he enters upon the pursuit with fair prospect of success. Those who have once learned how to keep Bees, will not soon abandon the pursuit.—*Western Agriculturist*.

For the American Bee Journal.

Queen-breeding and the Cost of Italian Queens.

I was once amused by a would-be wise Bee-man, under the following circumstance: I was on my way to introduce a number of Italian queens for a friend, when I reined my horse up to a watering trough, and the following dialogue took place:

What is that in your buggy, boxes of honey? (inquired Mr. Johnson, a portly farmer.)

No sir, I have some Italian Bees and queens in those boxes.

Now, Mr. Davis, you are doing wrong in scattering all those yellow jackets through the country. They are running the black Bees out, and they won't work, they don't make any honey. What do you get for those queens?

They are worth, when safely introduced, five dollars each.

Five dollars each! Oh! I thought you was a Christian man. Five dollars each—It don't cost anything to raise queens; not more than it does to raise flies.

I replied, Mr. J., you may possibly lie under a misapprehension of the facts

in the case. If Italian Bees were as you describe them, they would be quite likely to perish during our long, cold Winters. But, sir, you are quite mistaken about the industry of the Italian Bee; and I would like to ask how much experience you have had in queen raising?

Oh! I never raised any queens, but my Bees always have queens enough.

We argued the case at some length, but he "would not be convinced." Mr. J. was one of those men who hold to an error on any subject, with the same tenacity as to the most precious truth.

But let us try the figures on the cost of rearing queen Bees for the market, as it appears that an erroneous view has obtained in some quarters. Queen-breeding, like any other enterprise, should be prosecuted in the best modes of the art, to secure the best results. To do this we think that the nucleus system proposes the most advantages for producing queens in any considerable quantity. We will make an estimate of the results of 100 nuclei hives. The first item of expense will be the cost of hives, which for getting up in good shape, ready for use, will cost about one dollar each, or \$100.00 for the lot. To stock 100 nuclei with Bees, say by the first of May, will require the Bees and most of the combs of twenty-five fair stocks. To produce the sealed queen cells will take the labor of about ten stocks more, making thirty-five stocks.

Now for the results: In this latitude, good queens can not be produced more than four months in the year, viz., May, June, July, and August; and a good average is 400 queens for the season. Now let us see what our thirty-five stocks should produce in honey if not used for queen breeding. It has been estimated at 200 pounds extracted honey per stock, some stocks yielding 300 pounds. But we will take the lowest figure, 200 pounds each, or 7000 pounds, which at sixteen cents per pound would be \$1120. Add to this the labor of an experienced Apiarist, which for the four working months would be reasonable at \$100 per month—\$400. Add to this the difference in the value between thirty-five first class stocks with their increase,

and 100 nuclei hives, say \$275, and we have a total of \$1795 as the cost of 400 queens—or \$4.49 each.

We consider the above a fair estimate for any locality where strong colonies will average 200 pounds each, surplus honey. In less favorable localities the cost would be reduced. But where stocks could collect from fifty to fifty-three pounds per day, the cost of queens would be very much increased. In our estimate we have omitted a number of Items on each side of the question, but as they would so nearly balance each other, they would not materially affect the result.

W. J. DAVIS.

Youngsville, Pa.

For the American Bee Journal.

Feeding Bees out-doors the first days of December.

Thus far we have had a very favorable Fall and Winter for Bees. Only about one week ago, I was doing what perhaps ought to have been done sooner, viz., feeding up with sugar syrup a few of the weaker colonies. The weather was balmy and nice, and the Bees very lively; and for about three days, I had them very busily employed.

My mode of procedure was thus: I took some tin plates, and after putting straws, little chips, etc., as rafts and foot logs for the Bees, I removed the back glass partition of the inner chamber, and slid the plate, full of syrup, under the lower ends of the combs, on the top of the bottom of the frames, and as near to the cluster as possible. This is the best way I have tried to get the Bees to do "big work." When empty (which can be seen without opening into the brood-chamber), the plate can be replenished from the top of the hive through a hole in the honey-board. In this way they do not have any cloth to penetrate first, but have only to crawl down the cluster, which forms down to the syrup, and help themselves. Robber Bees did not trouble much, but one or two of the weakest I kept closed while feeding them. I will put these hives in the cellar whenever the weather is severe, and if they

are troubled with *Asiatic cholera* in the Spring, I will let you know it.

Black Jack, Kan.

M. A. O.

Bee Keepers' Association of Mississippi.

At a meeting held at the Fair Grounds, Jackson, Mississippi, on Saturday, the 15th of November, 1873, the following named gentlemen organized themselves into an Association, to be known as the Bee-Keepers' Association of Mississippi.

W. F. Standefer, Dry Grove, Hinds county, Miss.; L. F. Alford, Jackson, Hinds county; P. F. Rajan, Pelahatchie, Rankin county; S. R. Sorsby, Spring Ridge, Hinds county; T. A. Catchings, Jackson, Hinds county; M. P. Simpson, Jackson, Hinds county; D. M. Wilkinson, Jackson, Hinds county; J. M. Shaw, Jackson, Hinds county; F. S. Hunt, Jackson, Hinds county; D. V. Culley, Madison Station, Madison county; J. E. Goodlett, Terry, Hinds county; E. W. Cabaniss, Clinton, Hinds county; W. D. Smith, Edwards, Hinds county; J. W. Ennis, Auburn, Hinds county; J. S. Barfield, Jackson, Hinds county; Joseph Gray, Raymond, Hinds county; Col. John, Boltens, Hinds county; J. J. Lester, Jackson, Hinds county; W. S. Cable, Clinton, Hinds county; O. P. Wright, Jackson, Hinds County; George Boddie, Jackson, Hinds county; N. S. Elkins, Brownsville, Hinds county; S. J. Carter, Mississippi Springs, Hinds county; S. P. Baley, Jackson, Hinds county; T. W. Harris, Jackson, Hinds county; A. J. Frantz, Brandon, Rankin county; C. W. Hicks, Clinton, Hinds county; E. M. Alford, E. Cook, Dr. W. F. Graves, John H. Echols, L. F. Childs.

The following resolutions were adopted:

1. RESOLVED, That this Society shall be known as the Bee-Keepers' Association of Mississippi.
2. RESOLVED, That the annual meeting of this Association be held at Jackson, Mississippi, at the time of the State Fair, or at such other time and place as the President may direct.
3. RESOLVED, That we ask the co-operation and aid of all interested in Bee-Keeping, by reporting their successes and reverses, through the columns of the FARMERS' VINDICATOR.
4. RESOLVED, That a committee be appointed to examine and test all Apian improvements, that may be sent to this Association, and report on the same.
5. RESOLVED, That we tender our thanks to the Editor of the FARMERS' VINDICATOR, for the use of a column in his paper for the benefit of our Association.

L. F. ALFORD, President.

W. F. STANDEFER, Secretary.

The following officers were elected to serve for the ensuing year:

L. F. Alford, President, Jackson, Hinds County.
Dr. T. A. Catchings, Vice-President, Jackson, Hinds county.

W. F. Standefer, Secretary, Dry Grove, Hinds county.
Joseph Gray, Treasurer, Raymond, Hinds county.

The following committee was appointed under the fourth resolution: S. K. Sorsby, W. F. Standefer, W. S. Elkins, F. S. Hunt and Jas. Barfield.

The Bee and its Winter Habits.

Valuable extracts from an address delivered before the Bee-keepers' Convention, by Prof. A. J. Cook, of the Agricultural College, Lansing, Mich.

MR. PRESIDENT:—I think I hazard nothing in the remark that no manual labor pursuit yields as great a per cent. on the capital invested as apiculture. During the season just past—in no wise an extraordinary one as to the honey harvest—my Bees have netted me over \$33 per colony, about 200 per cent. on their value. Add to this the fact that I started with only one Italian colony, and have Italianized my whole apiary, and you are enabled to see that the profits of Bee-keeping are by no means inconsiderable. And this is not an isolated case. It is to be hoped that all of you are subscribers to that most excellent periodical, the AMERICAN BEE JOURNAL, of Chicago. In that you have read of Adam Grimm, of Wisconsin, with his several apiaries and immense returns, which are often fairly startling; of A. I. Root, of Ohio, who is doing wonders not only in obtaining prodigious returns of honey, but in fostering apiarian pursuits.

Yet I would not assert that this bright picture of profit—and I might aver of real pleasure, as well—has not its shadows. The agriculturist has his droughts, the pomologist his dreaded blasts of Winter, the merchant his eras of depreciated stock, so also the bitter is mingled with the sweet in the apiarist's cup, and how many apiarists all through our country, since the bitter experience of the past two Winters, have little of the sweet in their expression as you speak to them of Bee-keeping. They too can speak of the Winter of their discontent.

Let us therefore analyze closely the dangers in the way of successful Wintering of Bees, in the light of their history and habits, and see if we may not at least *hope* to avoid in future the stumbling block which has so essayed to overthrow us in the successful prosecution of our favorite business.

That Bees will endure very severe

cold is certain; that they are ever so frozen as to be thus destroyed needs proof. I knew a colony of Bees to winter well during the terrible cold Winter of 1871-2 in a hive with an unsealed crevice, and resting on the summer stand. Now all animals while hibernating take no food nor exercise, hence there is little destruction of tissue, and little exertion. Now it is not probable that, could we keep our Bees during all the months of Winter at an even temperature—at about the freezing point, or a little above—they would, if normal and healthy, Winter well, and consume scarcely any food at all. Does not this explain the not uncommon phenomenon of strong colonies wintering on three or four pounds of honey?

Now, if the above proposition can not be disapproved, is not one of our chief desiderata in wintering to secure such conditions as will insure even temperature?

With the best management there will doubtless be more or less food consumed during Winter; hence good food is indispensable. By good food I mean good thick honey gathered from the flowers, and all capped over, or else coffee A sugar fed by the middle of September, or so early as to be all capped over before Winter and rest comes on. Again, during the early Spring breeding must commence. This only follows upon warmth, activity and food-taking. Thus we need not only good honey to serve as food for the mature insect, but there must also be an ample supply of pollen or Bee bread, that the larvæ or immature Bees may receive proper food. Hence we conclude that our second desideratum, in successful wintering, is to have the stores which are designed for Winter consumption, of the best quality, and also a sufficient amount of Bee bread that the early Spring brood may not lack nourishment.

Again, it is a truth well understood by all physiologists that the greater the animal's activity, the more rapid the destruction of tissue, and unless the tissues can have periods of rest, they will soon become powerless to perform their allotted function, and hence death must result. Suppose we should labor constantly, taking no rest, how soon would

we succumb, becoming victims of unre-mitted toil. Would we keep our mus-cles in good condition we must give them stated intervals of rest. Thus we understand the phenomenon of sleep, which is only a generalization of that necessity which causes the woodman to lower his axe, being an imperative re-quisite to the recuperation of a tired body, a body so exhausted that the nerve as well as muscular system needs to rest.

Now, in the light of the above, can we wonder that the "busy Bee" ever active to obtain the most from a not over long harvest—or in quest of that which is not, so busy that the apiary not only swarms with life by day, but sends forth the full, joyous note of in-dustry all the hours of the long night through, should present a longevity so brief. Is it not beautiful, and does it not merit our gratitude—this fact that the little Bee becomes a willing martyr to the love of storing? Because of this unrivaled activity, the worker Bee lives only from two to three months. Now, suppose the queen ceases laying the last of August, as she is quite sure to do, if old or poor, especially if the Bees are gathering no stores. By the time Winter sets in the Bees will all be old, and in the Spring the few that have sur-vided will endure but few flights, so that colonies—as was the case with so many in our State during the past sea-son—will Winter through, only to suc-cumb to the more genial spring days, giving no signs of dysentery, nor yet of starvation.

So again, it is probable that to in-sure certain success in wintering, we must see to it that breeding continues well into the Fall, that every hive shall have brood in October.

Mr. Hosmer, of Minnesota, was the first, as far as I know, who gave this explanation, and reason certainly sus-tains the view, unless forsooth, the Bees that are old in Fall, revive by the long Winter's rest, renewing their youth. So we see, to uniform temperature in Win-ter, and sufficient and the right kind of stores, it is well to add the advice sug-gested by the above, to so manage as to have the brood reared in our apiaries late in the Fall.

Our last theory as to disastrous win-tering is an entirely visionary one; Epidemic—a very convenient explana-tion for we seem to give a reason, yet when we analyze it, it is no reason, nor are we usually able to give a reason when we decide thus.

A few years ago the chinch bugs, which for a long time had been very numerous and destructive in Illinois suddenly disappeared. Dr. Shimer, a distinguished entomologist, at once pro-nounced it epidemic. Later experience demonstrated that excessive rains ban-ished them. That exceeding dampness is, happily, very destructive to the chinch bug. So too the silk worm epidemic in France, yet the thorough and most praise-worthy researches of Pasteur, brought to light the real cause of febrine, and consequently the cure was made known and silk-culture saved from utter ex-termination.

So too in Bee diseases, I fully believe that the maladies which have been so disastrous the past two Winters come, as any one may prove, within the easy range of our understanding, and escape. Should I be mistaken, or should a more intricate trouble appear among us, we need not even then despond, for the ex-perience of the past bids us rest firm in the hope that with careful study, mak-ing use of the appliances which science brings to our aid, we shall be able to explain and conquer the most compli-cated disease.

Now having the theory of safe win-tering before us, which, as we have seen, combines even temperature a little above freezing point, good and sufficient stores, and late Fall brood, let us exam-ine and see if there be any experiments or experience that will sustain this theory.

The past Winter I buried my Bees in snow, making them the nucleus of a snow bank from the last of November till the 1st of March. The result was, they preserved an almost death-like si-lence, consumed very little honey, and in the Spring there was not in any hive a sufficient quantity of dead Bees to fill a small tea cup. In fact, I never saw colonies appear brighter, or do better than they did. It has long been the opinion of observing Bee-keepers, found-

ed on experience, that even Winters, with steady, continuous cold, are far less disastrous than changeable ones where there are many periods of warm weather.

Again, those who have cellars, or special depositories where they are enabled to keep the temperature uniform, have always been the most successful.

This also explains the—what some would call absurd theories of Gen. D. L. Adair, of Kentucky, and Mr. Balsch, of our own State, that Bees require no ventilation to ensure safe wintering. If in an even temperature, never rising above 35° F., the Bees are so dormant that they really do need very little air. To prove this I froze up the opening of one of my snow-bound hives, last Winter—the entrance of all of them were deeply covered with snow—so that it was hermetically sealed, and yet, I never had a colony Winter better. There was not a tablespoonful of dead Bees on the bottom of the hive in the Spring. This at least tends to prove that Bees, if kept from getting too warm, will need not only very little food, but also very little air. That it is not from cold Winters that the Bee-keeper need have apprehension, but from periods of sufficient heat to arouse the Bees from their torpor.

We next speak of the kind of honey. In the Fall of 1871-2, I placed twelve colonies of Bees in a dry, dark and quiet cellar at the Agricultural College, where I had for years kept Bees from the last of November till the last of March, without any loss. The previous Autumn had been, as you will remember, unprecedentedly dry. There were scarce any flowers in bloom, yet the Bees were very active gathering stores, even to the very verge of Winter. In October I prepared the colonies as usual for the cellar. Found much thin, unsealed honey. Supposing that it would thicken and be capped over in a few days, I took special pains to leave it in the hive, taking out all the nicely capped honey which they had stored early in the season. I did not sell all of this nice honey, but kept a little of it over.

Having placed the Bees in the cellar at the approach of cold weather, the last of November, not dreaming that

any bit of harm could come to my pets, I left the college, not returning till the last of January. Imagine my surprise upon visiting my Bees, at finding that the usual and supposed quiet had given way to a terrible uproar. Upon examination I found over half the colonies dead, and the five that were still alive were in a sore condition, indeed. I selected one colony, in no wise better than the others, on which to experiment. I assure you, faith added not a whit to my success. I took my fresh, good honey and placed it in the hive, taking out all that was tainted or besmeared. My surprise was equal to that of the prophet, for those "dry bones" did live, and that colony netted us about \$80 the next Summer. I need hardly say that the other colonies all died, though I gave them all the opportunity to drop their feces. The honey proved to be still thin and uncapped and very unpleasant to the taste—in fact, fairly sickening. The odor of the diseased colonies, caused no doubt by their excessive discharges, was also very nauseating.

I now think that the real source of the honey was in the insect secretions—though I did not think of it then. The dry Fall was very favorable to insect life. Our beach trees were fairly covered with a plant louse—(*Pemphigus imbricator*, Fitch.) Other nectar-secreting plant lice were very abundant. On the Tulip trees were hosts of large bark lice—a species of *Lecanium*, which also secreted a sweet substance—we may call this honey dew. I think louse secretion a more fitting cognomen. Now, as the Bees were seen constantly swarming in these trees, is it not more than probable that this was the source of the bad honey, and the cause of the terrible Bee malady of the Winter of 1871-2? I visited and examined a good many apiaries around Lansing and Owosso, some of which had escaped, while most had met this fatality, and it seemed to me that both of these conditions could be easily accounted for on this theory of poor honey, we only having to consider locality and management.

As many of you know, Mr. Hosmer, a very intelligent and successful apiarist, of Minnesota, accounted for the terrible

fatality of the Winter of 1871-2 by the absence of Fall brood in the hive. Now, while I was sure that this was not the correct explanation in the vicinity of Lansing, as I never knew my Bees to have more late Fall brood than during that Autumn, yet I thought that it might account for loss in some localities where the extreme drought precluded any late bloom, and where there were perhaps no nectar-secreting insects; especially as it was not difficult to find localities where Bees had died without appearance of dysentery. So during the Summer of 1872, I removed the queens from two colonies, preventing the rearing of brood from August till late Fall. In all other respects these colonies were treated the same as the remaining colonies of my apiary. All the colonies wintered well, with no appearance of dysentery, but these two died off so rapidly after setting them on the summer stands, that in a very few days my apiary numbered two less colonies. Those which had brood October 1st the preceding Autumn, not only came through the Winter, but have done exceedingly well during the past Summer. Hence, so far as this experiment goes, it proves that successful wintering demands that we should keep our Bees breeding well into the Fall. I quite believe that neglect in this particular was the direful spring of last Winter's woes—especially about Lansing.

Do you ask then, how would I prepare my Bees for Winter? I most cheerfully answer:

1st. I would arrange to protect them against warm winter weather, by so guarding them that they would not feel it.

This may be done by preparing a thick, double-walled special depository, by placing them in a cool, dark, quiet and dry cellar, which is beyond the influence of changeable weather; or, if it is preferred to leave them on their summer stands, by either making them the center of a huge snow bank, in which case caution must be taken to so arrange that water from melting snow can not run into the hives. (The wind-break of the apiary might be so constructed that nature would bank up the snow

for us, by placing our screen a little to the west of colonies which we wish to protect); or, by putting the hives near together, we could place boards about them, and pack in with saw-dust, straw or shavings, and thus protect them from the changes of Winter. Yet, if we are not sure to keep them cool and quiet, we must be careful not to stop up the entrances to the hives.

To secure good Winter stores we may either follow Mr. A. I. Root's suggestion, extracting the honey and feeding a syrup made of coffee A sugar, a safe and economical method, as the honey is worth enough more than the sugar to more than pay for the trouble; or, we may take pains that they have none other than honey gathered from flowers and all capped over as soon as the buckwheat harvest is past. I should prefer, too, that they have a good quantity of Bee-bread, that there may be no hindrance to early Spring breeding.

Again, I would have none but very fertile queens, and be sure to have brood in October, even though in extreme cases I might have to feed to secure it.

I should have some empty comb in the center of the hive, and should prefer to have at least thirty pounds of honey in each hive, though if rightly managed, I should expect my Bees to consume but a small part of it.

Having made use of the above precautions during the past Winter, not only with my own Bees and those of the college, but also by suggestions securing the same in a neighboring apiary, wintering in all of the three cases was attended by the very happiest success, while so far as I know there was not another colony of Bees Wintered in the whole locality.

Now, Mr. President, I would not be too positive that I have got to the core of this subject of wintering Bees, for it behooves us all to be very slow to express opinions adverse to those entertained by such cautious, candid men, as Mr. Quinby and A. I. Root, and even more slow to generalize in matters complicated by life, where very many experiments are ever necessary to render us certain as to results. Yet I feel con-

fidant that the above suggestions have experimental foundation sufficient to merit a hearing, and I as fully believe that if heeded they will very materially change the complexion of apianian pursuits in our State.

For the American Bee Journal.

"What Killed the Bees."

The answer given to this question by Mr. Quinby, in the December number of the JOURNAL, is—"cold." He says: "I have made diligent inquiry, and studied cause and effect with the best of my ability, and now repeat my conviction that cold is the cause of the failure to winter, dysentery being an intervening link." Again: "I know of nothing to produce dysentery, except cold weather." And again: "No doubt other causes destroy lives sometimes, but I have yet to find the first case where a large number, with sufficient honey, was lost, and cold not at the bottom."

Mr. Quinby, as well as Mrs. Tupper, to whose views on this subject he refers as coinciding with his, is deservedly high authority on apicultural questions. His long experience, close observations, and unquestioned candor, entitle his opinions to great consideration. But, at the wish of being considered presumptuous, I will take the liberty of stating a few facts in my own experience, which seem to me to refute this theory of Mr. Quinby.

In the Autumn of 1868 I had nine stocks, eight in box hives and one in a Langstroth, and all strong in numbers and rich in stores. They began to die about the first of November, some time before "cold weather" had set in. My attention was first attracted to the matter by an unusual number of dead Bees found in the morning before some of the hives, while the others were yet free from such trouble. The affected stocks continued to die, one or two of them so rapidly that before the last of November all of the Bees in them were dead. The surviving colonies were housed for Winter about the first of December, some of them at the time but slightly affected with the malady, and

others not at all. My house was made especially for the purpose. It was about eight feet square on the inside; had double walls, with the space of 10 inches between them filled in with saw-dust; and was slightly ventilated at the top. The temperature within was quite even, seldom falling below the freezing point in the coldest weather. With all this protection every Bee I had died *with the dysentery* before the last of February. All those hives had "sufficient honey," some of them having on hand thirty or forty pounds of solid comb; nor was it possible that cold was at the "bottom" of their loss.

As this disease was a mystery to me, I wrote to Mr. Quinby soon after my Bees began to die, for light on the subject, and received from him a very satisfactory answer. The cause, to which he then attributed the disease, was much more consistent with the facts, in my judgment, than that which he now assigns. It was *impure honey*.

In the Fall of 1871, I had over sixty stocks in Langstroth hives, which I put up for the Winter about the middle of November. These I placed in a dry, dark and warm cellar, under my kitchen and dining room. In the same floor I had kept through the previous Winter ten stocks, with the loss of not over half a pint of dead Bees to the whole lot; and on an average, by actual weight, of five and a half pounds of honey to the hive. This cellar is so warm that I have kept Irish potatoes in it, without any covering, through the coldest weather. My sixty odd stocks had not been in it over a month before they began to die with the unmistakable dysentery, and before the ensuing Spring, forty-three entire colonies had perished. It would be utterly absurd to assume that they died from cold, either directly or indirectly, for there was nothing cold about them. Nor did they starve. They had enough honey, such as it was. But the most of it was gathered late in the Summer, mainly from buckwheat. The prolonged drought in the latter part of the Summer had caused them to consume most of their early stores. The ten stocks that had Wintered so successfully the year before, had honey that was stored in the early part of the

season. This was the only perceptible difference in the condition of the stocks of the two Winters. If there was any difference in their temperature, the stocks that died were the warmer.

I have now twenty-seven colonies in the same cellar. They were stored away about the middle of November, and are now (Dec. 22nd) in excellent condition. About the 1st of October I found two or three of my strongest stocks literally starved to death. On further examination the serious fact was disclosed, that in the twenty-seven surviving stocks there were not *twenty-seven* pounds of honey! I immediately purchased a barrel of good coffee sugar, made it into syrup, and fed it to my Bees. They are now temporarily Wintering almost entirely on sugar syrup, a few of them only having the smallest amount of honey; and the less they have of it, the better, in my opinion.

It may be that cold will produce dysentery; but I feel certain that its absence, or rather, the presence of warmth, will not always prevent it. While Bees should be kept in a comfortable temperature, they should also have a pure and healthy diet. The food, my observation proves, is of more importance than the temperature. Why, or where, the honey is impure, I am not now prepared to say; but that it is at times unfit for the use of the Bees, I have no doubt. That good sugar syrup, well cooked, is a healthy and safe Bee food, I have demonstrated to my satisfaction. Hereafter, if the droughts do not render it unnecessary, I shall extract all the honey from my Bees in the Fall, and feed them upon syrup.

M. C. HESTER.

Charlestown, Ind.

The most complete check upon robbing Bees is to place a bunch of grass, or wet hay over the entrance to the hive. The Bees will find their way to the entrance to their own hive, the robbers will be caught by the sentinels in passing through the grass, and soon cease their pilfering.—*Exchange.*

Italian Bees increase faster and have many qualities superior to the black.

Translated for the American Bee Journal.

Dzierzon.

EXTRACT FROM THE HISTORY OF BEE-KEEPING IN THE GRAND DUCHY OF HESSE, IN COURSE OF PUBLICATION IN "DIE BIENE."

For the purpose of perfecting our essay, we shall here submit the general remark, that, not only France, who is well known to claim for herself the credit of all great discoveries and inventions, but also Germany has denied to Pastor Dzierzon the merit of having discovered anything new. They argued thus: The foundations on which the great discoveries of the present era rest, were present long before the appearance of Dzierzon; the incidental points at which the old and new eras separate, must be sought for where the first bright rays of light fell on that mysterious darkness of bee-life—the sexual relations of the three different orders of bees. Into this darkness, however, before Dzierzon's time, some faint glimmers of light had fallen; and he, like all great explorers of unknown territory, had his forerunners and pioneers. Already had a Janscha (died 1774), a plain farmer of Upper Carnolia and later, professor of Bee-keeping in Vienna, made, by his observations in the large apiary founded by the Empress Maria Theresa, the discovery that the queen is impregnated by the drone outside of the hive, and but once during her life-time. The discoveries of Schirack, that queens may be reared from worker eggs, was also earlier, as also his discovery of fertile workers. Based upon these discoveries, and also the investigations made by the Natural Philosopher, Raumer, did Francis Huber, with the eyes of his assistant, Burnens, (Huber having become blind in early manhood), make further observations, and located a chain of facts which spread a light over the natural history and domestic economy of the Honey-Bee. Then also the invention of the movable-comb system was worked out, in anticipation, by the frame or leaf hive, which served Huber in his observations, and was afterwards much improved by Morlot and others. Now,

only the man was wanting, able to make one grand, general experiment, embracing the preceding observations and discoveries; and who, like Huber, would be able, with unbending will, to pursue this new system of natural philosophy to the conviction of its opponents.

And this man was none other than Dzierzon. To desire to take away from him the merit of being the real founder and discoverer of this new system of Bee-culture, would be but the repetition of that old, and oft-repeated history, in which little minds seek to oppose the genius that discovered a new idea. This jealous spirit is so deeply implanted in mankind, that, among the ancients, it often served as a source of ridicule. When Pythagoras had discovered his renowned mathematical theorem, for thankfulness he offered to the gods one hundred oxen (hecatomb); and since that time it has been said, all oxen shudder when a clever thought is revealed to the world.

John Dzierzon, born in 1811, in a village of Middle Silesia, studied, in 1830, at Breslau, Roman Catholic theology, having at the same time, a strong inclination for natural history studies. In 1835 he was located as a priest at Carlsmarkt, in Silesia. His parish was small, and his labors light. All his spare time was given to practical Bee-culture, and the careful study of all the previously published Bee literature, and the careful testing of the various discoveries concerning the nature of the Bee. Of great value to him now, in his observations and experiments, was his arrangement of the hive with movable combs, which he used long before they were known in other circles. His first essays appeared in the *Frauendorfern Blattern*. His first contribution to the *Eichstadter Bienenzeitung* appeared in No. 12, of 1845, p. 122. Shortly afterwards, a new and improved system of Bee Culture, by Pastor Dzierzon, was published by Bruckisch, commonly called "Theorie and Praxis." So little profit did Dzierzon then anticipate from this valuable work, that he allowed it to pass into other hands, and it was published with various notes, which served to deteriorate

and mar it. Later, his supplement to "Theorie and Praxis," was published under commission by Beck, in Nordlingen. Since 1846, he has been a constant contributor to the *Eichstadter Bienenzeitung*, and, at the great annual gatherings of the German Bee-keepers, he is the king around whom they all cluster.

But he had a hard battle, until he had broken the way, and made such able opponents as Busch and Baron von Berlepsch, his friends and well wishers.

It is well known how he searched deeper into the natural history of the Bee, and called to his aid the honored Zoologists, Leuckart and Von Siebold. The result of all his scientific researches and practical experiments, he gave to the world in his great work, the second edition of which was published in 1869, by Schneider, in Mannheim, "Die Biene und ihre Zucht mit beweglichen Waben in Gegenden ohne Spätsommertracht." We are not exaggerating, when we call this work an achievement—an event which marked the beginning of the new era, since it is a storehouse containing within itself all the theoretical and practical knowledge of bees gained by past observation. More than this it points the way into those regions from which the veil has not yet been raised.

Is Black Comb Useful?

Black comb, unless it be very old and choked with pollen and filth, is as useful for breeding purposes as any other. For guide combs it is better than any other, as it is tough and will not break away from its fastenings as new comb will. Care should be taken, notwithstanding, to discard all comb from which the Bees of former seasons have not hatched out. Sometimes in old combs some cells may be observed from which the sealing has not been removed, some such cells may have small perforations in them, their crowns being sunken, and their contents dried up; others may still retain the remains of dead brood, but wherever these are seen the comb should be consigned to the melting-pot, for there is danger that the combs are infected with foul brood.—*British Bee Journal*.

For the American Bee Journal.

Novice on Wintering, etc.

DEAR BEE JOURNAL: Permit us to thank M. Quinby for his excellent and opportune article on Wintering, and also for the very fair and gentlemanly way in which he expresses it as his opinion that our views of the Bee disease are not wholly correct. If we have not been as respectful in expressing our views of some of the suggestions that he has advanced, and we fear such has been the case, we sincerely crave his pardon. In regard to the unkind way in which some other writers have persisted in treating us and perverting our language, we have nothing to add, more than that we shall never take the trouble to set them right. If the majority of our readers have misunderstood us in that way it is certainly time our regular contributions gave place to something more valuable.

In regard to Bees suffering with dysentery when properly housed, we will mention our own experience, first given in the JOURNAL, Vol. 4. The month of February that Winter was so warm for days together, that we could not reduce the temperature of our cellar below 50°, even by opening the door and windows nights, and every warm spell, it seemed to us then, only aggravated the disease. When we could reduce the temperature to 35°, the Bees became quiet, but nothing else we could do would keep them in their hives at all. A part of them were placed in the cellar in November, but the majority remained out until December. After placing them on their Summer stands, matters seemed no better, for they flew out and kept dying until May. Those who have followed our writings will remember that we have had such colonies every Winter since, more or less; and they have been invariably those that were allowed to have natural stores. Perhaps the Winter of 1869-70 may be considered an exception; for we then wintered every colony and they all had natural stores, which happened to be wholesome, as in years before.

Now in directing attention to those who have lost Bees carefully housed, in cellars, Bee houses, etc., we cannot

give a case where these repositories had been warmed by a stove, for we had no record of such an experiment. The principal trouble we apprehend is that Bees will leave the hives, even in the dark, when the room is warmed to 50° or thereabouts. In fact we have always had the most trouble in Wintering during warm spells. Last season we lost quite a number of small nuclei, which died under circumstances that convinced us that some kind of artificial heat might have saved them—*i. e.*, during times of very cold weather, such that the interior of our Bee house showed at times not more than 25°; but at the same time our strong colonies seemed to lose nothing.

After the coldest spell we have had this season, the weather changed suddenly, so quickly in fact, that while the walls, hives, etc., were near 32°, a stream of warm, damp air was pouring in through the ventilator to such an extent that everything was damp. A friend of ours, who has entertained the same opinion as Mr. Q., built a fire in a stove he had provided for the purpose, and raised the temperature quickly to 80° or more, and then let the fire go down before the Bees had time to become aroused. He says the result was quite satisfactory. His Bees, like ours, were confined to the hive with wire cloth. It may be that some such course will enable us to winter Bees safely, on natural stores even; and we shall be pleased if such prove to be the case.

We presume that Mr. Quinby, in speaking of the latter method, has taken into consideration the fact that Clover Honey now sells by the barrel at twenty cents, and that sugar syrup equally thick, costs not over eight cents. If a Bee-keeper had his honey in a barrel, and his colonies needed food, would he hesitate before deciding which to feed?

We would refer Mr. Quinby, to articles found in back numbers of the JOURNAL, to prove that Bees die, even when carefully buried, housed, or put in a cellar. Please see pages 5, 206, 253, 254, 261, Vol. v; 286, Vol. vi; 264, Vol. vii; 34, 92, 93, 248, Vol. viii. We call attention especially to the report of Mr. Johnson, page 248, Vol. viii. Mr J.

informed us in conversation, that he had thoroughly tried warming them in a warm room, etc., etc., but all without avail; and that sealed comb of the same honey given to a healthy colony brought from a distance, *will kill them in one week*, even in April. It is true that all of the above do not point in one direction; but they furnish a large number of facts.

We have at present a colony of Bees in a room kept constantly warmed up to from 50° to 60°. In spite of food, pollen, etc., and a wire-cloth house to fly in, we cannot induce healthy brood-rearing; but the Bees seem to be dying off every day, much faster, indeed, than those in the Bee house at about 40°.—We have had them thus for about three weeks. Although the queen lays eggs, no brood appears. The confinement seems to be very objectionable. They alight on the wire-cloth boundaries of their prison, and many will not voluntarily go back even at night.

Quite a large number of our Bee-keepers, with Mr. Gallup among them, contend strongly in favor of out-door Wintering; and such letters reach us from all directions—facts observed both practically and experimentally. Have you, too, abandoned double walled hives?

It may be proper to say that our remarks in regard to the hive which "Scientific" offered to furnish at 50 cents each, were intended only as pleasantry, and without the least feeling of ill nature. Should "Scientific" not feel inclined to accept the above explanation, we have nothing further to offer. He who will undertake to furnish good hives for 50 cents, or even \$1.00, will receive our earnest thanks for the good he will do our people, and we think we shall have no trouble in convincing the most incredulous of our sincerity. The hives shall be made to use any of the popular frames—those mentioned on page 266 of last June number, for instance, and the only other condition is, that they be approved of by the editor of the JOURNAL; and, to help the cause, we will pay for a standing advertisement of the same in this JOURNAL one year, unless some of those who find fault with our efforts will come forward and help pay for it, and thus show their disinter-

estedness. It is not "Novice," simply, you are opposing now, but the *cause of Bee-culture*. If you would see hives made to a gauge, like Elgin watches, stand up like a man, or "forever hold your peace." Chicago will perhaps be as central a point as any for the undertaking, and, what is better, will be so far from "Novice" that he can have no hand in it except to pay for an advertisement for the year.

We certainly did not mean to insist that Mr Muth had had no experience with Bee disease, we only conjectured.

Has no one else a word of encouragement for the fair stranger, Cyula Linswik, who has entered our midst? or are our sex all so intent on their own affairs that they cannot spend time to encourage real merit? In our opinion, the writer of those articles, although the information conveyed may not be of great practical value, has a power of delineation and a delicacy of touch, such as has never before, since Mr. Langstroth's book, graced Bee literature. Will both herself and "Sister Nellie" accept the thanks of one who means well, even if his efforts be at times ill-timed, and injudicious.

Mr. O. can certainly take off his box honey quicker than we could extract a like amount; but our honey would be all ready to ship at a low rate of freight by rail, while his would need considerable "fixing" before it could be safely shipped over one hundred miles at a like expense (see Dadant's articles). There is certainly no need that we should defend the cause of extracted honey longer, for attention seems being turned in that direction with a strong current from all sides.

Using cloth instead of perforated tin for feeding has been quite unsatisfactory, for the reason that if thick, it feeds too slowly, and, finally, not at all, after the syrup has dried on them; if the cloth was thin, the Bees gnawed through it, and then —

We are beset by reverses, as well as encouraged by occasional success. We still hope ultimately to succeed. To those who give us credit for feeling sincere pleasure in all the advances in Apiculture, we subscribe ourself as of old.

NOVICE.

Murdering Bees.

QUERY.—I have a straw skep with wooden top, in which my Bees were hived 18 months ago. They threw off a strong swarm last May, and I placed a super over them, containing a large and tempting piece of guide-comb, in which they made not a drop of honey. I took away the super early in September, and since then my Bees have been killing each other, hundreds lying dead under the hive, and I see them fight on the alighting board. The murdered Bees are all small compared with the generality of Bees in my hive, but certainly belong to it. These massacres take place at an interval of a week or ten days, and especially on Sundays. Can I prevent this?

REPLY.—We have had a precisely similar case in our own apiary during the past season. The Bees destroyed, were bred in the hive, but when a few days old were mercilessly massacred. The queen was a pure bred Ligurian, raised in May last, but from the backwardness of the season and the coldness of the weather we judged she had been imperfectly fertilized. Almost all her progeny were very small, had usually only one broad golden band across the abdomen, next the thorax, the remainder being jet black. They were pretty little Bees with sharp pointed tails, quite differently shaped to the ordinary Bees, and were evidently considered useless in hive. Having determined that the fault was with the queen we dethroned her, and gave the stock a fertile imported one, and since then all has been well. Whether the original queen (by stress of weather) became too old ere fertilization took place, or whether she met an imperfect drone, perhaps one of the progeny of a fertile worker which are said to be imperfectly developed we cannot say, but judging from our own case we think it probable your Bees will perish during the ensuing winter months unless you remove their present queen, and give them one whose progeny will be perfectly normal.—*British Bee Journal*.

In the Island of Madagascar, and the Mauritius Islands, a species of Bee is found (*Apis unicolor*) of a bright shining black, without spots or colored bands. The honey, which is highly spoken of, is at first of a green shade, but becomes reddish-yellow with age.

Plants and Trees.

BEE AGENCY NECESSARY TO FRUITFULNESS AMONG PLANTS, AND THE SORT OF TREES BEST FOR ORNAMENTAL PLANTING.

The name "honey," is said to be derived from a Hebrew word signifying delight. Whether or not this derivation is correct I cannot say, as I am no Hebrew scholar, but it seems very appropriate, as there is scarcely another word which has been so universally employed from the remotest ages, to represent what is delightful to the senses and as a figure of what gratifies the mental and moral perceptions. For this reason, amongst others, the labors and mysteries of the Bee-hive have been a source of profit and recreation to mankind in all ranks of life, as well as a fruitful fund of figures and illustrations to adorn the writings of poets and philosophers. Hence people can offer few truer forms of evidence of real sympathy with the most elevated and refined in past ages, than in the interest they take in this branch of rural industry. But aside from any interest in Bees as honey gatherers and waxmakers, there is another matter as important as this, arising from the service which Bees perform in the economy of nature in the fertilization of plants. All stock raisers understand well the importance of crosses in breeding. But few people are aware that the same principle holds good in the fertilization of fruit and flower blossoms. Which is to say, that though in the majority of plants the blossoms are perfect, each one containing the pollen necessary to fertilize the ovules, yet it is well known to botanists and horticulturists, that the pollen of one flower has a great deal more fructifying power on the ovules of another flower of its kind than upon its own, this causing the first to set better and adding to at least its quantity. Mr. Charles Darwin, Professor A Gray, and other eminent botanists have proved that many flowers in which the stigmas may be easily dusted with their own pollen, remain sterile unless they receive pollen from other flowers. This cross fertilization is effected through the agency of Bees and other insects. All of which may be

easily demonstrated by covering some flowers with thin gauze, admitting light and air freely, but excluding the Bees, and letting others remain exposed for them to work on.

And it is a significant fact in this connection, that naturalists have never, thus far, been able to discover that the nectar or honey deposited about the ovaries of flowers is of any use whatever to them, except to attract the Bees and other insects; seeming to show that this is a wise provision of the Creator to secure fertilization. But I propose to discuss this matter more at length in a future article, in which I will attempt to clear the Bees of the charge of being destructive to fruit and grapes. I desire here merely to point out that the Bee-keeping interest, like every genuine industry, harmonizes with and promotes other industrial pursuits; and that a wise regard for the common good is manifested by consulting the wants of the Bees in selecting flowers, shrubs and trees to shade the streets, and beautify public and private grounds. Especially as this costs no more, and it greatly enhances the primary objects of setting out the trees by giving the variety which is essential to beauty. Now it so happens, that of the trees which are not evergreens, those which afford the richest pasturage for Bees are the handsomest and most valuable for ornamentation.

A certain proportion of locusts and maples would be well enough, but they have been set along every street and in almost every lot, till they are so common that they cease to please. How much their appearance may be improved can be seen on a few places about this city, whose owners years ago had the good taste to intersperse with these a variety of other trees less common and more beautiful. If one-half the locusts in and around Lexington were replaced by lindens and yellow poplars, the city would present a much more attractive appearance, and the Bees would have a better range for gathering honey.

The best districts for Bees are those from which the timber has not been removed. The yield of honey in the mountainous parts of Kentucky is much more certain and abundant than in the Blue Grass Region, where white clover

abounds, which has generally been supposed to be one of the best honey plants, but which has proved of late years unreliable. The reason probably is, that trees being mostly deep rooted and shading the ground are not so much effected by drought as small plants. The linden or basswood, as it is called in the north, is so highly prized for its abundant yield of honey, that many Bee-keepers are planting orchards of it for their Bees. Mr. Furman of Iowa states that he has known a single stock of Bees to gather fifteen pounds of honey in a day from basswood blossoms. Mr. Hosmer of Minnesota, says that one of his stocks gathered fifty-three pounds. Mr. Cogshala of New York, says that his Bees gathered six barrels of honey from basswood in the time that it took the same Bees to gather one barrel from white clover, and that the basswood honey was better in quality. The yellow poplar yields as much honey as the linden, but the quality of the honey is not quite so good. Other trees might be mentioned of smaller growth than the above, but scarcely less value either for honey or ornament, as the sourwood and serviceberry. But those who care to give the matter any attention can easily learn what kinds to select, and to the consideration of all such I respectfully commend the subject.—*D. Burbank, in Farmers' Home Journal.*

A PLANT DESTRUCTIVE TO BEES.—The large-podded milk weed, almost invariably causes the death of every Bee alighting upon it. The Bee either adheres to the plant or else bears away a small scale sticking to its feet, and cripples itself fatally in attempting to remove the annoyance.—*Agricultural Report.*

“He may be regarded as a master in Bee-culture who knows how to winter his stock in a healthy condition, with the least loss of Bees, the smallest consumption of stores, and with the combs unsoiled.”—*Ex.*

The cross of the Italian drone and black queen is preferable to the other cross.

American Bee Journal.

W. F. CLARKE, EDITOR.

CHICAGO, FEBRUARY, 1874.

Bee-keepers' Meetings.

The importance of association, when there are common objects to carry out, is readily conceded by all intelligent people. The value of consultation about matters, in regard to which there is room for difference of opinion and practice, is also generally admitted. Our business interests are represented and protected by Boards of Trade. We have Agricultural Societies, Farmers' Clubs, and Granges, to look after the great foundation industry. Conventions and meetings, almost without number, are held to advance the multifarious enterprises, which have been set on foot by the active mind of man. No sensible individual undertakes to carry out, solitary and alone, the ends he is aiming to accomplish, when there are others, equally anxious to succeed in the same direction, with whom he can consult and co-operate.

One would suppose that very little reflection or argument would suffice to convince Bee-keepers that their interests call for organization and association. Yet it seems more difficult to bring them together for united counsel and action, than almost any other class of people who have interests in common. The patent hive business is no doubt largely responsible for this. It has introduced and fostered an Ishmaelish spirit among Bee-keepers. Apiculture has come to be regarded, not as a peaceful field where all might work harmoniously, and reap a harvest of sweetness, but rather as a hunting ground, where

prey is to be chased and spoil secured. We are glad to know that this state of things is passing away, and that a better day is manifestly coming, in which the clashing of pecuniary interests and antagonistic aims shall no longer operate to keep apiarians asunder. Already some progress has been made in the establishment of organizations, and the holding of meetings, but it is only a few of the great host of Bee-keepers who have allied themselves together, and met as "friends in council" for the advancement of apiculture. Indifference has, no doubt, had quite as much to do in keeping Bee-men apart, as business rivalry. It is remarkable how apathetic some are, even when their own advantage is manifestly involved. We do not believe that any thoughtful attendant at a Bee meeting, where experienced apiarians gave their views freely and fully, ever went away without feeling that the cost of coming was a mere bagatelle, compared with the benefit obtained. A single wise suggestion may turn the scale of a year's operations of the apiary, from loss to profit. Questions may be asked, and answered, to which no Bee-book furnishes a reply. The mind may obtain a clue, or be put upon a track, the results of which will be highly valuable. A Bee meeting is a school for beginners, and a college for those more advanced. We can help on the cause of apiculture on such an occasion, both by imparting what we know to others less informed than ourselves, and by sitting at the feet of apiarian doctors who have far outstripped us. There is moreover, the pleasure and profit connected with making the personal acquaintance of fellow-Bee-keepers, especially those of note, whose writings we have read with interest, and whom it is a great satisfaction to meet face to face, and

think of afterwards, as no longer strangers, but friends. Yet notwithstanding these and other obvious advantages of association, how difficult it is to obtain a large membership, or to secure a full attendance. How rarely do we read in the reports of these meetings, that they were unanimously attended, or marked by any enthusiasm. Even the National Society has never made such a muster as might reasonably have been expected at its annual sessions. Yet, if *all* had been imbued with the earnestness of *some*,—if every one had come who could as well have done so as those actually present, there would have been no cause of complaint, but rather abundant reason for jubilation. We regret to learn that the Louisville meeting was thinly attended, owing to a variety of unfavorable circumstances, but we hope this will not discourage those who from the beginning have had faith in the society, and have shown their faith by their works. Let every officer and member resolve, that the next meeting shall be the best ever held, and do all in their power to make it such. The place of meeting is conveniently central, and we have no doubt the Pennsylvania Bee men, with President Hoagland at their head, will spare no pains to make the needful preparations to secure travelling, hotel and hall accommodation, so that if there is only a grand rally from East, West, North and South, the Pittsburgh meeting of 1874 will far outstrip its predecessors.

There are other and local gatherings which ought to be well sustained. The Northeastern and several State associations, have yet to meet. Let there be an extra effort on the part of Bee-keepers to attend them. Do not grudge a little time or money. The outlay will pay *you* well, and be of service to others. This matter should be viewed not in

the light of inclination merely, but as a *duty*. Ease and comfort would perhaps dictate staying beside one's warm and cozy fireside, but if duty calls elsewhere, it is ours to obey the summons, in the assurance that the highest happiness comes in the train of doing right.

Too much stress cannot be laid on the importance of getting up and vigorously sustaining neighborhood meetings in all those localities where Bees are kept by a number of parties. Even if they are attended only by a few, they will result in much good. We do not know of a pleasanter or better method of promoting apiculture than by holding a weekly or fortnightly meeting from house to house around the little neighborhood of Bee-keepers. A case in point occurs to our recollection. It is that of three Bee-keepers who have for several years been in the habit of meeting in this way. They discuss each others' methods and experiences, read and criticize apicultural publications, and concoct questions, answers and articles for the Bee journals. It need hardly be said, that they are a most intelligent trio of Bee-keepers, and that it is a high treat to spend an evening in their company. We could wish to see their example followed wherever an association even as modestly small as theirs, can be formed and worked.

In our hurry, getting out the January Number of the AMERICAN BEE JOURNAL, several annoying errors occurred. We hope to have less of them in the future. A few corrections are important. On page 7, second line of article on "Feeding," for "keeping," read "feeding." Seventh line from top of second column, for "open," read "only window." In the third line, for "hives," read "sources."

E. Kretchmer & Co.'s Price List of Bee-keepers' supplies is on our table. It contains 24 pages, and will be sent free to any one desiring it. Address E. Kretchmer & Co., Coburg, Iowa.

Voices from among the Hives.

J. L. DAVIS, of Holt, Ingham Co., Mich., says:—"I write this in response to Adair's observation, that the clipping of a queen's wings is an injury. Some years ago, I obtained a swarm of Bees from the woods. Brought it home in the log, just as it was found; after sawing off pieces at both ends, we set the log up in our yard for a hive. The Bees swarmed in June; after alighting, I saw the queen and caught her by the wings, and called for scissors; before they came, however, she turned around so many times, that the wings came out by the roots. I supposed this would kill her, but she lived until her sixth year, to my certain knowledge (she might have been older). Her hive swarmed once every year, and sometimes twice. I could always recognize her by her peculiar appearance, and so kept track of her. I have clipped hundreds of queen's wings since, and never thought that it gave them pain, or injured their usefulness. In clipping queen's wings, have the comb on which she is hanging up before you with the queen in sight; with the left hand take hold of her left wing as she is crawling upward; hold on just hard enough to make her grasp the comb; then with the scissors clip about half of the large wing off. In doing this keep the breath from the Bees, work slowly and carefully, and you will be satisfied."

S. SCOTT, of College Hill, O., writes:—"Our season thus far is termed an open Winter. The weather report for December stands as follows: Rain, $6\frac{1}{2}$ inches; snow, $1\frac{1}{4}$; clear days, 1; average temperature, 36 degrees; lowest temperature, 10 degrees, morning of 30th. In our vicinity, as far as I have learned, Bees are wintering well with those who give them care and attention. The past season was a good one for honey, both in quality and quantity. Two swarms that issued on the 5th of June gave a surplus of twenty-one and thirty-two pounds respectively, of pure comb honey, besides their homesteads full remaining untouched on the last of July. Though black Bees do well when flowers are abundant, my preference is for the Italians. We read sometimes of moth-proof hives, but it takes a strong colony of Bees to keep a

good hive moth-proof. The plan of putting split elders under hives for the worms to crawl under, is an old one; but if destroying the worms is not attended to daily, the elder will prove a hot-bed for the propagation of the insect. It is far better to spend the time in encouraging the little wren by building small boxes, four by five inches square, with inch auger holes for entrances. Their keen eyes are ever on the alert for worms and insects, of which they consume a great many daily. I think it is also a good plan to have young turkeys as well as ducks near the Apiary. They can be seen early and late among the hives watching for millers. I consider them of great value to those keeping Bees."

J. F. MONTGOMERY, of Lincoln, Tenn., writes:—"Last year Bees did but little in the way of storing surplus honey, though after the main season was over, they stored honey enough to last them through the Winter. I have now thirty-eight colonies, all in good condition except one, which has a young queen reared after the drones were all killed. On 3d of this month, Jan., I put out rye flour, and in less than an hour they were swarming around it by hundreds. I am intending to move my Bees this year a distance of ten miles, to where there is an abundance of linn. I think I can make it pay me. If I do, I will report after the season is over. I use Murphy's honey extractor, which I like better than any other I have seen."

N. M. CARPENTER, of Ellington, N. Y., writes:—"Although the past two Winters have nearly cleaned out my Bees, my enthusiasm has not abated in the least, nor can I get along without the old AMERICAN BEE JOURNAL. All through this section of country, nine-tenths of the Bees died last Winter. But the past season has been a good one, and the business is rapidly renewing again, and with a few favorable years will be as prosperous as ever. No theory which I have ever seen offered in any of the Bee journals in relation to the late mortality among Bees is at all satisfactory to me; nor will I at this time attempt to offer any of my own, although I feel quite confident that I could go into Winter quarters with forty-eight swarms, and come out with more than one, which was my experience last Winter."

W. H. TENANT, of Eureka, Wis., writes:—"I wintered thirty-six swarms of Bees without any loss. I increased them to seventy swarms, and sold a little over \$400 worth of Honey Bees. At this date they appear to be in a healthy condition. Success to the AMERICAN BEE JOURNAL and all its subscribers."

ELI COBLE, of Cornersville, Tenn., writes:—"Bee-keeping is in a very backward state in this section of country. The Frame Hive has not been used here more than two years, though I believe, taking everything into consideration, we have as good a locality for Bee-keeping as there is in the United States. We Winter on their Summer stands, the hive remaining as it does during the honey harvest. Our Bees are Wintering finely, so far as we can judge by inspecting them. I have ninety colonies that I expect to come through all right, unless some accident happens. Our Bees Wintered well last Winter, and so far this Winter has been nothing to compare with the last, for cold weather. I wish the AMERICAN BEE JOURNAL success."

R. B. PRICE, of Delphi, O., writes:—"My little girl was stung on the bottom of her foot by two Bees, producing the usual symptoms. We first saw a red streak where one of the Bees had stung her, which soon spread until she became a brilliant scarlet, from head to foot. She looked as though she would have convulsions, and having a pitcher of ice water upon the table I bathed her head, which gave her temporary relief; whenever such symptoms appeared I applied the ice water I also gave her a dose of whisky. For several hours afterwards she had fever and thirst. My Bees are Wintering well so far; I am trying friend Muth's plan, and like it well, as it keeps the combs dry and Bees comfortable."

GEORGE O. TOMPKINS, of White Plains, N. Y., writes:—"The January number of the AMERICAN BEE JOURNAL has come to hand. Its new dress makes a very neat appearance, and I hope it may give better satisfaction than ever in the hands of its new manager."

AARON A. TRULLINGER, of Lake City, Ia., writes:—"My Bees Wintered well last Winter. I kept them up in my chamber. I am trying the cellar this Winter. I doubled my stocks

last Summer, and got forty pounds of box honey, per hive. My Bees went into Winter quarters in good order."

S. HOAGLAND, of Mercer County, Pa., says that "Our Bees are Wintering finely up to date."

Mrs. R— would like to enquire of any one who knows, whether Santa Clara, California, is a good locality for Bees.

"A LADY" wishes to ask "Novice" the following question, viz: "In seasons when honey, the natural food of the Bee, becomes so impure as to poison the Bees, is it not also unfit for table use?"

H. M. NOBLE, of Mount Pleasant, Iowa, writes:—"I have had very poor luck with Bees for the last three Winters. In 1870 and 1871, I lost twelve out of thirty-five swarms. In 1872 and 1873, I lost twenty-two out of forty swarms. In 1872 and 1873, I lost twenty-nine out of thirty two swarms. This left me with three swarms last Spring, and those very weak. I increased them to thirteen, and got three boxes of honey and one and a half gallon of extracted honey, and have now got them in a cave where they will not be likely to freeze, though they may die some other way."

C. L. YOUNG, of Ohio, writes:—"From circumstances connected with my Bees, I have good reason to believe that some of them have lived more than two years. According to my opinion, Mr. Quinby is the nearest right, in his opinion as to the cause of the much talked of Bee disease."

JOHN BARFOOT, Wellsville, Mo., writes:—"Last season was a disastrous one for Bee keepers—Bees scarcely sustaining themselves. There was but little surplus honey. The strong probability now is, that nearly all old hives will winter over, the Winter so far being mild and wet."

W. F. STANDEFER, Dry Grove, Mississippi, writes:—"Our County Bee-Keepers' Society meets again on the first Saturday in February, and will, hereafter, hold Quarterly meetings."

Our Correspondents will oblige by writing with ink. Pencil writing, after being rubbed in the mails, &c., becomes indistinct, and our compositors find it difficult to read.

American Bee Journal.

THOMAS G. NEWMAN, MANAGER.

RATES OF ADVERTISING.

SOLID NONPAREIL MEASURE.

First insertion, per line.....	\$0.20
Each subsequent insertion, per line.....	15
One square, 10 lines or less, first insertion.....	2.00
Editorial Notices, solid Nonpareil, per line.....	.30

Next page to Business Department and second and last page of cover, double rates.

A deduction of 20 per cent. made on advertisements inserted three months, 30 per cent. for six months, and 50 per cent. for one year.

Twelve lines of solid Nonpareil occupy one inch. One column contains 96 lines of solid Nonpareil.

Bills of regular Advertisers payable quarterly, if inserted three months or more. If inserted for less than three months, payable monthly. Transient advertisements, cash in advance. We adhere strictly to our printed rates.

Address all communications and remittances to the Manager.

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c. Strained 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb Honey 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16 cts. \mathcal{P} lb. Choice extracted honey 16@18 cts. \mathcal{P} lb.

ST. LOUIS.—Quotations from W. G. Smith, 419 North Main st.

Choice white comb, 25@29c; fair to good, 16@22c. Extracted, Choice white clover, 16 @18c; choice basswood honey, 14@16c; fair to good, extracted, 8@12c; Strained, 6@10c.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenpoint L. I.

The sale of honey is dull here, and a large quantity is now upon the market. The prices rule as follows:

White honey in small glass boxes, 25c; dark 15@20c; Strained honey 8@12c. Cuban honey, \$1.00 \mathcal{P} gal. St. Domingo, and Mexican, 90@95 \mathcal{P} gal.

The "National Bee Journal," published at Des Moines, Iowa, by Mrs. Ellen S. Tupper, is on our table. The January number is a good one. We have made arrangements to club the "National," with the old and reliable AMERICAN BEE JOURNAL, for \$3.00 a year, in advance,—thus saving our subscribers \$1.00.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

New Advertisements.

Our fresh announcements this month are numerous. Our subscribers will be interested as well as remunerated by reading all our advertisements over carefully.

E. J. Worst announces his reduced prices for Italian Queens for 1874, and also Premium Poultry Eggs.

Jas. J. H. Gregory's Catalogue of Vegetable and Flower Seeds is splendidly illustrated; and will be sent to all desiring it, free of cost.

The firm of Baldwin Brothers has been dissolved. L. W. Baldwin is breeding Queens, and quotes prices.

E. W. Hale is ready for an engagement to take charge of an apiary.

Wm. W. Cary invites every reader of the AMERICAN BEE JOURNAL to send for his circular of prices for pure-bred Queens.

Mrs. Tupper calls attention to her late purchase of the "National Bee Journal," and would not refuse subscriptions accompanied with the cash.

THE ILLUSTRATED JOURNAL, with its magnificent chromo, is announced; also its club rates with the AMERICAN BEE JOURNAL.

Nevins' Straw Mats are now on the market, and may be obtained of Charles F. Muth.

D. A. Pike has Italian Bees and Italian Queens for sale.

C. F. Muth's new announcements are: "Clover Seed," "Honey Plants" and "Honey Jars," with new price list.

An illustrated annual, entitled "The Busy Bee," is announced at 10 cents.

Dr. J. P. H. Brown mentions his importation and breeding of Italian Queens.

The Western Agriculturist is published at \$1 a year, and gives a Chromo entitled "The Sheperdess."

J. W. Winder has just finished his "New Honey Extractor," and promises to lay it before the readers of the AMERICAN BEE JOURNAL in the March number.

Adam Grimm offers to sell 400 colonies of Italian Bees, and quotes prices.

S. W. Cole will supply full colonies of Italian Bees and Queens, &c., &c.

J. E. Moore invites you to send for his circular giving directions for introducing Queens, &c.

J. H. Stevens will buy honey in St. Louis, and invites consignments.

HEYES' LINCOLN.—Having used this article in our family for years, we can confidently recommend it. See advertisement.

We want a few copies of the July and December Numbers of the AMERICAN BEE JOURNAL for 1873, and will pay twenty-five cents each for them.

To Those Interested in Bee Culture.

At the sixth annual meeting of the Michigan Bee-Keepers' Association, it was decided to hold a special meeting at Kalamazoo, to commence Wednesday, May 6, 1874. It is especially desired that all members be present, and, in behalf of the Association, we urge every Bee-keeper in Michigan to attend. A cordial invitation is also extended to all persons interested in the science of Bee-culture whether residing in this or other States. Surely much good may be derived from a comparison of experiences next Spring, and from the able papers that will then be presented. Timely notice will be given of all further arrangements. Address communications or inquiries concerning the subject to

FRANK BENTON, *Sec'y.*

Shelby, Oceana Co., Mich.

Newspaper Decisions.

1. Any person who takes a paper regularly from the post-office—whether directed to his name or another's, or whether he has subscribed or not—is responsible for the payment.

2. If any person orders his paper discontinued, he must pay all arrearages, or the publisher may continue to send it, until payment is made, and collect the whole amount—whether the paper is taken from the office or not.

3. The courts have decided that refusing to take newspapers and periodicals from the post-office, or removing and leaving them uncalled for, is *prima facie* evidence of intentional fraud.

Clubbing Bee Journals.

Several of our subscribers have requested us to say what we will club with other Bee publications for. We therefore quote the following:

The AMERICAN BEE JOURNAL and the "National Bee Journal," by Mrs. Tupper, for \$3.00 a year in advance.

The AMERICAN BEE JOURNAL and either "The Bee-keepers Magazine," or the "Agriculturist," by H. A. King, for \$2.50.

The AMERICAN BEE JOURNAL and "Novice's Gleanings," for \$2.50.

The AMERICAN BEE JOURNAL and the "National," the "Magazine," and "Gleanings," for \$4.00 in advance.

All the above one year, \$5.00.

Any of the above and the "Illustrated Journal," and our magnificent Large Fruit Chromo, for \$2.00, in addition to the RETAIL price of the Bee publication selected.

Publishers needing cuts or engravings, will do well to address the Manager of the American Publishing Company, who have a large supply for sale that have appeared in "The Illustrated Journal."

Should any subscriber wish to discontinue taking our JOURNAL, he should address a letter to the Manager, and enclose the amount due, and it will then cease to visit him. Any other course is dishonorable.

NEWLY PATENTED HIVES.—Three Bee Hives have lately been patented. Wm. S. Hough, Canada; Leonidas Adams, Mason City, Ills.; and Leander J. Diehl, Butler, Ind. are the patentees.

After February 1, 1874, we shall mail a Printed Receipt to every one sending money to this office. Those who do not get such Receipt by return mail, should notify us, that we may ascertain the cause of delay.

To new subscribers, we will send the AMERICAN BEE JOURNAL for three months for 25 cents, on trial. Now is the time to send in hundreds of such trial subscribers. Who wants to TRY IT?

Any one having paid \$2.00 for the AMERICAN BEE JOURNAL for 1874, and desiring to obtain the "Illustrated Journal," for 1874, and our magnificent Fruit Chromo, may send us \$1.50 more and obtain them.

We shall, hereafter, publish a Honey Market Report each month, so that Bee-keepers will know how honey is selling, not only in Chicago, but in St. Louis, Cincinnati, San Francisco, and New York. We shall do our utmost to make the JOURNAL in all respects an organ for Bee-keepers throughout the Union. We shall take pains to ascertain who is responsible, so that none shall be wronged out of their dues.

The "Home Grange" is published at St. Louis in the interest of farmers. It contains also profitable miscellaneous reading for the fireside. It is issued monthly, at the low price of \$1.50 a year.

Wilson's Herald of Health is issued monthly by the Southern Publishing Co., of Atlanta, Ga. Besides being a periodical devoted to the science of health, it has a department of Agriculture and Domestic Economy. It is the only popular work of the kind published south of New York. Its terms are \$2.00 a year.

Eight cents is now the fee for registered letters—instead of fifteen cents, as heretofore. Let all register, who cannot obtain a money order, but let none register who can.

Those who are owing for advertisements for the past year are requested to send the money to this office without delay, as we are closing up the old books.

AMERICAN BEE JOURNAL

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. X.

CHICAGO, MARCH, 1874.

No. 3.

Central Iowa Bee-Keepers' Association.

Cedar Rapids, Iowa, Jan. 21, 1874.

The third annual meeting of this association was called to order by D. W. Thayer, of Vinton, its President, and the following officers were elected by ballot:

D. W. Thayer, Vinton, President.

D. E. Blakeslee, Anamosa, 1st Vice-President.

Thos. Hare, Marion, 2nd Vice-President.

J. M. May, Cedar Rapids, Secretary and Treasurer.

W. H. Furman, Cedar Rapids, Asst. Secretary.

On motion of J. M. May, the following resolution was unanimously adopted:

Resolved, that the thanks of this Association are hereby tendered to Dr. A. B. Mason, of Waterloo, for his interest in its prosperity, and for his faithfulness as its Secretary; also that we learn with deep and sincere regret of his loss by fire, and tender to him our sympathy; also, that this resolution be recorded in the minutes of this Association and a copy sent to Dr. Mason.

The President appointed Messrs. Blakeslee, Furman, and Newcomb, to prepare subjects for discussion during the sessions of this meeting.

During the absence of the Committee, Dr. J. Oren of Laporte city, raised the question as to the condition the hive of bees is left in when the honey extractor has been used.

Mr. Furman stated that he had used the extractor three years and found it advantageous—could make more profit from honey extracted from the comb than by box honey, though sold at less price per lb., and when properly used, the brood-comb was unimpaired and the stock of bees would be quite as vigorous as those when the extractor was not used.

Dr. Oren thought when the extractor was used the best honey was thrown from the comb, and as the bees had only lately made poor honey, he thought that was one cause of the losses of bees in 1873.

Dr. Blakeslee and Mr. Hunt expressed the opinion that it made no difference whether or not the extractor was used.

Mr. Hare claimed that the loss of bees in 1872 and 1873 was due to the very cold winter, and unfavorable spring.

Mr. Hunt recommended a "clamp" as the means of securing the safety of bees.

In answer to an inquiry, the President explained that a *clamp* means an excavation in the ground about 8 or 10 feet square, across the top of which is placed timbers. On the timbers hives are placed in a pyramid form with a space, like a chimney, in the center for ventilation, communicating from the excavation, to the air at the top of the pyramid. On this pyramid, poles, scantling or boards are placed in a roof form, and on this a coating of straw 4 to 6 inches, and on the straw about 8 inches of earth is placed to make a roof.

The President gave his experience of wintering bees in cellars well ventilated. He spoke also of his uniform success in the use of the extractor.

Dr. Oren qualified his previous remarks on the extractor, by saying that he was not wholly opposed to it, though he did not use it.

Convention adjourned until 9 o'clock the following day.

SECOND DAY.

The President in the chair. The Secretary read a letter from Mrs. Tupper of the *National Bee Journal* stating that she would be unable to lecture before the Convention as announced, on account of a failure of the trains to make connection. Her communication contained the suggestion that the Central and State Societies consolidate, also an invitation to the Association to hold its next meeting at Des Moines. Ordered placed on file for further consideration.

The business committee reported the following questions for discussion:

1. What are the benefits of the honey extractor in the apiary?
2. What is the test of pure honey?
3. What benefits are derived from feeding bees in autumn?
4. Is the Italian superior to the native or common bee?
5. What is the best method of dividing swarms with a view to increasing the stocks? and is it desirable to divide them?

6. Will upward ventilation in the cellar or room where bees are wintered prevent dampness and disease?

7. What is the best forage for bees?

The *first* of these questions had been quite thoroughly discussed in the absence of the committee—but in addition, Dr. Blakeslee stated it as his opinion that if properly used the product of the apiary would be doubled, and agreed with Mr. Thurman that honey could be afforded at less price than box honey and yet the aggregate profit would be greater. Mr. Hare stated that some purchasers thought it was a spurious article because separated from the comb by a new and novel process, and the public mind needs to be disabused on this point. Further discussion showed a large preponderance of opinion in favor of the extractor when properly used.

The *second* question was briefly discussed. Dr. Oren said that a chemical test was the true one, while the President, Mr. Thurman, Mr. Hare and others believed that the experience of most persons would enable them to determine the matter, especially when considering the fact that the globules of the pure article were unlike the spurious. The pure would keep longer and not become candied, and the taste would also indicate the difference. By bringing pure honey to a boiling heat and allowing it to cool gradually, it may be kept years in a liquid state without injury.

On the *third* question the opinion was quite general that the swarms should be allowed a liberal supply of pure honey, and small, late and weak stocks should be fed in the autumn or incorporated with strong swarms.

The *fourth* question was warmly discussed. Dr. Oren said he could not respect the Italian bee as he once did, and yet he liked them very well. Messrs. Thurman, Hunt, Goodhue, Hare, Pierce, Thomas, Tangman, Newcomb, Porter, of Illinois, and others, were generally agreed in their praise of the Italian bee.

On the *fifth* question each had his own peculiar method for dividing and living swarms, all agreeing that the honey-bee, of whatever nativity, knew how to sting.

The *sixth* question elicited a full discussion as it involved the vital points in relation to the great loss of bees in the winter of 1872-3, and in the spring following—many losing their entire stocks, and others nearly all. The cellar, the *clamp*, burying them, allowing them to remain on the stands as in the summer and covering them with blankets, were severally considered. The concurrent opinion was, however, that in any case, a dry, pure atmosphere and a warmth or temperature of 30 to 50 degrees and uniform as near as practicable, should be maintained to secure safety and freedom from disease. Freezing and dampness should never be allowed. The severity of the winter of 1872-3, followed

by a backward, wet spring made very indifferent forage for those that survived the winter, and want of experience in giving proper care, contributed to superinduce disease and the heavy or total losses. Still, those who observed the most approved care and caution hitherto used by the apiarian, suffered heavy losses, indicating that much is to be learned, and that thorough search into the cause of the disaster should be made, and remedies sought; also, that special encouragements, legislative or otherwise, should be afforded those who, in the face of discouragements, diligently pursue a research that promises so much wealth to the State.

The *seventh* question was considered at some length. Linn and Alsike clover were highly appreciated. Mr. Hare, also Mr. Furman, said they had raised this clover for bee pasturage and were much pleased with it. It should be sown early, on well prepared ground—even on snow if the land had been thoroughly prepared in the preceding fall, and a hay crop, as well as honey, would be the result. Great care should be observed in selecting seed, lest sorrel (a bane to the farmer) should be mixed with it.

Convention adjourned until the following day, at 9½ o'clock.

THIRD DAY.

Convention called to order by the President. The question whether or not bees were taxable property was raised by Mr. Goodhue and discussed generally by the members of the Convention, when the Secretary offered as a means of solving the question the following

MEMORIAL.

To the General Assembly of the State of Iowa, in Senate and House of Representatives assembled:

Your petitioners, citizens of the State of Iowa, respectfully call your attention to the following considerations:—*First*, That Iowa has, until 1873, been deemed one of the best bee raising and honey producing States in the Union—its trees and flowers furnishing, in the language of apiarians, abundance of bee pasturage. *Second*, That in the winter of 1872-3, and in the spring following, about *five-sixths* of the swarms of bees in the State perished by disease. *Third*, that many persons have become discouraged, and have abandoned, or propose to abandon, the business, preferring to do so than to be taxed on so precarious a business. *Fourth*, That the native riches, in honey, of the tree and flower blossoms referred to, will remain undeveloped and valueless, unless the gathering and utilizing of this dormant wealth is in some way fostered and encouraged; and as the State may advance its material interests by encouraging those now engaged in apiculture and inducing others to do so, and as no injury can arise to the State or its revenues, but ex-

actly the reverse, we ask for the enactment of a law exempting from taxation, and from levy and sale on execution, honey-bees and their products until the year 1880. And your petitioners as in duty bound, will ever pray.

The above memorial was unanimously adopted as the petition of the Convention, and was ordered to be signed by the President and Secretary, and forwarded to Senator Kephart of Linn County, with a request that he will aid in procuring the passage of the law prayed for.

On motion, citizens, associations and societies similar to our own, favorable to the object, are requested to join us in our efforts to procure the enactment of the law desired.

After the customary vote of thanks was passed, the Convention adjourned to meet on the third Wednesday in January 1875, at Cedar Rapids.

D. W. THAYER, *Pres.*

J. M. MAY, *Sec'y.*

For the American Bee Journal.

Our Afflictions.

Not always is the bee-keeper's path strewn with clover-blossoms—

"Roses. Cyula! you mean roses," interposes Nellie, looking over my shoulder with a critic's eye.

No, indeed! What bee-keeper, worthy of the name, would exchange clover-blossoms for roses? Moreover, the phrase is more truly descriptive, besides being considerably less shop-worn."

Not always is the bee-keepers' path strewn with clover-blossoms, nor always to his eager lips may the honeyed draught of success—

"Which is his *mead*?" queries Nellie.

Putting down my pen, with mild severity I speak: "My dear, if you have any *sensible* suggestions to offer"—

A succession of brisk, snapping sounds accompanied by an odor as of burning coffee, creates a diversion which enables Nellie to make a not altogether inglorious retreat to the kitchen.

Resuming my pen with an unhappy consciousness of being unable to begin exactly where I left off, I spend some moments in perplexity, nibbling at the end of the holder. I become aware, at length, that it will be necessary to take an entirely fresh start.

* * * * *

Do my readers—any of them—remember our "maiden" swarm, of last

July? We thought its story told; but alas! there is a sequel. "Happy is the nation that has no history," says a wise old proverb; and no less true is it of a *colony*.

From the time that our "maiden" swarm—No. 7 by name—decided to accept the situation and make the best of it, they had furnished no occasion for criticism. Their ten frames were speedily filled with faultlessly regular combs, whereof but a trifling amount was drone comb. In some shallow frames above, they likewise put goodly beginnings of worker comb, for which next season will find use.

On the 16th of October, when I made for them winter passages and removed surplus honey, my only anxiety was lest there were too many bees for profitable wintering. At this time there was a little capped brood, but neither eggs nor larvæ. The day being somewhat cool, and unnecessary exposure an evil, I made no search for the queen, and did not see her.

The bees were unusually cross, and, in subduing them, I used a little tobacco—something I had never done before. (Be assured, however, that it was not used in masculine style.) Whether this had, or had not, any connection with what followed, I cannot tell.

Toward night of this day, an unusual commotion was noticed at No. 7. There was running to and fro at the entrance, and hurrying hither and yon, as viewed through the observation-glass. Applying my hand to the glass, I found an unwonted degree of heat. We agreed, Nellie and I, that it was curious! We agreed, too, that we were unable to solve the mystery, and also to wait calmly, and without much anxiety, for the excitement to subside.

A latent fear, however, awoke me early next morning, and impelled me to go forth to make renewed investigations before breakfast. It was a cool, frosty morning. To my surprise, the observation-glass was still warm, and the bees were still excited. While I pondered, I noticed at the entrance a dead body of unusual appearance, and bending nearer, I saw, to my unspeakable horror, that it had no wings! that it was a queen—even my poor Rebecca!

(The experienced bee-keeper, who has lost whole colonies, or mayhap, an entire apiary, by disease, or frost, or fire, will be kind enough to conceal the smile he may not be wholly able to repress. To lose the queen to one's strongest colony, so late in the season, was misfortune enough for a beginner. But *this* queen was peculiarly dear to me, as being the oldest queen of my own rearing, and the only queen whose wings I had heartlessly clipped.)

When sufficiently recovered to do so, I picked up the little body and vainly tried to warm it to life with my breath. Then, having carefully but hopelessly, deposited it in a warm place, I obeyed a summons to breakfast, and seated myself to pour the coffee, with what was meant for a calm and tranquil demeanor.

"Are you sick, Cyula?" inquired Richard.

"Oh no!" I responded, with a ghastly smile, and a sudden but nerveless attack upon a large potatoe.

"Shan't I make you some toast, Cyula?" anxiously inquired Nellie, a few moments later.

"Oh no, I believe I am not very hungry this morning."

"But wouldn't you like a cup of tea?" persisted Nellie.

"No,—your coffee is delicious, Nellie," hastily raising my cup.

"I believe that you had not tasted it!" she exclaimed, half indignantly. "It is one-half, at least, cold coffee warmed over!"

Conscious guilt prevented other reply than an apologetic smile. A little after, Nellie's hand stole across under the corner of the table, and gave my dress a sympathetic twitch. As I looked up,

"What is it?" her eyes asked.

"Nothing—that is—after breakfast I will tell you," I responded in an undertone; and then, having replenished the empty cups, I escaped to the next room, whither Nellie soon followed me: her breakfast, spite of my good intentions, having been almost as effectually spoiled as my own.

An hour afterward—various plans having been discussed and rejected meanwhile—Nellie suggested:

"Send to Mr. — for a queen."

"'Tis too late, I fear."

"Do you fear that he has no queens left? or that the weather may be too cold to send one?"

"Both."

"But since nothing better can be done you might try."

Briefly told, the trial was made. Fortune favored our attempt more than could have been expected; and about twelve days after Rebecca's decease, we received through the postoffice, a cunning little cage, holding the much desired queen, with about a score of attendants. The tiny colony had been amply provisioned with half a stick of candy and a small sponge of water. Not a bee had died during the four days which had elapsed between the posting and the receipt of the small package.

We felt then that our trial was over. To suppose that *our* bees could be unreasonable enough, and so ungrateful as to object to their new queen, scarcely occurred to us as a possibility. We had so identified ourselves with the colony in their loss, had been so affected by their plaintive moanings (or what, to our excited imagination seemed such), by their restless searchings, and aimless wanderings—in short we had made their grief so much our own, that—as in effect we have already said—we scarcely thought to ask ourselves, if *they* would sympathize with *us* in our joyful reception of the new queen. In our simplicity we took it for granted.

Nevertheless, we thought best to proceed according to rule: so, for more than forty-eight hours, the bereaved colony were permitted to make the acquaintance of their new sovereign, through the meshes of her cage. Then the final introduction was performed with great ceremony, and according to all the rules of etiquette for such cases provided. Apparently, it was successful. I had one night of peaceful repose.

Next morning, just to make assurance doubly sure, I sent out Nellie to examine the entrance of the hive, I watching her through the window.

She brushed away a few dead bees, examining them in a manner satisfactory enough to her interested observer, until, with a sudden start, she glanced

up at the window. It was enough—the story had been told!

I left the window, and presently Nellie came in to tell me, what I already knew—the new queen had been murdered by her rebellious subjects.

CYULA LINSWIK.

North Eastern Bee-Keepers' Association.

THE FOURTH ANNUAL CONVENTION, HELD
AT UTICA, N. Y., FEB. 4 AND 5, 1874.

FIRST DAY.

After the preliminary business matters were disposed of, President M. Quinby, of St. Johnsville, delivered his opening address, from which we print extracts as follows:

WHY DON'T FARMERS KEEP BEES.

This question put to most farmers might be briefly answered, Because I don't know how. But, like the Yankee, who answered one question by answering another, it indicates the importance of asking *why* we do not know how. And answering this involves the asking of a thousand others in the multiplied ramifications leading from it. Do not expect me to answer all, or even very many, for the very significant reason given above, *I do not know how.*

Bee-keepers desirous of promoting this branch of science, must present inducements to the farmers themselves, before they have any to present to their sons. Nearly all that have been offered have been presented very unskillfully. One class simply believes that improvements have been made in the hives, without understanding why they are improvements; and we find some hives patented, not because they are improvements, but because they are different from others. Bought and sold, not because they will promote bee-culture, but because money is expected to be made without labor. Practical knowledge of management can no more be bought with a price, than capacity for the school-boy. Failure has been the consequence of supposing it could, and to-day ten empty hives can be found piled up as wasted lumber, where one can be found containing bees. The result presents but few inducements for the farmer to begin bee-keeping. Another class—small to be sure—endeavor to make bee-keeping attractive to the masses. Owing to the peculiar training of the farmer, and his own ignorance of the subject, their efforts have proved nearly abortive.

Two years ago, some progressive bee-keepers attended the discussion on this subject, at the rooms of the State Agricultural Society. It was expected some success would follow their efforts, as some important points in their experience were given, the result of

what they knew—little in comparison to what will be known—and they gave it freely, without money and without price. It was shown very conclusively that a man had secured, in one season, 25,000 lbs. of surplus honey, and saved his bees for another year, his sales amounting to over \$7,000. We exhibited very clearly by this one case the amount that could be collected on a small area of land. And this in turn gave very clearly the amount produced in the area of the whole State—which amounted to millions upon millions of pounds—that of other States not mentioned. The object in making this statement was to show that there was no lack of honey to gather, now wasted, to engage all the enterprise likely to be enlisted in a hundred years yet. The object in stating the amount collected by one individual, was to show the difference in results, between the old and new method of bee-culture.

Understanding something of the manner in which farmers had been educated in this matter, and suspecting it might not be received as a truthful relation, it was suggested that a committee be appointed to investigate the statements made by the society. A resolution to that effect was offered, but never carried out. Had it been, it might have settled the point relative to the facts. A prominent member, an officer of the society and chairman of the meeting, who seemed to know something of bees by his own experience, said that he had kept bees many years, and never found them very profitable. Once in about five years in good seasons, they paid; other seasons it was more trouble to keep them alive, than they paid for, advised young farmers to be very careful how they invested in the business. In these remarks we find an answer to the question why a certain class do not keep bees. Coming from a prominent man, all would suppose him qualified to decide. On what grounds the decision was made was not asked. He evidently did not believe the statement made by the society. But his experience of twenty years ago could not be supposed to have any great value now, and it was hardly fair to give it as proof that bee-keeping would not pay, thus discouraging future effort. Sheep husbandry has been taught for thousands of years. Should a man that discovered some improvement over his neighbor's management at this late day refuse to give it to his neighbor; or should the neighbor, if it should be given him, refuse credence to his story because he had kept sheep many years and thought he knew about all there was to be known on the subject, and say that some years they paid very well, but he thought the chances of dry weather, poor pasture, poor fences and other casualties made it rather risky business? Should he not be careful how he discourages progression? This course, no doubt, discouraged bee-keeping the more be-

cause of the high source from which it came.

Teachers in any new science must expect to labor without recompense in worldly wealth. It must first be established beyond dispute that it is a science, that there is knowledge yet to be had for the inquirer. There must be created a desire to obtain this knowledge before any recompense is thought of. I will not say that some of the objections raised have their foundation only in spite, but they certainly savor a little of it. It would almost seem as if the greater the success, the stronger the opposition.

The greatest calamity that has befallen bee-keepers the past two winters, has been the loss of stocks. Whenever a similar calamity visits the dairyman or horse breeder, like the rinderpest or epizootic, the whole country is agitated. Not a paper but hoists the signal of distress, losses are enumerated, damages recounted, remedies suggested, and sympathy without stint given.

But when the bee-keepers are assailed with reverses like the devastations of the moth, foul brood, calamitous wintering, etc., etc., not a note of distress is sounded, nor a word of sympathy uttered, perhaps because we are weak in numbers. Unless we can help ourselves, it appears we must not expect to be helped. How much have we done toward solving the problem of the past two winters? Among all the theories yet advanced, only a small part, as yet, seem probable. Dysentery in one of its worst forms, is common immediately preceding the death of the colony. Most of us have inquired into the cause of dysentery. It has been suggested that it is in the unhealthy quality of the honey, and pure syrup of sugar has been substituted as food for the bees, hoping to avert the disease. Others have supposed that simply protracted cold will produce it. Others have taken this view of it: When the bee has filled itself with its food—honey or syrup—and is kept warm enough, the liquid portion passes off into the air, in the form of vapor, while the more solid part is changed into wax, or passes as excrement in a dry state. But when the single bee is chilled for only a short time, or when the cluster is chilled between the combs in the hive so as to prevent those on the outside of the cluster from changing places with warmer ones inside, the liquid portion is not exhaled, but remains in the abdomen till it can no longer be retained, and they leave and discharge it, soiling everything near at hand. They seldom return, and the cluster grows smaller, till gone.

It is proper that we should, like skillful physicians, examine the subject in all its bearings, and if we are fortunate enough to find the cause, we may possibly find the remedy; in which case we shall benefit bee-keepers as much as the philanthropist who helped discover the cause and remedy of rinderpest.

If bees can be made to pass the winter as safely as cattle or horses, we shall have taken one important step toward advancing bee-keeping. I think they can. Some of the younger members among us may yet consider this calamity a blessing. They may be led to guard against future disaster successfully, by the investigation of facts which would never have been thought of but for the disaster.

The fear of stings is greatly in the way of progression. Can we not do something more to remove some of this faint-hearted timidity? There is much to be done in this line. The man can do but little in studying the nature of the bee who is constantly thinking of stings, instead of his studies. If he makes the sting a study—and it is a broad one,—he must get rid of the dreadful fear of it, or he will not progress very much. He may sit quietly down, take the sting, with or without a magnifier, and he will see that he has only a small instrument of warfare, so minute that a puncture in the flesh made with it, would not be realized were it destitute of poison. He will then inquire what made the smart. Examining closer he will discover at the base of the sting quite a lump detached from the bee's body—apparently a part of it—saturated with a clear, transparent liquid; it may be seen glistening over the surface before parted from the bee. When thrust into the skin a very small particle of the subtle poison is transmitted into the flesh, producing the sensation so much dreaded.

When a quiet cluster is resting and disturbed moderately, they simply put up the abdomen in such a way that it will not touch another bee, put out the sting, and exude a tiny globule, nearly covering it, saying as plainly as actions can speak, "You must beware how you proceed further. See what the Creator has given us as defense against the ruthless spoiler. You have wronged us for ages. We begin moderately, as you have. Now we have given you a sight; we have given you a sniff; we *can* give you a taste." When he can understand their language, if he is judicious, he will set himself to interpreting it—will try to see under what circumstances bees are disposed to sting; see when this acrid poison is set afloat in the air, and what effect it has on other colonies; see if a quick motion, while this is in circulation, does not attract attention. He will discover that bees, when busily engaged bringing stores have less time to resent insults—real or imaginary—than when quietly reposing on a cool morning; and that on a pleasant day they are less spiteful; and that such time is the best to work with them. When this poison is floating about, informing surrounding bees that they have been disturbed, he will inquire if any substance will neutralize or destroy it. He will find that smoke of

raggs, paper, wood, or tobacco, thoroughly diffused through the atmosphere, will do it effectually. This has long been used. But he will ask if the best way of applying it has yet been discovered; if he is thorough he will find whether it can be applied so effectually that none of this poison will be perceptible in the air, and no bee have cause for anger or disposition to sting. And he may go into their midst without fear, nor tremble at the approach of a tiny bee; and he can pursue his studies and make discoveries unmolested, and add to our knowledge of the science.

When this is known, this pursuit will be made more attractive and profitable to ladies and children, and *even farmers' sons*. When we can trace the natural history of the bee as it is, not as said to be by thousands who have drawn on imagination for theories, that can be upset by the first scrutinizing observation of facts, we shall be more likely to interest the student. Witness the mistakes made—almost with his last breath—by one of the most profound naturalists of the age, before a college of students. It was copied by the agricultural press extensively. It was criticized by one who had made this branch of natural history a specialty. Few, probably, would dare sanction the criticism, not knowing enough of the real history of the bee, to decide upon its merits; they would be likely to conclude, as most of us would, that the eminent man was probably nearest correct. It is our duty to examine all these things, that we may be able to decide for ourselves, and advance science.

I have endeavored to show that we are not to blame for what we do not know—that we cannot *make* a thought. But when we have a thought, which, given to others, would make them think, and we refuse to give it, are we not censurable? I have endeavored to give some of the reasons why the people do not keep bees; also some reasons why they should keep bees. Will each of you go farther and explain things clearer.

Upon motion of Captain Hetherington, a vote of thanks was tendered to President Quinby for his able address. Mr. Alexander, of Camden, expressed his deep appreciation of the unselfish motives and generous good will which induced the President and other eminent bee-keepers to prepare addresses for the instruction of their fellow-men when no hope of pecuniary reward could incite them.

Mr. S. Alexander, of Camden, read a pleasing paper, of which the following is an abstract:

Whether the Darwinian theory of evolution be the true one, that matter is its own law-maker, or whether, with Agassiz, it requires some special hitches occasionally, or whether, with Davis' harmonial philosophy, that spirit acts in and through matter, is to me, at pres-

ent, of very little account—enough that this world contains bees and men, and that they are mutually advantageous, and, perhaps, mutually instructive. While others, with philanthropic intent, are hoping to educate them to resignation to be plundered scientifically, as we are legally, he mine the task to try to educate myself, by studying some of their peculiarities and characteristics.

Their polity, their government, their way of doing things, I think is somewhat instructive. They can not be said to be strictly communists but thorough co-operationists, which I think is as far as they have gone, and farther than we have gone. I think we might take some useful lessons from them; for instance, from their manner of disposing of gentlemen of leisure, though on humane and philosophical principles, I am opposed to capital punishment; but I am willing to let them try out-door exercise even if the coming season be somewhat inclement. Whether these gentlemen are credit mobiliers in the hive or out, or only go in for watering stocks, I will not attempt to say, but the patrons of husbandry of the hive seem to consider them as middle-men, only to be used when absolutely necessary, and at all other times worthy of immolation. Whether they go for salary grab, or civil-service reform, seems entirely inconsequential to the internationals, Italian or otherwise. Indeed the gold-ringed counts seem to be as radical as our black republicans. And then there is the woman question; here, perhaps we differ some, the most of our lady apiarians maintaining, I presume, that it is the best government ever devised by bees or men—queen in regal dignity, presiding with graceful authority; while others,—and that they should have the Quinby authority in their favor! that it is a strict democracy.

Captain Heatherington, Treasurer, read his report, acknowledging a total of receipts of \$51.00, including the previous year's balance. The receipts of the last convention were \$17. The expenditures for the year were \$21.09.

Agreeable to a suggestion, the Secretary read the Constitution, and an opportunity was offered for the enrollment of new members. Several new names were added to the list.

The election of officers for the coming year was effected with the following results:

President—M. Quinby, of St. Johnsville.

Vice President—S. Alexander, of Camden.

Secretary—J. H. Nellis, of Canajoharie.

Treasurer—J. E. Heatherington, of Cherry Valley.

President Quinby presented the following question for discussion: "Does the clipping the wings of the queen injure her capacity for usefulness?"

P. H. Elwood had never observed that clipping, properly done, injured the queen. If the clipping was too close he had known the workers to kill her.

Secretary Nellis asked how short to clip.

Mr. Elwood thought one wing two-thirds off was best.

Mr. Quinby stated that the object of clipping was to prevent the queen from flying when the swarm comes from the hive, and without the queen the swarm will not depart. The question is, Is the queen rendered less fertile by the clipping?

Mr. Nellis. At the Louisville Convention, a member read a paper on bees' wings, in which it was stated that several of the functions of the bee were located in the wings, such as breathing, etc. I think the theory very erroneous. I have practiced clipping for five or six years, and have seen no bad results. I have at present more than forty queens with wings cut off, and consider them as servicable as others.

Mr. Doolittle, of Onondaga Co. I would like to ask how many wings were cut, and what instrument was used?

Mr. Nellis. I have sometimes cut all the wings two-thirds off, and I did not consider the queen injured. Formerly I cut the wings with a knife, but now I use a small pair of lady's scissors. I would advise cutting the wings *on one side* two-thirds off.

Mr. Vandervoort. I have clipped queens for fifteen years, and never saw any injury from it, except where I had cut so short as to hurt the bone.

Captain Heatherington. I have practiced clipping some time. I have had three and four hundred clipped at once. Clipped queens are more likely to be superseded. I think this happens because the queen is regarded as a cripple by the other bees. But I shall practice clipping, nevertheless.

Mr. Doolittle. I am certain that clipping off both wings and one leg will not injure the queen's capacity.

Mr. Alexander. I have no doubt that the bees perceive the deformation, and are led to supersede her. I think, also, that continued clipping might, after generations, affect the insect. There are sensations located in the wings, and bees communicate by the noise made by them, but convenience calls for clipping, nevertheless.

Mr. Doolittle. I think I can prove the ability of clipped queens. I have clipped off a queen's wings and a hind leg close to the body, and the bee worked for four years.

Mr. Heatherington. The point needs wider proof than a single instance.

Mr. Doolittle. I have several queens all of whose wings are clipped close to the body.

Mr. Bettsinger, of Onondaga Co. I agree with Mr. Doolittle. I have seen his crippled queen. She is a good effective queen. I have clipped for eight years. I began by clipping one of the four wings, and the queen went with the swarm. I then clipped off every wing entirely. I have ninety queens without

a vestige of a wing, and I can say, Do not be afraid to clip off the wings.

Mr. Heatherington. I am certain that no queen with a wing clipped can light with a swarm upon a tree.

Mr. Doolittle. I have known of cases like that instanced by Mr. Bettsinger.

Mr. Nellis. I think even a little of the wing clipped would retard the flight. I can not comprehend how a queen with a whole wing gone could go with a swarm.

Mr. Quinby. I know of a case in which a swarm went out with a young queen, and left the clipped queen in the hive. Perhaps some of the contradictions may be accounted for by the fact of new queens.

Mr. Doolittle. A queen, after ridding herself of her eggs, becomes as slim as a working bee, and can fly with one wing gone.

Mr. Elwood. I claim that clipping off all the wings subjects them to hazard in falling, as a queen with part of a wing gone could not fall as one with all gone. I think clipping one wing on each side of the body might balance the insect and enable it to fly.

Mr. Heatherington. A clipped queen is most likely to drop from a cluster in moving.

Mr. Bettsinger. Black bees are more liable to drop than the Italians. Italians cling closely to the comb. I experiment continually, and have tried to see whether the clipping injured the queen. The wings are to bear the body through the air. They cannot use them in the hive. They cannot make a noise with them; they can not do anything with wings but go through the air. The queen's business is in the hive, wings are of no use there.

The question next presented was, "How soon after hatching is the queen capable of laying?"

Mr. Quinby had known them to lay in seven days.

Mr. Nellis believed, in the working season, the average was nine days.

Mr. Doolittle said the shortest time he had known was three days, generally from four to six days. Mr. Bettsinger approved of four to six days, under favorable circumstances, in the majority of cases. Mr. Elwood said, once his trouble was to get them to lay at all. Sometimes two weeks elapsed, and in the fall it was longer. Mr. Bettsinger would kill queens which did not lay in ten days. By favorable circumstances, he meant a full swarm, with bees working well and putting in lots of honey. Mr. Doolittle made a distinction between natural, artificial and forced queens. He thought forced queens good for nothing.

Vice President Alexander, assuming the chair, submitted the question whether those queens raised by artificial means are equal to the natural production of the hive.

Mr. Doolittle said he meant, by forced queens, those which are hatched in from seven

to ten days. An artificial queen, hatched in from eleven to fifteen days, is as good as a natural queen.

Mr. Quinby had raised queens for ten years. He never raised one which came out short of ten days. He knew nothing of five or seven days queens. He gave the bees brood and watched the time; they never gained but a few hours on the ten days. He could not see what was meant by forced queens. How are they distinguished from a natural queen? They are raised in a small box containing forty or fifty eggs. The bees find they have no queen and go to make one. The whole attention of the group is directed to producing a queen. In a full hive there are combs to be taken care of. In the box the bees can work for the queen. The fertility of queens raised in a little box shows the better care their rearing has had.

Mr. Doolittle's idea was that queens could be hatched in seven days, taking larvæ five days old. He had raised such queens and they were useless. It may be done in a full hive or in a nucleus box, the result is the same.

Captain Heatherington asked how he could estimate the age of a larva.

Mr. Doolittle said a larva five days old nearly filled the cell, and the bees can convert such a larva into a queen. His method of raising queens is by taking the queen out of the hive, and inserting brood of another species if he wishes to make a change. In the hurry to get a queen the bees will take the larvæ which can make queens soonest.

Mr. Bettsinger used the small box first, and then raised queens artificially in a natural way in a full stock of bees. First take away the queen, then in 6 or 8 days cut off the cells started and introduce eggs of the kind wished for. As the egg hatches into a larva, the bees feed it and thus secure natural queens, artificially.

Mr. Vandervort had raised queens since 1863, and had never known a queen to hatch in less than 10 days.

Mr. Doolittle said his experiments were very accurate, and he was satisfied with his results.

SECOND DAY.

Mr. Quinby called for the discussion of the question, "The best mode of wintering bees." Mr. Bacon said his trouble is in "springing" bees, and he wished that added to the question. The discussion followed:

Mr. Quinby. For forty years I have kept bees, and during the last two years I lost many more than usual. I propose to inquire into the causes of the fatality. If the cause is in the honey, or in the temperature, we should know it. The honey has probably not changed from year to year. The cold weather has been severe and protracted.

Experience should be related upon this question of causes.

Mr. Bacon, of Verona. My first lesson in bee-keeping was severe. I was nearly stung to death in childhood. I have kept bees ever since. I never had any experience with dysentery in bees until the last two years. I have, until two years, kept bees successfully in a cellar. I have had less difficulty with the old box hives than with the frame hives. I never had, until lately, any cases of dysentery with the box hives. Last year I noticed it, but it was in frame hives. I put out the bees in good condition in April. The weather was cold. My best bees were gone by the first of May. They died seemingly in the fields. I believe the cold winds killed them. Their constitutions were first weakened by the long winter and by the poorer quality of the honey, and the cold air struck them down. About the first of June the weather changed, and bees which had any life revived. I have now built a bee-house. I dug a trench two feet deep, twelve by eighteen feet. I filled it with stone. This was the foundation for the sills. My studs were five inches deep. I boarded outside and inside and filled in with dry earth. Overhead the ceiling was close and filled in to the tops of the joists with earth also. I filled the windows with closely fitting sawdust boxes. The doors were like safe doors and filled with sawdust. My walls have three thicknesses of boards, five inches of dry earth and two inches of dead air. I ventilate with a tube six inches square made of boards nailed together. This tube has a damper in it, and runs along the floor, and has holes bored in it to let the air escape into the room. I have top ventilation with two five-inch apertures, which may be closed. I put in the bees, packed closely, one stock above another. The room is darkened comfortably. I put the bees in, in November. The weather was very severe about the middle of the month. Before the bees were put in, I heated the room very warm to drive out the moisture, then put out the fire and let it gradually cool down. In January, on a fine day, I took out half the bees and gave them a chance to fly. After a time, those taken out had no dysentery, while those which had not been aired had it. I am very reluctant to enter the bee-house with a light. The temperature runs about forty degrees on an average. It is warmer than I ever kept them before. The cost of my building was \$125 in cash; no charge being made for my time. A building of the same kind might be built rougher and cheaper. I believe sugar feeding will not save bees. It may be a little better than honey in some respects, but not generally trustworthy. My frame hives which failed to winter were seventeen by nine and one-half inches. I never will use any frames short of a foot deep in the clear. Bees will winter better

in a deep hive. I put straw over some of the hives, and they did better than those without.

L. C. Root. In wintering bees, there are three things necessary: Proper condition when going into winter quarters, proper temperature, and quiet. Bees are usually in best condition to go into winter quarters, when the honey is stored from time to time during the season—the amount being increased as the brood diminishes. This leaves empty comb where bees cluster. The principal objection to late fall feeding is the hive contains no brood, and the honey or sugar fed is stored too much in the centre of the combs. We find that about forty-five degrees is the proper temperature where they are subject to any jar. I think if they could have perfect quiet, they would stand a much higher temperature, and consume a less quantity of honey. In our cellars the present winter, where the thermometer stands at forty-five to forty-seven degrees, one swarm consumed two and three-fourths pounds during November; one and three-fourths during December; one and three-fourths pounds during January. Another swarm consumed four and three-fourths pounds during November; two and three-fourths during December; five and three-fourths during January. The difference in quantity is owing to warmth and quiet.

S. A. Cleveland. I believe we should report our losses. A year ago I had forty swarms in good condition. From all my frame hives I had extracted the honey. I continued to feed one-quarter of a pound a day of sugar, until April 1. They seemed in good condition. I set them out, and they were raising young bees. About April 20th I noticed they did not eat the honey. I only succeeded in getting seven through the spring. Four out of six in box hives survived. They had no honey taken from them during the year before. Last year my record was all reverses.

M. H. Tennant. Quiet is what bees need. I went into my bee-house Wednesday evening, and I never saw better swarms than those fed with my feeder. I feed nothing but pure box honey. I have succeeded very well with straight "A" sugar. My house is fourteen by sixteen feet, above ground, with saw-dust-filled walls, ventilated above and below, the current of air passing up the centre of the room, and the bees standing around the sides. I put cleats on the floor, and then piled the hives one above the other, bringing them out a little from the wall. I think a floor should be avoided, as you can not step on it without jarring. One winter I only went into the bee-house four times, and only lost two swarms. In the spring I lost eleven. I found them around on the fences, where the wind had caught them and chilled them fast.

L. C. Root. It is protracted cold which ruins the bees. A wind from one direction

will drive the bees to the other side of the hive. They will eat all the honey on that side and die. They cannot get back to the food on the cold side. Getting excited induces the bees to leave the cluster, and then they get chilled easily.

R. Bacon. I am slow to believe that cold alone produces dysentery. We should learn the cause for a certainty, if possible.

S. Alexander. I believe with Mr. Root that long detention in the house will not injure the bees. We bought a hive of a neighbor who left it in until May 15. It was the best hive we had. We put out the bees early, and saved them, but those left in until May were the best bees. The idea in modern hives is to make them non-conductors. This, of course, makes it slow business to warm them. Thus protracted cold results. This might account for Mr. Bacon's bees not doing so well in frame as in box hives.

J. H. Nellis. This would work if bees were not capable of producing warmth. In an article written some time ago, Mrs. Tupper asserts that she wintered bees very successfully in a cellar, under a living room in which children were constantly romping. I once wintered bees, some in box, some in frame hives, under ten feet of snow, from January to April. I shoveled them out and rapped on the hive with no result. They were dormant, and it took an hour to revive them. They were in good condition. I have wintered bees very nicely in a cellar at a temperature of forty degrees. The last two winters have been disastrous, however. The winter of 1872, I had seventy-seven stocks in the cellar—forty-four in box hives. Lost more than one-half of those in box hives, and but few of those in frame hives. I think the bees in frame hives were stronger and more thoroughly bred. I lost about one-fourth of my stocks. In the fall I fed five stocks on sugar syrup. They wintered better than the average, yet not satisfactorily. Those subsisting on late-gathered honey wintered as well as those supplied with honey stored early. The cellar averaged probably about thirty-five degrees. I think they should be kept warmer—about forty-two degrees, and after the first of March they should be warmed frequently to fifty degrees. I would have them breed considerably after the first of March. I think the scarcity of young bees at the time stocks are taken from the cellar, the prime cause of disaster in the spring. The old bees die of natural causes, and leave what little brood is started, unprotected. I have known stocks in rickety box hives to winter well out of doors in the most exposed situations. Facts are so apparently contradictory, that I cannot reach any certain conclusion.

Capt. Heatherington. We bought some bees in Vermont of a Frenchman who had left his bees until May. His bees were in as

fine condition as I ever saw anywhere. I think they were put in early. The shelter was rather defective, but the walls were made of earth, and the principle was correct. The floor was of earth. I find a bee-room an excellent place for keeping honey in the summer, and to avoid the danger of jarring the floor, a coating of saw-dust might be used. I began wintering in a building, and was successful. I left some out of doors and they were stronger. I changed in-door practice to out-door wintering, and changed to straw hives to winter out of doors. Straw is a good conductor of moisture and non-conductor of heat; that is what we need. Since we changed to the Quinby hive and changed the temperature we have lost many swarms. I have now a special bee-house. The foundations are banked with earth. The floor is doubled, with thick paper between. The paper is made of prairie grass. The frame is a balloon frame, with plaster board on each side, and side boarding outside, and ceiling inside besides. The space between the studs is filled with planing machine shavings. The walls are "furred" out and another thickness of paper so put on as to make a chamber of confined air, and ceiled again inside the paper. The walls contain three thicknesses of plaster board, three thicknesses of boards, and six inches of stuffing. The joists overhead are three by eight inches. The plaster board and ceiling board are fastened beneath the joists, the space filled with stuffing and plaster board, and tight flooring placed above. The building is eighteen by twenty-four feet, with partition through the middle, and hives on shelves around the sides. I am favorable to the use of dry earth in the walls.

R. Bacon. I line with rough boards, and the influence of the dry earth can be gained through the cracks between the boards. I will give a hundred dollars for a method which, with fair management, will enable me to keep bees through the winter.

L. C. Root. The convention can afford to give \$5,000.

G. M. Doolittle. Mr. Bacon's trouble with dysentery was caused by his disturbing the bees left in, and not because some were taken out and others left in. I believe if a swarm dies before February 1, it was good for nothing when it was put in. I began with Mr. Quinby's method and wintered bees in the cellar. They did well the first year. The next year they came out well, but dwindled away because of the cold spring. Next year there were many soiled combs. In the spring I lost heavily. I then began out-door wintering, sweeping the snow around the hives after every storm. I used Novice's quilts, and packed straw in the caps above. Until January 1, all was well. Then they began to steam up. The hive was in commotion. I took off the straw, leaving only a quilt. The

quilt is calico cloth lined with cotton. The next morning they were still in bad condition. I took them into the cellar and got the hive through, but it was not of much use. I believe too warm weather is more dangerous than too cold. Fifty degrees I believe is too warm. It is too warm when they begin to breed. Last spring my bees came out in good condition. For two weeks we had warm weather and the bees worked well. Then came the cold weather. After five days the larvae were mostly dead. Many hives had only a double handful of young bees. I would not have bees commence breeding until after the first of February. I had a hive without brood until May, and it was the best hive I had. I made forty-five dollars from that hive.

L. C. Root. Don't close your hives at the bottom, so that the bees can not get out if the temperature induces them to fly.

R. Bacon. I tried shutting up hives at the bottom, and supposed they were doing well. I examined the bees, and found the boards covered two inches deep with dead bees. Don't let bees think they are imprisoned. I leave a good deal of ventilation at the bottom.

G. M. Doolittle. I have examined my closed hives, and found only five dead bees under one hive, and not more than a tablespoonful under another. I seal them up as tight as I can get them without sealing-wax.

N. N. Bettsinger. I winter bees out of doors, putting straw on the top, with a hood over the hole. The steam passes through the straw, and freezes the hood tight. This tight closing is continued from January to spring. The bottom entrance becomes frozen up, and the hive is almost air-tight, so far as I can see. My bees are wintered on honey gathered in September and October. I do not believe that bees can cluster on the honey without freezing. Bees can stand a low temperature, even when away from the cluster. When they die here it is because of moisture, not cold. There is less moisture in the cluster than in the honey-combs outside. I keep my bees out of doors, and sweep the snow around them, sometimes covering the hives.

Mr. Bacon. I have seen bad air burst from a closed hive in such quantity as to extinguish a candle. In opening the hives the bees were found to be dying fast. I want to know how bees can live in such air.

Vice President Alexander. I have in mind an instance in which bees, being much disturbed, generated heat enough to melt the comb and let the honey run down upon the floor. The bees were confined. I had a case of a ruined hive when closely shut in, and I think it came from lack of air.

Mr. Vandervort. If cold has caused the mortality among bees, why didn't it affect us years ago? I have known bees on the prairie

ries of Illinois which have withstood long periods of very cold weather and fixed winds.

A gentleman said: I think the more air the bees get the better they will go through the winter. I had a swarm with a season crack in the hive, standing in an old shed all winter, and they were in excellent condition in the spring. I think it is dampness rather than cold which kills the bees. I never had any trouble until within the last few years.

Mr. Elwood. The theory was advanced at the last Convention that carbonic acid gas settles in the bottom of hives. I have investigated the subject with care, and find the theory to be erroneous. The constant tendency of gasses to diffuse and intermingling renders it impossible for the hive to fill in that manner.

AFTERNOON SESSION.

President Quinby called the meeting to order at half-past two, and briefly reviewed the points made at the morning session concerning winter care of bees. He said: There is need of ventilation, and need of quiet from excitement. Dysentery is produced by the cold. The continued chill prevents proper digestion, and the disease soon follows. To prove that dysentery does not result from the food, I will refer to a hive fed with sour honey which did just as well as the others. Another hive which I kept in a cold place and fed with the best food, were taken with the disease. I argue further, that in a warm, healthy state, the liquid part of the food is volatilized and passes into the air. In the disease the assimilation is faulty, and the fluid passes out as an excrement and causes the dysentery. I think temperature will be found to have more effect upon the health than the lack of ventilation. Keep the bees healthy, so that the excrement is dry when discharged. It is not well to let them out to discharge a liquid excrement, which they will do when chilled, but keep them in and keep them warm, so that the discharge may all be dry.

Mr. Ellsworth. The fact that dysentery can be brought on almost instantly, is quite a corroboration of the idea that it is caused by sudden chilling.

Mr. Bacon. Bees used to be handled far more carelessly some time ago than now, and were chilled more often; yet they did not have dysentery.

The time having arrived for the discussion to be closed, the next business in order, the selection of the place for the next meeting, was called up, and Utica was chosen. After some desultory remarks, the Convention adjourned to meet in Utica the first Wednesday in February, 1875.

We, herewith, present a table showing facts concerning the stocks and yields of some of our bee-keepers, as reported to the

Secretary of the Convention. We believe this is the first publication of the kind which has been made in this region, and hope the beginning may lead others to furnish us with reports of their operations:

NAMES.	ADDRESS.	No. of Stocks.	KIND OF HIVE.	Am't of Honey.	Am't of Wax.	REMARKS.
		Spring.		Box.	Extr'd.	
M. H. Tennant,	Stanwix, Oneida Co.,	37	Union Hive.	1,800		50
G. D. Jones,	Kirkwood, Broome Co.,	12	King Hive.	300	100	8
Solomon Footman,	Seaward, Schenectady Co.,	30	Non-Swarmer.	3,500	580	100

* * A number of bee-keepers were unable to report. † The above report is estimated in part. Most of the stocks were in very poor condition in the spring.

For the American Bee Journal.
Wintering Bees.

In the experience related by Mr. Hester, in the AMERICAN BEE JOURNAL for February, I cannot recognize that in the cases reported there is bee-malady. Mr. Hester remarks, that in the autumn of 1868, one or two bee gums perished; the bees dying one after another, in November. Is it not probable that the colonies were queenless, and that the bees perished for that cause? In a normal colony, the place occupied by the queen is the central point for the bees to cluster. In a queenless colony, the bees, having no queen to keep them compact, the cold nights kill those which happen to be outside of the main cluster: and soon the number of bees is too much reduced to maintain the warmth necessary for their existence.

The surviving stocks were put by Mr. Hester in a room which was too much exposed to the effects of the external temperature. When the temperature of the room fell to the freezing point, and that accident, according to Mr. Hester, took place several times from November to the last of February, the bees were forced to eat more to maintain the temperature in their cluster, and of course needed to empty themselves; but as they remained four months in their repository, they got the dysentery. It is probable that the colonies would have been all alive in the spring, had Mr. Hester given them the chance of emptying their intestines once or twice in the course of their long confinement.

In the winter of 1870, Mr. Hester put ten stocks of bees in his cellar, and they wintered in fine condition. In the same cellar, in 1871, forty-three colonies out of sixty perished. This winter, twenty-seven colonies, put in the same cellar, in January appeared very healthy.

Nowhere can a bee-malady be proved by such facts. Certainly the unevaporated honey, which the bees of 1871 had to eat, was one of the causes of the death of the forty-three colonies; but the warmth of the cellar was very apt to help in the bad result. A cellar which, with ten or twenty colonies, is of a suitable temperature for the wintering

of bees, can be too warm, if there are sixty stocks heaped up in it. The bees become restless; fatigued by their exertions, they eat too much, and they die of dysentery.

But there was neither bee-malady, nor bad honey. In the first case, there was too much cold; in the second, there was unevaporated honey not fit to winter bees, unless they can go out sometimes to empty their intestines; and probably too much warmth for them to remain as quiet as it is necessary for their health in winter.

Do Bees Injure Fruit?

MR. EDITOR: Last fall I wrote an article, under the above heading, to the New York *Tribune*, in which I stated my observations, and censured that wise (?) Professor Riley for his bee-destroying recipes and advice. But they did not see fit to publish it.

Perhaps Prof. Riley knows all about bees; so did Agassiz, and yet we know he was in error, when speaking about swarming, comb-building, etc.

Had Prof. Riley made close observation, he would have found that bees do not puncture fruit, and would have had no occasion, to publish his ignorance, by giving his cobalt recipe. He would have benefited mankind a great deal more had he taken a dose of the mixture himself, for I think we can spare such professors better than the bees he has caused to be killed.

This fall I took a bunch of Delaware grapes (the most tender variety we have here), and put it on a hive, directly over the bees, and watched proceedings; but not a single berry was opened; then I broke a few berries, upon which they went immediately to work, sneaking them dry, thus showing that something besides bees does the mischief.

Now, if bees were so destructive to fruit as some try to make out, how is it that so many are kept in Germany, France and Italy, where fruit, especially grapes, is so extensively raised? They know that bees are beneficial to

fruit culture, and bee-keeping is encouraged instead of persecuted.

In Italy there is a law regulating the size of hives and frames. If the bees destroyed fruit, there would have been, in those countries, laws enacted long ago to prevent their being kept. And, further, if bees destroyed grapes, would they not do so every year, and not some years only, as several writers state in Report of Agriculture for 1871? It may be said that bees do not work on the same flowers every year (linden and buckwheat, for instance), but that is because they secrete no honey, but grapes always contain juice.

But no matter how foolish and groundless a theory is, it will have some supporters. H. O. KRUSCHKE.

Notes on Wintering.

So many different and conflicting theories have been advanced regarding this branch of our science, that I feel it must be approached with caution. The reason for this caution should be apparent to each of us who may care to instruct our brother bee-keepers on the subject before us. And why? That which will suit us in Pennsylvania may be greatly at variance with both the practice and interest of those residing in Iowa or Minnesota, or even those in Tennessee or Kentucky. The effect of the climate, the amount of honey gathered in the fall from natural sources in the various localities, and many other things should be taken into consideration if we attempt to solve the problem of the "successful wintering of bees."

I doubt not but that in the higher latitudes, a carefully constructed wintering house should be the prominent object of the bee-keeper; and even with us, it may prove an important auxiliary, but after many years of careful observation and experiment, I have concluded that he who will lead us to success by giving us a complete system of *out-door wintering* will be considered our greatest benefactor. With this object carefully in view, I have made the most of my experiments in relation to this matter. A few of them, with your

permission, I will give to your readers.

On the 17th day of November, I prepared my hives for winter (it should have been two weeks earlier), having previously cut winter passages in all the combs. I use the Langstroth hive almost exclusively — the double hive. I packed at sides with either dry leaves or old rags, and the caps with clean straw. I removed the honey boards from nearly all the hives, and in their place I put a box frame of proper size, made of plastering lath, and covered with burlaps or common bagging. This frame I filled with clean straw, left about one inch ventilation in front for the flight of the bees, and left the back ventilator in the cap open. Permit me here to say, that for wintering purposes I prefer the single hive, made of one and one-half inch stuff, to the double hive.

On examining stocks packed as described, I find at our lowest temperature (eighteen degrees) this winter, that the bees remained at the top of the frames among their stores. I have tried various coverings for the frames, cotton and woolen quilts, heavy paper, dry leaves, corn-cobs, etc., etc., but find nothing equal to the box frame filled with straw, except, perhaps the corn-cobs; these appear to be the best absorbents of moisture, and at the same time afford the most complete ventilation of the hive.

These are the only preparations I have made this winter, with the exception of the fact that I have covered every hive with light boards to protect them from rain and snow. This I also do in the heat of summer to protect them from the sun.

As I hope to give you further notes on this subject, I will close this already too long communication. "B"

What Gallup has Seen.

We have seen a stock of bees wintered under the following circumstances: They were in an old fashioned straw hive; confined in the hive, and set on some loose boards directly over the fireplace in a log dwelling-house, where

there was a fire kept day and night. In this case they bred all winter, and had no dysentery. Again, we have seen bees wintered, both in Canada and Wisconsin, in the Weeks hive, suspended two feet from the ground, with no protection from winds or weather, and the bottom-board suspended to the bottom of the hive, with one inch space all around the bottom of the hive. On this plan, also, the bees did well and had no dysentery. We have seen hives set on top of a stump, raised on inch blocks from the bottom-board, exposed to wind and weather with the thermometer forty degrees below zero at times during the winter, and no dysentery. We have seen bees in box hives, with a two inch hole in the top, the hive set on top of a stump exposed to wind and weather, two inch hole protected from rain and snow, bottom closed up tight, and no dysentery.

These were all single cased, or single boarded, hives, and, strange to relate, all wintered on their own stores—no coffee sugar or sugar syrup. It would seem that the Almighty, according to some theories, made a grand mistake in not making bees so that they could make their own sugar syrup, if honey was not intended for them.

We have seen twenty-five stocks wintered in a dry, warm room in the cellar, with cement floor, and kept so warm that they bred all winter. These were box hives, turned bottom up, with bottom-boards removed; and no dysentery. We might go on enumerating cases like the above.

If we understand Mr. Hosmer, his small stocks breed all winter and come out strong in the spring, etc. It has been remarked, that extra smart beekeepers cannot stop to theorize; but we must be allowed to theorize, for it was by comparison, or theorizing, that we gained our present knowledge in the business. Our theory is, that bees kept perfectly dry, as in the above cases, discharge the excremental portions of their food in small and perfectly dry pellets, or, in other words, all moisture is entirely evaporated from the excrement while in the abdomen of the bee, and then their discharge takes place in the hive, and lies on or in the bottom

of the hive without any detriment to the colony whatever.

Such colonies, in the above condition, do not show any specks on the snow in their first flight. Their abdomens never show any distention or enlargement from the retention of excrement. Of course, old bees die of old age in the hive, but they are all perfectly dried up, no mistake about them whatever. But in a damp cellar, if our bees breed, we always have to set them out occasionally, for the young, or pollen consumers, to have a purifying flight.

E. GALLUP.

For the American Bee Journal.

The Use of the Extractor.

In my article on "How to Feed and Winter Bees," in the January number, there are several mistakes.

In the first sentence the word *keeping* should be *feeding*. I did not mean to say that honey from other hives often proves fatal to the bees, but that honey from other sources often does, when the bees have been long confined to their hives. Nor did I mean to say that bees should never be fed much more syrup than they would consume in preparing food for their young, but that when feeding expressly for the purpose of propagating bees, care should be taken not to give them much more syrup than they would consume in preparing food for the young larvae, and for constructing combs for the brood when necessary. When there are more bees in the hive than are necessary for rearing all the brood the queen is capable of producing, they may be fed more, if suitable room is given them in which to store surplus honey, so as to prevent them from filling up the brood combs with syrup instead of brood.

I would also say that when there is found to be more honey in the brood combs in the spring than is necessary for the colony in rearing brood, it should be removed with the extractor, leaving honey only in the upper part of each comb. A good way of converting this surplus honey into combs and brood, is to insert an empty comb-frame in the central part of the brood nest as early

and as often as the bees can properly occupy and fill them without danger of chilling the brood, or checking its development. By this method, with a strong colony of bees and proper care, brood and combs will be produced rapidly in the spring, particularly during fruit blossoming. By this means, the colony may be made very populous, kept from swarming, and the largest possible amount of honey secured from the hive. If honey in the comb is preferred, then at the close of the main honey season feed the bees the extracted honey, or good sugar syrup, giving them all they will use while being fed.

For the American Bee Journal.

Review of the January Number.

Whilst reading the article on "Feeding Bees," page 7, I notice that the writer recommends the "most refined grades" of sugar. Now in this I beg leave to differ with him for the following reasons: In past years we have fed nearly all the various grades of sugar in the market, watching the result closely, and find that the "most refined grades," such as coffee A, loaf-sugar and crushed, are too much inclined to crystalize in the comb-cells and on the vessel wherein the syrup is used, and not one of the grades named seemed to be any better than coffee C, which, in fact, is better for bees, because less inclined to crystalize; it also costs less, is more readily dissolved, and readily taken by the bees. The various grades of brown sugar should not be fed, as the syrup is more liable to ferment. The writer further says: "Molasses or sorghum should never be used." I see no objection to the bee-keeper using them, but I have so far failed to induce my bees to use them in any shape.

Not too much can be said in favor and on the manner of spring feeding to stimulate breeding; many overdo the thing and have the brood-cells stored with syrup. Another portion of bee-keepers underrate the value of supplying their bees with meal or flour, and many of our western bee-keepers

express their willingness to supply meal, did not our high winds blow it away. Again the want of water in the hives, when cold days prevent the bees from getting it, causes a check in breeding, and very frequently the young worm, just hatching, perishes because the nursing bees cannot obtain the necessary water to prepare the food for the larvæ. To obviate this we have experimented for years to produce a feeder that will enable us to furnish bees in their hives, with syrup, water, or meal, until we have at last succeeded in perfecting it.

On page 8, we find a description of "Adam Grimm's Bee-feeder." As that article might lead some of its readers into trouble, it may not be amiss to state that the feeder was patented May 6, 1873; the perforated screw cap, and projecting rim forming specific features in said patent. If the patent was all owned by myself the "trouble" above named would not be very serious; but over one-half of it has passed into other hands.

As a contrasting item on "The Wings of Bees," page 9, I would say that I have an imported Italian queen bee that has had both of her wings clipped close to her body as a special mark, and this for *five* seasons; and last year she was one of the most prolific queens in my yard. If she lives another year she will do well as a specimen without *lungs*. But what is the use of lungs or their equivalent, if bees can live without air, as Mr. Adair stated some years since?

Coburg, Iowa. E. KRETCHMER.

Care of Honey Bees in Winter.

MANY successful apiarians contend that there is no better way to winter honey bees, than to allow the hive to remain isolated in the yard where they have been kept during the summer and autumn; and they point to their success in many years past for reliable evidence to corroborate the correctness of their assertion. The fact that honey bees have been kept satisfactorily in the foregoing manner, does not prove that such a practice can be recommended as the best under all circumstances; for hundreds of apiarians have attempted to

keep their bees without proper protection during the winter, and have lost nearly every skep. There is one fact in which all intelligent bee-keepers will agree, which is, that a colony of bees will pass the winter best when the hive is kept in a location where the temperature will not be rapidly affected by the rapid transitions from warm to very cold, and *vice versa*. One thing in particular should be guarded against, which is this: No hive should be placed where it will be exposed even for a single hour to the rays of the sun. When a hive stands in the sunshine for a few hours, the walls will be warmed up, the little workers will be enlivened and the pleasant outlook will invite thousands of them to spread their wings and fly away to the fields. But, before they have flown a hundred yards, they are frequently chilled to such an extent that they drop to the ground and perish, as they cannot recover sufficient strength to return to their homes. This teaches the eminent importance of guarding every hive from the fury of fierce winds and also from the cheerful sunshine. When the hive is in an isolated place it needs a cover to turn the rain and snow, and boards, rails or brush placed on every side to obscure the light of the sun and to break the force of a cold wind. So long as the bees are kept in the shade, well protected, where they can discover little or no light, the temperature of the interior of the hive will be more uniform, and only a limited number will escape from the hives and perish.—*N. Y. Herald*.

Ventilation.

Bees require honey in winter to keep up animal heat—the carbon of the honey is burned in the body of the bee as coal burns in a stove. If the hive is too cold, the bees will be found to flap their wings in the cluster and thus increase their heat as man does by clapping his hands in cold weather. This requires just so much more expenditure of honey as food. Dr. Carpenter, speaking of an experiment, says a bumble bee was found to produce one-third of a cubic inch of carbonic acid in the course of a single hour, during which its whole body was in a state of agitation, from the excitement consequent upon its capture, and yet, during the whole twenty-four hours of the succeeding day, which it passed

in a state of comparative rest, the quantity of carbonic acid generated by it was absolutely less.

From these considerations, it is manifest that unnecessary loss of heat is exactly equivalent to unnecessary loss of honey; the walls of the hive, therefore, should be as non-conducting as possible, and in order to make these the most non-conducting, they should be kept dry. Ventilation is a most important means of keeping the walls dry. This will be seen if we consider the fact that heated air has a much greater capacity to absorb vapor than cold air, and that the vapor thus absorbed rises. Now if there be an escape for this vapor at the top of the hive, the air heated inside the hive by the bees will pass off charged with moisture, and thus leave the inside dry. And the admission of air at the bottom will bring cool air, which when heated by the bees will absorb the moisture and pass it off at the top, and thus by a circulation keep the inside dry, and warmer than if this moisture were retained.—*Live Stock Journal*.

Letter from Miss Anna Saunders.

MR. EDITOR: I have just reached home after an absence of several weeks and find many letters applying for seed of the sage tree, and information concerning it. I am sending the seed to all applicants, but will answer most of the questions through the BEE JOURNAL, as they seem to be of general interest.

This tree was grown from a cutting and commenced blooming about the second year. I have never known it to be cut down, or injured by cold weather, as many of our tropical plants are; so, I think that with careful cultivation during its early years, it may adapt itself to your climate. I do not know whether it is honey or pollen, or both, that the bees get from its blossoms. It commenced blooming about the 1st of last July.

Peaches, plums, &c., are in bloom now (Feb. 9), and my bees are exceedingly busy. They are carrying in loads of pollen, and, I suppose, honey, but I have not examined the hives to see, fearing the little baby bees would be chilled. The mercury has been 62° the greater part of to-day. Will some wise bee-keeper tell us what is the lowest temperature at which it is safe to open hives out of doors?

Woodville, Miss.

American Bee Journal.

W. F. CLARKE, EDITOR.

CHICAGO, MARCH, 1874.

Italian Bees.

Joseph Barlow of Blackheath, Ont., asks:—
 "What is your opinion of the Italian bees? Are they more profitable than the common or black bees? Some say they are and some say they are not. I have the common bees, but if the Italians are better, I should like to get them."

The unanimous opinion of all bee-keepers competent to judge, is that the Italians are vastly superior, in several important respects, to the common or black bees.

1. They are better honey-gatherers. This is the main excellence to secure in bees. We keep them for the stores they will collect, and our profits come from the excess of what they treasure up after supplying their own wants. What percentage more of honey they will gather, over and above the average of what the black bees will do, has never been ascertained, but it has been sufficiently demonstrated, that they are more active and energetic workers, that they will go out on foraging expeditions during weather which confines black bees to the hive, and that they will gather honey from sources not accessible to the black bee.

2. They are more quiet and peaceable. This is a very important point, inasmuch as it is essential to the best success in bee-keeping, that the bees should be freely handled. Artificial swarming, change of queens, extracting honey, putting on and taking off boxes, and a variety of other occupations, necessitate access to the interior of the hive, and render it desirable to have bees to deal with, that do not easily become irritated and infuriated. It is frankly admitted that the Italians, when once made angry, are worse to contend with than the common bees, but there is no need to enrage them, and they are not easily provoked. When a hive is opened, the common bees incline to rush out pell-mell, while the

Italians cling to the comb, and remain quiet. With care, an Italian stock can be handled as well without smoke, as common bees with it. The utmost gentleness is requisite at all times in doing anything among bees, and if this is practised, it is remarkable how amiable the Italians will behave. Occasionally things will happen calculated to try the temper of most peaceably inclined bees, just as the gentlest of human beings will sometimes be exposed to provocation. But, under ordinary circumstances, the Italians will be found much more pacific than the common bees.

3. They are less liable to be infested with the moth. For some reason or other, the black bees more readily succumb to this insect pest, than the Italians. Possibly it is because of the untiring energy and resolute determination of the Italians. The moth is a stealthy, insidious enemy, burrowing in secret, and worming itself into possession of the sheets of comb, but an Italian colony of average strength, will hunt them out and prevent their making headway. Many bee-keepers who, when they kept the common bees, were greatly pestered with the moth, testify that on substituting the Italians, this annoyance came to an end.

4. They are more handsome. It would be foolish to sacrifice more substantial qualities for mere beauty, but, other things being equal, it is natural and proper to prefer that which is beautiful to that which is plain and homely. The Italian bee is a more genteel and shapely insect than the common bee, while its golden-banded jacket looks very attractive, whether glittering in the sun, or covering the sheets of comb. The queens of this breed are often very beautiful. Just as our best breeds of horses, cattle, sheep, swine and poultry are better looking than the common varieties, and please the eye more, while their nobler qualities commend themselves to the judgment, so it is with the Italian as compared with the common bee.

For these reasons, we certainly advise our correspondent to get the Italians. As a change of breeding stock only, they are worth the trifling outlay necessary to obtain them. There has naturally been very close breeding "in-and-in," as it is termed, among bees, and analogy suggests that this cannot fail to be

detrimental. The importation of Italian bees has been worth all it has cost to the bee-keepers of this continent, in this view of the matter alone. The pioneers in this direction were at considerable cost, and have not reaped so rich a return, as those who are indebted to them for bringing this valuable breed of bees within general reach. Five dollars per queen, the average price, is by no means a large sum, when the possible benefits are taken into account. By judicious management, a single queen may be made to Italianize a moderately sized apiary in the course of one season, thereby doubling the value of every hive it contains.

While on the subject, we may as well mention, for the information of the novice in bee-keeping, and the general reader, how the process of the Italianizing is accomplished. As all the eggs in a hive are laid by a single queen, it is only necessary to substitute an Italian queen for the common one, to accomplish the change of breed. It is usual to remove the common queen a week before her successor is introduced, by which time, queen cells will be far advanced. By cutting these out, all possibility of the bees rearing another black queen is destroyed. They will then more readily accept a strange queen. There are various ways of introducing queens, but the safest, especially for beginners, is to cage the queen about thirty hours, and fix the cage so that the bees can have free access to it. They will soon get reconciled to her, acquainted with her, and will feed her. After about the length of time specified, it will be quite safe to liberate her. When there are several hives to Italianize, the new queen must raise a supply of drones, and the black ones must either be destroyed or confined to their hives to prevent their mating with the young queens. This is the great difficulty in transforming stocks and keeping them pure. As bees mate when on the wing, there is a constant liability of the queens meeting common drones. A single hive is soon and easily Italianized. Bees in the summer time are very short-lived. Within three months after the introduction of an Italian queen scarcely a black bee will be seen in the hive. Italianizing several stocks with one queen, is a work of more time and difficulty.

Newspaper Decisions.

1. Any person who takes a paper regularly from the post-office—whether directed to his name or another's, or whether he has subscribed or not—is responsible for the payment.

2. If any person orders his paper discontinued, he must pay all arrearages, or the publisher may continue to send it, until payment is made, and collect the whole amount—whether the paper is taken from the office or not.

3. The courts have decided that refusing to take newspapers and periodicals from the post-office, or removing and leaving them uncalled for, is *prima facie* evidence of intentional fraud.

Clubbing Bee Journals.

Several of our subscribers have requested us to say what we will club with other Bee publications for. We therefore quote the following:

The AMERICAN BEE JOURNAL and the "National Bee Journal," by Mrs. Tupper, for \$3.00 a year in advance.

The AMERICAN BEE JOURNAL and either "The Bee-keepers' Magazine," or the "Agriculturist," by H. A. King, for \$2.50.

The AMERICAN BEE JOURNAL and "Novice's Gleanings," for \$2.50.

The AMERICAN BEE JOURNAL and the "National," the "Magazine," and "Gleanings," for \$4.00 in advance.

All the above one year, \$5.00.

Any of the above and the "Illustrated Journal," and our magnificent Large Fruit Chromo, for \$2.00, in addition to the RETAIL price of the Bee publication selected.

To Those Interested in Bee Culture.

At the sixth annual meeting of the Michigan Bee-keepers' Association, it was decided to hold a special meeting at Kalamazoo, to commence Wednesday, May 6, 1874. It is especially desired that all members be present, and, in behalf of the Association, we urge every Bee-keeper in Michigan to attend. A cordial invitation is also extended to all persons interested in the science of Bee-culture whether residing in this or other States. Surely much good may be derived from a comparison of experiences next spring, and from the able papers that will then be presented. Timely notice will be given of all further arrangements. Address communications or inquiries concerning the subject to

FRANK BENTON, *Sec'y.*

Shelby, Oceana Co., Mich.

Voices from Among the Hives.

E. S. FOWLER, Bartlett, O., writes:—"Bees in this part of the country were all wintered on their summer stands, without protection, seldom being confined to their hives more than six weeks without a chance to fly, and not that length of time more than once during the winter."

T. J. DODDS, LeClaire, Iowa, writes:—"My bees have now been in the cellar sixty-three days; all quiet; no signs of dysentery. The thermometer ranges from thirty-four to thirty-eight degrees."

WM. FAULKNER, Vevay, Ind., writes:—"Bees are wintering well here; no disease so far."

E. GALLUP, Orchard, Iowa, writes:—"Bees are wintering finely thus far. My bees are on their summer stands. They had a splendid flight yesterday. Those in the cellar are in excellent condition. No danger of bee disease in a mild winter, unless they have very bad management."

A. I. ROOT, Medina, O., Writes:—"In reply to the lady's query, on page 47 of the last JOURNAL, I would say, we have never found the honey that seemed to disagree with the bees when confined to their hives by winter weather, deleterious to the human family at all; on the contrary, it is oftentimes the very best table honey. I never intended to convey the idea that the honey was *poisonous*, only that it seemed to disagree with the bees some seasons; and that sugar-syrup was uniformly healthy for them. We never get bad tasting honey here, but a friend sent us a sample from a distance, saying it would kill bees at any season. It tastes like poor sorghum syrup. We have never had any experience with such honey, but have had bees die badly in March, when fed on very nice, sealed clover honey." "NOVICE."

W. F. STANDEFER, Dry Grove, Miss. writes:—"Bees are doing well. Three or four combs of hatching brood, and a few drone cells are observable."

W. S. BOYD, Bethany, O., Writes:—"I have been engaged in the bee business for three years, and when last spring opened, I had only one hive with bees in it, but had invested \$92. I bought three hives for \$8.75, and now I have seven, and have sold near one hundred pounds of honey. With the aid of your paper, and the knowledge I have gained (which I consider worth more than I have spent for the bees), I intend this spring to buy all the bees I can get at a reasonable figure; and by the use of the extractor, to have something to report to you next fall decidedly in commendation of the bee business."

THOS. J. CORNELIUS, Ludlow, Ky., writes:—"All the bees in this part of the country are doing finely this winter. We have had no dysentery, and none in prospect."

D. I. WELLS, Boliver, Tenn., writes:—"My bees have increased quite rapidly. I started last spring with four black stocks, which increased to ten, and three Italian, which increased to twelve, and one went to the woods. One Italian stock, purchased of Dr. Hamlin the spring before, sent out a swarm on the 11th, another on the 13th, and another on the 22nd of April, some of which sent out one or two swarms, but no surplus honey. Is there any remedy for such behavior? I suppose my bees are all in good condition, as they are flying very freely every warm day, which occurs in our locality every week or two during the winter."

H. E. CURRY, Walnut Hills, Cincinnati, writes:—"Bees in this neighborhood are doing well. To-day (Jan. 21), the thermometer rose to seventy-four degrees in the sun, and of course our bees had a good fly—the second this year. The previous one was on Jan. 4. My bees never looked so well at this time of the year, and I have no doubt we will begin the season with every encouragement. Last spring I tried an experiment, at least it was such to me, although the same thing is done in Germany. I found, on examining what was left of my apiary, one hive very weak. I will not pretend to say how many were left, but it was a sorry sight. I first made a box six or eight inches deeper than a one story Langstroth hive, and after putting six inches of manure in the bottom, I set my weak hive in, and then packed the sides and back with the same, so that it was surrounded with manure, except the front. I then put a blanket and mat on the top, and then left it undisturbed. In a few days, on looking into the hive, I was surprised to find what a number of eggs the queen had laid. The decomposing manure generated such a heat, that she did not have to confine herself to just such space as she had bees to cover. In a few weeks it was my strongest hive, and gave me the largest return of any stock I had. I took two hundred pounds extracted white clover honey from it, besides a swarm artificially, and, on November 16, they had at least twenty-three pounds to winter on. Although it will not do to jump at conclusions too suddenly, more especially in bee-culture, I am convinced that those who have weak stocks, in the spring, will find the above a great help with but little trouble. Of course enough of bee-bread and honey, and upward ventilation must be given, otherwise the combs will mould."

H. NESBIT, Cynthiaana, Ky., writes:—"Last winter I lost sixty-seven out of seventy colonies, and the three left were mere handfuls."

I bought six small black colonies in June, and now I have twenty-six in good condition, all Italianized. They are now carrying in two gallons of flour daily. Bees are wintering as well as I ever saw them. I have abandoned the bee-house and winter my bees out of doors."

D. D. PALMER, Eliza, Ill., writes:—"The seven diseased hives which I had, are now (Feb. 7) all dead, and fifteen more are diseased. I have seventy-eight left; the most of them look well."

JOSEPH M. BROOKS, Columbus, Ind., writes:—"My seventeen colonies of bees are in the cellar, wintering on sugar syrup exclusively. All are in the best condition, so far."

G. E. CORBIN, St. Johns, Mich., writes:—"By actual measurement, I find that fifteen worker brood-cells made by black bees, span three inches; while fourteen worker brood-cells made by Italian bees, span the same distance. That is, nine square inches of surface of brood-comb made by black bees, contain two hundred and twenty-five cells; whereas, the same surface of brood-comb made by Italian bees, contains only one hundred and ninety-six cells. Does not this difference in the size of the cells indicate a corresponding difference in the size of the bees? I believe the usual process of Italianizing supplies the queen with the combs of black bees only. Is it, therefore, possible to rear full-sized and perfect Italian progeny in those cells? If so, what sized cells will they, in their turn, build? Will some one of experience answer these questions?"

EDGAR McNITT, Centre Village, O., writes:—"My bees have done very well the past season. I am able to report an average of about fifty pounds of honey to the hive. One hive, furnished with empty combs, gave me three swarms and eighty pounds of honey. Including the increase in swarms, my nett profit for the season was one hundred and twenty-five per cent. Last year I wintered two swarms, one on sealed, the other on unsealed honey, and both came through in good condition. I had a swarm of half-bloods that died while I was trying to Italianize them. There were no signs of dysentery. To ascertain that the honey had nothing to do with their death, I procured a starved swarm, and put it in the depopulated hive without cleaning it out in the least, and the bees flourished as well as any of my other swarms."

JONAS SCHOLL, Lyons Station, Ind., writes:—"I am somewhat in doubt as to the best way of doubling colonies. In the past two years there has not been very good success in this region in the method of taking full frames from a hive to be doubled, and filling out with empty ones. It seems to cut the hive in two. The queen often will not cross the

empty space, but remains on one side of the hive. On the opposite side the combs will be filled with honey as fast as the brood hatches, while the new comb built on that side, will most likely be all drone comb. As a strong colony, with a prolific queen, when placed in an empty hive, builds comb rapidly, if the yield of honey is good, may we not conclude that when comb is to be built for all the increase, the best plan is to divide the bees only, not the comb? Bearing in mind that in this locality very little comb is built before May 15, and after June 25, will some practical bee-keeper give us the benefit of his knowledge on this subject? Bees are wintering finely here."

B. G. FORBUSH, Algona, Iowa, writes:—"I am but a novice in bee-culture. One year ago next April, I purchased twenty stands of bees. During the early summer of last year, I increased to forty stands, by artificial swarming. I am surrounded with basswood, but there was a total dearth in its bloom. About the first week in July, I was surprised with the sudden filling up of every available cell of my hives with a very thin, washy, acrid honey, which proved to be sumac honey. I was nonplussed, and wrote to Mr. Gallup in regard to it. He advised me to extract it, and keep it for feeding purposes. I had no sooner begun to follow this advice, when, to my surprise, it was evaporated to a fair consistency, and after six months I find it much less acrid, and good for table use. The months of August and September were gay with golden-rod and many other wild flowers. My hives were soon filled with honey of the best quality, and the hives were literally stuffed with bees and brood. In view of what Prof. Cook says about late brood, I tremble, for there was no speck of brood in my hives after the 15th of September. But I carried my hives into winter quarters full of honey, and populous with bees. I put thirty-two stands in the cellar, with from three to six inches of air-space under the combs, and heavy, white ducking over the frames according to Mrs. Tupper's plan. They are in good condition. I took out about three hundred pounds of surplus honey. Nine "New Idea" hives were left on summer stands, banked up with snow, *a la* Gallup. From this, my first year's experience, I prefer a four thousand inch hive."

JOHN WAILL, Greenfield, Ill., writes:—"Last season I went into winter quarters with forty-one hives, coming out in the spring with twenty-six. I had only four swarms winter on the summer stands. I use the Langstroth hives, of thirteen frames. The last four seasons have been so dry that we have had no flowers out of which to make honey, and so, whatever the breed of bees or the kind of hive used, our failure has been unavoidable."

American Bee Journal.

RATES OF ADVERTISING.

SOLID NONPAREIL MEASURE.

First insertion, per line.....	\$0.20
Each subsequent insertion, per line.....	15
One square, 10 lines or less, first insertion.....	2.00
Editorial Notices, solid Nonpareil, per line.....	.30

Next page to Business Department and second and last page of cover, double rates.

A deduction of 20 per cent. made on advertisements inserted three months, 30 per cent. for six months, and 50 per cent. for one year.

Twelve lines of solid Nonpareil occupy one inch. One column contains 96 lines of solid Nonpareil.

Bills of regular Advertisers payable quarterly, if inserted three months or more. If inserted for less than three months, payable monthly. Transient advertisements, cash in advance. We adhere strictly to our printed rates.

Address all communications and remittances to the Manager.

Not one letter in ten thousand is lost by mail, if rightly directed.

Single Copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Additional names to a club already formed may be sent at any time at the same club rate.

NEWLY PATENTED HIVE.—John W. Walker, of Nashville, Tenn., has obtained a patent on his new hive.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

Subscribers wishing to change their post-office address, should mention their *old* address, as well as the one to which they wish it changed.

☞ We want several copies of No. 1, Vol. 2, of the AMERICAN BEE JOURNAL, and will pay 50 cents each for them. Who will send us some?

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

Every subscriber is requested to look at the date after his name on the wrapper label of this *Number* of the AMERICAN BEE JOURNAL, and if it is not correct send a postal card to this office, and tell us and we will make it right at once.

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. ☞ B. Choice extracted honey, 16@18c. ☞ B.

ST. LOUIS.—Quotations from W. G. Smith, 419 North Main st.

Choice white comb, 25@29c; fair to good, 16@22c. Extracted choice white clover, 16 @18c. Choice basswood honey, 14@16c; fair to good, extracted, 8@12c; strained, 6@10c.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenpoint L. I.

The sale of honey is dull here, and a large quantity is now upon the market. The prices rule as follows:

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 ☞ gal. St. Domingo, and Mexican, 90@95 ☞ gal.

SAN FRANCISCO. — Quotations from Stearns and Smith, 423 Front St.

Choice mountain honey, in comb, 22½@25c; common, 17@20c; strained, 10@12c, in 5 gallon cans. Valley honey, in comb, 12@17c; strained, 8@10c.

Eight cents is now the fee for registered letters—instead of fifteen cents, as heretofore. Let all register, who cannot obtain a money order, but let none register who can.

Persons writing to this office should either write their name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

The postage on this paper is only twelve cents a year, if paid quarterly or yearly in advance at the post-office where received. We prepay postage to Canada, and require twelve cents extra.

Publishers needing cuts or engravings, will do well to address the Manager of the American Publishing Company, who have a large supply for sale that have appeared in "The Illustrated Journal."

Should any subscriber wish to discontinue taking our JOURNAL, he should address a letter to the Manager, and enclose the amount due, and it will then cease to visit him. Any other course is dishonorable.

Any one having paid \$2.00 for the AMERICAN BEE JOURNAL for 1874, and desiring to obtain the "Illustrated Journal," for 1874, and our magnificent Fruit Chromo, may send us \$1.50 more, and obtain them.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

For the American Bee Journal. The Bee Disease.

The question, What caused the loss of so many bees, during the two or three last winters, seems to be attracting more attention, at the present time, than anything else connected with bee culture. And there is probably no other point upon which there is such a diversity of opinion, or upon the proper solution of which, so much depends. That there has been some general cause for the losses which bee-keepers have sustained throughout the Northern States, is too palpable to admit of successful contradiction; but that there has been any cause operating that cannot, with proper care, be remedied by the apiarian, I do not believe. Neither do I believe with some of our apiarians, that the loss was caused by an epidemic; nor with others, that it was the result of the bees eating from honey. I believe that it was caused, mainly, by cold, and disease engendered by the same.

That there was dysentery, I freely admit, for I saw the most convincing proofs of that, among some of my neighbor's bees that died, but in every case it was where bees were wintered on the summer stand, or placed in cold depositories—no better, if as good, as the summer stand. I will mention a few of the many cases that came under my observation last winter:

J. W. Hulet, living about one-half mile south, put his bees, consisting of eight swarms, in a cold shed, filled in with sawdust, four inches thick at the ends and one side, the other side being inch boards. He lost six of the eight swarms by dysentery.

Lewis Skeels, living a short distance south-west, wintered his bees on their summer stand, and lost all he had, by the same disease.

I put eighty-eight swarms in my bee-house, which is frost proof. Three of the eighty-eight swarms were made up of bees taken out of my nucleus hives, at the end of the queen-rearing season. One of the three was queenless, being put in the house as an experiment, and the other two had young queens that had not laid any eggs, so far as I knew, when put into the house. I lost these three, probably from old age of the bees, as those taken from the nucleus hives were nearly all reared during the summer months, and two of my regular swarms by starvation, and that with from fifteen to twenty pounds of honey in their hives, the bees having clustered at one side of the hive, their stores being at the other; and one swarm from some unknown cause. The rest came through in good order. There was little or no appearance of dysentery, the combs of those that died being clean and bright, except where the cluster of dead bees had slightly caused them to mould.

Now, if it was bad honey that killed my neighbor's bees, by giving them the dysentery, why did mine not have it? Their honey could differ but little from what mine had, since they were kept so close together.

Mr. E. L. Arnold, living five miles north, wintered his bees, consisting of twenty swarms, in his cellar, and did not lose any, while his neighbors lost from one-fourth to one-half of all they had.

Mr. J. K. Miller left his bees on their summer stands until some time in January, and up to that date lost seven out of thirty-eight, and a number of the rest were so weak, he thought they could not live until spring. He then put the rest of them in his cellar, and only lost one swarm after they were carried in, and in that he thinks the bees were nearly all dead before they were put into the cellar.

It has been asserted that bees carefully housed, had suffered about as much as those wintered on their summer stands. There may have been such cases, in some localities, but there has certainly been none in this section.

I fear that extracting the honey and feeding syrup, in order to prevent the dysentery, will kill more bees than it will save, owing

to the feeding not being attended to early enough to give the bees time to seal up their stores before cold weather. In most cases, perhaps, there will be no necessity for deferring the feeding until it is too late, but where it is desired to extract the honey that is gathered late in the fall, before feeding, I fear in a fall like that of 1873, where the cold sets in earlier than usual, some of our most careful bee-keepers will sometimes be caught before they are through with feeding. In cases of that kind, I should certainly prefer sealed honey to unsealed syrup.

Too frequent disturbance of bees, after they are housed, is often, I think, a prolific cause of loss. The injunction to "see them often" is right to the point, so long as they can fly out, but when they are housed, my advice would be to let them "severely alone."

We should see that they have plenty of stores, and that those stores are in the right place, before they are put into winter quarters. Also, that the room in which they are wintered, be dark and warm, and the temperature as even as possible. I notice the bees are the most quiet in my bee-house, when the thermometer stands at about forty degrees. If it went much below that, I should want it, as Mr. Quinby says, to go enough above to make that the average. With these things attended to, we shall have but little cause to fear the ravages of the bee disease. At least, according to my experience.

JAMES BOLIN.

West Lodi, O.

For the American Bee Journal.

Do Bees Destroy Fruit?

The following letter by Mr. Kruschke and comments of Prof. Riley we publish from the *New York Tribune*, at the request of both parties. Barring the personal feeling, which is too common among controversialists, the articles will be found interesting.

Many complaints have been made that bees destroy fruit. Being a bee-keeper, I consider it also my duty to be a bee defender. Various theories are indulged in. Some assert that bees prevent the fruit from setting; others maintain that bees puncture the fruit when ripe. A correspondent of *The Tribune*, in the fore part of summer, complained that bees destroyed his peaches, and not knowing what to do, asked for advice through your columns, whereupon the learned and wise (?) Prof. Riley took it upon himself to give a recipe, with which to poison the bees, and he also stated that by such management he had known one-half of an apiary to give out. He would have benefitted man-

kind a great deal more, had he taken a dose of the mixture himself. Does Prof. Riley not know that his bee-destroying recipe has gone before the world, among people some of whom are still more ignorant than himself? Does it not trouble his conscience, to be the destroyer of the most admirable, busiest, and most profitable insect created? And all because some ignoramus imagine the bees destroy their fruit without any facts for evidence.

In the *Report of Agriculture* for 1871, some state that bees had destroyed their grapes, which led me to take close observation. Accordingly, I took a bunch of Delaware grapes (the tenderest I could get) and put them on the hive, directly over the bees, and watched proceedings, but not a single berry was punctured; then I broke a few of the berries, upon which they immediately went to work and sucked them dry—thus showing that something beside bees must open the grapes, or any other fruit, before they can touch it. Perhaps it is in the growth, or in the weather, or the work of some other insect, but don't lay it to the innocent bee. How is it that we don't hear of such complaints in Germany, France, and Italy, where fruit, especially grapes, are raised so extensively, and bees kept in great numbers? If the bees were so destructive to fruit, would they not have enacted laws long ago, to prevent their being kept? Such is not the case; on the contrary, bee-keeping is encouraged. In Italy there is a law regulating the size of hives and frames.

If these prejudiced complainants would only investigate a little closer, they would see how ridiculous their condemnations appear to a close observer. Practical bee-keepers of America are unanimous in their answer to this question. They declare bees do not injure fruit of any kind. Many of them are extensively engaged in fruit culture, and they say bees help in impregnating blossoms, by bringing the pollen of the male and female blossoms in contact. Finally, I would say to those complainants, Procure and diligently read one or all the bee periodicals published in this country, and thoroughly post themselves on bee culture, and not depend entirely on their own investigations, which is not sufficient, for even Agassiz makes blunders in the bee line.—[*H. O. Kruschke*, Green Lake Co., Wis., in *N. Y. Tribune*, Dec. 31, '73.]

COMMENTS BY PROF. CHARLES V. RILEY.

In the article which Mr. Kruschke attempts to criticise, I stated that I expected to have most bee-keepers down on me, and his protest is but one of several which, while they charge me with all sorts of ignorance and crime, only betray the ignorance of their authors, and utterly fail to disprove the facts

I have stated. All such protests that I have seen, so far, are marked by passion, bias, and personality, rather than dispassionate argument or presentation of facts.

Mr. K's isolated experiment is interesting, so far as it goes; but "one swallow don't make a summer," and one experiment cannot negative accumulated evidence. All the hubbub in the world, from prejudiced bee-keepers, cannot change facts that have been witnessed by hundreds of others, as well as myself. Bee-keepers may do their best to shear the fact of its importance, but all the most winning sophistry will not annihilate it. They may observe and cover it with the drift of adverse opinion, but, like the bowlder, it will remain unchanged by the superincumbent deposit, and stand forth boldly, long after the evanescent and incoherent surroundings have been washed away by the stream of truth. I am as confident that bees at times cut the skin of tender fruit, as I am that they cut their comb or the caps of their cells; and as Mr. K. does not seem to have much confidence in the reliability of my own observations, I will say that he will not only find proof of the direct injury which bees do fruit in the reports of the Department of Agriculture, but in the reports of the different State Horticultural Societies, and in the columns of industrial journals.

To the last assertion made by Mr. K., I was myself a successful bee-keeper for over three years; and not one bee-keeper of large experience and reputation, has undertaken to controvert the facts I have stated. On the contrary, Mr. L. T. Waite, of St. Louis, Mo., and Mr. L. C. Francis, of Springfield, Ill., well-known as successful and intelligent apiarians, have both admitted the truth of what I wrote; and "Ella," the bee-correspondent of *The Chicago Tribune*, whom I know to have large experience, in a recent discussion of the question, says: "Whatever our opinions may be, they must at least yield to stubborn facts, and, in case such facts, are presented to a court of justice, there can be little doubt that the bees will be convicted." A whole volume might be filled with evidence in support of my position, from reliable observers; but, not to waste more time, let me say to Mr. K., as to another article in *The Rural New-Yorker* [in answer to another correspondent of the JOURNAL, viz: Chas. D. Hibbard, who also has something to say against "this sapient Prof. Riley"—C. V. R.], that "in advising extreme measures in an extreme case, I by no means make general war upon bees: for I have too long communed with these busy little insects, not to have an admiration for them as great, at least, as that professed by some of their more noisy champions.

"If, in exceptional seasons, when no flowers offer their coveted sweets, these bee-keepers who have large apiaries, with fruit-growers for neighbors, would properly feed their bees, said neighbor would have little cause to complain." Mr. L. B. Hogue, of Belmont Co., Ohio, in *The Tribune* of July 23d, last, suggests as a remedy for the difficulties which fruit-growers experience from the bees of negligent and careless neighbors, that, instead of fly poison or the planting of *Asclepias*, a few acres of catnip (*Nepeta*) be planted for bee-food—an excellent suggestion, providing it is made to the bee proprietor, and not to the fruit-grower; for the latter must not be expected to take care of the former's property.

REPLY BY MR. KRUSCHKE.

Since the above was in type we have received the following reply from Mr. Kruschke:

In reply to Prof. Riley, Mr. Editor, I would remark that he says that he expects bee-keepers will be down on him. Well, I would like to know how many horticulturists have thanked him.

Not only bee-keepers are down on him, but all peace and justice loving persons must criticise him, for any such course as he advises would bring enmity and discord among neighbors, even if bees were guilty of puncturing fruit. It would be no more just to kill bees than it would be to kill cattle if they break into another man's enclosure.

He compares my *isolated* experiment with "one swallow," etc.; but the Prof. has not even a single "swallow" to offer in his argument, and says one experiment cannot negative accumulated evidence. But I say a single demonstrated fact is worth more than volumes of theory to the contrary; and theory is all the evidence he has to offer. When Galileo, by the means of his telescope, demonstrated to the world that the earth moves around the sun, his single *isolated* experiment upset all the volumes of theory accumulated on that subject. When Columbus sailed westward, and found land beyond the waters, his demonstration negatived all theory to the contrary.

So I, with a single experiment, overthrow all presumptive evidence to the contrary. For I have not, and do not presume the Prof. has, heard of or seen a like experiment proving the contrary. He calls my experiment *isolated*. I would like to know on what the Prof. bases his *confidence* concerning the fruit-destroying propensities of bees? Seeing bees on fruit is not proof that they puncture it. The question to be answered is simply this: Has he seen bees in the act of cutting the skin of the fruit? If he cannot answer affirmatively, all his gushing about a bowld-

er, truth, etc., amounts [to nothing, for it may prove a volcano. It is not necessary for me to consult horticulturists, or horticultural works, for they can offer no positive evidence, and I shall accept no one's *ipse dixit*. The same is true of those bee-keepers he refers me to—they merely admit it as possible, but I can give him the names of ten bee-keepers who deny the charge, to his one who admits it, but I should consider neither evidence, unless they have tested it as I did.

The advice given by Mr. Hogue, of Ohio, in the New York *Tribune* cannot be praised too highly, while his (Riley's) cannot be too severely condemned. The former will give equally satisfactory results whether practiced by a horticulturist or a bee-keeper, for catnip will grow with as little trouble as milkweed. His experience and experiments with bees must have been with a view of destroying them, since he knows so well how to do so; but he says he *loves* them and does not make *open war* upon them. Well, no; it would not be called warfare, but a *cowardly assassination*, criminal in its nature.

I shall continue my observations every fall, and at times when there is little or no bee forage, and if I find that bees cut the skin of grapes I shall acknowledge it. But shall not then indorse bee-destroying recipes and catnip culture. More might be said, but this is already too long.

For the American Bee Journal.

A Cheap and Good Feeder.

It is an infringement on Novice's. We use a good many of the ordinary self-sealing tin fruit cans, and each year my wife discards some that have been used and become a little rusty. Then with a punch of any kind, or an ordinary jack-knife, I make a number of holes in the lid or cover of the can, fill the can with honey or syrup, put on the cover, invert, and place over a hole in the honey board. The honey will not run out only as the bees eat it out. As these cans are thrown away, the only cost is punching the holes in the cover. These cans hold three or four pounds of honey, and cost, when new, from six to twelve cents. Mr. Grimm told me his improved Novice-feeder cost twenty-five cents each. If the price were the same, I think I would prefer his.

ANOTHER.

When feeding a very small quantity for stimulating purposes, when the weather is warm enough for the bees to remain at or near the entrance, I use ordinary sauce dishes. Put in two or three table spoonfuls of diluted honey, set the dish at the entrance, and if the bees do not immediately attack it, tap on the hive. Of course it will

not be long till the dish is filled with drowned bees, but in a little while bees and dish will be cleaned off perfectly dry, the bees none the worse for their sweet bath.

Repeated observations show that the secretion of honey is powerfully influenced by the electricity of the atmosphere: and bees never labor more actively than during humid, sultry weather, or when a thunder storm is approaching.

The Bee Disease in Western New York.

As my experience with the bee disease (so called by many good apiarians) has been of a character not to make its repetition desirable, I propose to give a few facts connected therewith, hoping that some of your correspondents will correct me if I have arrived at a wrong conclusion.

Our apiary is located on the western slope of the Genesee, about seven miles west of the river, in a line not far from one mile north of west from the village of Genesee. Although during cold nights the mercury in the thermometer sinks several degrees lower on the flats than on the uplands, yet, owing to protection of these flats from winds, in the middle of clear, calm days, the temperature at times was of sufficient warmth to admit of bees flying, whereas at the distance above mentioned they had no opportunity to leave their hives from late in the fall till the latter part of winter, consequently when the opportunity did come what had not been frozen out were in an emaciated condition and hardly able to regain the hive after once leaving it.

Thus reduced in numbers, they were unable to recruit, and consequently, they gradually dwindled away, leaving the hive well stored with pollen, comb and honey. Out of an apiary of over sixty colonies in the spring of 1873 we had but one swarm left.

Our neighbors fared no better, for throughout the length and breadth of this elevation of country—bordering both sides of the valley—from Ontario to Pennsylvania, (a part of the fairest and most fertile section of Western New York,) the same scene of disaster and desolation to a greater or less extent prevailed, and bee-keeping received a blow from the effects of which it will require some years to recover. Piles of empty hives stood where was once flourishing apiaries, and the busy hum of millions of industrious workers was hushed, and silence reigned supreme.

From the facts above stated I am led to believe that the great loss of bees throughout the country was by protracted cold weather without any favorable opportunities for purifying flights. In the valley proper, the loss was not above the usual average as they had several chances to fly, and consequently came through strong and healthy, but as you traveled east or west from the river, the elevation gradually increasing, the greater would become the loss, till you arrived at what might be termed the dead line.

Another circumstance which serves to confirm me in the opinion that there was no epidemic, is that I took some bees with frames of comb left by bees which had died from the disease the winter before, to a person in

Avon, who hived into them new swarms, which came out in the spring in fine condition, strong, healthy, and without any sign of disease. I again have all my hives and combs re-filled with bees and never had them do better than they have done the past season.

I will close by saying that if re-using hives and combs from which bees died out the season before, will not spread and propagate disease could there have been any epidemic connected therewith? When with due care we can count on wintering our bees with as small a percentage of loss as on other live stock, then will bee-keeping be established upon a surer basis, whereas, of late hundreds of dollars have been invested in the business, from which there has not been received any adequate returns.

Berlepsch on the Culture of Rape.

In order to make the introduction and culture of rape successful I have gathered testimonials in regard to its value as a farm crop, and honey plant, from the rape growers in Wisconsin. I have also written to Mr. Berlepsch, and received the reply which is given below. Since it is the most important report, and testimonial from such high authority concerning a honey plant, ever given in the AMERICAN BEE JOURNAL. I thought it of sufficient interest to publish. It will surely be found interesting, and will encourage the culture of rape, which, I am quite certain, can be made a success, here in America, as in Germany.

Berlin, Wis.

H. O. KRUSCHKE.

Munich, Bavaria, Feb. 8th, 1874.

DEAR BEE FRIEND:—Your appreciated letter of Jan. 19th, is at hand. In reply to your question, I would say, that I can answer you with certainty.

During the years—between 1841 and 1858—that I was a practical agriculturist, I cultivated rape (see pamphlet) to a large extent, and can, in consequence thereof, and from knowledge otherwise gained, testify most assuredly, that in all Germany there is no plant yielding more honey than rape. I know of instances, occurring in my own experience, where a very populous colony of bees, during the time rape was in blossom, gained a weight of twenty pounds and over in one day.

On the tenth of May 1846 there was near me a sixty-five acre field in blossom. The weather was excellent, and my strongest colony, which I placed on a platform scale, gained that day over twenty-one pounds in weight. I know only of one other plant that can be compared with rape as a honey-yielding plant, and that is esparcet. It is probably the best fodder-yielding plant for cattle and sheep. It flourishes on the poorest soil, if only not wet, and from ten

to fifteen years without re-sowing, and yields enormous quantities of fodder.

Concerning the value of rape as a farm crop, I can say it is very great, often yielding a net income of \$32 per acre. The soil however must be rich and well filled.

AUGUST, BARON VON BERLEPSCH.

For the American Bee Journal.
California for Bees.

MR. EDITOR.—I see in the February number of the JOURNAL an inquiry if this part of the world is good for bees, and in answer would say that I believe it is the best in the world, both as to quality of honey, quantity and healthiness of bees. In support of my assertion will give my reasons for making them.

In the winter of 1871-2 I bought eight stands of bees in box hives, transferred them into the American hive, and in May I divided each hive, making sixteen. I put them on a little place I put up at the foot of the mountain, as I was then suffering from a cough, caused from a wound received through the lung at the battle of Shiloh. I thought I would rusticate a few years, if I lived; but when the warm weather came on I felt so much better, I left the bees and ranch and went to town, leaving my bees in charge of a neighbor who lived a half mile away, I instructed him to put on extra boxes, and did not return until the last of July, when I found them all full. I took out all the honey I could, without disturbing brood nests, and fitted up a lot of extra boxes, and melted out the honey in the sun, as I then had no extractor, and left my bees again in the care of the neighbor, and did not return till the last of November, when I found all full again, and I went through the same process of pruning, and took the honey to market, and found I had 3,500 lbs. of good white honey, which I sold for 12 and 13 cents per lb.

I remained on the ranch that winter; and in the spring transferred all my bees to the Langstroth hive, and divided, so that I commenced the season with thirty-four swarms, and increased to fifty, and by using an extractor and remaining with the bees through the summer and giving them the attention I could, which was but very little on account of ill health, I got 7,000 lbs. of extracted honey of a very superior quality. I got from one swarm that came out in May, 402 lbs. of honey in comb, and left it in fall with twenty-two frames full of honey and brood.

I would like to make arrangements with some firm in the East to ship my honey to in the barrel, and have them bottle it and put it on the market for me. I am satisfied that the poorest honey we have will compare with your best basswood. Honey was very dull sale here last year. J. W. MONTGOMERY.

San Bernardino, Cal.

For the American Bee Journal.

Feeding Bees.

While I thank Mr. Marvin very much for his proffered instruction, allow me to say that our kind reporter made a mistake in reporting me to have said, "is there a remedy" for irritating bees, while shaking them from deep combs. I have no deep combs, and never expect to have. I would much rather use the Bingham depth of five inches, than fourteen.

I have all pure Italian bees (thirty-three colonies), and having no blacks to contend with, had thought of propagating queens for the market, but now am determined to purchase twenty or forty colonies of black bees for next season's operations, and practically test the superiority of the Italians (if they have any) over the blacks,—all things considered. Shall allow no increase from either; shall keep all in the same yard; give all equal chances.

I hold (with Mr. Dadant) that sugar is not honey, until it goes into the honey sack and becomes acidized. Hence bees should not be wintered on sugar poured into the combs, but on sugar *honey* made by feeding in the fall. My experience leads me to say, that all kinds of out-door wintering is good, that will give the bees plenty of oxygenized air of a temperature not lower than thirty-five degrees Fahrenheit. Have not heard of any such, however.

If Mrs. Harrison will take a two-quart fruit jar, and punch about seventy-five holes the size of a pin, through the cover, and then after filling the jar, screw on the cover, and insert through a hole in the honey-board, or cover, she will have a twenty-five cent feeder that will feed as little as she pleases, and will feed in autumn, enough for wintering in seventy-two hours, or three such on a hive, will feed the same in twenty-four hours. You can see at all times, just how business progresses. Have used the Grimm feeder with perforated tin, instead of wire, screen. For spring feeding, punch only ten holes. I have only inch holes in my covers, so I make a hole just the size of the jar top, through a board 6x6x $\frac{1}{4}$, and place this over the inch hole and insert the jar, which will not blow over, and leave a half inch space between the hive cover, and perforated jar cover. The same may be put over a slot in the honey-board. I used twenty-four such, to feed winter stores to sixteen colonies, the past fall. I believe (after much experience) that making hives double wall, is throwing away money. They are not as durable as single wall hives, and in no way any better. Have tried hundreds of each, side by side, and the above is *our* experience.

Dowagiac, Mich.

JAMES HEDDON.

For the American Bee Journal.

Letter from Kansas.

THE PROPER MAN.

A few days ago I received a letter from Mr. A. Chapman, of New Cumberland, West Virginia. He speaks of a man that met me with a lot of queens on my way home from Kelly's island. Then he asks me "who the proper man is to write to, to get queens from there, and whether I think the queens raised there are pure." He then goes on to say that "he thought Mr. — the proper man, and ordered a lot of queens of him, which, however, he regarded as impure, and he feels very much aggrieved." All of which questions we are unable to answer, because we are not the "proper man," and have never been to Kelly's island, nor received any queens from there. If the man that obtained a lot of queens at the Island, will answer Mr. Chapman's questions, no doubt he will take it as a favor. We find no fault with queen breeders that live up to their contracts, but when they advertise that they warrant the queen to be pure, and when they do not prove to be such, will furnish other queens, or refund the money, we naturally understand from such a contract, that we are buying queens that have not been tested, and take the chances.

If every one in a dozen should prove to be hybrids, we have no business to complain, if the money is refunded, or other queens sent, as we may elect. But would we not naturally come to the conclusion that if a large majority of the queens sent out by any breeders, were impure, that he was not the proper man? In buying that kind of queens, we are well satisfied if three-fourths or more of them are pure. But in ordering *tested* queens, it is a different thing. The breeder in that case cannot make you good by either refunding the money or furnishing you another queen. If the queen should prove to be impure, you have sustained a damage equal to the value of the queen, or more, besides having your money refunded.

THE MELIPULT.

I was sorry to see the opinion of Mr. Adair, thus: that the "extractor has been overrated. If bee-keeping is to be made a success, it will not be accomplished with the use of the Honey Emptying Machine." This decision, however, is logical, from the standpoint of the *melipult*. Will not somebody furnish the General with a good, common Honey Extractor, without so many scientific principles about it, as the "melipult?" That machine, we believe, would be a success in scattering hayseed among politicians.

WINTERING BEES.

What is the cause of the dysentery? Now who would not like to know that; and how

to winter bees without loss? The causes are laid down positively by Mrs. Tupper. "Too much honey; too many old bees; too much cold; too much disturbance." Mr. Quinby agrees with her, as far as the cold is concerned. And Mr. Root, with his sugar syrup, without *acid*, has the panacea. But what seems the strangest of all, is, that beekeepers wont believe it. There is no one that has faith in another's theory, and it is a mooted question whether success in each case depends solely on *faith* or merit in the prescription. Now, if it was the cold, the disturbance, the old bees, too much honey, or bad honey, why was it that my bees all wintered safely too years ago? All old bees—some full of honey, some nearly empty—swarms of all sizes, and disturbed every few days? But last winter, with my bees in the same cellar, treated the same way, only not disturbed as much, two-thirds of them or more had the dysentery, and last fall they were breeding a month later than the year before! Hives of all conditions were among the eighty that were put in last year, and those that escaped the dysentery, were some of the very smallest swarms. Some of the best and heaviest, and some medium, including four or five hives that were supplied with sugar syrup without acid, was among the first to die. As Mrs. Tupper says, they "miserably perished" every one. I might say here, that I was not testing the sugar syrup, because I had faith in it; but, from the fact that I had orders for more honey than I had a surplus to fill, extracted several hives clean, to get enough to fill the last order, so that a want of faith could not have been the cause of my failure.

RAISING BROOD WITHOUT POLLEN.

I take the negative side of that question. I tested it last season, by confining a queen on a frame, with young bees that had never had access to pollen, and they could proceed no farther than merely hatch the eggs. But a swarm of bees that had been feeding young, might have prepared food enough in their stomachs to raise a large number of bees, if confined to a hive that has no pollen in it. If pollen is not necessary, what fools the bees are for collecting it.

RECIPE FOR FOUL BROOD.

We noticed in the JOURNAL for November, a sure cure for foul brood, which being a compound of some nine different ingredients, we think would either kill or cure; but it looked to us as though there must be some mistake. Three of the ingredients amounted to eighteen pounds, which, with the rest, were to be pulverized and put in a flask, with a quart of brand, but it would take a pretty large flask—at least one that would hold four gallons, and then a quart of brandy would not moisten the compound; in fact, we think it would!

not more than lay the dust on the top. We look for more light on that prescription.

THE DYSENTERY.

We are satisfied that this is a disease that no one yet knows how to cure or prevent. We find at this writing (Dec. 16) that the dysentery has commenced among our bees. There has been no very bad weather yet—the coldest day was not more than ten or twelve degrees below the freezing point. We now have our plans in readiness, and we will, this winter, test two entirely new methods of wintering, and if either of them prove a success, it will be known in due time.

N. CAMERON.

Lawrence, Kansas.

For the American Bee Journal.

Our Queenless Colony.

All wise apiarians agree, we believe, in recommending that a colony queenless at the approach of winter, be united with another colony—the weakest you may have.

But if your other colonies are all strong, are quietly clustered, and in all respects have been cared for as well as your knowledge and situation will admit, do you improve their chances for successful wintering by disturbing their slumbers and unnecessarily augmenting their number?

This question we found ourselves called to consider, when, on the first of November, the murder of their new queen had left No. 7 in a hopelessly disorganized state. The weather was cold. Our well-regulated colonies were sound asleep. It would require at least three of these to provide room for our rebels. Should we disturb them? And should we trust their queens—beautiful Esther, dusky and capricious, but sprightly and interesting Cleopatra, and our well-beloved Eve—in the presence of these regicides? We decided that we would not.

Another course of procedure was to shake the bees from their combs, upon the snow, thereby saving some thirty pounds of honey. I cannot say this plan received much consideration. As what might be done by a stern old veteran bee-keeper, it was alluded to, and its comparative profitableness admitted. But our organ of destructiveness is too small for such heroic action, and not for one moment did we fancy ourselves capable of it.

On the discovery of our second loss we had dispatched a somewhat frantic appeal to Mr. — for another queen; but this was done as a drowning man catches at straws—quite hopelessly.

So, at last, we found but one course left to us—to take as good care of the colony as possible and wait for spring. We were the better satisfied with this decision, that a suggestion to the same effect accompanied Mr. —'s

reply to our request for another queen. To this was kindly added the promise of advice as to management in the spring. Thus encouraged, we began to regard No. 7 in the light of a new study, and, if the whole truth be told, with more of interest than either, or all, of our six more hopeful and praiseworthy colonies could elicit.

During November, which with us was extremely cold, the queenless colony were in a constant state of agitation. How to keep them dry, and sufficiently cool—for when the mercury went down to the neighborhood of zero, they were reasonably quiet—was a constant study. The entrance was shaded, but seldom was there a day so cold that a few bees did not find their way out, to perish in the snow, while in moderate weather the number thus lost was somewhat appalling. Whenever, after severe cold, the weather moderated, they impressed us as having rediscovered their queenless state.

About the first of December we discovered at the entrance a number of immature bees. On examination these proved to be tiny drones—a little thicker, and a trifle shorter than workers. The first warm, sunny day thereafter, Dec. 4, we eagerly improved the opportunity afforded for a peep inside. On the central combs we found hundreds of the dwarf drones, for the most part rather young and downy, but evidently in good health, and very much at home. Of course they had been reared in worker cells; and we puzzled ourselves with conjectures as to whether the bees knew what they were about. Were they quite satisfied with the questionable shape in which their carefully nurtured brood had emerged? And could we hope that the experiment had taught them anything, or must we look for a continuation of this profitless brood rearing? We saw at this time no larva, nor did we notice any eggs. There was one large, clumsy, half completed queen cell. We made a careful search for a young queen, (albeit we could not understand how there could be one,) and finally concluded that our little drones must be the progeny of a worker. From this time until Dec. 16, there was little change. As before, the bees were noisy and restless; as before they came forth daily to perish on the snow. Had not the colony been of unusual strength in the beginning, we fear that our experiment, in this way, would have come to an untimely end.

Dec. 16 was warm; and again we opened the hive. We were gratified to learn that no more little drones were being reared. There were, however, plenty of eggs—some cells containing a dozen. Many of these seemed shriveled, the same cell often containing two or three fresh ones. Opening another hive, I was fortunate enough to find some nice looking eggs, properly arranged. Cutting out a piece of comb containing about fifty

eggs, I inserted it in a comb belonging to the queenless colony. Would they recognize the superior value of these eggs, and properly care for them? I was curious as to this, but had nothing further in view. Three days later these bees had become as quiet as those of our other colonies. The mortality occasioned by their leaving the hive suddenly ceased, for they suddenly ceased to come forth. We marvelled greatly, and were happy enough when on Jan. 3 we were able once more to investigate.

On examining the piece of comb inserted Dec. 16, we found to our chagrin—nothing. Greatly disappointed for the moment, we proceeded to lift the next comb. Here we found a little capped drone brood, in drone comb. Near the center of this was suspended a long, slender, capped queen cell! The bees seemed to be deeply interested in it, and clustered about it so thickly that it was with some difficulty that we assured ourselves that the cap had a brownish and soon-to-be-lifted appearance.

"Have you your penknife, Nellie?" I eagerly demanded.

Nellie answered my query by coolly taking the frame from my fingers and carefully dropping it into its place.

"I think we will leave her to introduce herself," she said gravely. "These bees are so very peculiar and punctilious,—they might object to taking her from the point of a knife!"

"But," I remonstrated, "the cell may contain only a dead or dying drone; I should have found out."

"You don't think so, neither do I, neither do the bees, evidently; and you don't want to risk bringing about a relapse from the quiet of the past two weeks, to the old discontent and restlessness—you know you don't."

Nellie sometimes forgets she is my junior, but, in consideration of her ordinary docility, I usually yield to her upon such occasions, and console myself for the temporary abnegation of authority by holding the reins a little tighter when I recover them.

In the present case I only remarked mildly, "Well, admitting that a worker egg was carried across from the piece of inserted comb, and successfully deposited in the queen cell, what has become of the remaining forty-nine (more or less) worker eggs?"

"Oh," said Nellie, "they only succeeded with the fiftieth egg; the remaining forty-nine didn't bear transportation."

"An explanation more convenient than probable, I suspect."

"Well," said Nellie, "I *can* suggest another—shall I?"

"Certainly; why not?"

"Because it is rather shocking. Perhaps the eggs *were* hatched. Somewhere, I have

seen a suggestion, or an assertion, to the effect that for the compassation of royal jelly, young larvae—"

"That will do, my dear; I remember! I very much prefer your first explanation."

We closed the hive with the mental agreement that it would be well to search for our hypothetical queen on the next warm day.

Such a day—a day both warm and still—came not until Feb. 28. But with it, alas! came company; guests whom, on ordinary occasions, we delighted to honor. As it was—well, we womanfully choked down our bitter regret that our friends had not chosen washing day, or any other day but this—met them smilingly, and entertained them as best we could, while the warm, sunny hours of the afternoon—hours that for weeks we had sighed for—passed by, and our opportunity was gone!

We console ourselves only by reflecting that spring is at hand, and the colony is still alive. That it is much reduced in numbers, we must admit; but, we, nevertheless, regard it hopefully. The bees that we see at the entrance are, now, as bright, as small, and as active as their more favored neighbors. In any event, we shall not change our present opinion—that for truly *enjoyable* winter bee keeping, a queenless colony is indispensable!

CYULA LINSWIK.

For the American Bee Journal.

Clipping Queens' Wings;

SIZE OF HIVES; "NEW IDEA" HIVES; AND OTHER THINGS.

At the late meeting of the North American Bee-Keepers' Society I read a paper on the Wings of Bees, showing that they must be important organs aside from their mechanical use as organs of flight; in fact that they are a *part* of the pulmonary system, and that any injury to the wings must affect the strength and value of the queens. Mr. Root, in his "Gleanings," without publishing the paper at all, says I say that "bees breathe through their wings," leaving it to be understood that I state that they compose the entire lungs, when any one who will read the paper will see that I take no such position.

I wrote to Mr. R. an explanation of his error and suggested to him that it would be fairer for him to publish the paper so that the readers might judge for themselves. He publishes a part of my letter, only. He still refuses to publish the paper, for which he gives the following reason in his February number. He says:

"We declined publishing the paper then, and do now, on the ground that *very few people indeed are capable of deciding what is truth and what is error in the microscopic world,*" and he goes so far as to take to task

the *Rural New Yorker* and other papers, for publishing it, because, as he states it, "mankind are so prone to take up and disseminate error," etc. Now it seems to me that Mr. R. is assuming a censorship over the press that is not called for, and is assuming a dogmatic position that he would condemn in others. It has been but a few months since in criticizing me and the "whole popular science world," as he called it, he very learnedly quoted a Latin maxim, "*magna est veritas et prevalebit*," which might be paraphrased, and if not more original, be equally truthful, "*magna est vanitas et prevalet*," for self-sufficiency must prevail to an alarming extent with any one who pronounces "very few people capable of deciding what is truth," etc., and believes that "mankind are so prone to take up and disseminate error," etc., and relies on his own infallibility as one of the "few capable" of dictating what people should read.

Are the "people" who read the bee journals and the rural press in need of such censorship? I had come to the conclusion that beekeepers as a class had more than an average of intelligence, even in a country like ours, where the government is based on the intelligence of the people as a whole, and where the freedom of the press is based on the theory that falsehood and error can do no harm where free speech and an unshackled press have full license to combat them, for as Mr. R. says, "Truth is mighty and will prevail."

Mr. Root makes a quotation from "Carpenter on the Microscope" confirming the description I give of the wings, except he says, "This circulation [he is speaking of the blood and not of the nervous or pulmonic system of the wings], may be seen readily in the wings of bees young and growing, . . . those organs especially which are peculiar to the perfect insect being then in a state of rapid growth and having then a vigorous circulation of blood through them; but this movement soon ceases and the wings dry up."

The last italics are Mr. Root's. I might reply to this in the language of Mr. Root by calling it "sheer folly" or "twaddle" or some of the hard names he so freely applies to all that differ with him, but I cannot believe that Carpenter is a fool, (I believe folly is defined to be "the acts of a fool,") or that it is "idle silly talk," which a "tattler" is guilty of, for he would likely be surprised at the use that Mr. Root made of his language, so contrary to the observations of every other eminent naturalist.

In the larva state the bee is composed of thirteen segments, eleven of these have each two spiracles or breathing holes, one on each side of the body. As it approaches the pupa state these spiracles are gradually obliterated and grow up, so that all of those on the segments that finally form the abdomen disap-

pear, and those on the thorax are alone left. As the bee approaches the pupa state there appear on the thorax over four of the anterior spiracles little pad-like projections which are the wings doubled up in wads, which may be seen through the pellicle that envelops the pupa at that time. This skin sloughs off in the semi-pupa stage and releases the wads, and it is at this time that Carpenter says that the "circulation may be readily seen," as then the wings are but a pulpy mass and so translucent that there is no difficulty in observing the circulating fluid, for the circulation is "then vigorous" to promote their development and "rapid growth." "But this movement soon ceases and the wings dry up." Of course they do, for the limp, pulpy mass assumes a different consistency and develops the complicated elements of the wings, and there is no longer any necessity for an excess of moisture in the wings. The circulation is thence *hid* from sight inside of the horny tubes and under the covering of minute hair-like *papillæ* that cover the wings. And this is all that Carpenter means to say.

One other statement of Mr. Root deserves a little notice. He says:

"So far as eminent naturalists and entomologists are concerned, we have only to say it will be the worse for *them*, if they endorse the paper in question, and its *winding up especially*."

Now as friend R. is the only *naturalist* among the many who have read the paper who does not endorse it, the "whole popular science world" must be in a bad fix. I can't tell how he intends to punish them, but I suppose he will publish them in the "Humbug and Swindle" department of his *Gleanings*. Would not it be a sad spectacle? But what is the winding up of this paper that he condemns as "specially" outrageous? The last paragraph is the statement of a fact that has been settled among naturalists for a long time: i. e. that the bee inflates its body with air when about to fly, so as to decrease its specific gravity, and assist it in flying. This is not only applied to insects, but ornithologists state that birds do the same thing, even filling the hollow barrels of their feathers and quills with heated air or gas. In this fact lies a very strong reason why the wings of insects should perform the office of lungs, for when the body is inflated there are valves at the openings of the spiracles that close and retain the air, just as in holding the breath, so at the very time that free respiration is most needed, it is impeded most, unless the wings perform the office of pulmonary organs; for the blood always flows more actively to the members of the animal body that are most in exercise.

The great difficulty with Mr. R., and all of the unscientific, is that they overlook the fact that nature accomplishes the same end by very opposite and diverse means. Because

man and the higher animals have certain parts of their structure specialized as lungs, they infer that every thing that breathes must have like organs, and that the functions cannot be exercised by any other. The special breathing apparatus of worms consists of simple filaments placed on the head, and they do not take air into the body at all, and in addition to these filaments, the whole surface of the body serves as lungs, so that if a worm be cut in two both parts will live, and become independent animals.

St. George Mivarts, in *Nature* for December, 1873, p. 108, says our skin is by no means popularly credited with the great importance really due it. "Only the skin!" is an exclamation not unfrequently heard, and wonder is very often felt when death supervenes after a burn which has injured but a comparatively small surface of the body. *Yet our skin is really one of our most important organs, and is able to supplement, and to a very slight extent to replace, the respective actions of the kidneys, the liver, and the lungs.* (See *Huxley's Elementary Physiology*, Lesson V., §19.)

The same authority tells us that, "In the frog we have this cutaneous activity developed in a much higher degree. . . . Its *respiratory* action is both constant and important. This has been experimentally demonstrated by the detection of the carbonic acid given out in water, over the head of which a bladder had been so tightly tied as to prevent the possibility of the escape of any exhalation from the lungs. The fact of cutaneous respiration has also been proven by the experiment of confining frogs in cages under water for more than two months and a half, and by the cutting out of the lungs, the creature continuing to live for forty days. Indeed, it is now certain that the skin is so important an agent in the frog's breathing that the lungs do not suffice for the maintenance of life without its aid."

The only argument that Mr. Root uses against the theory is, that practical experience disproves it, and he gives instances where queens have been prolific afterwards and lived a long time. Mr. I. L. Davis, of Michigan, appears in your February number with an instance of the same sort. But I can not admit that the instances cited by either have any weight, from the fact that the hives in which the bees were kept required no great vigor in the queens to keep up the population and to swarm, and the fact that such queens lived from three to six years proves nothing, for it is not contended that it will take their lives. My experience is that queens with mutilated wings most generally live longer than those with perfect wings, just as you see many unhealthy men that exert themselves but little, outlive the more robust and vigorous, not so careful of their vital force.

It is now conclusively demonstrated that the conditions under which we have been keeping our bees have restricted the queens, and that in properly constructed hives, with management adapted to their nature and instincts, the fecundity of the queen is incredible. Some two years ago I published a small book drawing the attention of apiarians to what has become known as the "New Idea Theory." It has been much ridiculed by Mr. Root and others, but that has not prevented its successful use all over the country. I will not go into the details of the theory here, as this article is already of a tedious length. At the late meeting of the North American Bee-Keepers' Society, when the subject of artificial swarming was under consideration, I gave a statement of the main points of it. In the synopsis of the proceedings as published, it is too much abbreviated to give a fair understanding of it. I therefore send you an extract from the full report, giving the whole of it, and as it will answer many questions continually asked me, and at the same time show Mr. Root and Mr. Davis, why I do not consider their reported instances as tests of the wing theory, request you to publish it in full. If you have not room for it in the same number with this, give it in your next, if you please.

For the American Bee Journal.
Murdering Bees.

Under this heading the February number of the AMERICAN BEE JOURNAL copies an article from the *British Bee Journal*, in which an English bee-keeper relates that the bees of one of his straw hives destroyed each other, and says that the murdered bees are of a smaller size. The editor of the *British Bee Journal*, in answer says, that he has experienced the same with his bees and that he thinks it is on account of their small size that these bees are murdered.

I have seen sometimes a similar accident in my apiary, several years ago; and I searched for the real cause. Having movable combs, I have not been long in ascertaining it. The bees killed were very young, and the murderers were the oldest. These old bees were not killing their sisters to rid the hive of them, but the young were starved by the famished gatherers, which could find nothing in the fields and nothing in the hive to appease their hunger.

I have ascertained that the newly hatched bees consume more honey in the first fortnight of their life, than they have consumed from the egg to their last transformation. The newly born bee is very small; after two days it is very big, even bigger than the old

workers, and for fifteen days it eats plenty of honey and bee-bread, to perfect and harden its organs. During that time it remains in the hive and nurses the larvæ.

When the crop of honey fails, and when there is nothing to eat in the hive, the old bees seem irritated to see these young bees so fat, so well filled with the product of their work, and they force them to give back the honey that they have in their stomachs. The poor young bees are pinched and tortured until their stomachs are empty. Then they run into every corner of the hive to escape from their tormentors, which, still famished, do not leave them till they are starved to death. Then the poor young bees, which were so fat, in well provisioned hive, have their abdomens shortened and curved inside. When they are in such a state, it is impossible to restore them to health. I have tried it in vain. When I have encountered similar accidents, I had seen the provisions of the colony several days before, and it seemed that they were sufficient for the brood; but the brood after hatching, ate so much that the bees were starving, and the young were sucked dry by the old. For five or six years I have never seen such a case; for I take the greatest care to see that my bees have enough honey for their young.

In the case alluded to, the correspondent of the *British Bee Journal* says, that the massacre took place at intervals of one week or ten days, especially on Sunday. Some ultra Christian will probably think that these bees were killed because they had worked on the holy day. But the naturalist will, no doubt, think with me that the massacre happened on the day when nothing was found in the fields by the bees; and as our mother nature does not know the seventh day, the lack of honey in the flowers must come from some natural and not miraculous cause.

When a similar accident arrives, the surest and quickest way to stop the massacre, is to give the colony one or two good combs of honey. No doubt a few of the bees, too much famished, will perish; but the murdering will be stopped instantly, and the colony saved.

CH. DADANT.

Hamilton, Ill.

DESTROYING MILLERS.—Mr. Philipson, an extensive bee-keeper of Genesee county, Michigan, says: "In the evening, place a shallow dish filled with thin tar in front of the hives, with a small lamp so placed in the center of the dish as to bring the light near the tar. The millers being attracted by the light dive for it and go into the tar. In a short time all the millers in the vicinity of the apiary will be caught."

Artificial and Non-Swarming. The "New Idea" Theory and One Story Hives.

AN EXTRACT FROM THE UNPUBLISHED TRANSACTIONS OF THE NORTH AMERICAN BEE-KEEPERS' SOCIETY, AT LOUISVILLE, DECEMBER, 1873.

The question under consideration was, "Is artificial swarming as good or better than natural swarming?"
D. L. Adair.—Moved that the Society answer in the affirmative.

Winder.—Why? We should give some reason for such an answer.

Adair.—Because natural swarming is always the result of disorganization, and a colony of bees in a properly constructed hive, properly managed will not swarm, while it admits of extensive multiplication of stocks, by artificial means, without materially injuring the old colony; and as long as such a hive is so managed no drones will be produced, and all the comb built will be worker comb, and no attempt will be made to build queen cells.

A. J. Murray of Tennessee.—Did not think that giving the bees room would prevent swarming. While in the Confederate army he assisted in cutting a bee tree in which he found two colonies in one hollow, the only division between them was the direction of the comb; and in another cavity in the same tree there was a new swarm that had taken up its quarters, which he supposed had swarmed from one of the others; yet there was plenty of unoccupied room in the large hollow.

Adair.—Still the queen may have been crowded for room.

Murray.—Knew of another colony that passed through a ventilator tube in a house, into a large room, where they located themselves and they swarmed. They certainly were not crowded.

Adair.—The extent of room, however great, will not prevent swarming, unless other conditions are present. It is the circumscribing of the brood nest that produces disorganization, and whenever the queen produces more eggs than she has room in the brood nest to deposit the proper balance of the hive is destroy-

ed, and it will result in the disorganization that produces swarming. In the spring, when the queen is laying but little, the brood nest is small. The queen begins at a given point to lay; first occupying a spot of about one and one-half inches in diameter on each side of one sheet of comb; then taking into her circuit a point opposite on each side of the two adjoining sheets. Around this centre she continues to lay, gradually enlarging the nest for twenty-one days. At the end of that time the young bees produced from the first eggs laid begin to emerge from the cells and she returns to the centre to begin her circuit anew, filling each cell as it is vacated. Around this brood nest the bees fill the cells with bee-bread and outside of that honey. (Bees never deposit bee-bread away from the neighborhood of brood.) Thus a brood nest is formed and if nothing obstructs it, will extend equally on all sides of the point at which the queen began to lay, and as the cells around it are filled with food, when she again reaches the circumference she finds her limits restricted. By this time, honey is coming in freely and she is stimulated to produce more eggs than she has cells to receive them; the perfect balance of the hive is destroyed and preparations for swarming is the result, and even though the colony were located on the ceiling of this large hall, they would swarm just as certainly, for the queen would be as much crowded as if she were in a small hive.

To questions asked, he said that the remedy for this was to have a hive so constructed that it will admit of pushing apart the frames, in the middle of the brood nest and inserting empty sheets of comb, if early in the season, but if the bees were in a condition to make wax rapidly, then empty frames were best, as the bees would fill them with comb as fast as needed by the queen. It is important that the inserted frames, whether empty or with comb, should be placed in the middle of the brood nest, and not to one side, as the queen will thereby be induced to occupy them solidly with eggs, and while she is doing that, the bees emerging from the cells in the comb forming the old nest will be giving more room, and

greater fecundity will be the result; when, if the frames are inserted to one side, she will be slow to occupy it, and before she can do so it will be filled with bee bread and honey.

When the queen has thus, at intervals, been given all the room she can occupy, and all compactly together, it is not probable that any further care will be necessary to prevent swarming during the honey season, provided, there *is enough room in the same chamber* to furnish room for the work of all the bees she can produce. Room given in boxes or top or side apartments will do no good, for the bees will not work in them freely, and whenever the brood chamber is filled to the ends, the bees will double back on the brood nest, and, as they find empty cells in it, will pack them with pollen and honey, and in a little while the brood nest will be reduced in size so that the queen will be again crowded, and the swarming impulse brought on from the disorganization so produced.

The hive should be of one story, and long enough to be certain that it will afford sufficient room for the work of the enormous colony of bees that will soon result from such management. By careful estimate he had found in a single colony, so managed 170,000 bees. In it there was no drone comb constructed during the season, and not a drone was reared in it; and, although drone comb was placed in the brood nest, the queen did not lay in it, but the bees filled it with honey.

An ordinary hive with a broad chamber of 2,000 cubic inches capacity will not accommodate exceeding 20,000 bees with working room. Whenever it much exceeds that number a swarm is cast, regardless of the amount of room there is in the top or side apartments. For while there might be room for storing honey, the nursing bees and wax producers would be crowded into the brood chamber, and however large the brood nest may have been at first, it will soon be filled with stores, particularly bee-bread, and swarming is bound to result. Even if the bees do work in the boxes and the wax-workers and honey gatherers are drawn out of the brood chamber, it leaves the hive in

scarcely a better fix, for the nursing bees are left to crowd it, and the pollen gatherers will not store the bee-bread away from the brood nest, but near to the larvæ to be fed; and as they will gather more than can be used in rearing the limited brood that can be hatched in so small a space, the comb soon becomes packed full of it. The bees will remove the honey from the cells in the brood chamber to make room for it, and the bee-keeper will be pleased that his boxes are being so rapidly filled. But the bees swarm. Not a bee is left in the boxes. They are taken off, full of honey perhaps. He looks into his brood chamber, and what does he find? Somewhere he finds a few patches of brood mixed in with cells full of bee-bread, and perhaps the greater part of the comb stuffed full of bee-bread,—there is bee-bread everywhere, enough to feed a hundred thousand larvæ, instead of the few thousand that they have left cradles for. The melipult will not extract it, and perhaps it is left in during winter, excluding the weak colony from the cells, and they have to live as best they can between the cold sheets of pollen, or more likely entirely die out before spring, from cold and starvation.

This picture is not overdrawn, for every experienced bee-keeper has seen hives in that condition, without being aware of the fact that it was the fault of the hives, and not of the bees.

A Member.—What is the shape and size of the hives you use.

Adair.—The hive should be long, and as wide as the length of the frames.—The frames to set in it crosswise. If the frames are large the hive need not be so long. The entrance should be at only one end. *This is important.* But there should be *two* holes, three-eighths of an inch by three inches, and about five inches apart. The brood nest should be in the middle of the hive, and *in no event* should the bees be allowed to fill the hive, so as to reach either end, for as soon as they do, they will double back the honey and crowd the brood nest.

Murray.—Will a queen that lays so abundantly live long? Will she not soon become exhausted?

Adair.—She will not live long. At the end of the second season she will likely be worthless. The ovaries of the queen have the germs of a certain number of eggs in them, and, when they are laid, no more can be produced, and she should be superseded whenever she begins to decline in fertility, for when she begins to fail, preparations will invariably be made for swarming.

Murray.—What do you gain then if it shortens the life of the queen?

Adair.—You gain a great deal. A hive so managed produces as much in one year as, under the swarming system, it might produce in four or five, and it is but little trouble to have young queens to supply the places of the old ones.

A Member.—In what shape do you get your surplus honey; in the comb or extracted.

Adair.—Some of both; but comb honey is the most profitable, and the bees will make more dollars' worth of it, in most seasons, but he would not be without the melipult, as it could hardly be dispensed with.

A Member.—How do you get your brood nest in the middle of the hive? Will the bees locate it there?

Adair.—The bees will locate it as near to the entrance as they can. In the hive he uses, the frames are closed at top, bottom and sides. He can hook together any number of them, closing the ends with glass in the summer, so that the hives can be easily examined. In winter, he closes them with straw or shuck mats. He hooks together, at first, enough to accommodate the bees with room for a few days, and until the brood nest is established. When the bees fill them too *near* either end, he adds more on the ends to give room for the workers and in the centre to enlarge the brood nest, and afterwards, as often as demanded, so that the queen never wants for room, nor the workers for space to build comb and store all the honey they can gather.

A Member.—How long is your hive?

Adair.—At first he thought that a hive three feet long would be sufficient, but found it too small. He then made them four feet long, holding thirty-two frames ten by thirteen inches inside.—

This is large enough, when the extract-or is used or the comb honey is taken out often, but he had used them twice that size and had the bees to occupy all of the frames but five or six. Five feet long, with frames of that size, will do if attended to, but they must be larger if the honey is left in them.

A Member.—If your bees don't swarm how do you increase them?

Adair.—He made artificial swarms, and could increase his bees faster than from smaller hives, as the material was so abundant; for a nucleus, or even a good swarm, could be taken out without reducing the colony to the dimensions of the strongest colony you can have in a hive of ordinary size, and without materially checking its productiveness. He generally formed a nucleus of two or three sheets of brood, one or two of empty comb and one or two entirely empty. He hooked them together, set them in the cellar or a dark room for three or four days, then set them out, and as soon as they raised a queen built them up by adding brood as near maturity as he could get. The surplus queen cells were used in forwarding others. He had made as high as eight artificial swarms out of one hive, at one time, giving each a queen cell. With the addition of a little brood about the time the queen becomes fertile, they soon become strong colonies. Of course in such instances the parent colony was reduced to a small size, and was materially checked in productiveness, and it took them some time to recover.

For the American Bee Journal.
That Patent Bee-Feeder.

The March number of the JOURNAL is just received, and of course is devoured at once. Friend Kretchmer, on page sixty-six, refers to my article on "Mr. Adam Grimm's Bee-Feeder," and says the feeder was patented May 6, '73, and speaks about the perforated screw cap. The cap is not perforated in Mr. Grimm's feeder, as friend K. will see if he looks the article over. I certainly should not have given a description of it for all to use, had I known it was patented. Mr. Grimm uses a good many of them in his apiaries, and told me I could make and use as many of them as I chose, for the feeder was one of his *own getting up, and was not patented, and would not be by him.* Any one

was free to use it. He certainly did not know any one had a similar feeder, or that it was covered by a patent. Will Mr. Grimm please notice this, and explain the matter to us? I see in the advertisements, Mr. K. has his feeder described as using "water, syrup, honey, or meal, and ventilates the hive at pleasure." A different feeder altogether, from ours, which is not calculated for feeding meal, and is no ventilation whatever, to the hive.

We have had a mild winter, for bees in this part of the country, so far. A part in houses, packed in straw, of about a foot on all sides, with cloth quilts on, summer entrance open, with wire cloth tacked over them. One lot were shut up just one hundred days, and came out strong, bright and clean, with few dead bees. While some that were wintered on their summer stands, lost a large share of their bees. Some writers speak about banking their hives in snow. That might do in Minnesota, but not in Illinois, for we only have a few inches, generally, and that is liable to disappear in a few days.

W. M. KELLOGG.

Oncida, Ills.

For the American Bee Journal.
Plants For Bee Forage.

MR. EDITOR:—It would be an interesting item of information which *every* correspondent could communicate through your columns, if from all localities, they would give your readers an account, if only in a very few words, of the *plants*, with dates of beginning and ending of flowering season, which serve for bee forage in their neighborhoods. It would be interesting to note the quality of the honey made from different flowers. Many plants, whose flowers furnish either pollen or honey, are overlooked because either the flowers are inconspicuous, or do not constitute a very important element in bee-forage. Often are some of the earliest flowers, particularly of trees overlooked, because the spare honey is not obtained from them, although they are among the most essential to success. Furnishing early forage, they give the nourishment which is needed to get all things ready for the real honey-gathering we are more immediately interested in. Many a locality produces no spare honey, or very little, just because no good, early forage is at hand. In other places, as soon as bees can fly abroad in spring, they can obtain all they need to stimulate them to build up the colony to a good working condition. I repeat it, every contributor can give at least *one* item of interest, if he tells us, in order, what bees gather stores from in his region, from first to last.

Lockland, Ohio.

JOHN HUSSEY.

American Bee Journal.

W. F. CLARKE, EDITOR.

Bee-Stings.

One of the most formidable hindrances to the extension of bee-keeping, is the fear of being stung. If you suggest to any one well situated for the purpose, the advisability of starting an apiary, most likely the objection will at once be made, that the wicked little creatures are so mischievous with their stings, that there is no desire to have anything to do with them. The impression many people seem to have, is that the chief mission of the bee is not so much to store honey, as to sting all and sundry. Bee-keeping will always be confined to a select few, until popular mistakes are corrected, and more light is diffused in regard to this affair of stinging.

As a matter of fact, bee-stings are "like angels' visits, few and far between." It is only now and then that any one is punished thus, even in localities where large numbers of bees are kept. When it is considered that ordinary colonies contain twenty or thirty thousand bees, and that the population of, say forty hives, is about one million, it must be evident that stinging is a rare and exceptional thing, and so far from its being the chief business and constant aim of these insects, it is very seldom resorted to. Were it otherwise, and as too many unreflecting persons think; were bees as apt to sting as mosquitoes are, it would be absolutely impossible to keep an apiary.

All creatures have means of defence furnished them adapted to the repulsion of those enemies by which they are likely to be assailed. Self-preservation is the first law of nature. Man is the chief enemy of the bee. Though this busy little worker is intended to do important service for the human race, it must have protection against the very beings whose interests it is meant to serve. If bees were as harmless as flies, no honey would be stored for mankind. Their operations would constantly be interfered with. Every school-boy and little child would so "meddle and muddle," that the order, discipline, industry

and usefulness of the hive would be destroyed. The sting is therefore a beneficent provision of nature, without which the bee could not accomplish its mission or fulfill its destiny. Some exceedingly scientific apiarians, indulge the dream of being able some day, to breed out the sting, or at any rate, the disposition to use it. Whether this dream will ever be realized, is a very doubtful matter, and whether its realization would, on the whole, tend to advance the interests of bee-keeping, is perhaps even more doubtful.

Some people affect to despise a bee-sting. We do not. A bee-sting is no joke under any circumstances, and under some circumstances, it is a very serious and painful affair, as we can testify from personal experience. In parts of the human body, where there are important blood-vessels and main lines of nerves, near the surface, causing the poison to act quickly and spread rapidly, a sting is sometimes dreadful, especially if inflicted at a time when the virus injected is more than usually powerful. For it is well known by experienced bee-keepers, that the poison is more virulent at some times than it is at others. We were once stung in the central point of the upper lip. The poison took immediate effect, and spread with astonishing rapidity, upward to the head and downward to the throat and stomach. The pain was excruciating. Sickness, burning fever and various alarming symptoms quickly resulted. It was three or four days before the effect of that one sting passed off. There have been cases in which a single bee-sting has caused death. It is therefore no sign of wisdom to ridicule the matter, but rather to estimate the thing as it really is, and endeavor to guard against it.

Intelligent acquaintance with the habits of the bee, and the use of proper precautionary and remedial measures, will either prevent stinging altogether, or will secure immunity from any serious and fatal consequences.

In the first place, it should be distinctly understood, that when bees are out foraging, they are too intent on their work to sting, unless they are interfered with, fought at, crushed, or made fast in some way. If human beings would mind their own business as diligently as the bees do, it would be well

for them. Quarrels and disagreements would seldom occur. It is perfect folly to start with alffright at the presence of a bee. The music of their industrious hum, as they fly from flower to flower, loading themselves with honey, should no more awaken fear than the noise of a loom, a spinning-jenny, or machinery of any kind. If you meddle with the works, you may be hurt, and the same is true of the workers. But let them alone, and you are safe enough in both cases. Nor is there unusually any danger in quietly watching bees as they issue from and return to their hive. The stupid practice of hurrying about and striking at any bee that may happen to come near, is a sure way of exciting anger and provoking the infliction of a sting. Quiet movements, avoidance of all striking, standing stock-still, with the head slightly hung down, if the bees exhibit any signs of excitement and anger, will secure exemption from all harm. Even if pursued by enraged bees, gliding into a thicket of bushes, and remaining there a few seconds, will be found a sure means of escape.

The utmost liberties may be taken, and the most delicate operations performed among bees, with due care and precaution. As they are excessively nervous and irritable creatures, nothing should be done in a hurry. All sudden jars and rude movements must be avoided. They must be dealt with most gently and tenderly. Any kind of smoke is an effectual means of subduing and quieting them. It will prevent their becoming excited, and reduce them to composure even after excitement has commenced from any cause. Bee-keepers who smoke tobacco, are accustomed to employ the fumes of their favorite weed for this purpose, and it accomplishes it very effectually. But it produces a stupefying and irritating effect afterwards. Smoke from chips, saw dust, cotton rags, or even paper, will answer as well. The most convenient source of smoke is a bit of dry-rotted, hard wood, or "punk" as it is sometimes called. It burns without flame, will keep alight until the whole is consumed, may be laid close at hand, and readily used whenever wanted. When there is a necessity for opening a hive, it is well to blow two or three puffs of smoke in at the entrance; within

five minutes or so, it will have taken effect. Then with slow and cautious movements, the hive may be opened. Usually a quiet, contented hum, will show that the inmates are peaceable. But if there is excitement and more or less rush hurriedly out, a few additional puffs of smoke will reduce them to submission, so that it will be safe to proceed. Care should be taken not to crush or kill any of the bees. The slaughter of a single one will sometimes enrage a colony, previously quite docile. But should such an accident occur, a fresh dose of smoke will restore order.

Smoke is thought to have two effects. First, it creates a slight panic among the bees, leading them to fill themselves with honey, and in this condition they are no more disposed to sting than an Englishman is to quarrel just after eating a good dinner. There is a sense of fulness, contentment and satisfaction. Secondly, it neutralizes the poison-odor. Anger causes bees to elevate their tails, and a tiny drop of poison will ooze out, the odor of which rouses the war spirit. The same effect is produced when a bee is killed. Smoke counteracts this odor, and so induces quiet. There is a third effect of smoke which may be brought about, though it is not good policy to have recourse to it, because it leaves them cross and irritable. A strong dose of tobacco, or puff-ball smoke, will absolutely stupefy them, so that they will drop from the combs, and lie harmless and helpless at the bottom of the hive, until restored to their senses by fresh air.

Bees employ a substance called propolis to fasten frames and fill up crevices in the hive. In hot weather this is quite soft and waxy, but in cool weather, it becomes hard and brittle like glue. In opening a hive and taking out frames, the propolis is of course disturbed, and when it is hard, this cannot be done without some jarring. To avoid this as much as possible, it is advisable to use a form of hive and style of frame that can only be glued very little; and also to open the hive and operate upon it in the middle of the day, and when the weather is warm.

We advise bee-keepers, and especially beginners, to use a veil and gloves. They give confidence, induce calmness, and guard

against accident. A veil may be readily made of net or thin gauze, and the best gloves we know of, are the cheap harvesting ones made of sheep-skin to protect the hands from thistles.

Various remedies are used to antidote bee-stings. Any alkali application is good. Common washing soda and blue-bags, are generally at hand, and may therefore be recommended. A drop of honey, a little garden soil, spirits of hartshorn, alcohol, and tincture of iodine, are among the external applications advocated. In severe cases, a dose of whiskey or brandy is said to be good. A wet sheet pack is also recommended. But we have discarded every other application since becoming acquainted with a German remedy lately introduced. A drop or two will remove all trace and effect of a sting in a very few minutes. It costs but a trifle per bottle, and a single bottle will last a bee-keeper for a lifetime.

The A B C of Bee Keeping.

CONDUCTED BY PROF. A. J. COOK.

ARTICLE I.

Of course I have wondered why the wise managers of the dear old BEE JOURNAL, chose me from all the fraternity to conduct this department. I suppose the answer would be suggested by the oft repeated assertion of school directors: "Any one can teach our school, they are all beginners." But, slyly, they are fooled, for our best educators think that those just commencing need the wisest instructors. So all will see that there is one joke connected with this department, however dry it may be in the main.

BEGINNERS.

Who are they, who should be eager to lend me their ears each month, whom I am to lead understandingly into the ways of pleasantness, and the paths of rich pecuniary reward? All, I answer, whether in country or town, who have space for one or more bee-hives, who are not now keeping bees, and who desire either more money or more pleasure, and who can give a few minutes weekly to pleasure and to profit. Especially farmers, who need something to supplement, their regular business, and add to the length of their purse. I am a teacher, yet last year, by spending not

more than an hour a week, from May to October, and even that only when I needed the rest and recreation, my three colonies of bees netted me over \$100.00, and all may do this, if they will but inform themselves, and work intelligently. That able bee-keeper, Mr. E. Rood, so long the genial President of our State Society, used to say no one should keep bees, who could not make a neat hive. I have heard others say no one should become a bee-keeper who did not enjoy being among bees. But I would say: Let all keep bees, who have a taste for the wonderful in nature, which they wish to gratify, or a desire to "inflate their individual currency," which may thus be done with perfect safety.

But, say the eager ones, how are we to commence? Just what I am about to explain to those who will attend. And more, I will warrant success to all who will heed and obey. First, as a preface to your beginning, subscribe for the AMERICAN BEE JOURNAL, and purchase either Langstroth on the Honey Bee, or Quinby's Mysteries of Bee-keeping. The first to be carefully read, the second to be studied and kept ever close at hand for reference.

HOW TO GET THE BEES.

A beginner should be satisfied to begin with about two colonies. If you can find some one who has bees in movable comb hives, that suit you, for sale, by all means take them. If the hives do not suit, it will be cheaper to get those in box-hives, as in either case, you would wish to transfer them into a suitable hive. But you ask, What is a suitable hive? It must have movable frames, and then the more simple the better. Discard all doors, drawers, traps etc., which only involve expense, and are worse than useless. I prefer a square frame, say a foot each way, as permitting the most compact arrangement for wintering, and as less apt to be severed from its full comb, when handled or placed in the extractor. Those who know nothing of hives could not do better than send to A. I. Root (Novice) for a two story Gallup hive for a sample, and be sure to get the tin corners for the frames. His bent tins on which the frames are to rest, you can, as you make a hive, replace by a narrow strip of heavy tin, which you can easily tack on. This is cheaper, and I think just as good. Also replace the old honey board by Novice's quilt or a piece of old carpet or heavy cloth which will do as well. I am thus particular about hives, as very much depends on a correct start in this direction.

HOW TO SELECT THE COLONIES.

Go to the Apiary on a warm day, note those hives from which the bees rush out as though they were packed, and from such select your two colonies; for the beginner especially, should have none but strong vigorous colonies.

Your colonies home, (it will be well to place them where they are to remain for the summer, on separate stands four or five inches from the ground, a board standing off a foot or more from the entrance to the ground, facing the east, and set under a tree or bush, that they may be shaded from the sun during the heat of the day,) you had better feed them every day or two, a little syrup made either from brown or maple sugar. This will stimulate to a rapid production of brood, the great desideratum at this season. A cheap, easy way to feed, is to take an old oyster can, melt both ends out, then tie a piece of factory over one end for a bottom. If you have a movable comb hive, cut a flap, by cutting on three sides, out of your quilt or carpet, just the size of the can, turn this back, and set the can on and turn in the syrup. The bees will sip up the fluid as it oozes through the factory. This is covered by the upper story of the hive, or the same that covers the boxes in summer. The can may be as easily placed on the holes in the top of a box hive and protected by the same box that covers the honey boxes in the season of gathering. This feeding had better be continued sparingly till the fruit trees are in full bloom, and even afterward, if there are several successive days too cold for the bees to fly, or if there are no flowers to gather from.

But you ask, How am I to get the bees into my new hive? As soon as the bees are busy gathering honey, select a bright warm day, and when the sun is well up, and the bees all at work, don your bee hat and gloves, for every beginner should protect himself, and with a burning piece of rotten wood or roll of cotton cloth, blow some smoke into the entrance of the hive, keep doing this for five minutes, then invert the hive and place a box, previously prepared, at least of the capacity of a half bushel, and which just fits the hive, on top of it, wrap a cloth about the lines of junction, so that no bee can possibly get out, then rap on the lower hive with some small sticks for twenty or thirty minutes, paying no heed to the many bees constantly returning from the field; at the end of this time, take off the upper box very carefully set it on the old stand, and so raise it up that the "uots" can go in. Take the old hive, with the few still remaining bees, and carry it to some close room. Doff hat and gloves, for these bees will not sting unless pinched, and with hammer and axe pry the old hive carefully apart, striving not to break the comb. With a long knife cut out the cards of comb, entire if possible. Take each as it is cut out, place it on several thicknesses of thick cloth, which rest on a board say two feet square, which in turn rests on a barrel. Place a frame on the comb, and cut the comb so that it will just fit in the frame. Place the comb in the frame and fasten in by winding with two small wires or

strings. Do so till all the comb is neatly and carefully fitted into the frames. Be very careful not to injure the brood. Carry the hive, with its frames all in place, and quilt on top, back to the stand, set it on a board, with the front raised, say a half of an inch, place a wide board in front, and taking the box (you now have the veil or hat and gloves on,) shake all the bees on to the board close up to the hive. They will soon take possession, and feel entirely at home, and show their appreciation of their new home, by going speedily to work. In three or four days they will have fastened in the combs, and you can, protected and armed with smoke, proceed to take off the strings or wires. In all your handling of your bees be careful not to make a quick motion, nor jar the bees. If afraid, remember you are well protected and forget that you have any nerves. Do all this and keep studying your book, and in the next I will instruct you further.

Questions and Answers.

CONDUCTED BY CH. DADANT.

INTRODUCING QUEENS.

"What is the best mode, for a beginner, to introduce an Italian queen?"

J. E. B., Nauvoo, Ills.

As soon as the Italian queen is received, hunt for the black queen and take her out. Then put the Italian queen in a cage made with a piece of wire-cloth, about eight meshes to the inch, four inches square, and rolled in the shape of a tube. Both ends are stopped with a bit of corn cob. The cage is put horizontally between two brood combs, one inch or so under the top bar, and as much as possible against sealed honey, which should be scratched a little, so that the queen can feed herself, if the bees don't take this care.

The next day, remove the cage, and replace one of the hoppers with a bit of sealed honey. Put the cage back in the same place, and shut the hive, acting very quickly. The bees will suck the running honey, and cut the damaged cells. Some of them will cut at the cage and will caress the queen, who will go out very quickly and be well received.

The theory of introduction is fixed upon this fact, that if the bees are unaware of the call of their queen, they will construct no queen cells, and will more easily accept a strange queen, than if they had commenced their preparations to take a queen; and in the second place, if the colony is quiet, without robbers, and the queen herself quiet, too, she will not be considered as a strange bee.

As it is necessary to avoid robbing, when you open the hive the second day, if you have been annoyed by robbers, while hunting for the black queen, it is safer to wait until evening, when the bees are all at home. Yet the operation is more easily performed at mid-day, and the robbers are little to be feared, if you act quickly, although quietly.

"I see in the AMERICAN BEE JOURNAL, that Mr. Furman, and several other bee-keepers, at the meeting of the Iowa Central Association, have said that pure honey would not become candied. My expense is altogether different; I have quite pure honey entirely granulated. Can you give me your experience on the subject?"

J. M. A., St. Louis, Mo.

The honey from rape, granulates very quickly. I have seen, in Italy, such honey, gathered in April, granulated in the combs in August. The honey from clover, melilot, lucern, sainfoin, linden and buckwheat, granulates also, although not so fast as the rape honey; while the honey yielded by several trees does not granulate. I have seen honey as good and as liquid, after two years, as if it was newly gathered. It was acacia or locust honey.

Therefore, the granulating of honey does not indicate its want of purity; on the contrary, in France, where the best quality of honey comes from sainfoin, the thorough and even granulating is considered the best test of purity.

For the American Bee Journal. Simple Bee Feeder.

A very simple, and at the same time effectual, feeder may be extemporized by filling a glass vessel (a tumbler or a fruit jar is best) with honey or syrup, placing a saucer upon it and quickly inverting them. This allows the bees to take the food from the entire circumference of the vessel without their becoming daubed with the liquid, which may be made thick or thin as desired. Any number required may be quickly and inexpensively obtained in the dining room of any family. By using glass vessels the bee-keeper may tell at a glance how fast the food is being taken, and which need refilling. Of course they must be placed on the top of the hives or frames and securely covered to prevent robbing. Many feeders are based upon this same principle of atmospheric pressure, but none are more effectual, simple or inexpensive.

DR. D. R. PORTER.

Manhasset, Long Island.

Swammerdam found nearly four thousand cells built, in six days, by a new swarm consisting of less than six thousand bees.

Voices from Among the Hives.

CH. DADANT, Hamilton, Ills., writes:—"Bees are wintering finely."

JOSEPH A. HART, Craig, Ind., writes:—"Bees are wintering better here, than for many years past."

A. F. HART, Appleton, Wis., writes:—"Bees seem to be wintering here very well, although we have had a long winter."

H. O. KRUSCHKE, Berlin, Wis., writes:—"The JOURNAL improves with every issue. It has got into the right hands at last."

D. S. McCALLUM, Hornellsville, N. Y., writes:—"I have about eighty swarms of bees, and they have wintered finely."

R. R. MURPHY, Fulton, Ills., writes:—"Bees have wintered well in this part of the country, and the prospect is more encouraging for bee-keepers, than for several years past. The white clover has not winter-killed the past winter, as it did the two previous ones."

DR. JARED P. KIRTLAND, East Rockport, writes:—"As I am over eighty years of age, and have ceased to cultivate bees, I wish to be considered on the list of retired apiculturists, like my friend Mr. Langstroth. I began the pursuit in the summer of 1810, and with the exception of a very few years, have continued it till very recently."

J. A. MAXFIELD, Saxon, Ills., writes:—"Bees have wintered well, with me. I lost twenty-one swarms last winter and spring, leaving me three swarms. I increased them to six, and have wintered in the cellar for four winters. The first winter and this they wintered well. My cellar is under the kitchen, and was built on purpose for wintering bees. There are not fifteen swarms of bees within three miles of me. My bees are all black."

D. H. KELLER, Duncan Falls, Ills., writes:—"Last winter, I lost a few hives by placing them too close to the damp stone wall in our cellar, where they became wet and diseased. This winter, I put other hives in the same place, placed coffee sacks over them, leaving the tops off, and they did not become even damp. So it would be well to note, that after all, ventilation is what saved them this winter, and no ventilation killed them last winter. My cellar is a very dry one. I tried an experiment as follows: I set a strong hive in the middle of the cellar, covered it with a blanket, closed the hive below, and then put the lid tightly on the blanket. In about a week I examined, and found that the lid was covered with large drops of water, and the blanket was becoming wet. I then removed the lid, leaving nothing but the blanket on top. All went right from that time. I set them out about the middle of February, and they are now (March 3d) all alive. I have forty-nine stands."

P. D. JONES, Mt. Morris, N. Y., writes:—"I wish to make an inquiry in regard to extracting honey in the spring. Can it be done? I have fourteen swarms that are in good condition at the present time. I have examined five or six of them, and find they are breeding finely, but I think they have too much honey. I have estimated it to be from twenty-five to fifty pounds to the hive. I have kept bees for the last twenty years, and have never had them winter on so small a quantity of honey as they have had this winter. It seems to me, if there was less honey and more empty combs, that they

would build up faster than in their present condition. The honey is of a good quality, and very thick. The question with me, is, Whether the honey can be taken from new combs without destroying them. The combs are very white, and easily broken. I have never used the Extractor; in fact, I have never seen but one, and that a home-made one. I desire information from those that are not interested in the sale of machines. I am wintering my bees on their summer stands, by driving stakes in the ground, one foot from the hives, and packing with flax-straw to the top of the hive, on all sides, except the front, which I leave open. I give no upward ventilation. I use the American and Langstroth hives. Last winter I lost fourteen out of twenty swarms, with a disease entirely new to me, but have seen nothing of it as yet, this winter, and hope that I never shall again."

THOS. HUTCHINS, Wyoming, Pa., writes:—"I am that you would call a careless bee-keeper. I have about ninety hives of bees. Some in the American and some in the Queen hives; but most of them are in the Quinby hive. I am living in Wyoming Valley, Luzerne Co., Pa. We have not had a good bee season here for the last five years. There are no basswood or linden trees in this locality. Buckwheat and white clover are the principal honey producers. Honey varies here in prices; the nicest box honey brings from thirty-five to forty cents. The most I ever got from one hive, was forty pounds, fourteen-pound boxes. That was from the Quinby hive. It seems almost incredible to me when I here of such large yields of surplus honey, in other localities, to keep bees. The winter here has been very favorable for bees, not being very severe; but we are now having very cold weather, to what it has been the past few months. Last winter I lost forty stocks of bees, the weather being very severe. My opinion is, that when bees are strong enough, and left on the summer stands during the winter they do the best; but all late and weak swarms I put in my cellar, it being very dry, turning my hives upside down. I feed them about every two or three weeks. I feed them syrup made of two-thirds "A" sugar, and one-third water, boiled and strained. I feed them by pouring it in among the bees. I see by your JOURNAL, that some feed their bees in November. Is it because they have no honey? If they have honey, do they want feeding? I think it would be small business to rob them of their honey, and have to feed them sugar syrup or any other food."

A. R. RICH, Metamora, Ill., writes:—"The winter thus far (January 17th) has been very moderate, and my bees are weathering it very well out of doors. I have always wintered in the cellar heretofore—or rather tried to do so—but I think that in reasonably mild weather the bees are better off outside. I have most of mine in straw hives, and think them superior on many accounts for both winter and summer. Fully nine-tenths of all the bees in this section of country froze to death, or died from some other cause, last winter. Some persons made special preparations for winter, others made none, with perhaps no perceptible difference in the result. The most successful man I have heard of in this region, however, had his bees in rickety box hives, on the west side of his smokehouse, which stands right in the teeth of the northwest winds. The hives stood on a bench nearly three feet from the ground, and, in some cases, the front edge of the hive projected five inches beyond the edge of the bench! He lost not more than one in five or six. An-

other neighbor, who had graded Italians, got through the winter with nine out of twelve, but before swarming time he lost all but one. In all the other cases, except my own, the bees were blacks. I predict—that is, I simply guess—that there will be this present winter far less loss in this region of country than for two years past. My own bees, and I presume it was the case generally, kept breeding for nearly three months later in the summer and fall than heretofore, and went into winter quarters with a goodly number of young, strong and healthy bees, and I hope there will be less freezing this winter and less loss next spring. I increased my four stocks to twelve, got considerable extracted honey, mainly from heartsease and buckwheat, and it is that kind of honey they are wintering on now—the same that gave them the dysentery two years ago."

SEYMOUR RUGGLES, Saratoga, N. Y., writes:—"The bee business in this section, is in a very backward condition, with few exceptions. Many use box hives, without a chance to put on boxes, unless put on the outside of the hives. They leave their bees on the summer stands through the winter. I have noticed this winter, some bee-keepers had hives without bottoms, set upon four one-inch blocks, protected from west winds only. I don't see how bees can stand such an airing. I could not winter bees that way, unless the hives were large, filled with comb, and colonies very populous in the fall. The fact is, most bee-keepers around here know nothing of modern bee-keeping. I informed one man not long since, that he ought to have Quinby's or Langstroth's book, and the AMERICAN BEE JOURNAL. 'Oh,' he says, 'they want money for their books, I can get along without them.' The same afterwards said the drones laid all the eggs. Last fall I set box hives in the cellar; January 23d set the bees out at 12 o'clock, it was warm and still, 55° in shade, at 2 p. m. it was cloudy, and a furious wind arose. Many bees were blown away, as they were flying quite briskly. The next day I set the box hives back into the cellar. They have not shown any signs of dysentery, whether in the cellar or out, up to this date (March 10). Mr. Perry, the only person here, besides myself, that uses movable comb hives, had 1,400 lbs. honey in glass boxes last year. He has 80 colonies, winters in cellars, but never saw Quinby's or Langstroth's book or the JOURNAL. It has been a favorable winter for bees so far."

E. S. FOWLER, Bartlett, O., writes:—"There are no bees kept in this part of the country (save what few I keep) in movable frame hives, except as the farmers keep them the old-fashioned way. We have never had bee cholera or dysentery as an epidemic except the winter of '68 and '69. It was not an unusually cold winter with us, while the winter of '72 and '73 was the coldest for ten years or more without any dysentery; hence the cold weather theory don't suit my experience. I have always been able to produce dysentery by leaving a colony queenless for two months, before the time they quit breeding in the fall.—Old bees not wintering as well for me as young ones, at least I am not able to give another reason for the difference. I have no reason for doubting nor any experience to confirm the opinion that the honey gathered some seasons is not healthy for the bees. Perhaps different causes operate in promoting and aggravating the disease in different parts of the country—hence the different opinions. Let us not be in too great a hurry to see who will have the honor of guessing right first."

American Bee Journal.

THOMAS G. NEWMAN, MANAGER.

RATES OF ADVERTISING.

SOLID NONPAREIL MEASURE.

First insertion, per line.....	\$0.20
Each subsequent insertion, per line.....	.15
One square, 10 lines or less, first insertion.....	2.00
Editorial Notices, solid Nonpareil, per line.....	.30

Next page to Business Department and second and last page of cover, double rates.

A deduction of 20 per cent. made on advertisements inserted three months, 30 per cent. for six months, and 50 per cent. for one year.

Twelve lines of solid Nonpareil occupy one inch. One column contains 96 lines of solid Nonpareil.

Bills of regular Advertisers payable quarterly, if inserted three months or more. If inserted for less than three months, payable monthly. Transient advertisements, cash in advance. We adhere strictly to our printed rates.

Address all communications and remittances to the Manager.

Not one letter in ten thousand is lost by mail, if rightly directed.

Single Copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Additional names to a club already formed may be sent at any time at the same club rate.

NEWLY PATENTED HIVE.—John W. Walker, of Nashville, Tenn., has obtained a patent on his new hive.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

☞ We will club the AMERICAN BEE JOURNAL with A. M. Purdy's *Fruit Recorder and Cottage Gardner* for \$2.25.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

On the Pacific Coast, we are informed by Stearns & Smith, they have had twenty inches of rain, and the season is very late and cold.

Subscribers wishing to change their post-office address, should mention their *old* address, as well as the one to which they wish it changed.

Langstroth's patent on movable-frame hives expired last year. There is now no patent covering movable frames—all such are public property.

☞ We want several copies of No. 1, Vol. 2, of the AMERICAN BEE JOURNAL, and will pay 50 cents each for them. Who will send us some?

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

Newspaper Decisions.

1. Any person who takes a paper regularly from the post-office—whether directed to his name or another's, or whether he has subscribed or not—is responsible for the payment.

2. If any person orders his paper discontinued, he must pay all arrearages, or the publisher may continue to send it, until payment is made, and collect the whole amount—whether the paper is taken from the office or not.

3. The courts have decided that refusing to take newspapers and periodicals from the post-office, or removing and leaving them uncalled for, is *prima facie* evidence of intentional fraud.

Persons writing to this office should either write their name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

The postage on this paper is only twelve cents a year, if paid quarterly or yearly in advance at the post-office where received. We prepay postage to Canada, and require twelve cents extra.

Hereafter we shall mail a Printed Receipt to everyone sending money to this office.—Those who do not get such Receipt by return mail, should notify us, that we may ascertain the cause of delay.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

Publishers needing cuts or engravings, will do well to address the Manager of the American Publishing Company, who have a large supply for sale that have appeared in "The Illustrated Journal."

Should any subscriber wish to discontinue taking our JOURNAL, he should address a letter to the Manager, and enclose the amount due, and it will then cease to visit him. Any other course is dishonorable.

Every subscriber is requested to look at the date after his name on the wrapper label of this *Number* of the AMERICAN BEE JOURNAL, and if it is not correct send a postal card to this office, and tell us and we will make it right at once.

BINDING.—We have been requested to get sets bound for some of our subscribers, and have made arrangements to get the nine Vols. bound in three vols. for \$4.00, or the same in four vols. for \$5.00. Those who wish to avail themselves of these liberal terms must send their numbers by express to the Manager.

No. 5.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

For the American Bee Journal.

Items from Argus.

MR. EDITOR:—Your remarks in the February number on bee meetings are to the point, and demand the attention of every bee-keeper, inasmuch as it is for their interest to meet, tell their experience, compare notes and criticise. A bee friend suggests that every Town, County and State ought to have meetings as often as desired, and that delegates be sent to the State Convention, and let these again send delegates to the National Convention, having their expenses paid.

In this way the best talent will be collected, when subjects of the most importance will be discussed, and a greater interest awakened, and, too, the published reports of such meetings will be of far greater interest as well as benefit to every progress-loving bee-keeper. As a rule, so little has been done at these meetings it really did not pay for the time and money spent. And another thing: some of the ideas advanced are not fit to be published unless we intend to progress crawfish fashion.

Take for instance the Convention at Topeka, Kansas, held last September (see AMERICAN BEE JOURNAL for November) where some new ideas were advanced that may lead to a "great discovery in apicultural science." Mr. Meador says after the queen is impregnated "*all the eggs produce females, and that the male bees were generally produced by eggs from the worker bee that was fed for the purpose.*" Now all practical, intelligent bee-keepers know that is not so, for a hive in a normal condition never has a fertile worker, and all the drones in such a hive are produced by the queen. One season's operations in an apiary will convince a mere tyro of this.

Again, Mr. O. Badder says he "removed a dozen or more eggs from worker cells to drone cells, and at the same time removed the queen from the hive, and all the eggs thus removed hatched perfect drones as far as the eye could detect. No other solution could be given to this experiment than that the bees removed the spermatozoa that changes the character from male to female after they had been placed in the drone cells."

From these statements I conclude as follows:—

1. The experiment was a very imperfect one, because there was not that careful microscopic examination necessary to test the truth of his statement.

2. His conclusion is a very erroneous one, because the egg is not fertilized by the life-giving principle, the spermatid filament, remaining on the outside, as his language would seem to imply.

3. The whole shows an unpardonable ignorance of physiology, because it overturns the well-established facts in the reproduction of the honey-bee. It is very evident that the nature and permanent location of the spermatozooids is not understood, for we learn from the best authority that when an egg leaves the ovary it slips past the seminal duct, where it receives a portion of its contents, and the seminal filaments being very active soon find their way into the micropyle or opening of the egg. Now how the bees could remove the spermatozooids from the egg without destroying such a delicate article I will leave for Mr. Badder to explain.

I was somewhat surprised at the secretary sending the statements, and more so when the Editor published them without note or comment. A good deal has been said regarding the cause of bee disease, and some, I think, have arrived at pretty near the truth, but it is just fun to see Friend Quinby astride his hobby, old Boreas, and shouting with all his might, "I tell you, gentlemen, it is cold that kills the bees, for what I know! *know.*"

Behind him, away in the distance, is another hobby, old *Sirupy*; its rider is hatless, coatless, and belaboring his nearly worn out favorite. He is also shouting at the top of his voice: "Taint cold that kills the

bees, depend on't;" "'tis bad honey;" "'twont do;" "'twill kill every time;" "'twould be a great gain in honey if sugar-syrup were used, besides nary a bee will catch the disease."

I also see betwixt these two, another rider on his stout, short lard favorite, old *Truth*. I think I hear the gentleman say, Well, if those two friends would only meet hereabouts they would find out they were both right.

For the American Bee Journal.

"Novice."

MR. MANAGER:—Allow me to congratulate you on having made arrangements whereby you can furnish a good, patented, two-story Langstroth hive in Chicago for the moderate price of \$3.30. We would also suggest that as the preference is now strongly turning in the direction of *double-width* instead of two-story hives, you make arrangements, if practicable, to have them made in that way when they are to be used exclusively for the extractor. We believe the expense of making is a *little less* if anything.

As your offer will doubtless furnish a good many with sample hives to work from, we somewhat regret that the size of the frame is between any of the sizes in our classification of frames. As you give only inside dimensions we cannot tell the exact size of your frames, so much depends on the thickness of the lumber used. Is it not best when speaking of frames and hives to give *outside* dimensions of the former, and *inside* dimensions of the latter, for *these must be exact*?

While we are anxious to give Adair full credit for all his suggestions, we cannot think it proper to call double or treble-width hives all "New Idea Hives," for the "New Idea" *was*, if it is not now, set forth as a *patent* hive, and in some respects, it seems to us, a little inconsistent. See *Progressive Bee Culture*, inside of first cover, where he condemns the extractor. His price then given for a Langstroth hive fitted up on the "New Idea" plan, *with right to use*, is ten dollars. Double-width hives were used in our county before this work was published, for he had mentioned in public, making hives four or more feet long. Such hives have an undeniable advantage over the two-story hives, for the extractor, but it certainly was not Mr. A's reason for recommending them thus. We at first doubted their giving an *equal* amount of honey, but should they give more, as he claims they will, we certainly owe him a vote of thanks for his labors in turning the attention of apiarists in that direction. The testimony from those using them is strongly in favor of them, instead of the two-story hives, if we

make some few exceptions, although reports seem to equally favor side entrances, in place of only one at the end, as Adair insists on.

In regard to the "queen's wings" business, we are perfectly satisfied to leave the matter with our readers as it is. Adair has opened and closed the subject, and we have had "our say" in the interim, which we have no wish to change or modify since his last. 'Twere no more than justice, however, to say that we *did publish* Mr. A's letter in full, *every word contained* in it, yet he accuses us of publishing only a part. If we thought that any one besides Adair, understood that *we* were intending to take upon our shoulders the task of punishing "Eminent Naturalist" we might reply to that.

Agassiz's lecture on the honey-bee might have passed uncontradicted twenty years ago, but in the present stage of bee-culture it was only the "worse for him" his persisting in his absurd teachings. How many of our readers have questioned with themselves whether he might not have committed great errors in other matters as well as bees, and as that would be out of our domain should we not hesitate before accepting his teachings as truth when we were not prepared to discriminate? 'Twould be a *huge* joke indeed to think of giving the task of "root"-ing out all the error in the "popular science world," to let alone the task of punishing them for their folly, to

Your old friend,

Medina, O.

"NOVICE."

For the American Bee Journal.
Out-Door Wintering.

"Novice" says on page 41, February number: Quite a large number of our beekeepers, with Mr. Gallup among them, contend strongly for out-door wintering." I must here make an explanation. I do not advocate wintering small standard stocks in ordinary standard hives on the summer stands, by any means; but large powerful stocks such as I now raise and such as I want for profit, I believe it would be rather difficult for the most of people to winter in a cellar. Then again such large hives are unwieldy to carry in and out. I have them so heavy that they are all that two men can lift, let alone carry about etc., I have stocks that have as many bees in them as four ordinary standard, strong stocks, or six common stocks. Every person ought to know that such stocks would be difficult to keep cool enough in a cellar. I have been led to experiment in the direction of large hives by seeing bees in a room or small house fixed on purpose. We have seen at different times extraordinarily numerous and strong stocks in such cases, and it occurred

to us that with the extractor and movable combs, we might make this available; and thus far we have not been disappointed in the results. If we have strong, powerful stocks there is always warmth enough to properly evaporate the honey; whereas in small standard stocks it is frequently the case that the honey is not properly evaporated and especially is this apt to be the case in cool, wet seasons. In the large hives there is no tendency to stop breeding at every cessation of honey gathering, for a few days at a time, as there is in common or small standard hives.

Novice will probably say, as he has said before that we are trying to befog or puzzle the novices in bee-keeping. But let him consider that others besides Gallup and Adair are trying those experiments and arriving at like conclusions. We are aware that a hive of four times the capacity of the ordinary standard, or two thousand cubic inches, looks large, and we are perfectly willing to admit that it is large. But what will you do about it; that is the question.

If I mistake not, Mr. Hosmer says, that in the past season he has made some for experiment, of fifteen thousand cubic inches. I know of no law to prevent, and so we will have to let him go on as he sees fit. But Mr. Hosmer says that he has been raising or keeping his best or most prolific queens. Now that is just what I contend—that I cannot afford to sell a queen for one dollar that I can build up a stock from that will occupy a hive of six or eight thousand cubic inches. My impression is that Novice's Hives and Queens are both cheap at one dollar each; and my hives and queens may be cheap at five dollars each. Who knows. Let every one decide for himself. I have sold queens at fifty cents each, but they were only fifty-cent queens, and I never claimed that they were anything else.

The bees are wintering splendidly in this vicinity.

For the American Bee Journal.

Criticisms Examined.

A friend having called my attention to the last number of *Gleanings*, I borrowed the paper, and found that "Novice" quoted from my circular to show that a calculated yield of one or two hundred pounds of box honey, or two or three hundred pounds of extracted, is a little too much. He "wrote Mr. Q. asking the question," etc. I do not see that this amounts to anything more than an effort to show that I have made a false estimate, and at the same time give an excuse for a sort of tirade against the hive.

He would be pleased to hear where any one had succeeded in obtaining that average.

Had he quoted a little further from that same circular, he would have told his readers where it was done. He very ingeniously gives the number as twenty-five or fifty stocks, which I said nothing about, and it did not belong to him to do it. Why did he not put it at five hundred? He would be still surer not to hear of a case.

I ask of any man of even common fairness, to decide if it was so very absurd to calculate that what had been done, and repeated, might be done again.

I don't claim to know it all, and doubt not, much will be learned after we have all gleaned to the best of our ability. A calculation of even a few pounds more may yet be made. He asks if it "was wise to put it so high when his own apiary averaged less." Without claiming to be particularly wise, I may venture to express a fear that Novice is partially blinded by prejudice. I would ask if it was just to hold forth what my apiary does before his readers, as a criterion to judge of what *can* be done by others, and withhold the fact—which I presume he knows—that I have sold my best bees every year. When I get an order, I select the best—sometimes sell off all the best, and then take from the next best, bees enough for several swarms for the purpose of rearing queens, which do not store surplus, and often have to be fed what others have stored.

Justice would take this into "calculation." I rather think that my estimate was made when thinking of the bees that I sold rather than of such as I kept myself. Of course I meant *good* hives.

We all know of the reduced condition of a large number of stocks in the springs of the last two winters. Few men would depend on such for a fair average, especially if they took into account the fact that brood had to be taken from the best of these reduced hives to build up the poorest.

Now about the hive, which seems to trouble him, in view of "blasted hopes," etc. He asks, "Has he ever considered that the hive itself is only a plain, simple box?"

No, sir. I have not so considered it. When I have made a bottom board of the size I want, and a frame which I hook to it, and it stands alone, and I make a half dozen more, and stand by the side of it, and then take boards just the width and length of the frame and set one on each side, and one on top, I claim that it is a hive of itself, not "a simple box," nor particularly "cumbersome." The frames constitute a part of it. Much has been said about getting hives the right size. This one is adapted to the wishes of all. Frames being added any time to accommodate a large swarm, or taken off if the swarm becomes reduced. It is easier managed, and is much more efficient than

any hive with which I am acquainted, though of course, as it is, there is no more room to set the boxes for surplus than the cheap one he describes.

He continues:—"Full directions could be published in the circular, or even given in the journals, at the trifling expense, to him, of making the measurements and descriptions *encc.*" Now if he feels that he has not done his share of working for nothing, suppose *he* gives "descriptions and measurements," at the "trifling expense" he speaks of. I would very much like to see it given so plainly that it "could be easily made for four dollars." Two or three years since, I sent him a hive, without charge, appendages and all, rather than undertake to describe it myself. I would like to see the late improvements belonging to the appendage—a device to clasp the corners—*fully* described. Perhaps he could tell how to make it cheaply. If a man does not want anything but the simple hive, to be used for extracting only, I still think it best, and I would like to see it fully described as well as appendages.

As it is desirable for many to secure box honey as well as extracted, I have endeavored to adapt it to either, the advantages of which are easily understood. The boxes that sell best in market are made of glass, costing more than if made of wood to hold the same amount. These boxes, when put on the hive at the side or top, must not be exposed to the light or storms. I have enclosed them by getting out boards for the sides and top, of the right width and length, and have succeeded, after much thought, in having the clasps at the corners—that hold as firmly as nails—so that they can be loosened, and each piece taken away separately, without a jar, and so quietly that not an angry bee can be seen. It was not completed with one effort. Like all else that is worth much, it had to grow gradually; was altered again and again, and when at length I succeeded in getting the present hive and appendages, I found it had cost me in experiments, mechanical labor and brain work ten times the amount asked for it. If any man wants what I use, he can have it by paying a very small part of what it has cost me for the "know how." There are a few men—I mean those with some generosity—who are willing to share somewhat in the expense of getting a good thing. Suppose a man disposed to get up a paper. First, he must have matter, which ought to be his own, to put in it. Then he must reckon type, ink, paper, press, and the labor of printing, etc. He does not get his expenses back when he has printed one or a dozen papers, at seventy-five cents a copy. But when he has everything ready, he can print the second copy, or the thousandth, for a few cents only, and then, if he does

enough of it, he can get remuneration, and a little more, at seventy-five cents a copy.

It may look to some like "pecuniary profit." Now it would be hardly possible to find a man so ungenerous as to claim that because his last paper cost a few cents only he should furnish it at cost before he got recompense for making the first, or even then. Is there any parallel in the two cases—in making a hive and making a paper?

As it is pretty well known how "cumbrous" the hive of itself is, I will not dwell on that, but when it "seems" to him that the smoker would be "cumbrous" I fear that some of his readers might take his "seems" for facts, and I beg that they suspend judgment till they see it work. If I should send him one, it might turn out as with a friend of mine who says he sent him a patent feeder. If he did not claim the invention, he substituted a tea-kettle for the tin tube to hold the feed, and sells it without changing the principle, calling it the "Tea-kettle Feeder." There are some men in the community from whom there is no protection, a patent will not do it. A man can spend his time and money till all is exhausted, endeavoring to assist his fellow men, and when he offers to let others share a small part with him, he finds men ready to discourage him by offering the same thing for just what it costs them after being shown how to make them. How has it been with Mr. Langstroth, who has benefited bee-keepers thousands of dollars, and expended time, money and intellect in giving us a hive—in principle worth more than all before it—in procuring a new variety of bees, and has due him some recompense. But here is a man that has apparently done his best to discourage anything of the kind, by telling where hives and bees can be had for the trifle that would go but a small way towards it. It tends unjustly to deprive Mr. L. of his rights, and gives him to understand that *he* will not be paid for employing his talents to promote bee-culture, and he seems compelled to relinquish the pursuit. What have we gained in the end by being persuaded to purchase a hive or buy a queen for a dollar? We have all heard of the man who peeled the flint for a penny, and spoiled his knife costing fifty cents.

There is much more that ought to be said, but this must suffice at present.

St. Johnsville, N. Y. M. QUINBY.

H. O. KRUSCHE, Berlin, Wis., remarks as follows: "In my article, 'Do Bees Injure Fruit,' in the March number of the AMERICAN BEE JOURNAL, I stated that the New York *Tribune* had not seen fit to publish a similar article. But since that, I find that it was published in the *Tribune* of Dec. 31. It had escaped my notice, and hence I thought it had not been published. I herein apologize to all concerned."

Apiary for May.

This month the labors of the bee-keeper will begin in earnest, populous colonies will begin to prepare for swarming towards the last of the month, and where artificial swarming is not resorted to, they should be kept constantly under the eye of the bee-keeper, in order that they may be hived, and not be permitted to escape to the forest. When the swarm has been shaken down in front of the hive the bee-keeper should sprinkle them with cold water, (especially if the weather be quite warm), and all the bees should be brushed up to the entrance of the hive and driven in, after which the hive should be moved without delay to the stand it is to occupy, as, if it is left where the swarm is hived until night, the bees will have marked the location, and many will visit the spot the next day and perish, for on leaving the hive after being moved to a new stand the bees do not view and mark surrounding objects, having done this the day previous where they were hived and left till nightfall. As a natural consequence many must be lost, not having marked the last location of their hive.

It will still be highly necessary to see that the colonies are not destitute, for it often happens that the weather is so cold and wet, whilst the fruit trees are in bloom, that they are not able to collect honey sufficient to last them until white clover blooms. This will often be the case at the North; in the Southern States it will of course be otherwise. At the South bees may be expected to store a surplus of honey for their owner, and swarming will be quite brisk. A close lookout should be kept after the moth, as many colonies will still be unable to cover all their combs, and are liable to be destroyed by these ravagers. If wren houses are put up, so as to induce these little birds to build close to the apiary, they will catch many moth millers. It is stated by pretty good authority, that ducks are exceedingly fond of moth millers, and that they will catch many of them if permitted to take up quarters about the bee hives. If, however, the bee hives

are kept in the kitchen garden, where cabbage plants are growing, it may puzzle the bee-keeper somewhat to hire his ducks not to eat them along with the moth miller.

It will be well enough for the bee-keeper to select his ground this month, in which to sow a patch of buckwheat, for the special benefit of his bees. When the time of the season arrives for sowing it, the farmer who keeps bees can also afford to make preparations to sow Alsike clover seed another season, as the seed will not be likely to cost as much as at present. This variety of clover is not only superior for bee forage, but is also excellent for hay, being inferior to no other variety cultivated in this country, but is said by many to be superior to our best red clover, giving a larger yield of both seed and hay. Care should of course be taken in the selection of parties to purchase seed from, as it is not always pure. I have seen some that was simply common white clover seed and green besides, so much so that it would not grow.—*Scientific Farmer.*

For the American Bee Journal.

A Visit to Adam Grimm.

He isn't *grim* at all. A round faced, clean shaven German, of medium stature, perhaps fifty years old; very earnest, and withal pleasant in manner, impressing you at once as a thoroughly candid, honest man. Slow to adopt new ideas, his careful conservatism will, no doubt, sometimes appear to the more volatile Yankee as old fogy stubbornness.

On a very hot day last summer, just at the beginning of the bass-wood harvest, I went to one of his apiaries, and found some eighty hives under a little eluster of lindens, in the centre of which sat his daughter Maggie, pretty well covered up with a huge sun-bonnet (Katie is married—the one who did the big day's work extracting). Very shortly Mr. Grimm put in an appearance on his round of visits to his different apiaries, for he had in all some seven or eight hundred colonies. For a bee veil he has what looks for all the world like a Dutch night-cap made of heavy sheeting, having the face covered with a wire cloth, in the centre of which is a round hole, through which passes streams of tobacco smoke and words of wisdom. He occupied himself principally that afternoon in putting on boxes, taking off the honey board entirely, and

putting the boxes directly on the frame. The boxes did not quite cover the frame, leaving a space of an inch or so at the back end, and then he blocked up the back end of the cap or cover so as to allow free upward ventilation. Bee-keepers take a note of this, as Mr. Grimm considers it a *strong point*, making a decided amount of difference in the amount of honey stored. In the spring he had fed several barrels of extracted honey, and considered himself largely the gainer by it.

Mr. Grimm thinks he can do better with boxes than to depend upon the extractor. Certainly, with his large number of hives, it would be a difficult thing to keep the honey extracted. He does not get so large a yield per hive as many others, but having so many hives his aggregate yield is, I believe, larger than that of any other. The question of extractor *versus* boxes, perhaps, depends upon the number of colonies kept. If I had Novice's number, I certainly should use the extractor—if Mr. Grimm's, I should be inclined to boxes.

After all, is not the important question, how to get the most money from one's whole stock of bees rather than to get the largest yield per hive? If so, I think Mr. Grimm is entitled to the palm. He showed me, on a previous visit, accounts of one year's work, yielding him ten thousand dollars. His own belief is that his success is due mainly to the superior breed of bees he has. As is pretty well known, he prefers the smaller dark Italians. I mentioned to him that I had kept my bees the previous winter in a cellar with tight cement bottom, and they had come out very mouldy. He replied that he had been obliged to abandon the nice cellar with cement bottom that he had built a year or two previous, and believed a cellar for bees should *not* have cement bottom.

Recently Mr. M. M. Baldrige mentioned to me one or two cases in which bees had kept unusually well in cellars with open eisterns in them. Perhaps the water absorbed the impurities of the air, and the earth bottom of a cellar may act in somewhat the same way.

Mr. Grimm thinks highly of Novice's bee-feeder, but doesn't like his quilt. He uses for a honey board a plain pine board, an inch thick, with a hole (inch hole, I think) for the bees to pass through to feed. Instead of feet as Novice has under his feeder, he has a close rim of tin which supports the feeder and prevents the escape of heat.

Mr. Grimm has lately commenced the banking business, but thinks he can make more money *bee-ing*, so he will continue in both departments.

As I took no notes of my visit but depend entirely on my memory, I may possibly not

represent everything exactly straight, but I should not be so *very* sorry if I did tell a few lies about Mr. Grimm, if thereby I could get him to give a correct version with his own pen in the AMERICAN BEE JOURNAL.

Although a very *busy* man, I don't believe he is so selfish as to deny us the benefit of his experience if he really thought it was wanted. What little business I have had with him has been most satisfactory, and if I were buying bees or queens I would rather *not* see them, but trust to his selection. If having all the bees one can take care of, a pleasant wife and family, and a comfortable home, can make one happy, Mr. Grimm *ought* to be happy.

B. LUNDERER.

For the American Bee Journal.

California as a Bee Location.

MR. EDITOR:—The enclosed letter will explain itself. If you think it is not too lengthy to publish in the AMERICAN BEE JOURNAL, it would be interesting to many readers, as it has been to me—especially those seeking good "bee" locations.

Cynthiana, Ky.

H. NESBIT.

H. Nesbit, Dear Sir:—I hasten to answer your letter, which was received a few days ago. Most of the honey shipped from here is strained by the heat of the sun, by putting it on perforated iron plates in a boat-formed, glass covered reservoir, from which it runs into the "tank." The wax melts after most of the honey has run out, goes through the plates, and when cold is removed from the strainer.

Three years ago I got a honey-extractor, and since then several other bee-keepers have commenced using it. A few only put honey up in the comb—mostly in two pound cans. It is difficult to ship comb-honey in frames to San Francisco, owing to the many changes it has to go through: from apiary to railroad, from there to a lighter, then to a steamer, and finally to a wagon, before it is received at the store. This will, however, be remedied, when we in a few years, get a railroad through to San Francisco.

This, as well as the adjoining counties of San Bernardino and San Diego, is a very good locality for bee-keeping. As we have no snow except on top of the mountains, and very little frost, in many places none at all, we leave the bees on their summer stands without any protection, and the bees are flying every day except when it is cloudy or rains, which, alas! does not happen as often as we desire. There is no time during the year when there are not some flowers to work on. The last four or five years have been very dry, owing to a scarcity of rain in the winter. It is a miracle if it rains here between May and No-

ember. Consequently the bees have swarmed very little, and the only safe mode of increase is by artificial swarming.

This winter, however, we have had more rain than of late, and everybody expects a good honey season. By using the extractor you can in any ordinary season rely on getting an average of at least one hundred pounds of honey from each swarm, besides doubling your stock, as I shall further explain. The honey season lasts from May till the end of September. In July the flowers give very little honey; in August and September the bees gather some, but the principal harvest is during May and June. It does not require much to take them through the winter, but we generally leave them all the honey they have in the lower story at the end of the season. The bees here are, with a few exceptions, all black. Foul-brood troubles us some, but not enough to discourage anybody.

We plant nothing for the bees, although it might be well to have a field of rape or other honey-producing plants coming in by the first of July. Bees are worth from \$2.50 to \$5 in box hives. Mr. Harbison, I believe, sells Italians in his frame hives at \$12 a swarm. Box hives are still much used, the honey being cut out of the upper part, and strained as described above. The same method has been used a good deal with the Harbison hive, which for a long time has been the principal frame hive in use here. A couple of years ago, however, Mr. John Beckley of Minnesota introduced the Langstroth hive, which is being adopted by a number of bee-keepers, and, no doubt, will be "the" hive within a few years.

The size of our frames is eleven and three-fourths inches long by nine and three-fourths inches deep, outside measure. The hive, being eighteen inches long inside, will take from ten to twelve frames in each story, according to the thickness of the comb. All the apiaries kept for business are situated at the foot of the mountains or in the canons. Many bees are found scattered round in the valleys, but only a few at each place, as the harvest-time is short, and the bees will just gather enough for their own use and for home consumption. They swarm, however, much more and earlier in the valleys than in the mountains, because the willows and some other plants commence blooming about New Year, and give an abundance of pollen and some honey, which stimulates the bees to breed early.

The honey from willow and mustard, the principal honey-sources in the valley, is strong and not very palatable, besides granulating very fast. Wild sage gives a fine flavored, colorless honey, sumach a straw-colored honey with good flavor. The former always takes the best price. So in

looking for a location for an apiary, or "bee-ranch," as it is here called, these are the principal plants to have near and in abundance. Alplalaria, yellow alfalfa (wild), sycamore, oak, mountain-mahogany, grease-wood, and a variety of other plants and trees give considerable honey. In some localities the alders are often covered with honey-dew in the fall.

A few enterprising bee-men are this year trying an experiment, which, probably in time, will be repeated by many others. About New Year they moved their bees to the valley, where they are already preparing to swarm, raising queen-cells and drones, and a few hives have even before this date been divided. By the first of May they will have been doubled, moved back to the mountains, and commenced their honey harvest in good earnest. As I have only been in the business four years, I cannot tell you what the increase would be for so long a time as you ask; and being inexperienced and "bothered" with an unmanageable patent hive, I have not had much success in that respect. Moth-worms have been more troublesome than foul-brood, seeming to thrive exceedingly well in this warm and dry climate, and aided, no doubt, by the half-hundred safe retreats in the just-mentioned hive, where the moths are proof against the attacks of the bees.

Nearly all the honey from here goes to San Francisco, mostly in five-gallon tin cans, and sells at from eight to fifteen cents for strained and extracted, and twelve to twenty-five cents for comb-honey. We have had considerable trouble in disposing of the honey for the last two years. It would remain in the store, there being no demand for it, until it was candied, and then be sold for a very low price. Twelve and one-half cents is, however, the average, and regarded a fair price for strained honey.

The Bee-Keepers' Association of this County has now taken the matter in hand, and we hope to succeed in getting better prices and quicker returns by putting the honey up in cans and glass jars of sizes to suit customers, and by placing the bulk of the honey in the hands of one firm, which will prevent the price from falling as low as it has of late. At the last meeting, a few days ago, the president was authorized to go to San Francisco, and confer with merchants there about the sale of honey for the coming season. We are also in communication with Mr. Chas. F. Muth of Cincinnati, O., in regard to the sale of jars, no action having been taken yet on that matter by the Association. Several members expressed, at the last meeting, a desire to take their part in a car-load, but it was thought best to wait until we hear from San Francisco which size of packages will be most desirable.

If you are an "old bee-keeper," bee-keeping will no doubt pay you well here, and if you want to raise fruit, you can, on suitable land and with the necessary water for irrigation, add this branch to your resources. It is customary here to take bees "on shares," giving half the increase and half the products to the owner, the same receiving back the original stock at the end of the term, and both parties sharing the expenses equally. Few bee-keepers hire any assistants except in the height of the season, and the wages range from fifteen to forty dollars and board. From one to two hundred hives may be kept in one place, according to the size and quality of the range. Clarke's and Harbison's apiaries are in San Diego County, south of here, and about one hundred miles distant. Harbison has formerly resided at Sacramento, but I see by the AMERICAN BEE JOURNAL that he has removed his bees south.

We move the bees from twenty to thirty miles when moved as above mentioned.

I believe, now, that I have answered all your questions. Any further information shall be cheerfully given, as far as I am able. You are at liberty to publish this in the AMERICAN BEE JOURNAL if you think it will interest any body else. My address is at present, Los Angeles. Care of Henry Beckley, Esq. Respectfully,

WM. MUTH-RASMUSSEN.

Los Nietos, Feb. 24, 1874.

For the American Bee Journal.

Wintering Bees.

Could I have ordered the weather the past winter I could not have been suited better. Our losses had been severe the two preceding ones, causing much anxiety. The past winter will throw much light on many points that have been suggested as the cause of loss. We have had warm spells frequently, which seems to be additional proof that steady cold was at the bottom of the trouble.

That dysentery is not caused by the quality of the honey is strongly proved by there being none of it when they have been kept sufficiently warm. I know a lot of bees that have been kept in the cellar since the tenth of November, where the mercury has not been below forty-two degrees nor above fifty degrees during the time. Never in better condition—combs bright and clean. I hope that whoever has kept *strict* account of the temperature will report condition of their bees, whether disquieted from any cause, and how much. We shall, after a while, get the proper temperature, so that we can winter bees as safely and surely as cattle or horses.

I have much more to say on this subject some day.

M. QUINBY.

For the American Bee Journal.

A New Smoker.

MR. EDITOR.—Seeing so many contrivances for smoking bees, I will send you directions for making a smoker that I have used and like very much. Take a piece of paper eight inches by twelve, and with corn silk make a solid roll of about one inch thick; paste down the edge of the paper and you will have a smoker that you can depend on. You can blow the smoke where you want it; it leaves no bad effect on the bees.

A great many bees have been lost here this winter, I think it was because they were all old bees.

C. W. STOKES.

Atchison, Kan.

For the American Bee Journal.

Which is Best?

We keep bees for the honey and wax they secure us. Aside from these objects, we should no more think of keeping them than of keeping hornets and wasps. As honey is the principal object, the number of colonies kept, and the character of our hives and honey receptacles, should be formed and regulated with reference to that object. They, in the number of their colonies and hives, may be so regulated as to give a very handsome return at a very trifling expense, or so as to require considerable expense, a great deal of care and perplexity, and their product be very trifling and unsatisfactory.

In the opinion of many, success in bee-keeping depends upon luck and chance. Care and skill, with intelligence, will be likely to secure good luck or success. The careless and inattentive will fail, there is no chance in this matter. If the number of colonies in a field exceed the capacity of the field, some of them must perish. If the capacity is greatly exceeded by the number of colonies, probably all of them will perish. The number of colonies will be increased by swarms in the swarming season something in proportion to the size of the hives. Very small hives will probably give most swarms. Very large hives will probably not swarm at all. If standing in the hot sun, the size of the hives does not secure against swarming. Effectively shaded from the sun, a hive of one thousand cubic inches, or more, will not be likely to swarm; a hive of two thousand cubic inches, or less, will be likely to cast from one to four swarms. The operation of these hives will be, the small ones will average two or three swarms each. The providing for three or four colonies for winter will leave little room for surplus.

If we commenced with one, at three swarms from each hive, the first season there will be four, the second season sixteen, the third season sixty-four, the fourth

two hundred and fifty-six. In a field that will sustain but about thirty swarms, they must most of them perish the third winter. In a field that would sustain sixty swarms only, they must perish the fourth winter; and some of them have been fed the third winter or have perished then.

Suppose that, instead of thirty small swarming hives, we place eight or ten swarms in hives of about twenty-five hundred cubic inches in a breeding and wintering apartment, with surplus honey boxes to contain one hundred pounds of surplus honey in intimate connection with the breeding apartment; if effectively shaded from the sun, they will average in a good season one hundred pounds each.

If they are screened from the heat of the sun, and in a cool place, there will very few, if any, swarms issue from them. If the season is an unfavorable one, they will find honey enough to fill their wintering apartments, and furnish some surplus. There is no danger of starvation. There is room for thirty colonies with little surplus; there is surely, then, room for ten colonies and some surplus in a poor season.

The investment in bees in such hives has something of permanency. The keeper need have no fear of loss from starving. He need not have any anxiety about his bees running out. If his stock is kept within the capacity of his field, if his surplus boxes are placed on in season, and his bees duly shaded, he has but little trouble or care about them but to remove the surplus boxes when filled, and supply the empty ones when needed, and secure his surplus honey.

It is necessary to observe these few things:

1. Limit the number of your colonies to the capacity of your field. Better to fall short of than to exceed the number that will have full employment in gathering the honey.

2. Give ample room in the breeding and wintering apartment—two thousand five hundred inches at least. Then if you have not too many bees in your field, it will be unnecessary to feed them, with the ample room for stores; and it is simply the question whether you will have the honey in your field with little trouble and care, or will you live in constant care and perplexity, get at most not one-tenth of your honey, and have your bees almost all perish in every three, four or five years.

JASPER HAZEN.

Woodstock, Vermont.

Waldridge, a German writer, says he saw forty large bee-hives filled with honey, to the amount of seventy pounds each, in two weeks, by being placed near a large field of buck-wheat in flower.

For the American Bee Journal.

"Our Contributors."

I find the AMERICAN BEE JOURNAL invariably both interesting and instructive. Often re-reading many articles which have appeared in the last eight months I feel like thanking all the correspondents, both old and new, for contributing to make us such a readable paper.

While I deeply regret that Mr. Langstroth has been unable of late to contribute anything to the pages of the JOURNAL from his rich store of knowledge and experience, I am pleased that Mr. Quinby again favors us with occasional articles. Although this is an age of progress and new ideas, we cannot well dispense with the safe counsel and instruction of these two veteran bee masters. Mr. Quinby gave us a noble and dignified article on one of the knotty questions of the day, and while I must dissent from the conclusion he arrives at, in regard to a warm house being the only safe way to winter bees, I admire the spirit and style in which his ideas are given.

Mr. Chas. F. Muth tells us of the successful wintering of bees on their summer stand by himself and some of his neighboring bee-keepers, and thinks that it can be made uniformly successful. Will not those who adopt this plan of wintering, give us more particulars. I know that there is quite a difference in wintering in the vicinity of Cincinnati and colder locations, though that vicinity was not exempt from the bee disease. But I don't intend to discuss this subject here, I merely wish to call out "Our Contributors."

We have not heard lately from Mr. Bickford who used to practice successful wintering out doors, in a colder climate than Cincinnati, and who gave some very interesting articles on several subjects. I know that the readers of the JOURNAL would be pleased to hear from him again.

Let not "Novice" be discouraged in the good work he is doing, even if patent hive men and others who are trying to humbug the bee-keeping community, do fly into a passion and use discourteous language because their tricks are exposed.

And "Gallup"—how could we do without his practical, strong, common-sense articles; deducted from his close observations and reasonings. Though an old hand at the "bee business" he is far from being an "old fogey" and don't intend to be a whit behind any new ideas and progress in his favorite occupation.

Thanks to friend Adair for his many excellent contributions. I hope that he will continue to give us the results of his scientific and theoretical investigations, and the practical working of his "new ideas."

There are many other names I might

mention which I would like to see continued upon the list of contributors, in fact I would like to have them all continued.—Some who used to write very acceptably do not write as often now as I would like,—such as Grimm, Argo, Price, Nesbit, the Davies, etc., etc., with my quondam friend Thomas, who, although he may not be able to convince us that he still has the “best hive in America,” I know he can write interesting and instructive articles on other subjects. His idea about that bee disease, in my opinion, is about the best that has been advanced.

And will not our sister bee-keepers let us hear from them oftener? What say you Miss Cyula Linswick, Miss Ella Dunlap, Miss Katie Grimm, Mrs. Harrison, and other sister bee-keepers? I can assure Miss Linswick that her delightful sketches are eagerly read and admired by one, and I believe by all the readers of the JOURNAL. When we have young ladies visiting us and I wish to interest them in bee-keeping, which I am sure to do, I read to them Miss Cyula's narrative of her experiences and Miss Katie Grimm's account of her great honey harvest.

Last but by no means least is the contributions of selections and translations from foreign bee journals, which I hope to see continued.

It requires variety in a paper devoted to such a specialty as bee-keeping to make it interesting, and that the numerous correspondents of the AMERICAN BEE JOURNAL have given it, and that is one cause of the strong attachment felt for it by its subscribers.

THADDEUS SMITH.

Bees Eating Grapes.

As I have cultivated bees in a part of France where grapes are the main crop, near the hills of Burgundy, celebrated for the wine produced by the culture of the sugared pincen, a grape richer in sugar than all the American kinds, I think I can bring some light on the discussion existing between Prof. Riley and my friend Kruschke.

There has been considerable discussion between the wine growers and the bee-keepers, in the above named district, and it is, to say, very well established that bees are unable to cut the skin of grapes.

In order to ascertain the fact the most juicy and sugared grapes, pears, sweet cherries, plums, apricots, etc., were put inside the hives; never have the bees attacked them, if they were not previously scratched. The ex-

periment was repeatedly made, it was discovered also that the first cutting was made by a kind of wasp, or by birds, or caused by the rain falling when the fruit was ripe. (See the seventeen years of the French journal *L'Apiculteur*.)

In Italy the same experiments have led to the same result.

It is therefore unjust to accuse the bees of the mischief. It is to be regretted to see such distinguished men, as Prof. Riley, bring forward the accusation, and some bee-writers sustain it, who, with a more careful observation would have arrived at altogether different conclusions.

It is not the first time that scientists have received lessons from practical bee-keepers. At the end of the last century Shirack had to contend with the scientists of his time, to prove that bees can raise queens from worker eggs.

Later, Dzierzon has proclaimed the parthenogenesis, in spite of the European scientists, whose ideas were knocked down by the discovery.

Later, Langlois, a french scientist, made an ass of himself in advancing that the cells and the food were able to change the sex of bees.

Last year, Prof. Agassiz was laughed at by the bee-keeper, for his idea on the building of the cells by the bees.

It happens too often for the progress of science that, in order to get fame, some writers bring forward as fixed facts, some ideas altogether contradicted by experience. Some years ago Prof. Warro amused the readers of the *American Bee Journal* by his theory of procreation in bees. To-day it is Mr. Adair who has inherited that situation, with his balanced colonies, his wings which act as lungs, and probably as nose and ears. Fortunately these hazarded assertions are too baseless to obtain credit among the bee-keepers. They show how great is the diversity of minds in the human race.

CH. DADANT.

Hamilton, Ill.

East Friesland, a province of Holland, containing 1200 square miles, maintains on an average, 2000 colonies of bees per square mile.

How to Extract Honey.

With a good extractor, one that will hold the comb firm, you can extract honey from new comb without breaking it; and—in addition to obtaining enough from a few hives to pay for a machine—extracting it will leave the bees in a much better condition.

Take out the outside combs in which there is no brood. You can not extract old, *thick* honey from combs in which there is brood *unsealed*, without throwing out more or less brood and it is best to let such combs alone. If the day is warm extract the honey at once. If the weather is cold, put them in an empty hive and carry them into a warm room, where they should be left a few hours, or until the comb will bend slightly without breaking, before extracting the honey.

Townley, Mich. J. H. TOWNLEY.

Bees vs. Fruit—A few Facts.

"ARGUS" TO PROF. RILEY.

With all due respect for Mr. Riley as an entomologist, allow me to say that, in my humble opinion, he has signally failed to justify himself in recommending the destruction of bees, even in extreme cases. But to the question, "Do bees injure fruit?" Mr. Riley says they do, and also says, "I never fear the truth and *never write anything* that I am not *ready* and *competent* to defend." Now, all this may be true, Mr. Editor; but we must make considerable allowance for youthful zeal. I find, as I grow older, I change my mind on many things; and I even dare to think as Mr. R. gains in years and experience he, too, may change his opinions, not only upon this subject but upon others, his ideas on the grape vine aphid included.

Permit me now to look briefly at the proof that he offers, to establish what he pleases to call the truth. The first is a letter from I. W. Penn, who says:—"I like fruit, large and small, to become thoroughly ripe; but from early to late in the season the place is infested with myriads of bees belonging to persons that fail to provide food for them. * * The choicest peaches, the sweetest pears and the most delicious grapes are hollowed out by the starved and ravenous insects." Looking at this testimony your readers would be apt to come to the conclusion, if they had never seen bees, that they had a bill like a bird or teeth and stomach like a squirrel. Look at the statement "the fruit was hollowed out;" and again, "I and others of the family were severely stung by the bees lurking within." Now, would this kind of evidence satisfy a competent jury? True, it might be called circumstantial evidence, but not enough to

convict and punish with death. Now, would this species of reasoning satisfy Mr. Riley on any other subject? Would he not require a more careful examination before jumping to a conclusion? If not, I do not think he is the fortunate possessor of the mantle of Father Walch.

The next witness on the stand is J. H. Werlady, who says he was so annoyed by his neighbor's bees that he lost his entire peach crop, which was rendered unfit for market by their injuries. This witness might just as well be dismissed without comment, seeing there is not one single proof offered. Now let us hear the testimony of Mr. Riley himself:—"This objection to bees under certain circumstances comes from the real and direct injury they do to the fruit." This is merely gratuitous assumption. Again, "The mouth of the honey bee is fitted both for lapping and biting." Well, for the sake of the argument, suppose it is; how far would this testimony go to convince a jury, if Mr. Riley was brought up on a similar charge? It will doubtless be very clearly seen by every intelligent and candid reader that the statements given are very far from being sufficient to establish the fact that bees injure fruit.

Now let us go back to Mr. Penn's orchard and see if we can't find some other cause for the destruction of his fruit. "Here are also some ornamental trees and evergreens, including an Arborvitae hedge to shelter the small birds, which became very tame under the kind of treatment they received." I ask Mr. Penn what he thinks the birds live upon? Not all insects I can assure him; and, to convince himself of this, let him go into his orchard by the peep of day, and perhaps he will find the birds as well as the bees enjoying themselves. I have been longer in fruit than bee culture, and I know the birds have had many a dainty meal of the best of my grapes, cherries and strawberries; and I also know that at times they have had the lion's share. Mr. Penn says he is kind to the birds, doubtless convinced that they are his friends. A few years ago a fierce controversy was waged upon the bird question; some thought they did more harm than good; but mercy and truth at last prevailed, and now they enjoy their full liberty both in the field and orchard, for the good they do. Again, Mr. Penn says, "My loss last year in money value was considerable." This is only one side of the money question; he has failed to give the bees any credit; but I hope in time he will learn better, and, as R. Holland truly remarks, "Any one who goes through the world with his eyes open, is sure to find out something that even professional naturalists did not know before."

Some seasons fruit "don't set good." Why? I have in my mind at present a large

pear tree whose branches in the spring were white with bloom; but there came one of those heavy, dashing rain storms and washed out the pollen, and of course there was little or no fruit on the tree, except one branch, and that was loaded with fruit, for it hung under and was protected by the eaves of the house. If there had been plenty of bees in the neighborhood to have fertilized the rest of the tree, more fruit would have been the result. Providence never works without means; and it is admitted by all naturalists, and Mr. Riley himself will not deny it, that the bee is a means of not only giving us more fruit but a greater variety. Art in this has done much, but Nature more. With this view of the matter the means that Mr. Riley has recommended for the destruction of bees will not justify the end; for it has been observed, from the days of Aristotle to the present time, that where there is an abundance of bees there is an abundance of fruit; therefore the more fruit the more money. These facts are so well established no proof is required.

But there is something else, of a serious nature. The flight of a bee is ascertained to be about a mile in two minutes. Now, the bees that fill their sacs (or first stomachs) at Mr. Riley's poison dish will not all die there, but thousands will fly home and deposit their load in the hive. If this honey is used at home or taken to market, who will be responsible for the consequences? I think friend Riley has made a great blunder, and I would counsel him to be careful where he buys his honey, for if he has any facts to communicate upon this important subject, the public cannot well spare him at present. In conclusion I would ask him if he ever kept bees and how he managed to keep them at home?—*Rural New Yorker*.

For the American Bee Journal.
A Prolific Mother.

In the queen bee, the mother of the colony of bees, we have an abundant breeder, amounting to many thousands each year of her life. All the bees in the old colony are her progeny until three weeks after the issue of the last swarm from the hive. As the old queen issues with the first swarm, all the bees in that colony for the whole season are produced by her. Likewise all the bees which constitute the after-swarm, sometimes amounting to three or more swarms. The first swarm with which the old queen issues sometimes gives a new swarm. That is her progeny.

We have many thousands in the first swarm, many thousands in the after-swarms, many thousands in the first swarm produced by the old queen after her establishment with the first swarm in her new home, and many arising from her

brood left in the old hive at the time of her issue with the first swarm. I will not name numbers, as there are great differences in the strength of different colonies, and it would be only guessing; this one can do as well as another. It is enough for our present purpose to understand that it is a sufficient force, with the late additions made by the young queens, to carry two, three, four or five colonies through the winter. But the expectation of much more than this may be considered a vain hope. By following this course from year to year with small hives, a large number of colonies may be secured. But little surplus honey is secured, and the point is soon reached where the field will not supply food for their support, and large numbers, sometimes all of them, winter-kill or starve to death.

I think it must be apparent to every reasonable, reflecting man that if the labor can all be expended and its profit all secured in one hive, and all but that part of it necessary for winter stores be secured in surplus boxes; instead of being very trifling in amount, from one-half to three-fourths of it may be secured in surplus boxes in the best shape for market. Of this I have no doubt, having secured from one hive in one year one hundred and forty pounds, in another year one hundred and forty-five pounds, and in another two hundred pounds. In other years less, varying from one to two hundred pounds.

In my operations with this hive, I have known no swarms to issue except from neglect to give the room furnished by the surplus boxes before the preparations for swarming had commenced, or from neglect to sufficiently guard from heat.

Last November I removed from the vicinity of Albany to Woodstock, Vt., probably to close my days. My bees I left in care of my son, who informs me by letter that but one colony has died.

JASPER HAZEN.

For the American Bee Journal.
A New Subject (?)

The subject in regard to the mortality of bees, during the last few years has been discussed in nearly every number of our journals, ever since that fatal winter.

I would now like to ask: Have we finally discovered the true cause? Can we prevent it in the future? Quinby, Dadant, "Novice,"—in fact, nearly every bee-keeper of importance in the land, have given their experiences and opinions. One says it is on account of the long continued cold; another lays the fault to bad honey; another to bad ventilation, and dampness; another calls it an epidemic.

If these questions, as to the cause, were

put to me, in conclusion at the end I would probably reply "yes"; for there seems to be some truth in each statement. I think many have come to the conclusion, after perusing the various reports, that if we keep our bees in future in a place where the temperature will average forty to forty-five degrees, and where the dampness will not accumulate, and where the bees will be kept dark and quiet, there is but little danger of loosing them by dysentery.

The loss of *our* bees, winter before last was the cause I have no doubt of too cold winter quarters. We kept our bees last winter in a clamp made similar to one described in the AMERICAN BEE JOURNAL, Vol. ix, No. 2, page 38, by Chas. D. Hibbard. We, however, made some improvements by packing one foot of straw against the ground walls, and also on the bottom. We turned the bottom boards of hives upside down and set the hives on the four inch cleats that are nailed on the bottom of the bottom boards, thus giving them four inches open space on two sides for ventilation. We put them two deep and covered them with two feet of straw. The covering of the clamp consisted of one foot of straw upon which we threw about one foot of dirt. Next time however, we will put on even more to make sure.

We put in sixty-one colonies, in a room eleven by sixteen feet, centre of roof ten feet from bottom. Could put in about twice as many.

In this nest of straw as it were, they kept up a temperature ranging from thirty-five to fifty degrees—forty-five being about the average. They came out effected a little with dysentery; those that set in the upper tier were generally less effected than those on the bottom; and as some of the frames were a little mouldy, we came to the conclusion that there was too much dampness. Three were found dead, four have since died. The death of a couple might be laid to the fact that they were but few in numbers, and these were mostly old bees. If there be any truth in the young bee theory, the more we know about it, the better. Another fact came to my notice that might assist in verifying the young bee theory, it is this;—I made three stands in August, two were supplied with capped queen cells, the other had an old queen, these are all living though they were weak in numbers in the fall, but as I fed them well with sugar syrup, they kept on breeding longer than others not fed, neither were they badly effected with dysentery.

Make it then a rule to give bees the conditions above named, viz: warmth, dryness, plenty of ventilation, feed them *all* in the fall, keep them in perfect darkness, disturb them as little as possible, and I think dysentery, or "that bee disease," will be extinct.

J. D. KRUSCHKE.

For the American Bee Journal.

Apiculture in Kansas.

MR. EDITOR:—This winter has not been a very favorable one on bees in this State. It has been a winter, like all its predecessors, peculiar in many respects. The thermometer in this vicinity has never once been below zero during the winter months just past. There has been a vast amount of freezing and thawing, with protracted spells of weather during which the air was in a very humid condition. In noticing my bees lately, I saw more signs of mouldy combs than any preceding winter. Such is especially the case with those wintered on their summer stands. Why combs become so very mouldy in some hives while in others the combs are perfectly bright, where all probabilities would lead one to suspect a like result, has always been to me a little mysterious; but the ventilation, quantity and age of bees, and quantity of comb in the hive, are conditions which if properly understood would solve the problem to a great extent, no doubt.

The Legislature of this State passed an act approved March 6th, 1873, relating to the collection of statistics of the industries of the State by assessors. Apicultural statistics were collected under the following heads, viz.: "Number of stands of bees, native and Italian, to be stated separately, kind of hives used, number of pounds of honey produced, and the source from which the greatest yield of honey is gathered." The secretary of our State Board of Agriculture in his report for the year 1873—which was laid before the Legislature a short time before its adjournment—gives the following, which is the aggregate synopsis taken from the statistics relating to bee culture, and which were taken for the first day of March, 1873:—

Number of stands of native bees,	13,245
“ “ “ Italian “	1,640
“ “ pounds “ honey,	135,384
“ “ “ “ wax,	3,686

The secretary also reports the following: "According to the census returns of 1860, the number of pounds of wax returned was 1,181; in 1870, 2,208; in 1872, 3,686. The number of pounds of honey returned in 1860 was 16,944; in 1870, 110,827; in 1872, 135,384. In 1873, 14,885 colonies of bees are reported, 13,245 of which are native. . . . Allen County reports 'sunflowers and weeds and flowers generally' to be the best source of honey in that county. Twelve counties report buckwheat; three counties report linden. Linden, sumac, white elder and smart-weed, appear in most of the reports. . . . Buckwheat, clover and basswood, are reported as giving the greatest yield of honey."

Perhaps the report by counties as given

by the secretary would give the reader some idea of where the best portions of the State for bee-keeping are found, but we have not deemed this of sufficient importance to the general reader to copy it from the report.

M. A. O'NEIL.

Black Jack, Kan.

For the American Bee Journal.

My Experience.

Mr. Adair, in his article on the wings of bees, holds out the idea that to cut a queen's wing is like taking away part of a man's lungs. I will give you my experience during the last year with stocks of bees with queens' wings clipped—some a little off, some half off, and some more than half off, just as it would happen in giving a clip as they would run on the comb.

I moved twenty-four of my best stocks to a large poplar grove (*Liriodendron tulipifera*) on the 17th day of last May. They were in two-story Langstroth hives, twenty frames, ten by seventeen inches, and by June 5th they were crowded and began to swarm. By the 13th I had to take 1263 pounds of honey from them with the machine, except 161 pounds that was in boxes. I was careful to remove all queen cells, but in about eight days they were swarming again, sending out enormous swarms, so that on the 24th I had to take 1440 pounds more honey with the machine. By this time I never had stocks so strong in numbers. Now if clipped queens do that way I say "*clipp em*" every time—Gen. Adair to the contrary notwithstanding—for had not these queens' wings been clipped, I perhaps would have lost half of the bees, for on the day before I went to take the last honey there were eight swarms out. The owner of the lot where the bees were, knew nothing about taking care of bees. I had them so arranged that the queens could crawl back into the hives so of course the swarms would go back themselves. Now if any one knows of queens being injured by clipping let us hear from them.

I then moved those bees to a linwood grove on the 26th (except two stocks that were so crowded that they smothered on the way). The weather set in very wet and linwood bloom was worth but little, so that I only got 850 pounds of honey from that source. Eight of the best of the twenty-four hives had on three boxes each (that would hold about sixteen pounds each) from May 17 until June 13, and only had 161 pounds of honey, while the other sixteen hives gave 1102 pounds of honey, being 69 pounds each, while the others only gave 20 pounds in the comb, each, making a difference of only 49 pounds each in favor of *stung* honey.

I have now one hundred and twenty-two stocks in the bee-house. I gave them in the fall about 1100 pounds of "A" coffee sugar, made into syrup by putting one pound of water to two pounds of sugar and let it boil a few minutes, and feed so that the bees and honey in each hive would weigh about twenty pounds, my bee-house is an upper story, inside sixteen by eighteen feet, eight feet high, double walls filled with saw-dust, the temperature has not been below thirty-nine degrees Fahrenheit this winter. In the last twenty-three days I have swept up eighteen pounds of dead bees—please tell me what is the matter. The summer entrance of the hives are open, upper story off, and the cover laid on the lower story. The hives are piled three to four hives high, in four rows, with room to walk in front of each row. The temperature has been up to fifty-five degrees, two or three times for perhaps a little over a day at a time; it generally stands at about forty-four degrees. The room is perfectly dark with ventilator eighteen by eighteen inches regulated at will. I enter the room through a trap door in the floor.

On April 15th my bees were reduced to ninety-two in number and several very weak. In the last ten days I have fed my bees two hundred and eight pounds of "A" coffee sugar, and if this cold weather continues ten days longer, I will have to repeat the dose, which goes to show that the weight of the bees and honey in the fall should be more than twenty pounds for some winters. That has always been enough with me, heretofore.

Last spring I had bees in forty-four hives, which gave altogether a little over 4,000 pounds of honey. I have sold 3,600 pounds of it, at an average of twenty-three cents per pound. The balance we have used, except about 200 pounds of bass-wood honey, that was gathered in very wet weather, and has soured a little. This I will feed to a few hives when the weather gets warm, and observe the effect it will produce on them. P. W. McFATRIDGE.

Carthage, Ind.

The instinct of bees in the construction of their cells has always been an object of wonder to those who are capable of appreciating it. Every cell has straight lines and sharp corners; but never does any cell present its sharp corner to its neighbor's cell—a soft even side to every neighbor's side. Each fit to each, firm to support, and yet soft in the contact. No interstices are left where filth might accumulate to annoy and defile. Thus let man meet man as they tread the crowded path of life. Always a side to your neighbor that is soft and strong. No sharp corner of selfishness that will pierce your brother.—*Arnot*.

American Bee Journal

W. F. CLARKE, EDITOR.

CHICAGO, MAY, 1874.

Clipping the Wings of Queens.

For some years past it has been customary with the best apiarians to clip the wings of queen bees as a precaution against swarming.

At the annual meeting of the North American Bee-keepers' Society, held at Louisville, Ky., in December last, doubts as to the propriety of this course were raised by Gen. D. L. Adair, one of the best apiculturists, both as to theory and practice on the continent. In a paper on the wings of the bee, it was contended that various important functions, breathing included, were performed by these organs, and it was argued that they could not be mutilated without injury.

This paper having appeared in the reports of the Louisville meeting published in this and other journals, has naturally led to the matter being pretty freely debated among bee-keepers, "Novice" in his "Gleanings," has pronounced strongly against Gen. Adair's views, but failed to do him the justice of publishing the paper itself. Our last issue contained a very able reply from Gen. Adair, to "Novice's" criticisms.—The subject has also received attention in other quarters.

At the annual meeting of the North-Eastern Bee-keepers' Association, which met in Utica, N. Y., during the first week in February, this subject was very fully discussed and a number of the most experienced bee-keepers gave it as their decided opinion, that clipping a queen's wings does not injure her capacity for usefulness. Secretary Nellis had practised clipping five or six years, and observed no bad results. At the present time, he had more than forty queens with wings cut off, and considered them as servicable as others. Captain Hetherington, we believe the largest bee-keeper on this continent, also practised clipping. He sometimes had three and

four hundred clipped at once. Mr. Doolittle had done more than all the rest, for he had tested the capacity of a queen who not only had her wings but also a hind leg clipped off, and yet did effective duty for four years. The general weight of testimony was decidedly in favor of clipping. Mr. Quinby however, who proposed the question for discussion, was very reticent in regard to it, expressing no definite opinion, but merely testifying that he had known a case in which a swarm went out with a young queen, leaving the clipped queen in the hive. Other speakers incidentally admitted that clipped queens were apt to be superseded, the bees evidently regarding them as deformed or crippled.

We have never tried this practice, and are therefore liable to be considered incompetent to say anything against it. But we can at least be permitted to state why we have never tried it. One reason has been, that we object, on principle, to the unnecessary mutilation of the creatures domesticated by man. Docking horses' tails, clipping terriers' ears, ringing pigs' noses, picking the feathers off live geese, cutting off the combs of game cocks, and the like, are all of a piece with clipping the wings of queen bees. Another reason for our avoidance of the practice has been, that we are unable to see how it can be kept up without injury. If it is a wise and necessary thing to do, then it must be done to successive generations of queen bees. Now, though no serious evil may result from its being done once in a while, it must entail weakness if done continually. A woman, here and there, may, by accident, lose an arm without perceptible detriment to the race; but if every bride were deprived of an arm on or before her marriage, we are of opinion that the mutilation would tell disastrously upon coming generations of human beings. If General Adair should prove to be right, and the important functions he suggests are in reality performed by the queen's wing, then assuredly serious injuries must result from the mutilation.

Moreover, we are opposed to all unnecessary meddling and fussing with bees. There is a wise management and supervision of the busy little workers, which is man's part

in the production of honey, but beyond this it is impertinent interference and annoyance to disturb their wise economies. The swarming instinct may be checked, regulated, and watched over, but we do not believe it can ever be annihilated, or if it can be, it will be at the cost of such a change in the disposition of the bee, as will greatly lessen its value to man as a gatherer and storer of honey.

Finally, we believe the All-wise Creator made no mistake in giving the queen-bee wings, and that it is, on the whole, best she should be permitted to retain them. One of the speakers at Utica said he began the clipping business by clipping off one of the four wings. Then the queen went with the swarm. So he took to clipping off "every wing entirely." Another said, "Queens cannot do anything with their wings but go through the air. Their business is in the hive; wings are of no use there." It is astonishing to see with what cool presumption some people constitute themselves advisers extraordinary to Infinite Wisdom, and proceed to carry out improvements in the Creator's plans. The queen-bee had wings when the Lord God surveyed his finished works, and pronounced them good. An inspection of them now would not result in the denial of wings to the royal insect, or in any other improvement whatsoever, seeing that all the Divine works are, like their glorious Maker, perfect. The Creator's fiat is of more weight by far than the creature's fancy, and we are content, in our bee-keeping management, to conform to all the Divinely-established laws of bee-life, instead of trying to change, or even presuming to suspend them.

Why don't Farmers keep Bees?

Mr. Quinby, of St. Johnsville, N. Y., a high authority on everything pertaining to bee-keeping, discussed the above question in a paper read before the North-Eastern Bee-keepers' Association at its recent annual meeting. He assigns four reasons for the neglect of bee-keeping on the part of farmers. 1st. They don't know how. 2nd. They doubt if it will pay. 3rd. They have had such poor success in wintering bees. 4th. They are afraid of being stung.

To these reasons, quite sufficient in themselves to account for the fact that very few farmers keep bees, we would add another—namely, want of enterprise. There is a quality for which successful men of business are noted which is very scarce among farmers, and which we call "enterprise." It leads to the trial of new and improved methods; to the making of ventures here and there on the principle, "Nothing venture, nothing win;" to an intelligent scrutiny of things generally; and to energetic action in any direction that seems to promise adequate reward for diligent effort.

For some cause or other, this quality is lacking in the great majority of farmers. Were it not so, there would be more manuring and better tillage of land; fewer bars and more gates; some display of taste about rural homes; a general adoption of improved stock; carefully kept farm accounts; and many other things that are as rarely found around country homesteads as hives of bees.

Enterprise is the result of education, and of that sharpening of wits which comes with the association of minds and the friction of ideas in the social and business contracts of life. Agricultural colleges for farmers' sons, and for any who contemplate rural industry; the circulation of agricultural periodicals and books; more visiting and travel on the part of farmers and their families; the establishment and energetic working of farmers' clubs; and such like means, will tend to cure an evil whose presence is indicated all around us in bad farming, woe-begone looking homes, tumble-down fences, ill-bred stock, absence of gardens, and last, but not least, neglect of bee-keeping.

THE ILLUSTRATED JOURNAL.

As a specimen of typography this magazine is deserving of all the praise that has been bestowed upon it by the Press of the country. All the engravings are, without exception, of a high degree of merit, both as respects the subject and the execution. The literary department is well sustained. The number is filled with interesting reading of permanent value. A volume of this beautiful journal will be a source of pleasure to every possessor of it. Published by the American Publishing Company, Room 27, Tribune Building, Chicago, for only \$2.50 a year.

QUESTIONS AND ANSWERS.

CONDUCTED BY CH. DADANT.

QUESTION.

In Vol. ix, No. 5, page 100, of the AMERICAN BEE JOURNAL in an article from C. P. D. that no queen can occupy more than 80,000 to 85,000 inches of brood at one time. J. B. R. Aberville, Pa.

ANSWER.

There is a *lapsus plumar* or typographical error, it is not 80,000 inches, but 80,000 cells of brood.

QUESTIONS.

1st. I have four swarms. One I want to transfer to a Langstroth hive, I would like to know how to transfer them.

2nd. Give me some recipes for bee stings, and tell me where I can procure bee gloves and a good smoker. Mrs. W. M. Elyria, O.

ANSWERS.

The best time for transferring bees is April and May. Choose a warm day; send some puffs of smoke in the hive to be transferred and remove it, putting a decoy hive in its place, carry the hive a few yards from the apiary, invert it and put upon it a box or empty hive, as nearly as possible of the same width, wrap them up with a cotton cloth to prevent the bees from running outside, while drumming the bees in the empty box.

The drumming is done with two sticks of wood and should last from fifteen to twenty minutes. It is not necessary to drum all the time, but at intervals. When only a few bees remain in the combs, remove the box, in which the swarm has ascended, and put it in place of the decoy hive. The bees that are hovering about will enter it. Take care not to shake or jar it, for the bees would fall on the ground.

Bring the hive, deprived of its bees, in a room; with a long knife loosen the combs from the sides of the box, and pry off one side with chisel and hammer. If there are sticks across it, remove or cut them.

You should have prepared beforehand some No. 16 wire, cut in pieces half an inch longer than the height of the frames, in which you intend to transfer. The wires are bent at right angles, three-eighths of an inch from both ends. With an awl bore a small hole in the edge of the upper part of the frame, three or four inches from the end; then, with a light hammer drive in the end of one of the wires; the opposite end is driven in the lower part of the frame; put two or three wires at equal distances. Then lay the frame upon the table, with wires under. You sever the first comb from the hive; cut it off the exact measure; put it, or part of it, in the frame, so as to fill it, you fasten two or three wires to hold the combs in place, where they will remain straight and firm.

To fix the small bits of combs, put across the wires some stiff straw or dry weeds to make a kind of grate which will hold the combs firmly.

Take care to have the comb in the same way that they were in the hive. Do not put drone comb in the frames, and when you put the frames in the hive be careful to put all the brood combs together.

The vacant space in the hive should be filled with empty frames, or better, with worker combs fastened in frames, if you can get some. The proper place for drone comb is in the surplus box if you have an extractor.

Do not put the frames in the hive as soon as the combs are fastened in them, but put them somewhere to drain; for the less running honey you have in the hive the less will be the danger of robbers. When all the frames are placed, shut up the hive and bring it on the stand where the transferred hive stood. Remove carefully the box containing the bees, put the frame hive in its place, spread a cloth in front of it, and shake the bees on this cloth. As soon as they have nearly all entered, contract the entrance to help the bees in repelling the robbers.

Six or eight days after you should visit all the frames, one after another, and remove the wires with a knife.

Some bee-keepers in transferring use twine, some employ sticks of wood. I have tried both, but I find wire greatly superior. Do not be alarmed at the *immensity* of the work, but try it and you will succeed. The transferring is the work best adapted to familiarize the beginner with the bees and the building of comb.

2. Several recipes are given to remove the pain and prevent the swelling of bee stings. As both these effect very capriciously, sometimes the pain and swelling being immense, while at other times they are a mere nothing, all the remedies applied have in turn won and lost the reputation of being good for bee stings, while the truth is that not one is altogether effectual. The small drop of venom being deposited *under the skin*, no drug applied on the skin can penetrate deep enough to neutralize it. Yet when one fears that the subsequent effects will prove fatal, the application of compresses soaked in cold water are to be resorted to in order to remove the subsequent inflammation.

It is also an obvious fact that the human body can get used to the venom of bees, and that the more you are stung the less will be the pain and swelling of the sting. But as this last remedy is not very pleasing, I advise the beginners to avoid the sting as much as possible, and they can obtain this result in learning to handle bees.

First. Use a veil of black material put upon a round hat with a large rim, a common

laborer's summer hat is very good for that purpose. The veil passed around the rim has a rubber string which ties it against the neck.

Second. Use smoke to prevent the anger of the bees. For a smoker nothing is better than a small lump of white rotten wood perfectly dry, or a roll of linen or cotton rags interspersed with some sprigs of dry grass.

I have seen in Italy and in France several kinds of bellows and smokers; one which seemed to me very easy to manage was a tube of tin a little more than an inch in diameter and about eight inches long. This tube was filled with a roll of linen or cotton rags which burned slowly. To extinguish it the cotton roll was drawn inside of the tube and the tube was driven in the ground.

If bees are unusually cross, go before the entrance of the hive and send in two or three puffs of smoke; remove the cover of the hive, raise carefully the honey board, sending some smoke inside the hive. Remove the honey board, send a little smoke between the combs, and your bees will be in good disposition for the time of your operation. As soon as you see some bees running to and fro on the tops of the frames, quiet them with a little smoke.

Remember that the handling of bees is more easy between ten in the morning and three in the afternoon—in a clear than in a cloudy day—in spring and summer than in fall, and with Italians, pure Italians, than with black, gray or hybrid bees.

As to gloves, I cannot advise their use, for they are inconvenient. It is better to leave them alone, and to learn to handle bees.

QUESTION.

I prefer artificial swarming. How should I start the nuclei?

ANSWER.

It is impossible to answer your question. That will depend on the force of your colonies and the season. Here in Hamilton, Hancock Co., we start the first nuclei in May, but some years we have to defer it till the first of June.

QUESTION.

Are the bees, placed on a lawn, disturbed by the noise of a mower close to their hives, and will the moving of their stands to mow the grass have a bad effect? C. E. S.

Buffalo, N. Y.

ANSWER.

The noise of the mower will not effect the bees if it does not strike their hive. But the man would be exposed to their stings. To remove the bees at every mowing would be a big job if the colonies are numerous; and unless closed up before removing the hives the bees would be greatly disturbed. I advise to close up the hive before sunrise, and to mow immediately, so as to keep the bees closed as little as possible, taking care to open the entrances before the heat of the day.

To Beginners in Apiculture.

BY PROF. A. J. COOK.

ARTICLE II.

During the coming month—from the last of April to the last of May—our little models of industry and thrift will need but little care and but little attention, though they had best receive a great deal of the latter. How often we hear something like the following from our lady friends: "How I wish the same luck would bless me that attends Mrs. M. in the care of house-plants;" and as often we feel like saying: Undoubtedly it would, my dear madam, did you love them as well and care for them as assiduously. It is loving care, not luck, that keeps the noxious dust-particles and scale-insects from the houses, and makes the ruinous attempts of the little aphid and wee spider futile. So, too, with our bees. He who loves to watch, closely observe, aye, and tenderly fondle, will be the one whom "luck" will bless. So I say commence at once those frequent attentions which will acquaint you with the wondrous life-history of your little help-meets, make you to understand their needs, and so cultivate a reciprocal acquaintance that your closest scrutiny, so far from disquieting them, will be rewarded by the discovery of all their usual operations. The wax secreters will yield their palets, the little cell architects will rear their marvellous structures, the labor-worn gatherers will empty their stomachs, the staid old queen continue her egg-laying, and the old drones—those bummers of the hive—will stare at you. And all this before your very eyes. If you wish the best success, you must open the hives and make very frequent examinations, and thus very soon you and the bees will become mutually fearless, and you can abandon the sooner those cumbersome appendages, your bee gloves. But in all this, strive never to jar the bees, nor make a quick motion.

WITHIN THE HIVE.

Now, on the warm, pleasant days—you will open the hives on no other—what will you expect to see as you peer into the secrets of the hive's interior? First, if you have followed instructions, you will find almost every card of comb literally covered with bees; and if you examine closely enough, you may see the old queen herself. You will know her by her very long body, looking as though it needed a prop. Trouble not at its length, for from the queen's abdomen are to come those millions of eggs, the very germs of the apiarist's success—not now, but in a few weeks. You will also see the fat, corpulent drones, shorter than the queen, but larger than either queen or workers. Don't grumble at the plump, lazy gentry, for, unlike their

prototypes among us, they have their use in the economy of *their* society.

You next examine the comb. You discover that some cells are much larger than others. In these the drones are reared, while in the smaller cells the queen only places worker eggs, from which only workers will develop. Bending closely to the comb, in your eagerness to see all, you behold the long, cylindrical, slightly curved eggs, fastened to the very bottom of the smaller cells, for so early—in April—no drone eggs are to be seen. At the top of the cards of comb you note considerable capped honey, and so sharp has become your observation that you even observe that the caps are light colored, and slightly concave. Lower down on the cards you see patches of small cells capped over, but the caps are darker and convex. While looking at one of these cells, you behold with utter astonishment the emergence of a young bee all fresh and wrinkled. This, then, is the brood, and you are in raptures to see the large amount of it, and lisp something about the profit of early stimulative feeding.

Along the last of May, perhaps not till June, though the experience has been mine even the first week in May, you behold drone brood, in the large cells of course, and here the caps are not only convex, but even project, so that drone brood is a marked feature of the hive. Happy are you if you find very little of this. If there is much, cut it out and cast it away, for more than a very few drones are worse than useless. Now you must watch very closely, for soon there will be built from the face or edge of the comb great queen cells looking like wax thimbles. Now let your sharpened observation have its perfect work. Note which of your colonies is strongest in bees and brood, and cut all drone brood and queen cells from the other hives. Here is your opportunity to select in breeding bees.

TO REAR QUEENS.

Now watch for queen cells in your best colony, and so soon as you see them, with a creamy looking substance at the bottom, or at the risk of the bees swarming you can wait for them to be capped over, take one good one on each of four frames, or if this is not possible, cut out of the comb containing the cell a wedge-shaped piece, widest above, and place in an opening cut in other combs, being very careful not to press or injure the cell. And thus with four frames each containing a capped queen cell you can proceed. Now if you have a hive with frames a foot square, that will take twelve, divide the hive into four separate apartments, entirely close, by inserting division boards, and cover each apartment with a separate quilt. Place this

on a bottom board so cut that the bees can pass out of and into each apartment from different sides of the hive—to the end apartments from the ends, to the middle from the sides. Now take the frames with the queen cells, also well covered with bees, but in no case containing the queen, and place one in each apartment. Go to the other hives and take four frames with much brood and some honey, and also covered with bees. Put one of these into each of the apartments. The old bees will return to the old hives, while the young bees will not quarrel, and will be sufficient in numbers to cover and care for the brood. Thus in about sixteen days you will probably have four good queens, and will be prepared for artificial swarming, which I will describe in good time. Of course you will insert empty frames in the old hives, four in each, and destroy all the queen cells except the four you used. With the added room the old colonies will not probably build more queen cells. If they do build more, destroy them.

Be very careful that the bees in your nucleus hives cannot pass from one apartment to another under the quilts, else the first queen hatched will destroy all the others.

If before cutting out the queen cells the bees should swarm, you can hive them in another hive—which of course you have all ready—by shaking or brushing them into a box or basket, and emptying them on a board in front of the hive. In all such cases put at least one comb of brood in the new hive, for then they will scarce ever go off, but in this particular case it would be better to take from their old hive four frames containing the least brood, also four frames from the other hive containing brood—though in this case shake off all the bees—and give them to the new colony with four empty frames, and make the four nuclei in the old hive. The convenient form for nuclei is another recommendation in favor of the Gallup frame. Thus well started in queen raising, we will read the old JOURNAL, study our book, and by all means not forget to look very often at the bees, and wait for further instruction.

S. R. PECK, Newport, Ky., writes:—"The April number of the AMERICAN BEE JOURNAL contains an *Editorial* on the subject of *bee-stings* and their remedies, and concludes thus: "But we have discarded every other application since becoming acquainted with a *German* remedy lately introduced. A drop or two will remove all trace and effect of a sting in a very few minutes. It costs but a trifle per bottle, and a single bottle will last a bee-keeper for a life-time." Please inform us in the May number of the AMERICAN BEE JOURNAL where, and of whom, the remedy can be obtained, and oblige a subscriber."

Voices from among the Hives.

W. M. STEELY, California, Mo., writes:—"The black bees around here have all died during the past winter, except five colonies. I shall Italianize mine as soon as the weather will permit."

MRS. ELLEN S. TUPPER, Des Moines, Iowa, writes:—"My bees have wintered well. They have come out of the cellar in splendid condition. There will be a small fortune in bee-keeping this year."

W. S. IRISH, Norton Centre, Ohio, writes:—"The AMERICAN BEE JOURNAL is a welcome visitor, and I wait anxiously for each number. Long may it prosper and continue in its good work."

ABRAM BADGEROW, Georgina, Canada, writes:—"My bees are in splendid condition. I wintered them in the cellar under my dwelling-house. There was one hundred swarms, and I lost only two. I placed them on their summer stands March 18th. Last season I had about two tons of box honey."

H. W. S. writes:—"I think it would be well to call the attention of bee cultivators who also raise grapes and other fruit to the charge made by many that bees *depradate on fruit*, and to request them all to notice particularly the coming summer to ascertain the truth or falsehood of the charge. It would also be well to notice whether bees do any service in fructifying blossoms of fruit or vegetables. If many observers would publish the result of their observations it would be of great benefit. Fruit-raisers who have no bees are threatening to poison the bees, which they can easily do, and it will be very useful to convince them that the bees are their friends and not their enemies."

SAMUEL PORTER, West Oden, Mich., writes:—"I have been engaged in practical bee-keeping for the last two years. In the spring of 1872 I transferred six swarms into the movable frame hive. I increased them to nineteen, and lost nine in the winter of 1873. I then bought three, which raised my number to thirteen. I increased the thirteen to twenty-seven last summer, and got two hundred pounds of surplus box honey. I think that is not so very bad for a beginner. Bees wintered well and are in splendid condition at this time. I am now feeding mine on corn and wheat flour mixed. They seem very fond of it. Take from two to three pounds per day."

CHAS. F. MUTH, Cincinnati, O., writes:—"Bees wintered well everywhere apparently. It is, therefore, no wonder that mine have done so well under their straw mats. At an examination on the first of March I found them all (thirty-four stands) in first rate condition. Only one (one of the strongest hives at that) had lost its queen, and had to be united with another. Twenty-nine stands had two sheets with brood. One hive had brood in three sheets; two in one sheet; and one hive had fresh laid eggs only. A few days ago I found a queen crawling on the roof. The hive she had come out of had two sheets with brood. It was not very strong, but would pass for spring. The queen died, and the bees had also to be united with another swarm. To sum the matter up—I do not believe that another lot of thirty-four hives of bees in our part of the country wintered better than mine did, whether they were wintered in-doors or not, or whether they had sugar syrup for winter stores or honey."

H. E. CURRY, Cincinnati, writes:—"Vegetation is very forward. A week's fine weather will bring everything out in leaf. Bees that went into winter quarters in any kind of condition have come through with *flying colors*. I have heard of but few losses, and those were no fault of the bees. We are expecting the apples to bloom the middle of April, and then our honey season commences. If the weather is favorable, there will be considerable honey gathered from the fruit blossoms. All we need is the honey, and for that we have only to wait."

D. M. HALL, Lima Centre, Wis., writes:—"I commenced the winter of 1872-3 with 14 stocks of black bees and 2 of Italians. They came out all right in the spring. I did not lose any through the winter, but as soon as I stood them on their summer stands the black bees commenced swarming out and leaving their hives. I examined them, but saw no reason why they should, as they had plenty of honey. I changed them to eleven (Kiddier) hives. But it did no good. They would swarm two or three together, till I had only six left, and some of them were very weak. My two Italian swarms went to work well. I increased my six to twenty-two, and Italianized them all. I kept them in the cellar under my kitchen last winter, and they have come out strong this spring, and do not show any signs of leaving the hive. They have gone to work with a vim, and every pleasant day they make the air ring with their music."

A BURNT CHILD from Georgia, writes:—"I have been perusing the AMERICAN BEE JOURNAL of the last year, and like it so much that I want to continue it, and send herein the needful. I did not like the recrimination which was so rife, and am glad to see it lessened. Another objection I have is the space occupied by the business routine of the meetings of societies. It is not of interest to nine out of ten to read who is president or secretary of this or that society. Let us have more honey and less comb. But the article by Dzierzon—page 220 of the January number—is worth the full yearly subscription. In the March number, "Why don't farmers keep bees?" I will in part answer. Because they see some trying to do so, first swindled by a patent hive vendor out of four times the worth of the article; then buying a swarm of Italian bees, and finding the queen but two thirds the size of the representations of her on letter backs, and having her killed in a day or so by her followers, and thus losing enough to buy honey for years."

JAMES BOLIN, West Lodi, O., writes:—"Where the bees were properly cared for, they have wintered well, but where their owners trusted to "luck" in wintering, the loss, in some cases, has been quite severe, amounting, in one case that came to my knowledge, to four out of five, and in another to the entire stock. I put one hundred colonies in my bee-house Nov. 19th, and took them out March 2nd, and found them all right, but had the misfortune to lose one colony by starvation, with plenty of honey in the hive, during the severe cold weather that occurred the second week in March. The bees had clustered at the south side of the hive, which stood facing east, and the honey being at the north side the cold wind prevented their reaching it, so they perished. I have made the loss all right again, however, by putting the bees from a bee tree I found in the woods in the hive with the combs and honey left by the swarm that perished. Bees are working on rye flour, with a rush, whenever it is warm enough for them to be out of their hives."

M.D.D., Newburgh, N.Y., writes:—"I have a little to relate in the bee line, having just commenced the business by purchasing three hives of common bees, one of them without any honey, as I soon discovered. Of course they had to be fed or starve. I determined to feed candy.

Last fall a candy store in this city was overrun with honey-bees, so completely were they starved out here. I asked them what kind of candy they worked on, they showed me some made in bars called vanilla chocolate candy, that is candy made very soft and flavored with vanilla and covered with chocolate to keep it together. The bees would take every bit of the inside out and leave nothing but a mere shell of chocolate. I bought some and fed it to the bees, they seemed very fond of it, I also put some in sugar syrup and they were perfectly crazy for it. It appears to me to be just the thing with plain syrup making it taste almost as good as honey. Would not vanilla be a good thing to perfume the hive, to give them all one smell when miting them etc., etc? Has any one tried it?

I want a bee feeder, and getting an idea from one of your correspondents about a tin can with end melted off, I am going to make one a little different. I will describe it thus: Tin can, ends off, over this tie factory muslin (outside), letting it down inside to near bottom, placed over the hole on top of the box. Then fill nearly full of syrup. But you may say it will run out too fast. Well, that can be easily obviated, put clean fine sand into the bottom, with syrup sufficient to regulate the flow, then you have a feeder, and a perfect filter also, costing less than two cents."

J. P. MOORE, Binghampton, N. Y., writes:—"I commenced the season of 1873 with seventeen stocks of bees, having lost four in the spring and sold one. Ten were in fair condition by the 20th of May; the other seven were much reduced, but by taking brood from the strong ones, I was able to build up five of the weak ones by the time honey commenced to yield. The other two I run for increase and surplus queens, and was able by feeding and using my four hives of empty comb to increase the two to eight full stocks and five half stocks or nuclei. Two of the nuclei died in the winter, and the other three are very weak (I prefer full stocks for winter), and raised ten surplus queens. The fifteen that the boxes were put on, were run entirely for box honey, without increase, as we have things so arranged now that when we get a hive filled with brood, in time to put on boxes, we can have them put all their surplus in boxes, if the queen is prolific, without attempting to swarm, and without the trouble of handling the brood. The product of the fifteen stands thus:—

By returns from honey shipped, 1864	
lbs. at an average of about 27% c.,	\$498.32
Honey sold at home, 120 lbs. @ 16c.,	\$19.20
Honey reserved for home use, 50 lbs.	\$8.00
Total.....	\$525.52

Or an average of about 135 lbs. (\$35.00) per hive. Two of my neighbors have done quite as well, and perhaps better. Their average has not been quite as high on surplus, but they have more increase. Bees have wintered very nicely in this section, but the weather is quite cold now, and snow is on the ground."

WM. HOUTZ, Milton Centre, O., writes:—"My losses are heavy this spring. I say this spring, because I lost no bees until after the 4th of March. Since that date I have lost thirteen swarms, and am sure of losing more,

because the weather is so cold that they cannot increase any, and the clusters are so small that they will not live long enough to raise any brood. Out of thirty swarms put in winter quarters I think I will probably have ten left. How is that for improved hives? I visited a bee-keeper that used nothing but a box about twelve inches square and fourteen inches deep. He started into the winter with thirty-six swarms, and let them set on the summer bench without any protection at all, taking off the surplus box that sat loosely on top, and laid on a thickness of brown paper, and then laid boards tight on that, and he saved every one. I was surprised to see that he lost none, while I lost heavily. Yet I am more enthusiastic than ever this season. I am determined to make it a success in winter. We can all raise bees and get honey in the summer-time to our satisfaction, but winter—or ought I to say long-continued cold springs?—is the great and important question. Well, if I had worked last fall to the ideas that I had in view at that time, I would have been a good many stocks better off, but it got too cold before I commenced, consequently I could not handle the bees as I knew they should be."

FRANCIS M. WOODLAND, Fairfield, Ill., writes:—"Last spring and early summer the rains were so constant that the flowers secreted no honey, or at least the bees could gather none in this part of south-eastern Illinois. In consequence, the drones were killed off, and the bees swarmed out to leave the few drops of honey in their hives to the hatching brood. They then turned their attention to the grocery stores, and bushels of them were destroyed in the windows before they could be relieved by feeding. On the first of June they were weaker than at any time in the winter, and were all poor, besides, with no brood. The black bees did not recover, but the Italians soon rallied, and became so strong by August that they poured out in large swarms to such an extent that I had my hands full for more than two weeks. Then the Spanish needle bloomed and—I will only say that I believe Gallup and Hosmer both. Spanish needle bloom lasts ten to twelve days; does not yield as much as Lin, but is of a better quality, of the color of bright gold, and very thick. My bees are now in fine condition, with brood and stores, and peach buds are just opening. And now I wish to know if any one has a similar experience, as I do not remember to have seen anything written on the subject. It is this: when a fertile worker was "running a hive" and a card of brood and eggs were given them, I have never succeeded in procuring queen cells on that card at the time. But always, upon the introduction of a second card with eggs and brood, queen cells were at once started on it. Query: Were the old bees of the hive *too old*, and the young bees from the first card *too young*, to start queen cells before the eggs were too old? And did the bees hatched from the first card start the cells on the second? Who will answer?"

ABNER J. POPE writes:—"At the last meeting of the N. A. B. K. S., the following resolution was adopted: 'Resolved, That the Secretary make an official report, in pamphlet form, of the proceedings of our annual meetings, as soon as he has the funds to do so.' All that desire to become members and have the proceedings, should send immediately their names and postoffice address, and the annual membership fee of \$1.00, to Abner J. Pope, Sec'y, 170 Park Avenue, Indianapolis, Ind."

SOLID NONPARIEL MEASURE.

First insertion, per line.....	\$.20
Each subsequent insertion, per line.....	.15
One square, 10 lines or less, first insertion.....	2.00

Next page to Business Department and fourth and last page of cover, double rates.

Twelve lines of solid Nonpariel occupy one inch. One column contains 96 lines of solid Nonpariel.

Bills of regular Advertising payable quarterly, if inserted three months or more. If inserted for less than three months, payable monthly. Transient advertisements, cash in advance. We adhere strictly to our printed rates.

Address all communications and remittances to the Manager.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Additional names to a club already formed may be sent at any time at the same club rate.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

Subscribers wishing to change their post-office address, should mention their *old* address, as well as the one to which they wish it changed.

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

The postage on this paper is only twelve cents a year, if paid quarterly or yearly in advance at the post-office where received. We prepay postage to Canada, and require twelve cents extra.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

BINDING.—We have been requested to get sets bound for some of our subscribers, and have made arrangements to get the nine Vols. bound in three vols. for \$4.00, or the same in four vols. for \$5.00. Those who wish to avail themselves of these liberal terms must send their numbers by express to the Manager.

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. $\text{\textcircled{P}}$ lb.

ST. LOUIS.—Quotations from W. G. Smith 419 North Main st.

The Honey marked is improving. A No. 1, box honey is scarce, and can be sold at good figures.

The spring is late and the bees are still confined to the hives. I have heard of very little mortality in the bees in Missouri, so far.—Common strained honey will sell here now and at good figures. We quote:

Choice white comb, 25@29c; fair to good, 16@22c. Extracted choice white clover, 16@18c. Choice basswood honey, 14@16c; fair to good, extracted, 8@12c; strained, 6@10c.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 $\text{\textcircled{P}}$ gal. St. Domingo, and Mexican, 90@95 $\text{\textcircled{P}}$ gal.

SAN FRANCISCO.—Quotations from Sterns and Smith, 423 Front st.

The season is about two weeks late. The prospect is very flattering for a big yield. We shall have no new honey until June. We quote:

Choice mountain honey, in comb, 22½@25c; common, 17@20c; strained, 10@12c, in 5 gallon cans. Valley honey, in comb, 12@17c; strained, 8@10c.

 We want several copies of No. 1, Vol. 2, of the AMERICAN BEE JOURNAL, and will pay 50 cents each for them. Who will send us some?

Every subscriber is requested to look at the date after his name on the wrapper label of this *Number* of the AMERICAN BEE JOURNAL, and if it is not correct send a postal card to this office, and tell us and we will make it right *at once*.

If you paste anything on a Postal Card, when you send to this office, we have to pay six cents postage on it. The law demands that there shall be nothing attached to it in any way, without paying double letter postage.

Some articles in this number are too personal. As the articles were of value, we concluded to publish them attended with this *mild rebuke*.

The Michigan Association of Bee-keepers will meet at Kalamazoo, on Wednesday next, May 6th.

Our subscribers in Europe, can *now* procure Postal Money Orders on Chicago. This plan of sending money is *safe* and economical.

AMERICAN BEE JOURNAL

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. X.

CHICAGO, JUNE, 1874.

No. 6.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

For the American Bee Journal.

Adair Talks About Novice.

MR. EDITOR:—When the New Idea Hive and theory was first made public, Mr. Root became terribly excited over it, and time after time, in your columns, warned bee-keepers against it, as he does against everything he knows nothing about. Why, sir, he skinned Gallup and me over and over. We told him then, that the *two-story* Simplicity Hive had so completely filled his brain, that he had no room for anything else. The hive has now been tested for three seasons, and everything claimed for it has been established as true, by the best apiculturists in all parts of the country.

Root is too much of a Yankee, not to see how the thing is going, and consequently we now find him recommending, manufacturing and selling the much-abused "New Idea." He has even gone so far as to adopt the "Adair" size of frame, and now charges an extra price for an extractor that fits any other. We are glad to see this, but we must say that he submits with a bad grace. As long as he fought it, he never once thought that the Idea was old. If it turned out to be a failure, he was willing to saddle the whole disgrace on me and Gallup, who he charged were trying to puzzle and befog the "ignorant" bee-keepers. But as soon as it turns out successfully, he joins in with others. See AMERICAN BEE JOURNAL for May, 1874, where he admits that "the testimony is strongly in favor of those over the two-story hives" but is ungenerous enough to suggest that it is no "New Idea" at all. He says, "Double width hives were used in our country before this work (Progressive Bee Culture) was published, for he had mentioned in public, making hives four or more feet long." I did mention it at the first Indianapolis convention in 1870, and had a hive

there on exhibition. I had then used it several years investigating its practical workings. In the same article he insists again that "The 'New Idea' *was*, if it is not now, set forth as a patent hive," as if that was an objection to it. But why does he so often repeat what is not so? I have repeatedly stated in answer to him, and others, that I never asserted a patent on it. He refers the reader to inside of the first cover of "Progressive Bee Culture," where he says, "His price then given for a Langstroth hive, fitted up on the 'New Idea' plan *with right to use* is ten dollars." Now nothing of the sort is to be found *there nor in any other place*. The proposition made on the cover of "Progressive Bee Culture," is just the reverse of what he states, and is as follows:

"In order to enable all to secure the benefits of the 'New Idea' Hive, I will furnish them with samples of Langstroth hives or those of similar construction, arranged for frames in the centre, and the ends filled out with my section honey boxes, with a right to use the honey boxes on any hive, for \$10.00, etc."

I sometimes think, Mr. Editor, that I will quit writing about bees, for I must be incompetent to make myself understood. It is annoying in the extreme, to have what I consider the plainest sentence I can frame, perverted into just the opposite. Another is to be found in the same article of Root's, where he says I "condemn the Extractor." I have never done so, but merely stated that its value is overestimated by such enthusiasts as Mr. Root. *I have never condemned the Melectorator*. On the contrary, have always advised every one keeping bees, to use it. It is indispensable to successful bee-keeping. But if I find that I can make box or comb honey more profitable than extracted, can I not have the privilege of saying so without subjecting myself to such unfounded charges? If I find that the clipping of the wings of the queen is injurious, and attempt to show on physiological grounds recognized by the most eminent naturalists, why must I subject myself to being called hard names, and ridiculed by men whose experience has not been such as to enable them to detect the damage and cruelty of the mutilation? and

must I have the perversion go forth that I state that the wings are "lungs, and nose, and ears?" If I have ideas of the respirations of insects, differing from those stereotyped in the bee books, which I think lead to injurious methods of ventilation, is it fair to have every one who wishes to cast a slur, to be repeating that "Adair says bees live without air?"

I don't wish to be understood as entertaining any ill will towards Mr. Root. I like him. His spicily flippancy is refreshing, and he makes a lively little paper well calculated to tickle the fancies of the people, and is doing a good work. His monthly dish of gossip, seasoned as it is, with interjections, ejaculations, and occasionally with about as much poison as turns pickles green when made in a brass kettle, but don't kill anybody, ought to be read by everybody, for he will stick in, at intervals, something of value; but we think it should not be made a "legal tender" among bee-keepers, for so fallible an adviser won't do for an oracle. Has he ever settled down on anything? Take his writings for the last seven years, and see how often he has changed his notions about almost everything connected with bee-keeping. He first got up an Extractor, which he thought was perfection, and that he would not exchange for any other, particularly if it was "patented," but we do find him a season or two later (1871), throwing it aside and using the Peabody, which is *patented*. He accepted an agency, and let no occasion slip to puff it, and induced many a bee-keeper to buy it. After using it a year or two, he turns around and condemns it, and gets up another.

He first started out with the tall frame, in the American hive. Suddenly he vibrated to the opposite extreme, and tells us no frame will answer unless it be the Shallow Langstroth. If it is any deeper, it is too tall, if any narrower, it won't do. In 1872, (AMERICAN BEE JOURNAL of April) we find him a little unsettled on the subject, for he says, "Our greatest objection to the Gallup frame, is the labor of handling so many. Quinby uses the largest frame we know of, and we *really* like the idea." In the AMERICAN BEE JOURNAL for July, he gets down a little, and says:

"The best colony in our apiary, we believe, is in a two-story hive, *frame one foot square, and they are really pretty to handle*; just the thing for ladies to handle, but for some other reasons we prefer the Shallow frames."

Since then he has had no settled notions about it, until lately (that is since the "New Idea" has struck in on him.) He now adopts the Adair size that is 10x13 inside measurement, and can give as good reasons for its being the best size, as he ever gave

for any other, and it is hard to tell what his notions will be a year hence.

As to hives,—a year ago he was particularly horrified that any one would use any other than a two-story Simplicity Langstroth, but to-day his wind mill buzz-saw with all hands, P. G. blue eyes, "and such neighbors as call in, are putting in extra time on the "New Idea," that he has so heartily condemned. In fact, he has abandoned every principle of his former hives, even to turning the frames across the entrance, instead of following Langstroth and all the hive men that he has at times patronized.

I am not finding fault with these last changes, but am surprised that after the war he has waged on everything I have written, that he should in the end adopt every principle that my ridiculous theories have established, for it was out of the "theorizing" that he found so much fault with, that the new hive grew. If he will disprove the theory advanced in Progressive Bee Culture, the hive he is now recommending as a "Standard," is worthless as all hives are that are not adapted to the instincts of the bee. He will find, however, that he will have to abandon his \$1.00 notions before he can work the hive perfectly. A hive 30 inches long, is too small. The smallest I have, are 36 inches long, and cannot nearly accommodate the bees, even in a poor season. If he will give more room, and disturb the brood nest as little as possible, except to give plenty of room to a vigorous queen, with all her members and organs perfect, including her wings, he will soon have an opportunity to verify all of the theories that he has considered so absurd. He cannot do it in a 30-inch hive, for such a queen will fill it all with brood from end to end.

Do you remember how many feeders he has adopted as the best, and then abandoned for something else, from his triangular glass feeder, all the way up to the "Tea Kettle" that Mr. Quinby says he plagiarized, or something of that sort,—and how many vagaries he has indulged in, and recommended, such as sending bee eggs by mail, hatching them by artificial heat, and his many crude notions about wintering, ending in covering his hives with horse manure, and the loss of the most of them, which he informs us in May Gleanings, will prevent him from supplying those \$1.00 queens that he has talked so much about? If you will look way down in one corner of page 55, of Gleanings-in-Bee-Culture, or How-to-realize-the-most-money-with-the-smallest-expenditure-of-capital-and-labor-in-the-care-of-bees-rationally-considered, for May, under the head of "Depository of blasted hopes, or letters from those who have made bee-culture a fail-

ure," you will find him whispering to himself as follows :

"That you cannot winter bees, is very evident, and unless you can show us that you can summer them, we shall have to conclude you are no bee-keeper at all."

(He certainly must have forgotten to feed his bees on A. Coffee sugar syrup).

For these, and many other reasons, we long ago concluded that Root, or "Novice," as he takes pride in calling himself, is not a safe guide, nor capable of the job he has undertaken of regulating the whole bee world.

Sundry Questions and Answers.

CONDUCTED BY CH. DADANT.

QUESTION.

How am I to subdue bees, and shake them off deep combs? I find it makes them cross.

O. S. BROWN.

ANSWER.

Here is the way we remove the bees off the combs, to be emptied with the extractor: We take out of the hive the combs to be emptied and we replace them by as many dry combs; we close the hive; then with a small broom of blue grass or with a goose wing we brush the bees in front of the hive. As the work is done quickly the bees do not have time to become cross.

QUESTIONS.

- 1st. At what time does basswood blossom?
- 2nd. How many basswood trees are required to furnish a colony of bees with as much honey as they can gather? How old are they when they first blossom?
- 3rd. Will they grow on poor dry sandy or gravelly land of drift formation?
- 4th. Has Esparcet ever been tried in this country? Where can the seed be obtained?
- 5th. Is there any honey yielding hedge plant that sheep will not browse?

H. A. SPRAGUE.

ANSWERS.

1st. Basswood blossoms about as soon as the main blooming of clover is over. Here (Hancock Co., Ill.) it blossoms between the 1st and 10th of July. There are two kinds of basswood which can thrive in the northern States and which do not blossom exactly at the same time.

2nd. It is impossible to answer the second question. Some times the basswood flowers seem to have been dipped in honey, while at other years the blossoms contain nearly no honey. We have planted a nursery of basswood in order to give the trees to our neighbors to plant as shade trees around their dwellings. We think that plan a good one. Lindens will bloom after six years, may be sooner, if planted already large.

3rd. From what I know of basswood which is growing extensively in France, around the

cities, I think it will grow in the poorest soils.

4th. Esparcet is a plant so useful that I cannot but suppose that it has been tried in this country. May be the hard winters have killed it, or perhaps it has been tried on wet soil. Yet I believe that it can succeed in some parts of the United States.

Esparcette, or sainfoin, of Burgundy, (*Hedysarum onobrychis*) like a calcareous soil; its flower is a rose and pretty. It is very good for hay, as its French name indicates: *sainfoin*, healthy hay, and is unsurpassed for honey, as to quality and quantity.

There is in France a great quantity of plants pertaining to the same family (*the leguminous*) which for the greater part would prove a good acquisition for this country. I can name:—the carnation clover, or farouch. (*trifolium incarnatum*) which can be sowed in March to be cropped in July or August, or sowed in June for September. A very good plant for hay and honey.

The Lucern (*medicago sativa*) varieties: media, falcata, etc. The lucern gives three to six crops yearly for six or eight years, in France, its flowers are deep violet and give very good honey.

The lucern lupulina (*med. lupulina*) annual with yellow flowers; good for hay and honey.

The lotus corniculatus—good for wet soils.

The gesses (*lathyrus*) varieties: sativus, hirsutius, cicera, pratensis, etc.

The vesces (*vicia*) varieties: sativa, cianis, eracea, this last so pretty that it is called in France *vesce elegante*.

The ers ervilla (*ervum ervilla*)

The Lentil (*ervum lens*)

All these plants belonging to the same family are good for honey, and are cultivated for hay; the last named is commonly eaten by the French people; it is with its seeds that the French house-keepers make the *puree de lentilles*.

I think it is impossible to find the seeds of the above plants on this side of the Atlantic. If any bee-keeper wants to try one or many of them, I will be glad to get them from France for them, without charging anything for my work. I am acquainted with several French bee-keepers who will cheerfully take the trouble of buying and sending the seeds desired.

5th. I know of no honey yielding plant good for hedging in this country.

In describing the "smoker" on page 121 of our last issue, the printer made Mr. Cutler's name Isaiah instead of Josiah, and it ought to have stated that had but just commenced the 84th year of his age.

For the American Bee Journal.

Italian Queens—Cost of Raising.

In the Feb. issue, M. Davis writes on this subject, and puts the cost at a reasonable sum—taking his climate into consideration.

Being the first person to reduce the price of Italian Queens from \$20.00 to \$2.50 each, let me say that I have never made any money at that price. In this part of the country, we are not sure of getting a fair honey crop oftener than three out of five years, and have often sent out as many as 900 queens in a season.

A Ohio man, who advertises to sell Queens at \$1.00, is honest enough to say that he does not warrant them pure, as he has so many black bees in his locality—neither will he warrant safe arrival. I will not attempt to raise queens at less than \$3.50 each; if my bees would store one-half as much honey, as this \$1.00 queen-bee-man claims that his bees will store for him.

Adam Grimm says that good queens cannot be raised for \$2.00, even in the best of localities.

Some think Mr. Quinby correct about the bee disease, and some do not. My opinion is that the cause is *poor quality of food* gathered by the bees in the fall previous.

Last season the quality was never better here, and my bees seem to be doing well on summer stands, and we have had only three weeks of very cold weather. Next season I intend to build a bee-depository on the plan of Mr. T. C. Ware, of Towanda, Ills. Will Mr. W. give his plan to the readers of the AMERICAN BEE JOURNAL? We consider it the best one yet, as it requires but little labor and expense.

H. ALLEY.

Wenham, Mass.

Doolittle's Article.

Our last article carried us to Dec. 6. About that time the snow all disappeared from our hives. The mercury stood at 57 in the shade, but it was windy. Our bees had not had a chance to fly since Oct. 23, and they did fly some, in spite of the wind, although nearly all that went out never returned. Dec. 16, bees had a nice fly with the mercury at 45 in the shade. We had very mild weather from Dec. 6 to Jan. 4. Jan. 4, the mercury stood at 63 in the shade, and our bees flew to their hearts content. Jan. 22 it was very mild, until Jan. 30, when it became cold, and on the night of Feb. 1, the mercury stood at 18 below zero, which is as cold as we very often get here, and 3 degrees colder than any time during the winter of 1872-3. March 2nd and 3rd were splendid days for bees, and

we had a chance to examine nearly all of them; we found our 54 colonies and 4 nuclei, all in good condition, with the exception of one colony and one nucleus, which had decreased in numbers so they occupy but three rows of comb. We found brood in all we examined from four square inches of comb, with eggs and forage in the cells, up to 200 square inches, with brood in all stages, and plenty of young workers.

The winter on the whole has been a very mild one, with but little snow. We have never known the mercury to sink to zero, unless we had snow enough to bank at least to the height of the broad chamber of the hive. As mild as the winter has been, we have kept them banked out of sight nearly half of the time. We put straw in the caps to our hives march 20, to set them to breeding rapidly. It makes them so much warmer.

We tried two, during the winter, with caps packed with straw, but when we came to bank them with snow, they became so warm and uneasy, we had to take it out again. We keep entrances closed as tight as we can make them, except when the bees can fly, and take no trouble to have any crooks or holes in the cap; neither do we fear their smothering.

G. H. DOOLITTLE.

Bowdens, N. Y.

Bee Notes and Queries.

"*What is the Best Hive?*"—asks a correspondent. Probably there are not a half-dozen bee-keepers in the country who would unite in recommending the same hive as "the best."

Asters as Bee Plants.—A correspondent writes:—"I am satisfied the common Aster is an excellent honey-producing plant. A friend of mine, an experienced bee-keeper, recommended it to me, and my experience with it two seasons confirms the recommendation."

To keep Moth out of a Hive.—An Illinois lady says, "A teacupful of Italian bees will keep all the moth out of a hive. You need not buy a hive which runs to a point at the bottom so that the moths will roll out; an Italian swarm of bees are a perfect protection against moth."

Remedy for Bee-Stings.—A bee-keeper says:—"I have made one discovery—that a preparation or *Ledum palustre* (Labrador Tea) homeopathically prepared, is a sovereign remedy for bee-stings." But he does not tell us *how* to prepare it.

SAMUEL PORTER, West Ogden, Michigan, writes:—"The May number states that I took 200 pounds of surplus honey from my hives. It should have been 1200 pounds."

Novice.

DEAR OLD AMERICAN BEE JOURNAL:—

We are right glad to see your pleasant face so early in the month, and also to find that your humble servant is still remembered occasionally on its pages. Tell Argus that "old Syrupy" has got his hat and coat on now, for in fact this 29th day of April has been about as cold as any day in January. The ground is frozen, and snow has been on it for two days, yet we are happy to add our *twenty-two colonies* stood it without any further diminution of their numbers. If he did call us "old Syrupy," we thank him for his remark that *Truth* might be found somewhere betwixt Mr. Quinby and our own "hobby," although the "meeting" seems unlikely just now for some time to come, from the tone of Q's letter.

We are so used to being taken to task, that we think we have become almost hardened, *i. e.*, in such a way that we can take a "big crack" right square on the top of the head, and look up pleasantly after it, instead of feeling about for something with which to give our opponent a "harder crack" back again, as we have done *by far too often*, and thus keep up controversy. We are perfectly willing to leave the matter to the judgment of our readers, and will abide by their decision after having submitted enough from Mr. Q's circular to show just what he does claim for his hive. He says:

"In consequence of the advantage which this hive enables us to take of the labors of the bees, by preventing their swarming, etc., it is safe in a good season to calculate on an average of one or two hundred pounds of box honey, or two or three hundred when the combs are emptied with a machine—which will sell for more in one season than the price of colony."

The only question is, whether Mr. Q. is justified in offering his hive for sale to *novices* with so high an estimate, and more especially using the words, "on an average."

Mr. Q. did make us a present of the hive, and he has our sincere thanks for the same, for we presume he then supposed it would prove profitable in our locality also, but the fact would not deter us an instant from giving our honest opinion of the merits or demerits of anything prominently before the people.

With Mr. Quinby's *full consent* and approval,—and it must be given more pleasantly than in his article alluded to, we will undertake the task of giving full directions, with illustrations, on these pages, for making a perfect *fac simile* of his hive for four dollars. After that, if no one can be found to do it, we will make them singly or by the quantity for that price, or 25 per cent. less. packed ready to nail, *everything*

furnished. The sample we are to model from, shall be some one that he has sold before this appears in print.

Mr. Van Deusen did also send us a small bee-feeder, but we wrote him at once (thanking him), and telling him we had been using the same thing for some time, and that we were sure a patent would not "hold" on the simple idea of covering any utensil with perforated tin, to be used inverted, as a bee-feeder. This was some time ago, but *long before* that the same device had been described many times, (and is now) in the earlier volumes of this very AMERICAN BEE JOURNAL. Instead of using fruit jars and oyster cans, with many holes punched in them, we suggested using a whole "tea kettle," because it would hold from twenty-five to thirty pounds,—or enough for winter, at once. E. Kretchmer, on page sixty-six, March number, mentions the same thing again, as being *patented*, and so far as his caution is concerned, we would respectfully invite him to try the "strength" of such a patent on ourselves to commence with, before trying to convince the public that the very useful and simple device is not free property to every one. If this appears hard on Mr. K., we would say by way of apology, that he is an old offender, and has led many good people to question whether they had a right to make and use such simple feeders.

Mr. C. C. Van Deusen, Sprout Brook, New York, has *now* a patent on a very simple device, for filling these feeders, and as they are sold at a fair price, "right" included, it may be many times best to purchase them of him. We feel sure he will agree with what we have said in this matter. We respect our patent laws, and would uphold them when they are not made a pretext for the now almost obsolete "right"-selling swindle.

On the contrary, we think quite favorably of Gallup's strong stocks for out-door wintering, and agreed with him in thinking they perhaps would not do so well in-doors. Had he and Adair explained in a few simple words that their "New Idea" was "a long, one-story hive, with lots of bees in it," we should have had no trouble in getting at it. Some way, there always seems to be more of a temptation to "hit back," when Gallup gives one a "clip," than any one else. Why do so many keep tilting at *Novice's* dollar queens and hives? We only proposed that it would be a benefit all around for any one to sell *any queen* before she was tested, for \$1.00. Would such queens be in any way inferior in fertility? Very many excellent breeders now offer untested queens for \$1.00, and their customer stands an equal chance of getting the very best. Selling queens *known* to be poor, for \$1.00 each, would

be an act of dishonesty, and would sooner or later bring its own reward.

Please do at least give us the credit of disinterestedness in this matter, for we feel sure the business will pass along more briskly if queens are sold as soon as fertile, at a low price, and the accommodation will be on both sides. When the possessor of a queen has tested her himself, he is satisfied, and he is rarely otherwise.

Many are the bee-keepers who would feel that the business paid tolerably well, were it not for the unceasing demands and continued outgoes; if we have shown any, how they could lessen expenses and still be just as well off, we shall have fulfilled our purpose in writing. If in our zeal we have now and then gone to extremes, please excuse it on the ground that it was only what might be expected from your old friend
NOVICE.

P. S.—When we get each one of our twenty-two colonies built “out” so that they fill a ten-foot hive, we suppose the queens will be worth ten dollars each, and were it not for spoiling their wings, we might cut them up in ten square slices at a dollar each. Speaking of wings, reminds me that we have read of ants biting off the wings of the mother ant as soon as she was fertilized, for some reason best known to themselves. Can't some one tell us more about it, and are the ants to be censured for going contrary to nature?

For the American Bee Journal.

Do Bees Injure Fruit?

W. F. CLARK:—*Dear Sir*:—In the March number of the AMERICAN BEE JOURNAL, (p. 63) Mr. A. O. Kruschke, of Berlin, Wis., accused the *N. Y. Tribune* of not publishing an article on the above-mentioned subject, in reply to and in censure of “that wise (?) Prof. Riley.” To show that the accusation was unjust, I mailed the correspondence of the *Tribune*, which you have kindly published in your April number (pp. 76, 77). Permit me to say further, in reply to Mr. K's remarks, that I have no personal feeling in this matter, and I can well afford to leave it to your readers to decide, from which side comes the personality. For while the charges of crime and presumption, the taunts of sapientcy and “wisdom,” and cowardice might well arouse some feeling of the kind, I have endeavored to avoid such. My object is to state the truth, and my opinions are based not on a single experiment, but on repeated observation. Mr. K. may stigmatize them as presumption, but others will show more consideration and less egotism. Mr. K. may consider it his “duty to be a bee-defender,” but I know no other duty as a naturalist, than to state my convictions as to

the truth; and herein lies my “crime.” I have seen bees cut into fruit, and there is no imagination about it. The wisdom of my recommendation to the horticulturist who in extreme cases suffers from bee-injury, may be questioned; but none but prejudiced persons will *doubt* my statement of fact, and call my opinion based thereon presumption. Facts so often witnessed in the vineyard are not overthrown by a single adverse experiment. We have laws to protect us from the inroads of cattle left roaming at large, and if in exceptional times when the ordinary food of the commons is short or entirely lacking, our neighbor does not take proper care of his four-legged stock, but allows it to depredate on crops, legal redress is at command. But under similar exceptional circumstances, we have no legal protection from his six-legged stock.

Finally, I hope Mr. K. will, as he promises, continue his experiments; and as they may not all turn out like his first, he may yet learn to cultivate a due degree of modesty in the use of unpleasant and personal epithets; for truth will in the end “shame the devil.”

In line 15, p. 77, “observe” should read “obscure.” Yours, etc.,

C. V. RILEY.

For the American Bee Journal.

Bee-Keeping in the South.

We of the South, the native home of the bee, know but little yet of his management as practiced by our Northern neighbors; and, in fact, the results produced by some, as at least claimed, are perfectly astounding to us. Some, however, pretend to account for it by saying that bees know their necessities, and prepare for them accordingly; that in cold climates they lay up greater stores than in warm ones, and that on the peninsula of Florida, where there is no frost, they lay up no stores at all. This theory I believe to be nothing more than theory, and that upon trial will be proved to be wholly without a foundation in truth.

We have none but the native bees here, yet, and I wish to learn to manage them more successfully before making any further investments. I saw the first movable comb hive last year. Transferred two colonies on the 25th of July. One was destroyed by moths; the other did well. They are now working vigorously, and, if not prevented, will throw out a swarm in a few days. I have watched bees more closely the past winter than ever before, and I do not think there were ten days in succession at any time during cold weather that they could not fly out; and by the 14th of Feb. they were in full blast, gathering honey and pollen from a thousand flowers. This must

appear strange to you in the North, who are compelled to keep the poor fellows buried in cellars half their lives, in order that they should live the other half. I do not know what particular flower here gives the greatest yield, but I guess the bees know, and I suppose the supply is ample. Where the flowers are so numerous and so buried as they are here, there can be no excuse for idle bees, if there are any such. I can see no reason why the business should not be more profitable here than farther north, if managed with the same care and skill.

J. B. MITCHELL.

Hawkinsville, Ga.

For the American Bee Journal.

Bee-ology in Kentucky.

I will give the readers of the AMERICAN BEE JOURNAL a sketch of Kentucky Bee-ology as practised hereabouts. There is but one scientific bee man in this part of the country. I allude to R. M. Argo, of Lowell. The farmer, the mechanic, the merchant, indeed all hands here, keep—or rather, “keep at”—a few stocks of bees, but pay little or no attention to them. If one or two stocks, say out of ten or a dozen, happen to do pretty well, the owner will say he had “good luck,” if not, “bad luck.”

Kentucky until the last two or three years was, perhaps, as good a State for bees and honey as any. Our principal dependence for honey here is upon the white clover and basswood, or rather, as a Kentuckian would say, “Linn.”

In 1872 we had a short crop of both, last season scarcely any of either; consequently our bees did no good whatever. Out of a dozen good, strong hives I did not get over twenty-five pounds of cap honey.

I imported the first Italian bees brought to the State. In the year 1861 I purchased two queens, one of Rev. L. L. Langstroth, and the other of Mr. K. P. Kidder of Burlington, Vt. I received the one from Mr. L. all right, and with the aid furnished by his instructions had but little difficulty in getting her safely introduced into a stock of common black bees. When I received the one I ordered of Mr. Kidder, the comb in the box had been broken down and the queen crippled. I introduced her, but she soon died. I informed Mr. Kidder, but he would not replace her.

I watched the progress of the other with much interest, and in about fifteen days saw her progeny begin to come forth. As no one in the county had ever seen an Italian bee it was quite a curiosity, and many persons came expressly to see it. I afterwards ordered some queens from Mr. L. for some friends, but owing to the great quantity of full-blooded black bees in the

county it was impossible to keep them pure, and until Mr. Argo, of Lowell, went into the business, some years afterwards, and purchased all the black bees in reach of his apiary it was impossible to raise anything like pure queens.

Pleasant Remarks.

On page 41 “Novice” intimates that we have had feelings toward him, because on page 142, Vol. ix. we resented his imputation that we sought to advertise our simplified Simplicity Hive and frame in the pages of the JOURNAL. We are certainly pleased to learn that he was only indulging in one of his pleasantries. We are frank to say that the aforesaid “pleasantry” touched our sensitiveness, and we wrote the answer on the spur of the moment, and when it appeared in print we were sorry. If Novice feels hurt, let him consider the hard raps he has given others who have feelings as well as he. Those free criticisms have produced wounds that mere explanations will never heal.

We rejoice to see a different tone in the writings of some of our bee men, and in the conduct of our Bee Journals. Instead of being conducted for selfish interests, and utterly ignoring each other's existence, there has arisen a brotherly feeling and a disposition to lend a helping hand. We observe that since the birth of *Gleanings*, Novice has come down to a milder way of expressing himself than formerly. We are happy to see it, and if we have written anything not in accordance with kindly feelings we crave pardon. We will accept “pleasantry” as an explanation, and trust Novice will treasure up nothing against us for our hasty remarks.

Bees' Breathing.

“In your April number, page 84, second column lower half, Mr. Adair makes some assertions which have often been made by others, but which appear to me so foolish that I cannot help noticing them. He says: “The last paragraph is the statement of a fact that has been settled among naturalists for a long time, *i. e.* that the bee inflates its body with air when about to fly, so as to decrease its specific gravity when flying. This is not only applicable to insects, but ornithologists state that birds do the same thing, even filling the hollow barrels of their feathers and quills with heated air or gas.” Now I want Mr. Adair to explain. I will grant *for the sake of argument only*

that the bees' body has hollows in it, not filled with anything but air or if he chooses not even air, and also that birds have hollow bones and feathers. This latter is not peculiar to birds. Animals have hollow bones where great strength is not needed and because nature does not put material where it is of no use. Now if these hollows in bees or birds have no air in them before they fly, how can they make them lighter by putting air into them. That would make them heavier. If these hollows have air in them, that air is at about the same temperature as their bodies. If they could make it warmer it would be no lighter unless they could expel some of it and thus make a partial vacuum. But they cannot make it warmer and therefore cannot expel it. They might press more air in but that would make their bodies heavier.—In short, bees or birds have no power to make their bodies lighter or heavier at will. I think Mr. Adair cannot properly call his supposition a *settled fact*. W.

For the American Bee Journal.

The Extractor versus Honey Boxes.

A great many experienced apiarians are advocating the exclusive use of the extractor for obtaining surplus honey, speaking of boxes (with them) as things of the past and looking upon those who use them as inclined to "old fogyism."

In this age of the 19th century, progress and improvement are the watchwords; are we not then a little too much inclined to go after things of the "new idea" order—throwing up our hats every time we hear of anything in bee-culture which strikes us as being a deviation from the old path—running our apiaries upon windmill principles—talking about barrels and hogheads of honey to be secured the coming season in spite of drouth or storm, when in fact our stocks are daily diminishing in numbers, and it is only by exercising the greatest vigilance that we can prevent the native blacks from running out our pet Italians.

That the extractor is an indispensable article in a well managed apiary, probably all acquainted with its working will admit; but that beautiful comb honey is to be supplanted by the extracted article will only take place when the eye hath lost its admiration for beauty, and fancy and style have nothing to do with the sale of this staple luxury.

So long as the idea of crushed bees and other impurities is connected with the sight of strained honey, just so long will that put up in fancy boxes continue to command the higher price.

Were all honey raisers the coming season to run their apiaries exclusively for extracted honey, and the season be as good as was

the past, I fear our markets would be glutted and the crop find, at wholesale, a price but little above that of ordinary strained. The low price at which it was quoted the past fall and winter in the principal places of consumption throughout the country I think will bear me out in making this prediction.

While honey in glass boxes in New York was quoted at from 30 to 35 cents a pound, wholesale; extracted and strained was only put down at from 12 to 15 cents a pound. To be sure we sometimes get a better price for it when put up in jars, but how are we to keep it from hardening? In the language of D. W. Quinby, commission merchant, handling large quantities of honey, and brother to M. Quinby, "it soon candies, looks like lard and don't sell." I have a doubt as to whether these advocates of the slinger theory believe they obtain as nice an article by using the extractor, as that stored away, evaporated and sealed by the bees themselves. Has it the luscious richness to the taste? I have heard good judges of honey say it has not.

For example, take from the box a flake of white comb honey built just the right size to fit a small plate, and it is of itself an ornament even to the table of the rich and will tempt the palate of an epicure. Slice that comb up into small squares to be passed to each individual, and can anything in the shape of liquid honey excel, or even compare with that which drains into the bottom of the dish from the severed cells—clear as water from the limpid spring—aromatic as the flowers from which it was culled—tempting to both eye and taste and pure as ever are the unadulterated productions from nature's laboratory.

The symmetrical beauty in the structure of the comb, each tiny cell a perfect hexagon and solving a mathematical problem in Euclid, furnishes a subject for conversation, and all are ready to praise the industry of the little bee endowed with such wonderful instinct. No wonder the old poets sang to its praise; for the product of its labors furnished an article of export from the islands of the Mediterranean to an extent beyond anything we hear of in these modern times of imported queens and honey slingers.

I do not make these comparisons in a fault-finding spirit, but merely to look the subject square in the face without ignoring what others have done before us.

For the past few winters bee-keepers have had a serious difficulty to contend with and I fear the advantage gained in building up swarms by the use of the movable-comb frame is more than offset by disastrous losses in wintering, and a close canvas would probably show that in the United States there is not more than

one bee-keeper where there were ten several years ago, and is not this loss often greatly endangered by the too free use of the extractor, often leaving hives in a starving condition at the close of a good season?

Some of our largest raisers and shippers of box honey are among those who do not report their experience through the bee journals.

A few years since Capt. J. R. Hetherington of Cherry Valley, in this State, sent to New York market 25,000 pounds of box honey "as reported" of his own raising. The same fall Baldwin Bros., of Sandusky, N. Y., shipped to the same market 10,000 pounds, mostly from their own apiaries, although at the same time extensively engaged in raising Italian queens for sale.

I was informed by a commission merchant that a firm in Steuben Co., made one shipment of 5 tons. Besides these larger quantities there were a great many smaller lots varying from 500 to 5,000 pounds yielding to the producer an income of no mean significance. The same course has been pursued every fall since, except perhaps not on quite so extensive a scale. Could the managers of these apiaries be induced to give their experience through the columns of the bee journals, what an amount of testimony would be given in favor of using boxes, besides adding a large amount of practical information to their columns already so replete with useful knowledge. It matters not how large may be the crop if we have our surplus in suitable shaped, four-sided glass boxes, it will find quick sale at good remunerative prices without return or loss of barrel, as box honey in this shape sells at gross weight without any question, the boxes often paying 100 per cent. above cost of manufacture. We are well aware that glass weighs heavy, yet consumers want it in this shape and are willing to pay a fancy price for a fancy article, and in this case it pays better to let them have their own way, and not be quarelling about tare on old wooden boxes. The season for 1874 is now at hand, and as many apiaries will be run almost exclusively either for box or extracted surplus, I hope at its close those of us whose lives are spared will have the benefit of a good many favorable reports pro and con; yet with many others I am loath to believe that fancy box honey will ever be supplanted by the extracted article.

C. R. ISHAM.

When a hive of bees is kept in a state of alarm by the tormenting ingenuity of mischievous boys, the time in which they would be ranging over the fields in search of honey and pollen, will be lost in defending their premises.

For the American Bee Journal.

Report from my Apiary.

On making an examination of my sixty odd stocks last August, I found all except about ten, on the verge of starvation. I immediately commenced feeding, and in the early part of September united so many as to reduce my stocks to fifty, and then fed my bees over three barrels granulated sugar. Wintered on their summer stands without the loss of a single one. Found one this spring, queenless, which I united with a weak one. My bees now, are in splendid condition; good brood in all, and plenty of stores.

On returning home from church on yesterday, and after getting my dinner, I walked out in my bee yard, and the first thing that attracted my attention, was a swarm just issuing, this one being the first of the season. Was not expecting a swarm so soon. I have to report the loss of hundreds of colonies in our county last winter. The cause was nothing more nor less than starvation. The old idea of luck in bee-keeping has with me entirely exploded. I am buying plenty of nice, empty worker comb at twenty-five cents per pound. The season so far has been very unpropitious for the honey-gatherers. The "oldest inhabitant" says we have had more rain this spring than was ever known before. The rains are followed by cold and cloudy days. The main honey crop here is gathered from white clover, which is said to be (this spring) unusually good. As last season here was the poorest ever known, I am in hopes this will be the best known for years.

Queen Clipping.

The extent to which this practice is now being carried, is to my mind, truly alarming; bids fair to endanger the very existence of the Italian race of bees, and thus, if persisted in, break up bee culture as a pursuit.

I do not stop to enquire how far Gen. Adair may be right or wrong in his scientific theories, or his opponents in opposing them; but am firmly convinced that to maim anything, impairs its efficiency. There are a few considerations which seem to me conclusive arguments against this practice.

1st. Those from analogy. We look for stout offspring from stout parents; weak from weak. We are told that fish found in the Mammoth, and other caves are blind, having been shut out from the light for generations,—showing that the proper exercise of the muscles, nerves, and other

organs of the eye is necessary to preserve the sight. Should we clip the fins of these fish for a like number of generations, would not the muscles which propel the fins, wholly or partially perish from lack of proper exercise, and thus produce either a finless race or one with puny fins. Confine the arm in a sling from childhood to manhood, and thus suspend the exercise of the propelling muscles of the arm, and what is the result? a shrunken and useless limb; on the other hand, for the same length of time, wield the blacksmith's sledge with the same arm, and powerfully developed muscles are the result.

We are told that a race of bob-tailed dogs has been produced by the successive severance of the dorsal extremity.

We know the turkeys, and other domestic fowls, as well as animals, have by domestication been dwarfed in their powers of locomotion by the no longer vigorous exercise of those muscles which speed their movements; and their progeny are likewise feeble in the muscles of propulsion. Thousands of analogies might be adduced to show that "like begets like" but these would seem to suffice. In all the cases of impaired locomotion the propelling muscles have been idle for generations, and thus weakened. The progeny of the succeeding generation partakes of the weakness in this respect of the preceding.

If bees should excel in any one thing, it should be in their powers of flight. Now clip the wing or wings of the queens or mother bees, and keep up this clipping for generations, thus stopping in the line of descent the healthful exercise of the wing muscles, must it not inevitably result, if not in a wingless, at least in a race with impaired wings. Long before they became wingless the operations of the hive would cease.

2nd. I believe the workers regard a clipped mother with suspicion, and at times supersede her, or else she dies more readily from this cause. Three out of five of my clipped queens died last season, two of which I found dead in front of their hives; whilst out of thirteen unclipped queens, I lost not one that I know of.

3rd. Clipping does not always prevent the queen from trying to lead the swarm, in which case she falls and may perish.

4th. It is inconsistent with the spirit of the age, which is to improve both animals and plants rather than to deteriorate. Clipping cannot improve or produce a more perfect insect. Some writer even advocates clipping one leg. If the queen has any use for wings and legs, that use is impaired by this practice; and is it not wiser and safer to pursue that course which to say the least cannot injure, in preference to that which may, and let her wings and legs alone?

Natural and Artificial Food.

Among the many peculiar conceits of mankind, there is none perhaps more common than that of investigating one's own ideas with a great deal of importance; even though the same ideas, or supposed discoveries have been common to others long before and not emblazoned as anything at all wonderful or astonishing.

An Ohio bee-keeper having been led from some cause or other to feed sugar to bees with seeming good results, straightway proclaims the fact to the world, as a great discovery of his own, when the truth is that it had often been done before, and without very greatly agitating the bee world.

Doubtless bees can be wintered on sugar syrup, if properly prepared; but that it is in any way superior to the food which nature has taught the honey bee to gather for its own use, I am very far from believing.

Man may often by scientific knowledge concentrate, intensify, or direct nature's forces to certain ends and objects, but when he attempts to substitute one of her provisions for another, he very rarely improves upon the original. While I disbelieve in the superiority of sugar as food for bees, still less do I believe in its prophylactic properties. At its first suggestion as a remedy for or preventive of so called dysentery in bees, I am incredulous for the foregoing reasons, and the results of many experiments of eminent apiarists as well as my own, has tendered to dissipate entirely the idea of its sanitary qualities.

Perhaps an item of my own experience, bearing upon this question might not prove uninteresting.

In August 1872, after basswood had ceased to yield honey—which is the last we get here of any consequence—I found that my bees' stores were insufficient to winter upon; consequently I fed to some 25 stocks, 1½ barrels of A coffee sugar made into syrup. It was fed during the hot days the last of August, so the bees could put it in good shape for winter; and in order to thoroughly test the properties claimed for it, I fed a few late swarms, which had made considerable comb, but little honey, sufficient sugar syrup to last till spring. In order to show that the syrup was well prepared, I would say that I can show any amount of it to day in the combs of the hives, out of which the bees died, that is not grained at all, but is of good consistency and in fine condition for bees.

About the 1st of January following, my bees commenced dying of dysentery, and

the first to die were some of those fed on all sugar syrup, and before the 1st of May every one fed with sugar, was dead.

I do not wish to be understood as saying that those fed with sugar suffered particularly worse than those not fed at all—for the mortality was very great among all—but that it had no effect in preventing disease, nor has it in any other cases that came under my observation. It may not be out of place to say that my bees were wintered on their summer stands, in movable-frame, double-cased hives, and nicely quilted on top. I went carefully through my apiary and placed (after feeding was done) empty combs in the centre of the hives, and the honey or sugar each side of them.

The great mortality of bees for the past two winters is a fruitful subject for discussion; as yet, but little light has been thrown upon the matter, although I have full faith that it may and will be finally understood.

I will not attempt at this time to give any theory of my own upon the most vexed question, but may at some future time give some facts of my own experience bearing upon the subject. N. M. C.

Ellington.

For the American Bee Journal.

My Experience in Bee-Keeping.

I have kept bees, more or less, for the past four years. During this time my experience has been of a varied character. Through the summer season my bees have done well, and amply rewarded me for my labor and trouble. But my high hopes and bright anticipations were destined to be blasted by the loss in wintering.

In the winter of 1870, seven swarms came through all right on summer stands. I bought two in the spring of 1871; took four on shares, increased, and commenced the winter with twenty-three swarms on summer stands. They all died, and the spring of '72 found me without a bee,—but not discouraged. I concluded to stick to the old motto, "If you don't at first succeed, try, try again," and "what other folks can do, why with patience may not I?"

In July I again ventured to invest, and bought four young swarms, also one swarm of Italians. As they were late colonies, they did increase, and I again attempted to winter these five swarms on summer stands, with but light protection. I was again doomed to disappointment and loss. The spring of '73 found my bees all dead, with plenty of honey in their hives, which showed they were not starved to death. I now made up my mind not to try out-door wintering again. I was determined not to give up if it took my "bottom dollar." In

April I bought ten colonies of hybrids, six of which died before the first of May. Then, besides, one colony of pure Italians, bought of E. Gallup, in June, proved to be very prolific, I Italianized and increased artificially to nineteen swarms. Took from them 300 lbs. honey, twenty-five of which were comb honey, and the remainder "extracted." Did not get my extractor till late in the season. Sold both comb and extracted honey for 25 cts. per lb., and could have sold 1,000 lbs. more if I had had it. The extracted was taken in preference to comb. I prepared my bees for winter, by taking the covers off and raising the honey-boards, to give ventilation, and setting them in the cellar, about two feet from the ground. All except two had an abundance of natural food. The temperature ranged from 32 to 40 degs., usually 35 deg. They are in fine condition, except two, which we have fed on candy.

E. A. SHELDON.

Independence, Iowa.

For the American Bee Journal.

Gallup's New Idea Hive and its Advantages.

Some one has asked for a description of the New Idea Hive, as I use it. For an experiment, I have used my standard frame. But if I was going to commence anew, I should make the frame *wider*, for reasons which I will not now attempt to give. I make the hive four feet long (inside measure) twelve inches deep, and fourteen inches wide. This hive holds thirty-two worker combs. I double case the sides, leaving one-fourth inch dead air space between outer and inner case. The object of double walls is, if bees cluster against the wall, it is warm; while if they cluster against a single wall in extreme cold weather, the consequence is chilled bees and dysentery. I use three honey boards, or the Bickford quilt will answer, just as any one fancies. I use a four-inch chamber, spread cloth over the frames for winter, and fill in with two or three inches of sawdust. Now place the roof over all, make winter passages through the centre of all the combs, but the two front ones, close the rear entrance and you are ready for winter.

I make entrances in each end just alike *nearly* across the end at the bottom, and regulate with entrance blocks; and a little above the centre I have an inch hole in each end. With a full stock, and in hot weather, both ends are open. The inch hole in summer, while the bees are gathering honey rapidly, allows the moisture to pass off which is evaporated; and we never have a puddle of water for the bees to pass through early in the morning; and in winter, providing the hive gets buried in snow, the bees

will never smother,—even if the lower entrance should become fastened up with ice.

You will see that the combs run cross-ways of the entrance in this hive. The advantage of this hive is, bees winter perfectly, and with as little consumption of honey in proportion to the number of bees, as they do in a cellar or special repository. They never fly out in winter, providing we have the cluster four combs from the entrance, unless the weather is warm enough for them to take a flight without loss. We never have to shade the entrance as we do other hives, with combs running from front to rear to prevent the bees from flying in winter. It is a perfect non-swarm, providing we take their honey from them and do not allow them to restrict the queen from breeding. We can raise more bees in this form of hive with less manipulation, than any other form we ever saw, and it always takes bees to gather honey, with us. Mr. Langstroth, in a private letter, says, "*The improvement in hive culture, is as great an advancement in bee culture, as the invention of the movable comb or extractor.*"

Again, providing we place a large swarm in this hive, all the comb is built worker-comb, and if we take out a comb and insert an empty frame, it is filled with worker-comb every time with us, and this is an item of no mean value. Mr. Adair has been ridiculed for advancing such ideas, and I may be also. But *there* are people that wish to advance in bee culture, and there is no harm in giving our ideas to such. I have fully tested the hive, and am so well satisfied that I shall make more of them. I have a stock that now occupies twenty-six combs, with bees. I wintered one small late swarm in the hive last winter, for an experiment, and I never wintered with better satisfaction in the cellar, and my strong stocks wintered splendidly, and every one knows that the winter of 1873 was severe enough as a test, to satisfy the most fastidious.

In this hive we have no use for a division board. Understand that what I call a strong swarm would be two swarms put together from ordinary 2,000 cubic inch hives. We have ascertained to our own satisfaction, that one good queen without any care whatever, will occupy over 4,000 cubic inches of comb in the ordinary manner with brood, in this form of hive. We use the extracted or cell-comb honey in the frame. In this climate we can extract all the honey made up to the middle of August, with perfect safety. In such a hive, and with the Italians, and good, common sense, we have a permanent institution.

No cold, chilling, dampness, or imperfectly evaporated honey, causes dysentery. We have no dysentery in this hive, providing we use good, common sense. The Italians

will renew their queens almost invariably, and with my management there is no feeding to be done at *any time*. They are self-supporting. They breed later in the fall and earlier in the spring; consequently are always strong in numbers, and with us strong stocks are the sheet anchor to successful bee-keeping.

The past season was the poorest that I have seen since I came West. I sold my stock down to fifteen all in large twin and New Idea hives. From seven I increased up to thirty-six, and from the other eight I took 800 lbs. surplus. Now I am not the only person that has been testing this hive. But I have had it tested in Michigan and other parts of this State, and think I am not mistaken if I do claim that every person will like the hive, or that every one will succeed. But I claim that what I have done, others can learn to do. This morning, with the thermometer 20 degs. below zero (Feb. 24, 1874) by listening at the front of my twin hives, the bees are making a loud, roaring noise, showing conclusively that they have to consume honey largely to keep up the warmth. But listen in front of the long hive, and we only hear a gentle buzz or hum, and in moderate weather we can hear nothing, unless we jar the hive, showing just as conclusively that the consumption of honey is but a trifle in comparison.

Now I have used two-story hives, and could use them again, but I know that a two-story hive is not adapted to wintering on the summer stands; neither can we raise anywhere near the same amount of brood that we can in the horizontal hive and continuous chamber. The difference is so marked when we take the season through, that any person must be terribly prejudiced that cannot see it. The hive will cost more than one dollar, and it will be worth more.

E. GALLUP.

For the American Bee Journal.

Top and Side Surplus Boxes.

A question in which some are interested is: "Are top or side surplus honey boxes best?"

When a new swarm enters an empty hive and commences work, they commence at the top of their hive. For this there is a very obvious reason. The form of their bodies and the nature and form of their comb, makes this the most convenient way to operate. From the top they can hang in clusters and work upon the comb and build down half way to the bottom of the hive before the top is fully completed. If top surplus boxes are used when first placed in the hive, they will probably enter them first. If it is a small colony it will be some time before comb will be prepared for the deposit

of eggs in the body of the hive, and brood will be raised in some of the boxes, injuring the surplus honey. If the breeding apartment is as high as the boxes, the boxes on the sides, may be entered by a part of the swarm, at the same time with the commencement in the breeding apartment without danger of brood in the boxes. If the swarm is a large one, from 50 to 100 lbs of surplus honey may be expected the first season.

The side and top boxes both may be placed on as soon as the weather becomes warm enough, that no delay may be caused to the breeding.

"Which are best for surplus?"

This question sometimes receives an answer according to the interest or prejudices of the writer. If a man uses top boxes only, in his operations; he probably thinks and pronounces them best. If one has used only side boxes, he probably is decidedly in favor of side boxes.

I have thoroughly tried both. I have had 24 side boxes upon a hive and no top boxes. I have had 18 side boxes and 9 top boxes upon a hive at the same time. I have been unable to discover any important advantage of one over the other, as to time of commencement or success in using them. Those upon the top have some advantage from the warmth arising from the body of the hive. The side boxes may have the advantage of ease of access and proximity to the entrance to the hive.

I have made it a rule to place guide comb in my boxes to encourage early commencement in them. In the top boxes, the entrance is through the bottom, and the guide comb is attached to the top. My side boxes have glass on the outer and inner end of the box. Inside glass is from one-half to one inch narrower than the height of the box, leaving an entrance of one-half to one inch wide between the glass and the top of the box. I attach guide comb to the top of the box so as to come even with the glass, of about one inch square. I remove the movable partition having the sheet of comb in the breeding apartment entirely uncovered. I then set the nine side boxes on each side; three on the bottom of the hive with the inner end of the box, one-half inch from the comb in the breeding apartment; bringing the guide comb so near that the bees can pass to it as readily as from one sheet of comb to the other in the hive. I then place the nine top boxes upon the top of the hive and the side boxes. With boxes thus prepared and arranged; the nine boxes were as readily entered and occupied and fitted as those on the top. I think the important points are; have your boxes on early; place them in intimate connection with the hive, with small pieces of guide comb to encourage early commencement in storing surplus.

To attach the guide comb, when constructing the boxes, I prepare 10 or 12 more or less ready to receive the top, I lay the top bottom upwards, cut as many pieces of guide comb as are required; I take a lighted candle in my left hand with pieces of guide comb in reach, heat the edge of the pieces in the candle and then press them to the top board; and when cool nail the top board in its place. It is some gratification afterwards to see the bees engaged in filling them all up.

JASPER HAZEN.

Woodstock, Vt.

For the American Bee Journal.

Machine-Extracted Honey.

Since the introduction of the honey pump, bee-keeping has become quite a source of income to the intelligent bee-keeper, and machine-extracted honey bids fair to end the demand for comb honey. The public are very easily convinced of the superiority of the machine-extracted honey, however persistently the people in general stick to old customs. The most these Thomases need in order to be convinced, is to be shown the mode of extracting.

The production of machine-extracted honey is of so much more profit to the bee-keeper than the production of comb honey, that it is worth while to take the trouble to convince the ignorant that the former is the best and purest honey of the two. Every respectable bee-keeper soon gets a good patronage among his neighbors, but the quantities of honey we produce are so large that it requires a little extra exertion to dispose of them. Our *best* honey should be put in glass jars, in small quantities, and every store in the neighborhood should be supplied with "pure machine extracted honey." It should be put up about like canned fruit, in boxes and jars—properly marked with the name of the producer. I adopted some years ago, the square jars holding 1 and 2 lbs. honey, and find them to work admirably. I put a dozen jars in a box, and find a ready sale at the following prices:

1 gross (12 boxes)	1 lb jars	honey@	\$42.00
1 "	2 lb "	"	82.00
1 doz. (1 box)	1 lb "	"	4.00
1 "	2 lb "	"	7.50
1 jar	1 lb honey		.40
1 "	2 lb "		.75
1 "	3 lb "		1.00

For 1 lb jars, especially, I found a good wholesale trade, while the retail trade in my store was about alike in 1, 2, and 3 lb jars. I wish to add that 99 out of every 100 of my customers buy my machine-extracted honey in preference to the choicest comb honey. I have bottled and sold, since last season, more than 10,000 lbs of honey, I sold it, not with the aid of an

agent, but as customers would call for it at the store.

Having bought respectable lots from different parties, I had some experience in the different ways of putting up. This is what I wish to speak about for the benefit of all concerned. We are all apprentices yet, and may be profited by a liberal exchange of ideas.

Crystallization spoils the ready sale of honey, although we all know that pure honey will crystalize. Some kinds will do so quicker than others. Linden honey for instance has, in my experience, crystalized when white clover honey has shown no signs of it, and some white clover honey has crystalized while other white clover honey has kept perfectly clear.

I have now on a shelf a dozen or more of 3½ jars of my own honey, which show not the least signs of crystallization, while I have bought no honey of anybody since November, or end of October but was crystalized. My own honey is very clear, of a rich golden color, and thicker than the thickest syrup. That part of my honey which formed into crystallization, did not expand in the jars but rather contracted, like lard, after having cooled off. And when brought to its fluid state again, by putting the jars in hot water it retained the same substantial thickness. Not so with any other honey I had bought. I had filled several barrels of honey in half gallon fruit jars, to prevent it from candying in the barrels. The jars had tin covers slipped over the mouths. After crystallization had taken place, I found the covers as if on icebergs, sticking one or two inches above the jars, honey running down the shelves, several jars burst in the lower tiers where the covers could not give, and more jars would have burst but for my partly emptying them in time. One and two pound jars, being corked and tinfoiled, had the corks driven out etc. Nothing of that sort happened with my own honey. What was the reason?

I had been particular to leave my honey standing for a day or two after extracting, in tin buckets made for the purpose—stone jars, when buckets did not hold out etc., when I had a good chance of having it skimmed perfectly. I think it essential to not leave a particle of wax in the honey before we put it away for safe keeping, whether in barrels or jars, as that particle of wax may form the nucleus for the crystallization of the honey. I used to heat all of my honey, but found the honey would get dark whenever the fire was too strong.

Next season I shall have a receiver made of tin to hold 500 or 600 lbs, when I shall have a better chance to let the honey stand a few days after extracting, then skim the

top perfectly and draw from below the pure article. The last out of the receiver may be heated over a slow fire if necessary. I should never be satisfied with the honey running through a strainer from the pump into the barrel which was then to be corked up.

Here I would ask: Has the honey too, something like animal heat, which should evaporate before the honey is put up in tight vessels? I have heard of pure honey souring in jars or barrels, and I see it stated by prominent bee-keepers that uncapped or fresh collected honey is too thin and watery to extract, etc. Now I may say there is no thicker honey than mine, and I never had any sour. May not this hasty shutting up be the cause of all this trouble? I have never let the bees cap any honey when I could help it, have pumped every week or whenever the cells were filled. This saved time and labor to both parties, and I have not yet seen my honey excelled. During last month a customer ordered a gross of honey and asked me to exchange two boxes, which had crystalized. They would have been sold long ago, he said, if the honey had not been candied. Accordingly we opened our boxes to dissolve the honey by setting the jars in hot water, (no need to uncork them, but they have to be relabeled) before delivery. The last four boxes in one row had stood there ever since the last honey harvest, it was my own honey and not a jar had crystalized, while all the rest of the jars had crystalized perfectly, most of them with corks driven up a little, as far as the lid would admit.

To sum up the matter I would say: Honey should stand sometime after extracting—to cool off, (?) and be skimmed perfectly and freed from all other substances (running through a strainer is not sufficient) before it is put up in air-tight vessels.

Some bee-keepers have the bad practice of sticking a piece of comb honey in a jar of nice machine extracted honey. This may look nice in the eyes of the ignorant, but it does not look well in the eyes of those knowing better, and it is no more the pure honey, it contains also a piece of wax with those impurities which always will adhere to the comb. Besides it does not take a piece of comb to convince consumers that the honey is pure. Pure honey recommends itself.

Hives not only require a proper handling of the bees but also a proper handling of the product to make bee-keeping a success.

Cincinnati, O.

CHAS. F. MUTH.

If bees are not allowed to possess anything analogous to reason, the regard for their queen, and the watchful care of their young, must result from some pleasurable sensations derived from them.

For the American Bee Journal.

Shall we Clip our Queen's Wings?

Gen. Adair, to whom I think we are much indebted for his "New Idea Hive," holds that the air tubes, which help to form the veins of wings, are important aids in respiration; hence, clipping the wings, clogs respiration, and renders the queen imbecile.

Again, accidental peculiarities are inheritable; should we then crop our queen's wings, at the risk of creating a race of wingless queens? First, as to the facts:—Surely, neither structure nor a false physiology, can hope to refute the well-grounded facts gleaned from experience. The real proof of the pudding is still in the eating; and who of us, that are experienced beekeepers, have not demonstrated that wing-clipped queens are, in every way, the equals of those with "undamaged respiration." An Italian queen, with clipped wings, procured from Mr. Langstroth, and three years of age, netted me \$40.00 during the season of 1873. Half of my queens had wings clipped, and they were fully the peers of the others. All these netted me over \$30.00. Now, friend Adair, is not that pretty well? I believe the experience of nearly all, will refute your theory.

Now for the theory:—To be sure, there are trachea in all the wings, whose certain function is to convey air to arterialize or oxygenate the blood which is to nourish the wings; but after the wings are once fully formed, they need no further nourishment, unless broken down by use. The queen, after her marriage flight, has no further use for her wings in a well-kept apiary; so they need little or no nourishment, blood or air: in fact, are effete appendages, and may as well—yes better—be cut off. In both the white ants (neuropterous), and common ants (hymenopterous), the economy of the colony, and also the nature and functions of the individuals, are very similar to the same among bees; and in their case the workers bite off the queen's wings, to prevent swarming. Yet these queens are very fertile, and apparently very healthy. Can we doubt that nature would have provided for the despoliation of the queen-bee's wings, except that, in nature, swarming was a necessity, and demanded perfect organs for flight? Domestication changes affairs, and thus should change management.

No! Air and trachea are only needed to insure growth and nutrition of the part (the part gone), the air and tubes are no more needed. As well declaim against amputation of a limb, because it would cut off the supply of blood. I believe the two cases are strictly analogous.

But would not the deformity become a

permanent inheritance? It has not, with ants; nor in higher animals has cropping the ears, branding or cutting off the tails, for untold generations, given us cause to fear any danger: and this too, with organs of far greater vitality. Because some tailless cat, in some distant clime, is reported to have brought forth tailless kittens, breeders have made very much of a principle, which every dog experience proves to be exceptional. Congenital deformities, to be sure, are apt to be transmitted, but the same is not true of deformities acquired after birth.

The editor of this journal, compares this practice to the obsolete practice of docking horses' tails. The cases are no ways similar, I think. This is painless, and beneficial; the other, cruel, useless, and shocking to morality and good taste.

Again, God would not have made wings for the queen, etc:—Surely, our friend, the editor, did not offer this as a serious argument. This argument would strip us of our clothing, take the shoes from our horses, and render the males of nearly all our domestic animals much less useful and tractable.

Domestication makes changes desirable; and man has been given a mind capable of suggesting improvements upon nature; else why our houses, barns, or even our improved hives?

It is strange that Dr. Packard should have added his commendation to this theory. He must have supposed that practice or experience demanded it. Yet this is not the first mistake, or hasty conclusion, from men of rare scientific acquirements. Else why did Prof. Riley give credence to the error, refuted by anatomy, and contrary to all experience, and correct observation, that bees eat into grapes, when, forsooth, they only lap up what is rapidly going to waste, through the mischief caused by the stronger jaws of wasps, or frugivorous birds? Extraordinary Swarming in March.

On the 11th. of Feb., the day being warm and suitable, I carried my hives out of the cave and let them have a purifying flight. The day following being cool, they were returned to the cave and left there until the 17th of March when they were carried out and placed on their summer stands. The day was suitable, being warm and calm, and in a short time the air was alive with them. Before we had finished their removal and while carrying others out, I noticed a great many bees about a certain hive, and remarked to my son, who

was assisting me, that there was an extra strong colony. We placed the last one on its bench about 2 o'clock p. m., and I must confess I felt much gratified that all the colonies were alive and in a condition to do well; for my experience the two winters before, had been attended with such a loss that I felt quite a relief when the last hive was out and each one contained a colony of living bees. (For during the winter of 1871-72 and spring following I lost 26 colonies. And in the winter of 1872-73 and spring following I lost 93, leaving 23 to start out with in poor condition. They all died with dysentery.) About 3 o'clock p. m. the supposed strong colony was found to be swarming out and the bees lighting on several hives around, rushed in but soon came out again, joined by the inmates, and such a swarming mania was a new thing to me. The air was full of bees from all the hives and it appeared as if most of those too were seized with the same excitement and joined the big crowd.

After going through the regular course of swarming they settled in two clusters several rods apart, and each one contained enough bees to make ten or a dozen fair colonies at this season of the year. Well, here was a damper, and as I stood and looked at those two huge piles of bees, the pleasant visions of swarms in June, and honey too,—Oh, my, how quick they vanished! And this unlooked for "matter of fact" in its huge proportions hung before me, and the question was: How can I save these bees?

The sun was within an hour of setting, the wind had come in from a cool quarter, and soon the bees would be much chilled. One queen seen on the ground was used to make a colony with; then hastily passing round among the hives, the weakest were selected and an ordinary sized swarm of bees given it, until they were all disposed of. The weather becoming too cool to meddle with them, they had to be left for some time. As soon as it became warm enough, I began transferring the colonies, to clean hives, and helping the destitute as well as I could.

I find I have lost 26 out of 81, with quite a number of feeble colonies to build up. The greatest loss sustained was by the depopulation of the hives from the bees in the air at the time of joining the swarming party and leaving the numbers in the hives so small that they perished during the cold spell that followed. I have kept bees for over 35 years, and have on some occasions had colonies in the spring, destitute of stores, come off and attempt to enter another hive but all these except the first one that came off left stores and brood.

My hives are placed on benches in rows and about 8 feet apart. If this should

come under the notice of Messrs. Quinby, Grimm, Gallup, or any other apiarian of extensive experience, and they perceive wherein I have erred, I shall feel much obliged if they will point it out to me.

Atlanta, Ill.

L. JAMES.

An Enterprising Settler in Nebraska.

The *Lowell* (Nebraska) *Register* prints the record of an enterprising settler. Mr. M. S. Budlong settled on the edge of Franklin Co., Nebraska, bordering on Kearney Co., in March, 1872. When he arrived on his homestead, with his two sons, he had two spans of horses, but only eleven dollars in money. At the beginning of 1874 he had 100 acres of land under cultivation; an orchard containing 500 young apple trees, 100 pear trees, and 100 cherry trees, and a vineyard of 500 grape vines. Mr. Budlong is now about to plant 200 apple trees, 200 peach trees, and 500 additional grape-vines.

The homestead is in Southern Nebraska, and on the level prairie; and no man, who has the spirit of Mr. Budlong need fear to settle where there are no trees to shade his roof-tree from the sun. If he plants as Mr. Budlong has done, in five years his orchard will be coming into bearing; and, if he has made a wind brake of cottonwood, he will have ample fuel for his stoves.

Certainly, eleven dollars in cash is not adequate for the needs of the ordinary settler, though there are numerous instances in Nebraska of men starting in this way upon nothing, as it were, and in a few years working themselves into positions of comfort.—Such men are brave and enterprising; but a capital of \$500, at least, is a good thing upon which to start. The larger the capital—given skill, enterprise, courage and industry, without which money is of little moment—and the greater the gain. There is abundant room and ample scope in Nebraska for men like Mr. Budlong.

For the American Bee Journal.

Rape and what to do with it, etc.

Many readers of the AMERICAN BEE JOURNAL enquire of us where they can find a market for rape near them, in case they sow some? In our pamphlet we state that the proprietors of the Fond du Lac Oil Works will establish an agent wherever a car load of rape can be bought, so you can have a market right at your door. But if that amount cannot be had, the seed may be sent to them in grain bags. Or it may be fed to stock; there can hardly be anything better for sheep, it is, of course, much richer than oil cake; therefore only a very small quantity should be

given at a time. It could be mixed with ground feed, we cannot say in what proportion as we have not tried it. It would thus make very rich and healthy food for cattle and horses.

Our thanks are due to friend Dadant for the light thrown on the grape and bee subject. Fortunately for me it lights up my side only, while it leaves Mr. Riley in the dark; it will afford him a sort of magic lantern view, where, in order to see the object, one must be in the dark.

Hope the advice given by H. W. S. will be followed by those who care to know the facts. It is certainly important to know whether bees are guilty or not. And by fruit and bee cultivators taking close observations, we shall know for a certainty, leaving no room for doubt. In some parts of the country *bee-haters* are crying aloud for laws forbidding bee keeping; asserting that they are a nuisance, and that they destroy fruit, and raise the deuce generally. And if bee-keepers do not remonstrate they will finally succeed in making such laws.

We as bee-keepers should stand by the bees and their keepers, if these charges can be proven to be false. H. O. KRUSCHKE.

To Beginners in Apiculture.

BY PROF. A. J. COOK.

In the article of last month was given the method of queen rearing. Perchance aye, very like, the beginners first effort will be fruitless. Or instead of four queens he may succeed but partially, obtaining but one, two, or three. In this case, or even if his first attempt be an entire success, he had better repeat the operation and be sure that the first year's experience has made him an adept at queen rearing. Any time that we desire queen cells, we have but to remove a queen from the colony—always from our most esteemed colony—and queen cells will be immediately built, and very soon filled. Not only beginners, but every bee-keeper should always have a good number of extra queens during the honey season. The reason for this will appear in the sequel.

TO INCREASE OUR COLONIES.

It is not in the province of these articles to show that artificial division of colonies is superior, hence preferable to natural swarming. But all experienced bee-keepers know this to be the case. Convenience, as well as the best success, demands that the beginner should practice artificial swarming. The apiarist may make two colonies from one, or what will be better for our beginner, be content with an increase of one colony at a time.

Take your rotten-wood and smoke both the

old colonies very thoroughly, and also one of the nuclei, which has hatched out a queen.—The queen should have been hatched 7 or 8 days, that you may be sure that she has met a drone and been fertilized.—Place after the thorough smoking, the nucleus frames, queen, bees and all into a separate hive, then take 3 or 4 frames, bees and all, from each of the old hives, being very sure not to include the queen, as such a mistake would involve the loss of a queen and a check in the operations of the old hive, and that too at a season, when inactivity is attended with serious loss. Put these frames in the new hive with the two frames taken from the nucleus. Now fill in all three hives with empty frames.—These may be put between full frames so as to insure straight comb building, or as I prefer all at one end, so as not to separate brood, in which case the apiarist must see that the comb is built true to the frame. Now place your nucleus hive say, one foot to one side, and place your new colony so that the entrance shall be very near where that of the nucleus was. By moving a few inches each day the hive can soon be placed where desire may dictate. The old bees taken from the old hives will return, while the young ones, the bees from the nucleus, and the rapidly hatching brood will soon make a strong colony. The free use of smoke will prevent fighting which would seldom ensue without it, as the new hive through mixing of bees, together with the great number of young bees, will almost always change anger into surprise.

Now as the bees grow in strength, the colonies may grow in number by a repetition of the above process. By thus making new colonies from several, all the colonies are kept strong as they do not feel the loss of the few bees, few frames, and comparatively small amount of brood. I now have hives (May 9th) with ten frames of brood—frames one foot square. They could easily spare 3 or 4 frames. The great point in successful bee-keeping is to always keep the colony strong, as this fortifies against nearly all the ills in bee-keeping. Another point equally important already hinted at is to suffer no pause in the labor of the hive during the honey season. See to it that no hive is queenless even for a day.

As the warmth and bloom draw on see to it that your bees have plenty of room. If the queen has no room to deposit eggs from the fact that all the cells in the breeding department are full of honey, buy an extractor and extract it. If the workers need more room for storing, put on boxes or put some frames in your upper story. If both queen and workers have plenty of room and are shaded from the hot sun. I think the bees will never hang idly from the outside of the hive.

American Bee Journal

W. F. CLARKE, EDITOR.

CHICAGO, JUNE, 1874.

What is Honey?

Gen. D. L. Adair is reported to have said at the North American Bee-Keepers' Convention: "Strictly speaking, there is no distinct substance that can be called honey. The bees gather from flowers, from the different sweets known as honey dews, and from the saccharine juice of fruits and plants, substances that consist chiefly of sugar in some forms, mixed with other secretions and essential oils, and store it in the comb cells, and it is called honey. It necessarily varies widely, depending on the source from which it is derived. All honey is sugar containing vegetable substances in solution with it. Sugar in all three of its forms is, in a general sense, the sweet principle of plants, fruits and trees. Cane-sugar, fruit-sugar and what is known as grape-sugar, vary but slightly in their constituent elements, and can be chemically converted into each other. They differ only in the proportion of hydrogen and oxygen, or the element of water. Bees will gather and store up anything that sugar in any of its forms are mixed with, so as to give a decided sweet taste; and while it may be true that in the process of gathering and transferring to the hive, no chemical change takes place, they mechanically change its taste by its absorbing the scent peculiar to the hive, and often change its consistency by a process of evaporations of any excess of water."

Gen. Adair is a very scientific and successful apiarian, and we can usually endorse his views to the full. But he is occasionally hyper-philosophical, and pushes science too far. It may be quite true that sugar is the basis of all sweets, honey included, but it is convenient, to say the least to have distinctive terms for the various saccharine substances, though the one luscious principle pervades them all. Only confusion of ideas can come to the popular

mind, by forcing too much philosophical accuracy into common modes of speech. Thus, we call one form of sweet, molasses; another, syrup; and still a third, honey. What is the good of arguing that there is no distinct substance that can be called molasses? It is the popular and commercial name of a liquid sweet obtained from the West Indies, having a peculiar flavor, and capable of being distilled into rum. Yet we all know that its main constituent is sugar, or the saccharine principle. So of honey. It is a liquid sweet, gathered from a thousand flowers, acted on in some peculiar way by the honey-gatherers, and possessing a flavor and properties peculiar to itself. But mankind were pretty well aware, before Gen. Adair delivered his philosophical disquisition, that honey was mainly composed of sugar.

There is a question as yet unsettled among scientific bee-keepers, to which Gen. Adair seems to give the go-by altogether. He says, "It may be true that in the process of gathering and transferring to the hive, no chemical change takes place" in the sugary stores collected by the bees. On the other hand, it may be true, as many suppose, that a chemical change *does* take place, and that the formic acid in the body of the bee so acts on the gathered sweet as to transform it essentially. There may be more than an influence mechanically exerted by the odor of the hive. Each hive is generally considered to have its peculiar scent, and hence in joining swarms or introducing new queens, it is good policy to introduce smoke or some perfume to confound the bees for a time, until the new colonists or newly-introduced queen come to smell like the rest. But honey, if gathered from the same flower, is all alike, no matter in what hive it is stored. At any rate, human senses cannot detect any difference. It is therefore quite as probable that the change is chemical, as that it is merely mechanical. On the whole, we are inclined to think that the great majority of people will persist in believing that there is such a thing as honey. If they should come to a different opinion, and conclude that it is mere sugar, "only that and nothing more," we fear it will spoil bee-keeping, and that it will no longer be possible

to obtain twice or three times as much as for common sugar. "Where ignorance is bliss, 'tis folly to be wise."

Successful Wintering.

To the Editor of AMERICAN BEE JOURNAL.

Sir:—I notice an item in your valuable paper, as follows:—"He may be regarded as a master in bee culture, who knows how to winter his stock in a healthy condition, with the least loss of bees, the smallest consumption of stores, and with the combs unsoiled."

Well, then, I am a master in bee culture, for I have succeeded in all of the above particulars, combs nice and bright, bees all alive, and my strongest stocks have not consumed more than 15 lbs. apiece. I will tell you how I proceed. I study the "Bee-Keeper's Guide," use the "Thomas" hive, have built a bee-house according to the "Guide," only I make the walls 18 inches thick, filled with oat straw well packed in, have two doors, one to open inside and the other out, and put newspapers between these two doors. Through the winter I open the bottom ventilator when the weather is warm, and close it again when the weather grows cold.

I prepare my hives for winter by removing the honey board, and place on a frame of inch stuff covered with wire cloth, then fill the cap with wheat straw, by turning it over, and filling it in nicely, so that it will not fall out when placed on the hive. I leave the bottom ventilator of the hive open. My bees are always healthy on natural stores, and I think it too bad to extract all their honey and winter them on sugar syrup. Yesterday my bees were working lively on meal prepared of two parts of buckwheat flour, one of wheat flour, with a little sorts and bran mixed in.—I am, etc.,

ILA MICHENER.

Low Banks, April 14th, 1874.

[We congratulate our correspondent on his attainment of the degree of M. B. C.—"Master in Bee Culture." His plan of wintering is undoubtedly a good one, though we should fear, without a large amount of ventilation, the bees would be too warm in an ice-proof house, with the hive cover stuffed full of chaff. Growing experience, however, inclines us to the opinion that bees are oftener hurt by getting chilled than by being kept over-warm. To judge by the small amount of honey consumed, we should be inclined to think Mr. Michener has hit the happy mean

between the two extremes of heat and cold. We should like to know if his house is regulated by the use of a thermometer, and if so, at what degree of temperature he keeps it. We should also like to know if the past winter is the only one during which his bees have been treated in the manner described, or if he has had several years' experience of the method. We are acquainted with numerous bee-keepers, whose experience has been very variable in wintering their bees in a similar way. We believe that this was the case with Mr. Thomas himself, whose plan, as described in the "Guide," Mr. Michener has substantially followed. We can testify that it has been ours. "One swallow does not make a summer," nor does one season's success in wintering a lot of bees constitute an apiarian a "Master in bee culture." What is wanted is a definite method, which has only to be followed to secure uniform and certain success. So far as we know, no such method has yet been demonstrated.]

Back Volumes.

Complete sets of back volumes are scarce. But few can be procured at any price. We have a set, consisting of the nine volumes (complete), which we offer for sale, either bound or unbound, for a reasonable sum. Many of the numbers we have paid fifty cents each for, to complete them.

We have several single volumes (complete) which we will send postpaid for \$2.00 each.

Several volumes, which lack only a single number of being complete, we will send postpaid for \$1.50 each.

Vol. 1, we can supply in cloth boards, postpaid, for \$1.25. Bound in paper covers, \$1.00, postage 10 cents. This volume is worth five times its price to any intelligent bee-keeper. It contains a full elucidation of scientific bee-keeping, including the best statement extant of the celebrated Dzierzon theory. These articles run through eight numbers, and are from the pen of the Baron of Berlepsch.

Beginners in bee-culture, who desire to read up in the literature of bee-keeping, are earnestly advised to obtain these back volumes. Many of our best apiarians say they would not sell their back volumes of the AMERICAN BEE JOURNAL for ten times the sum they cost, if they could not replace them. They are exceedingly valuable alike to beginners and more advanced apiarians.

Voices from among the Hives.

ARCHIBALD SMITH, Roswell, Ga., writes:—"The season here, although *mild*, has been so *wet* since January, that bees have hardly got a living; notwithstanding the fruit bloom was very abundant."

JOHN DAWSON, Pontiac, Mich., writes:—"This has been a poor spring for bees. They wintered well enough till March, but there have been many days that were just warm enough for bees to fly and get lost. I have known bees to gather pollen from the gray willows, on the 7th and 8th of March; but it was April 30th, this year, before any were taken in, and we have had frosty nights and cold, bleak days ever since. The buds on fruit trees have hardly begun to swell yet."

W. A. B., Bridgeport, Ct., writes:—"The best thing I have ever tried for ee-stings, is to first pull out the sting, and then take a small tube, the end of a hollow key for instance, and firmly press round the sting for a short time. The reasons for its action, I think, are two; first, it presses out the poison; second, it bruises the flesh so as to partly stop its spreading. It must be done very quick to do any good. I have tried it, and a good many other remedies, and this has done the best."

H. W. WIXOM, Mendota, Ills., writes:—"The past winter has been easy on bees, but the spring has been very rough. I have lost nearly one-third of mine since the middle of March. There has been so much high and cold wind it seemed to prevent them from breeding, and the old bees are thinning out very fast. Those that are left will be very weak. The case is about the same generally throughout this section of country. It is now raining and cool, and it is hard to tell what the final result will be."

HENRY CLAUSSEN, Mishicot, Wis., writes:—"My bees have wintered well. I put them into the cellar Nov. 5, seventy-one in number, and carried forty-two of them out April 2, and the rest April 8. I lost only one hive, because they had nothing more to eat. Three colonies lost their queens. One was an old queen, but the other two were raised last summer. My bees are all in good condition, although the weather has been cold almost all the time since I took them out. On April 20 we had a snow storm; the snow was lying about a foot deep, and a good deal of it is lying on the ground yet (April 15). Some of my colonies have brood in four, and some in five frames. I hope for a good season."

E. A. SHELDON, Independence, Iowa, writes:—"My nineteen stands of bees that I put in cellar on Nov. 18, were taken out April 17, all alive and in splendid condition, save two that died for want of bees enough to keep up natural heat. They had plenty of natural stores. The seventeen that are left are working at a rapid rate, bringing in both honey and pollen, although no fruit trees are in blossom yet. They have gathered from the willow, mostly, of which we have an abundance here. I wintered in a dry cellar, with caps off, board raised, and front entrance open full size. The thermometer ranged from 32 degs. to 40 degs., generally from 34 degs. to 38 degs. Occasionally I raised it to 50 degs. by artificial heat. They were quiet all winter, and had no disease or mouldy combs, are now about one-half full of brood. I use the Gallup frame hive. I have used other sizes, but like this best."

WM. MORRIS, Sidney, Iowa, writes:—"The past winter has been a long one with us, but rather mild, and bees seem to have consumed more honey than usual. The spring is very backward, and now (April 30th) the ground is covered with snow. We have had two days since the elm came out in bloom, that the bees gathered pollen. With that exception, they have been unable to get any forage, except flowers fed them. I am trying to keep bees, and hitherto have had reasonable success, up to within the last two weeks. Since that time, the conceit has gone from me, I went into winter quarters, with twenty-seven colonies. They were in the Champion hive, part of them in the size containing eight frames, and part ten. In the fall I removed to the cellar twelve colonies, part in the large, and part in the small hives. In February, those in the cellar were all in good condition, but those on their summer stands were more or less affected with the dysentery. On examination I found every small hive affected, but no signs of dysentery in a single instance among the large ones. A few warm days seemed to set all right, and I was pleased at having come through the winter without losing a colony, but my rejoicing was of short duration. About two weeks ago the weather was pleasant, and the bees flying, when to my surprise four colonies left their hives. We succeeded in settling one, but the other three went "where the woodbine twineth." I examined the deserted hives, and found all nice and clean, and plenty of honey-brood and eggs. It is a mystery to me what caused it. At first I feared that it was caused by having previously examined them to see if all was right, but my neighbors suffered loss in the same manner. They had a large colony in a hive, which came out and settled on a tree. They knocked the hive to pieces and transferred the comb with what honey they could save, to a movable comb hive, and then lived the bees in it. They went to work immediately, as if nothing had happened. The remaining honey in the hive weighed 40 lbs. So neither disturbance nor want of honey could be the real cause. Now what I desire to know is: Are large hives less liable to be affected with dysentery, than small ones? And what is the cause of bees leaving their hives, stores and brood, as ours have done? Can some of your numerous correspondents give the desired information?"

D. D. PALMER, Eliza, Ill., writes:—"Wishing to procure a basket-full of new chips, I left New Boston at 4 p. m. April 16, in a covered buggy drawn by the iron horse and reached Keokuk at 9: 15 p. m., crossed the Mississippi on the iron bridge, and on awaking next morning I found myself at Hamilton, Ill., and within about two miles (bee-line) of Ch. Dadant and Son. According to directions I followed up the creek, occasionally stopping to view nature's works, which in this place is grand and picturesque, till I came to a town composed of bee-hives of various colors and arranged in rows under the shade of a natural grove. At the upper end of Main Street and near to the above mentioned town is the residence of the proprietor; to which I hastened my steps and found myself in time for breakfast. Bees and bee-keepers was the topic of conversation during which I was shown photographs of a few apiaries and of many eminent bee men of Europe and America, besides an endless number of circulars of bees and hives. Every letter and circular received finds its appropriate place for preservation.

I have formerly thought, when reading an

article translated from some foreign bee journal that, we should be very thankful to Dadant and others for that tedious task; but finding that C. P. Dadant can take a French or Italian journal and translate in English as fast as we usually read, I have concluded to give him credit for his ability instead of a tedious task. C. P. Dadant announces that it is warm enough to open hives; we arm ourselves with bee hats, made by attaching bobonette to a straw hat and at the lower end is a piece of elastic which fits around the neck, a shallow box with a handle in the middle and divided into suitable apartments in which is carried the different articles needed in the apiary.

A number of hives are to be fixed for shipping and now for the *modus operandi*. Each hive is examined to see if pure and if strong enough to fill the order. To secure the frames an ingenious bent wire is used at the bottom, it being one of Ch. Dadant's inventions, next the frames are properly spaced and nailed with brads, then the honey-board is nailed and cover etc. I saw several queens and they were very uniform in size and color. They are well located for shipping facilities, but the honey resources are not plenty when compared with Sweet Home. In all things they have system and order. The hives are all numbered behind and to each is nailed a tin black-board holder, the black-board being about 3x4 inches, having upon the corner of one side the number of the hive and upon the opposite side a liquid-slating on which is written with pencil the condition of the hive, age of queen etc., the writing is turned inward to prevent being erased, when empty the black side is turned outward. The numbered side can be inverted or changed in various ways to mean as many different conditions. I said that his hives were numbered, the nuclei for raising queens were numbered by letters of the alphabet.

They use the wax comb-guide described in *Gleanings* page 12, vol. 2. Also the divisible frame, *i. e.* dividing a full sized frame into equal halves for the nuclei—see Ch. Dadant's description on page 29 of *Gleanings* vol. 2.

They believe bees should have salt, and for that purpose they have a stand in the apiary on which they invert a small-mouthed jar, having previously filled it with strong brine and covered with muslin which is tied around the neck. Is salt necessary or beneficial? Of what use do bees make of it? Why do they prefer water that is salty?

C. P. Dadant used a slate pencil for his black-board writing, it suggested the idea to me that a slate would be better than a board, I accordingly procured me eight school slates for 70 cents, which I cut in 64 pieces about $2\frac{1}{2} \times 3$ inches each of which is large enough. On one side I have put the number of hive and on the opposite I put the record and condition of the hive. While talking with W. T. Kirk of Muscatine, Iowa, about the above he said: "Why not drill a hole in the slates and hang on a nail?" If slates could be procured without frames they would not cost, labor and all, over one cent each, which is less than the black-board, and so far I think much better to write on. With a rule and slate pencil I laid off the slate and then I sharpened one end of a file with which I cut it on opposite sides and then broke as glaziers do. And with a brace and the above file I drilled the holes, slate is soft and easily cut.

I forgot to mention in its place that Dadant uses the "quilt" or rather a very heavy muslin, they dip the edges in bees-wax to prevent the bees cutting, then the original honey-board is placed on top to hold it down.

J. M. SIMMONS, M. D., Lauderdale, Miss., writes:—"I bought 4 box hives, and one of King's \$10 close-top hives and transferred my bees and combs to them.

King has the idea in some respects if he would cut the frames to $\frac{3}{8}$, leave off his supers and make the hives longer and deeper. Last fall having read so much by Novice about wintering I reduced my 10 stocks to 6, but I think the 10 would have wintered better and now I would have 10 stocks instead of 6. Last fall I sent to R. M. Argo for two Italian queens and he sent me some fine-looking ones, but no directions about making queen cages, so I lost one in introducing them. After my loss I introduced one of the old queens and they must have killed her, as I found the hive queenless when I examined it in January. I commenced this year with six hives but having to unite the queenless one and letting one starve I reduced my stock to four. In wintering my stocks last fall I did not kill any of the queens, and the first warm spell this year, two swarms came out of two of the united hives and went back. I examined the hives and found a dead queen in each and many bees dead in the hives and outside. Well, I supposed just then that I was minus two queens and many bees from disease, but I found upon examining the frames two very fine large queens and they are to-day the finest queens I have, and have the largest stocks.

These swarms remained in those hives all the winter and as soon as the weather moderated they took a notion to separate but finding it rather too cold outside, they returned and were killed. In March I was examining one of my hives and found them killing their queen, superseding her, for they had started a queen cell. I cut it out and gave them a frame of eggs and brood from my Italian stock and now have two fine Italian queens and two stocks instead of one, but I am afraid they met common drones instead of Italian as I had some of both. I have tried to keep the common drones out of my hives by killing and uncapping. I want to Italianize all stocks this year.

I find there are two kinds of native Southern bees in this section, one a little black bee, cross and spiteful, stinging every thing that comes near, the other a large yellow bee as large as the Italian and very much like them in their disposition and habits, but they have none of the Italian marks, they must be a cross of the Italian, for my queens are as large or larger than the Italians, but much darker. I never use smoke unless I want to unite them, and not always then. I have dispensed with supers and converted my two-story hives into single story hives 34 in. long holding 21 or 22 frames 12x9 in. inside measure.

My bees have quit sugar since they got natural supplies, unless it is cool or raining, then they work on it. I don't think handling bees often injures them, if the weather is pleasant, for mine don't stop working unless I disturb them a good deal, and I think sometimes that opening the hives is a benefit and starts them out when if left alone they would do nothing.

I am trying a small patch of Alsike clover to see if it will do for our hot climate. Buckwheat does well here, tried it here last year and bees worked on it freely. This has been a bad season for bees but they have commenced gathering honey. The great trouble with us is insects, and want of frame hives, most all use the box and gum hives and call the queen the king bee, and say it is wrong to sell bees but you can steal them and all is 'O. K.' "

Room 27, Tribune Building, Chicago.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

The German Bee-Sting Cure can be obtained at this office. Sent by Express for \$1.00. It cannot be sent by mail. See notice.

Our subscribers in Europe, can now procure Postal Money Orders on Chicago. This plan of sending money is safe and economical.

Subscribers wishing to change their post-office address, should mention their old address, as well as the one to which they wish it changed.

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

The *Scientific Farmer*, the finest and cheapest paper of its class in the world, will be sent for three months for 25 cents, or with its Chromo, "Just One," for 50 cents.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. $\text{\textcircled{P}}$ 1b.

ST. LOUIS.—Quotations from W. G. Smith 419 North Main st.

Choice white comb, 25@29c; fair to good, 16@22c. Extracted choice white clover, 16@18c. Choice basswood honey, 14@16c; fair to good, extracted, 8@12c; strained, 6@10c.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 $\text{\textcircled{P}}$ gal. St. Domingo, and Mexican, 90@95 $\text{\textcircled{P}}$ gal.

SAN FRANCISCO.—Quotations from Sterns and Smith, 423 Front st.

Choice mountain honey, in comb, 22 $\frac{1}{2}$ @25c; common, 17@20c; strained, 10@12c, in 5 gallon cans. Valley honey, in comb, 12@17c; strained, 8@10c.

New Club Rates.

THE AMERICAN BEE JOURNAL will be sent one year with

Novice's Gleanings, for - - -	\$2.25
The Scientific Farmer, for - - -	2.50
The National Bee Journal, for	3.00
The Bee Keepers' Magazine, for	3.00

A CHOICE OF SIX VOLUMES for \$5.—Having a few back volumes complete, and some lacking only one or two numbers each, we will give the purchaser the choice of six of such volumes for \$5.00, until they are disposed of. As only a few can be supplied, those who wish to avail themselves of this offer, should send for them *at once*.

$\text{\textcircled{P}}$ We want several copies of No. 1, Vol. 2, of the AMERICAN BEE JOURNAL, and will pay 50 cents each for them.

The postage on this paper is only twelve cents a year, if paid quarterly or yearly in advance at the post-office where received. We prepay postage to Canada, and require twelve cents extra.

If you paste anything on a Postal Card, when you send to this office, we have to pay six cents postage on it. The law demands that there shall be nothing attached to it in any way, without paying double letter postage.

Send stamp for a sample copy of THE SCIENTIFIC FARMER, an illustrated monthly for the Farm and Fireside. It will be sent from now to the end of the year 1874, with the AMERICAN BEE JOURNAL one year for \$2.50, or with the choice of Chromos—the Fruit Piece, or the new and lovely household gem, "Just One," for \$2.75.

No. 7.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

For the American Bee Journal, Wintering, etc.

I felt very much encouraged as the winter months passed away, to find all my bees alive, as well those left in my charge for the winter by the firm of Nunn Bros., of Oberlin, amounting in all to 133 stocks—30 of my own and 103 being one of Nunn Bros.' apiaries. But the spring months brought very different results. On Feb. 5th all were alive, and apparently in good condition. A few lacked stores, and had to be fed accordingly. On the 7th of Feb. I found 8 of my own dead, and 4 or 5 of Nunn Bros.' and every warm day in which the bees could fly showed that another one or more had run its allotted time—but the worst had not yet come. It was certainly hard to see 50 or 60 stocks die, and *apparently* no cause, but to see the remaining ones dwindle down to small, weak stocks and have to unite them and notice them in a few days still diminishing, and that in April, and uniting as many as 3 or 4 together, and in May still be weak I felt *blue* as I had never before. I united and united, until I reduced my own to 3 stocks and Nunn Bros.' to 26, leading them with the choicest queens. Then some of them seemed very undecided whether life was worth the living or not, but others prospered remarkably well.

Before I ask the cause of such mortality, I must give the circumstances somewhat in detail. Hives, Standard Langstroth; some well packed with straw; nearly all had blankets; about 20 with honey-boards, all of which died; straw packed in upper stories. Last time of extracting, in September. The week following each hive had an average of 35lbs. of honey, and 8 or 10 frames of brood, (some even 16) and many of them young queens. There were very

few older than 2 years—that is queens of the fall of 1871, mostly the production of 1872.

The strangest part is the manner in which the bees acted. In the month of May I opened a weak stock and discovered that the bees were not clustered, but spread all over the hive; brood scattered around in all stages; bees paying little attention to it, and the queen trying to be where most of the bees were. On opening one hive, the queen appeared to be disgusted with the ungallantry of her attendants, and flew out without a follower. They all left honey in abundance with the exception of about 6, which left little or none.

If Adair's theory is correct, that a queen can lay all her eggs in a season, then it is possible that the queens being unable to keep up the colony, was the cause, as some of them had kept from 15 to 20 frames full of brood all the summer. But on the other hand there has been a number of stocks die around here, or rather in a certain direction, and I am inclined to think that Prof. J. P. Kirtland is correct in attributing it to an epidemic; for when travelling 18 or 20 miles from here, I found a section of country where all the bees had died, whether in movable frame or box hives. On either side of it, very rarely one had died.

Perhaps some one will account for it a little more satisfactorily than I can. I would like to know the opinion of others about it.

I spoke of Nunn Bros. leaving their bees in my charge for the winter. Their object was to take a trip to Europe; and while in Italy they purchased 30 queens, and arrived at their destination (Oberlin, O.) with 27 living, which I think is rather remarkable.

I see an Advertisement in every Journal of "Winder's New Extractor," working from the bottom, PATENTED. If your readers will refer to the April or May No. of the AMERICAN BEE JOURNAL for 1873, they will find an article headed "A new contributor." They will see that I used one then, (before Mr. Winder's was patented) and I have had it for 3 years. I do not claim to be the inventor. It was suggested to me by Nunn Bros., and I carried out their principle, and as they did not wish to

patent it, I spoke of it in the JOURNAL thinking others might value it as well as myself.

I would like to know wherein Mr. Wind-er claims his patent. AVIS.

For the American Bee Journal.

Artificial Swarming.

I take from my prosperous colonies, two frames of brood with adhering bees, until I have enough to fill a hive. Watch carefully, about the time the first queen hatches, and cage her, before she destroys the other queens. This week, I caught the first queen that hatched, in one of my new colonies, put her in a cage, leaving her until the next day in the hive where she hatched. I then made a new colony, and placed a frame of brood and adhering bees, with a queen ready to hatch from this hive; I then released my queen in the hive where she hatched.

In a few hours queen No. 2. was out and was well received. I intended to catch her before she destroyed her rivals, but was too late. I obtained four queens in this way, from one new colony. I have never succeeded in cutting out a queen cell and giving it to a queenless one.

I wish the fathers in apiculture would stop grinding their axes for a little while and give us their *modus operandi*.

Peoria, Ill.

MRS. L. HARRISON.

For the American Bee Journal.

How to make Artificial Swarms.

Those who have movable comb frame hives will find it to their interest to artificially swarm their bees. There are many ways by which this can be done, and of all the different modes, I have found the following to be the most satisfactory in my experience:

I will first go to stock No. 1 and take away one-half of the combs, taking about one-half of the brood and one-half of the honey, putting in their place empty frames. Do not put two empty frames together, but between frames of comb, so that the bees will build the new comb straight. I brush the bees all off of those frames of comb etc., and take a new hive and place them in it, with alternate empty frames as above stated, for same reason. Now I go to stock No. 2, between eleven and twelve o'clock, and remove to another part of the apiary, always selecting a strong stock, and put the new-made hive in its place, and you will be surprised at the number of work bees that will go in and take possession of this new hive; and finding they have no queen, will soon commence making queen cells. But I generally, nine or ten months prior to this time, have set my best and choicest colony

to raising queen cells; so that I now save ten days by going to that colony and cutting out a queen cell and inserting it in this new made stock, which I do from four to six hours after I let the workers in as above stated. In this way the apiarian can keep his stocks strong all the time and increase them remarkably fast; and should any stock from any cause become weak or need strengthening, you can give it a comb of brood and all the bees that cling to the comb, from a strong colony; but you must be careful not to take the queen with them; better shake the bees from the comb unless you know that the queen is not on it.

J. M. DORR.

For the American Bee Journal.

The Bees and Grapes.

One word about bees eating grapes. The past three Falls have been dry with us. I have two fine vines on the south side of my house within 20 feet of my bees. Not a grape did they touch. In my garden not 40 feet my bees, I have several vines. Two years ago I caught the yellow birds eating the grapes. They would alight on a stem and pick a hole in every grape; then the bees took the balance. I put up some rags and scared the birds away. I had no more trouble with the bees. Those on my house they did not touch; I had 171 stands of bees. I have watched them closely, and I don't believe a bee ever molested a grape until they had been opened by birds or something else. A man is to be pitied that would recommend poison for bees, or would kill the little songsters for a few grapes that they kept the worms from them all summer. I never write for publications as it would tax the editor too much to put it in shape. F. SEARLES.

Hadley, Ill.

Not a bit of it. Give us your best thoughts and we will always be glad to put them in shape. Every practical bee-keeper is invited to write. We want *variety*, and our bee-men are invited to send us everything of interest.—EDITOR.

For the American Bee Journal.

Sundry Notes.

Spring has been so lagging that our pets have not done as well, up to this time, as is usual; and what was quite remarkable the cherry, apple, pear, horse-chestnut, sugar maple, lilac, and currant were in bloom at the same time, and of course stimulated breeding greatly, although a fortnight later than last year.

I attempted to raise a few queens as early as the first week of May, but the bees would not respond.

There is no pleasure in the apiary, next to a healthy condition, equal to that of queen raising; and no disappointment greater than when you have put your trust in man, and have sent for tested queens at a price and find them wanting.

I passed a good part of last summer in such disappointments, and as it is three weeks at least before one can detect the imperfections, it is a great loss of time in any apiary; and it might be a serious loss to one who depended upon queen raising as a source of income. Late in the season I sent for a low-priced queen, and by return of mail received a beauty, which proved to be pure and prolific, and from her I have raised my early queens. Such has been my experience with high and low-priced queens.

For my part I do care whether the color of the queens, young or old, are of the rich chestnut, or the lighter and as some think more beautiful golden, but I do not want too much of the "horrid black," as this makes me distrust the purity of the ancestry.

If the queen cell is started from the egg, or from the worm only a day old, and is attended by enough bees to keep it liberally supplied with food and sufficiently warm, I have found no difference between such a raised queen and one from a crowded colony at swarming time.

Have you ever known queenless bees to take an egg from a laying queen that was caged and put over the frames? I suspected it, this spring, from the fact that the first two or three queens that hatched from a breeding hive, in which I had placed a caged hybrid queen for safe keeping, were of a beautiful golden color, while the rest were nearly as black as common bees. To test this I twice made a colony of bees in empty combs, or combs to which no queen had had access, for at least a fortnight; and in both instances queen cells were formed near the top of the combs, and eggs deposited in them. In one of them I let the bees raise a queen which proved to be a hybrid. May not this be a source of error, and a really good queen condemned?

In two instances last summer, I found two laying queens at the same time in the same hive. One of these old queens rather liked the colleague idea for I put her into another colony and after filling the hive with brood, repeated this partnership operation. In trying this again I lost her, by introducing.

E. P. ABBE.

New Bedford, Mass.

The odor exhaled from the hives, and the size of the bees on their return from foraging excursions, are always sure indications whether the flowers contain honey.

For the American Bee Journal.

The Bee Malady.

The all-absorbing topic of the unusual mortality among bees during the past few years, seems to be neither exhausted nor satisfactorily explained. My experience in handling bees commenced more than 40 years ago, and I have been an interested bee-keeper the greater part of my life. I have wintered them and closely observed their habits and conditions in the States of New York, Pennsylvania, Indiana, and Northern Minnesota, where we had four months of steady cold, every winter, and for the last four years in this place, near Cincinnati, O.

I have read all of interest or importance that has been published on the subject in this country; besides considerable from Germany. I have, during the last five years, visited many apiaries to try to ascertain the cause of loss or failure, where there had been such. The result of all this research has been to convince me most fully and firmly that I have obtained enough of the experience of others, combined with my own, to enable me to winter bees in any climate between the southern line of Ohio and Lake Superior region with as little loss as horses, cattle, mules, poultry, or any other farm stock. I am prepared to give facts and figures which will demonstrate the correctness of my views and render them acceptable. While nearly all the prominent bee-keepers of the country have given their views upon the subject of the recent great mortality of bees, no one has, seemingly, solved the problem, even to his own satisfaction; but nearly all have made some point or points in the right direction.

Mr. James Bolin of West Lodi, O., says, in the April No. of the AMERICAN BEE JOURNAL, p. 75: "I believe it was caused mainly by cold and disease engendered by the same. That there was dysentery, I freely admit, for I saw the most convincing proofs of that among some of my neighbor's bee that died; but in every case, it was where the bees were wintered on their summer stand or, placed in cold depositories—no better, if as good as the summer stand."

Then he goes on to state a number of interesting cases which would strongly indicate the correctness of his conclusion, and the same has been so often expressed by Quinby, and many others, and demonstrated by stated facts which cannot reasonably be doubted, we may as well mark down right here one point gained.

Now we will try to demonstrate as clearly that no degree, or continuation of cold experienced in any portion of the United States is sufficient to cause this mortality

among the bees when all other conditions are right.

In the winter of '66 and '67, the first winter that the disease appeared in epidemic form, I was living 200 miles north of Hosmers' place in Minnesota, where the bees are usually confined to the hive for months at a time by the cold, and during some portion of this time the mercury was frozen at 42 below zero, and, as Major Jack Downing said, "it would have been a good deal colder if the thermomikin had been long enough." Here it was common for the bees to remain on their summer stands 2 or 3 feet above the ground, in the open air, with no protection whatever except what a single inch board afforded. The hives were mostly the box, of the *tall* persuasion. Some of them were made with a chamber above for surplus. These had a cloth laid over the holes above and filled in with fine hay. Others were made with a partition through the centre and one apartment used for surplus. This apartment was left empty and the passage holes open at the top, middle, and bottom. All had fly-holes open half way from top to bottom. It was a very rare thing to hear of any loss among bees there. An old bee-keeper who had been there much longer than I had, said to me "our bees are never injured by the cold if they are properly ventilated." But, said he, "you must never depend upon lower ventilation for the moisture will condense and run down, freeze and stop it up, and then the bees are gone."

We never fed anything but honey up there. I heard of no extensive loss there, except in one instance. One man wintered 60 swarms in a depository made for the purpose, and lost 40, mostly after setting them out in April.

Is it natural stores that causes disease among the bees? Friend Hill, who took the premium for the best conducted apiary at the last Cincinnati Exposition, keeps from 80 to 100 swarms which he winters on their own stores, and has had no sign of disease among them during the last four years. His bees winter on their summer stands, and he uses a blanket and dry leaves over them in the cap. Hives shallow, Langstroth.

Friend Muth winters on top of his store in a bleak situation, same hive, blanket and straw mat laid over the frames, a strip of board an inch thick laid across each end of the mat leaving an inch space between the mat and the cover, for the circulation of air, to keep things dry. The situation is in the business portion of the city. He has near 40 swarms I believe. All wintered on their own stores, also without trace of disease for four years past. He wintered a swarm two years ago that

contained less than a pint of bees, outside, in a full-sized Langstroth hive, without division board—also natural stores.

Friend Gano,—a wholesale hardware merchant in the city, keeps about twenty swarms for pleasure. Has had them for many years, is very observing and well-posted in their habits and needs. He is situated in the suburbs, 2½ miles from me: winters out, on natural stores, and no protection except abundant ventilation, in this wise: fly-holes open below, surplus boxes removed, leaving the passage ways all open through the honey board into the surplus chamber, and the caps so open as to give the occupants below abundant opportunity to see the stars. He has had no disease among his bees. A portion of his hives are tall and a portion, the shallow Langstroth. In cold winters he has had quite a number of swarms starve to death in the shallow form of hive, with ample supplies all round them, but none above the cluster. During the long cold spell a year ago last winter, he removed the honey board from one of these shallow hives and laid several pieces of honey in the comb on the frames and set up a couple of thin boards to partially cover them inside of the cap; and they came through the winter in that condition and made one of the most prosperous stocks he had that season.

Last season I kept the combs in the brood-nest of all my hives clear of honey with the extractor, until the last week in June, and the consequence was, the hives were crowded with bees and the combs full of brood. On the 1st of July honey gathering ceased almost entirely. After this no brood was reared of any amount except what the combs contained at the time, and when winter set in they were more reduced in numbers than I ever had them before in the fall, and were all old bees. In October they got a little honey from the aster. In November I gave them a thorough examination, and estimated the amount of supplies by taking out and weighing a part of the combs and estimating the others. The heaviest stock was 10 lbs. Hives were numbered and the amount in each noted. I then fed them syrup.

April 10th the 34 stocks were in fine condition. Two lost their queens, one queen was a drone layer, not pure, and I killed her. And a few days since I found a queen in a knot of bees, and made a mistake and gave her to a wrong stock and the queenless stock was robbed during my absence. My bees were all in the Langstroth hive, on summer stands with straw mat and quilt or blanket over the frames; the cap on, with the cover raised ¼ inch all round by tacking on bits of thick leather for the cover to rest on. M. NEVINS.

Ohio.

Michigan Bee-Keepers' Association.

SPRING SESSION.

KALAMAZOO, Mich., May 6, 1874.

Pursuant to a call for special session of this association, a goodly number of beekeepers assembled at the Corporation Hall, in this city, to-day. Convention called to order at two o'clock P. M. In the absence of the secretary—Frank Benton—H. A. Burch was elected secretary *pro tem*. After the usual reading of minutes of previous meeting and the transaction of business relative to the financial affairs of the Association, the programme for the meeting was taken up. Papers were presented and read as follows:

Standards of Excellence in Bee-Culture, by Herbert A. Burch; in which the writer took occasion to demonstrate the necessity, and urge the adoption of "standards of excellence" by which very efficient aid might be rendered the apicultural fraternity.

Transferring, and Surplus Honey, by C. I. Balch; delineating a simple and safe plan for beginners in apiculture.

Artificial Swarming, by T. F. Bingham; a novel method, having much to recommend it.

Low Hives, by Julius Tomlinson; in which the writer portrayed the advantages of shallow frames.

Wintering, by Prof. A. J. Cook; setting forth in brief and concise form, the essentials of success in wintering bees.

The discussion of the topics embraced in the foregoing essays, though somewhat desultory, possessed much interest, being instructive withal; a brief epitome of which, we give as follows.

T. F. Bingham.—Can we rely upon obtaining drones from young queens?

C. I. Balch.—Yes, in abundance.

A. C. Balch.—I have no difficulty in inducing young queens to fill all the drone comb I give them. Am troubled with superabundance, rather than paucity of numbers.

Henry King.—Is it safe to open hives in cold weather?

T. F. Bingham.—Yes at any time when the bees will not freeze. Though the books caution against chilling brood, actual experience has demonstrated that this danger is wholly imaginary. The more hives are opened, the better for the bees.

H. King.—Can we not ascertain the presence or absence of the queens, without the trouble of closely examining each hive, separately?

T. F. Bingham.—There is no more necessity of opening hives to ascertain queenlessness, than there is of employing a microscope for that purpose. Place your ear

close to the hive and tap it sufficiently hard to wake the bees; if the response is energetic and ceases almost instantaneously, they have a queen; but if the response is languid and dies out slowly, they are queenless. I have found this rule so invariably correct, that I never open hives to ascertain queenlessness, even if examining hundreds, and never make mistakes.

Julius Tomlinson.—I have fully tested Mr. Bingham's plan, and have found it simple and perfectly reliable.

Mr. Evarts.—Are there outside indications of a queen's presence in the hive?

T. F. Bingham.—If immature young bees are seen in front of a hive, it is satisfactory evidence of the presence of a queen. Queens, like some persons, are erratic in their movements, eluding the most careful search; and to ascertain to a certainty the presence of "her majesty" without examining the combs, is a great saving of time in managing a large apiary.

Mr. Evarts.—Will queenless stocks gather pollen?

Pres. A. C. Balch.—Not to any extent.

T. F. Bingham.—They will in the fall.

C. I. Balch.—Yes, if they have drone layers.

James Heddon.—Queenless colonies are easily distinguished by the diminutive pellets of pollen that the bees gather in spring.

Dr. Southard.—Has any one experienced difficulty in regard to queens dying the present spring?

T. F. Bingham.—I have lost a great many, and had it not been for reserve queens which I wintered, should not have had a swarm left to-day. Have lost 160 stocks as it is. Two years ago, when I lost heavily, the queens died from overwork; but the present spring, there has been but very little brood to be found even in the strongest colonies.

Pres. Balch.—Will Mr. Bingham tell us the cause of his loss in wintering?

T. F. Bingham.—Special interposition of Divine Providence through the hand of man.

C. I. Balch related instances of queens deserting their hives. One queen that persistently refused to stay at home, deported herself as "becometh" a queen, when given to a queenless colony.

Albert Caniff.—Why this loss of queens? My own theory is that the old bees die and the hive becomes depopulated; they swarm out.

T. F. Bingham.—My queens died in their hives. I experience little or no difficulty in wintering bees; but how to "spring" them; that's the question.

Pres. Balch.—My bees have become very much reduced in numbers, by the bees getting lost while "out a foraging," on chilly spring days.

James Heddon.—I can only account for the loss of bees by desertion, on the ground that they become dissatisfied and seek to better their fortunes, the same as people do by "going West."

J. P. Everard agreed with Pres. Balch relative to the cause of the weak condition of bees the present spring.

A. Caniff.—Why will one swarm with only a pint of bees stick to their home, and prosper, while another with two quarts swarm out and die?

James Heddon.—Some bees, like human beings, can stand more grief than others.

C. I. Balch.—When my bees were first placed on their summer stands they were in good condition, though having but little brood. A cold, stormy spell of weather soon followed, which materially injured them. Returned them to the cellar soon after, and had they been left out two weeks longer all would have been ruined. When replaced on summer stands in April, a dozen stocks did not have as much brood as one should have had, when first taken out in the previous February.

After some further discussion of the why's and wherefore's of losses sustained in wintering, the subject of hives was taken up and discussed at considerable length. From the brief synopsis given below, it will be seen that a wide diversity of views were held and expressed on this "knotty question" of what is *best* in a bee-hive.

J. R. Everard favored the size and shape of the "New Idea" frame. The advantages which will accrue from this style, will, in my opinion, render it the coming frame of the future.

James Heddon.—I cannot agree with the ideas advanced by Prof. Cook, relative to the square frame. The long frame recommended some years ago by Quinby is preferable, especially for wintering.

C. I. Balch.—If we expect to succeed in making apicultural pursuits a success, we must use a frame that will give us a compact brood nest. This will greatly augment our success in wintering. Several years ago I constructed several hives holding ten frames in the usual manner, with a stationary division board in the rear.—Back of this was a space for holding two combs, a one-inch hole giving bees access to them from main apartment. In winter, left it open and have never lost a swarm in them.

James Heddon.—In my county, there is but one hive that has been continuously occupied by bees during the past seven years. This was an old box hive, that had remained on summer stand every winter, having abundance of ventilation. In transferring it in April, obtained 250 pounds of honey, and bees enough for two good swarms. I found drones in abundance.

Though this additional evidence in favor of large combs.

Sec. Burch.—What were the dimensions of the hive?

James Heddon.—Three feet square, and thirty inches deep.

Mr. Evarts.—I have experienced difficulty in obtaining box honey on large hives. What is the remedy?

James Heddon.—To get the most honey you must have it stored in close proximity to the brood.

C. I. Balch.—I have had 216 pounds of honey stored by a swarm in a large hive. It was comb honey obtained in small frames. I get more than twice the amount of surplus honey in large hives than I do in small ones, while the bees in the latter are very apt to come up missing in the winter.

J. P. Everard.—Difference of locality influences the result. We should not lose sight of this.

James Heddon.—Cause and effect follow each other. Can we not ascertain the cause?

Pres. Balch.—When bees are wintered on summer stands, I find old box hives, full of cross sticks, do the best. Ease of access to all parts of the hive, and little ventilation are thus secured. The space around movable-frames is a great detriment in winter and early spring. If we could dispense with it entirely, so much the better.

A. S. Haskins.—Which is the best location for surplus honey, heavy timbered land or "openings?"

H. A. Knapp.—I prefer a location which was originally an unbroken forest.

C. I. Balch.—Much depends on the season. One season timbered land may be the best, and the next *vice versa*. White clover is very uncertain in its yield of nectar.

Adjourned till eight o'clock p. m.

EVENING SESSION.

The convention was called to order promptly at eight o'clock. President Balch in the chair. The subject of discussion for the evening was announced by the chair to be "*Wintering Bees*," in its broadest sense. Pres. Balch read an able paper on "Ventilation" and the relation it sustains to the loss in wintering bees.

The discussion was opened by

James Heddon.—Ventilation is an important feature of successful wintering. Wintering 36 stocks in a special repository that would hold 150. Gave ample upward ventilation. When the temperature was 10 degrees below zero outside, it was 34 degrees in the repository. Bees are more quiet with a higher temperature. In order to attain the best results, keep the temperature at 45 degrees or above.

H. A. Knapp wintered in a cellar several years without ventilation, and lost heavily. The past two winters had taken off honey boards, filled the caps with straw, and had good success.

Pres. Balch.—Did you winter in a house cellar?

H. A. Knapp.—I did.

Pres. Balch.—That accounts for the loss.

H. A. Knapp.—I think not. The two past winters I had the bees directly under a living room—never had better success. My cellar is very dry.

James Heddon.—It seems from reports that bees have wintered well with and without ventilation, and *vice versa*. One thing is certain: long continued confinement and severe cold weather produce disastrous results.

H. A. Knapp.—Ventilation should be given so as to avoid direct currents of air through the brood nest.

T. F. Bingham.—Notwithstanding this learned discussion on ventilation, success depends altogether (!) on luck.

The secretary read a paper entitled a "New Method of Wintering" by H. E. Bidwell, detailing the success attending experiments made with a view of attaining complete and uniform success in wintering bees. This method gives promise of being a simple and efficient safeguard against loss in "Winter Bee-Keeping."

T. F. Bingham.—Mr. Bidwell's plan is certainly unique; and if it shall prove what is now hoped for it, will be one of the greatest achievements of modern apiculture. I am convinced that one-day's fly with the mercury at 45 degrees is only an aggravation. Not until the bees had flown three or four days in succession with the temperature at 60 degrees, was dysentery checked in my own apiary. It is a disease, just as much as typhoid fever. Cold may aggravate the disease, but does not cause it. An affected swarm will communicate the disease to those around it, either by contagion or the uneasiness caused by excitement. Gave lower ventilation—none above. Think the last immaterial. Bees must fly at least once a month, commencing in December.

James Heddon.—I tried Mr. Bidwell's plan; success limited.

C. I. Balch.—When I learned of the "Bidwell method" I decided to test it at once. Did so and failed. I then visited Mr. Bidwell and found it a complete success with him. My own failure was owing to non-compliance with the requisite conditions.

T. F. Bingham.—Much has been said in reference to dysentery being caused by honey. Close observation convinces me that, while honey *may* aggravate the disease, it is never the prime cause. "Novice"

has lauded sugar syrup to the skies, asserting that it will winter bees without loss. Had he not better demonstrate that *he* can do this, before making such sweeping assertions.

Jas. Heddon.—I wintered in a special repository. Sugared one half; all wintered equally well. Those left out-of-doors in 1872 all died before those inside had any disease.

Dr. Southard.—Have tried many plans, and lost in nearly all. Wintered in cellar the past winter. Bees went into winter-quarters very strong. Combs moulded badly, but lost only one swarm when set out; lost very many since. Honey was of a better quality than the year before, but lost more bees.

C. I. Balch.—Have had more candied honey the present spring than ever before, and have lost more bees also.

T. F. Bingham.—I used artificial heat in my building the past winter, and think it indispensable. Had no dampness—no cold—and not a mouldy comb. Every comb is bright and clean—the bees leaving the hives to die. Think 35 degrees the right temperature. High temperature and breeding go together. Science may aid us, but after all we must trust to luck (?) and Providence for results. What are moth-proof store-combs worth, provided they can be made?

James Heddon.—Double value; that is, if natural combs are worth \$6 per hive of ten combs, artificial ones would be worth \$12. I would willingly make that difference.

T. F. Bingham.—If we can procure drone comb for wintering, we can avoid all disease. Bees gormandize pollen and rear brood, which is the *cause* of dysentery.

James Heddon.—In feeding sugar syrup last fall found little or no brood—abundance of pollen. Deprived a portion of natural stores and pollen, substituting the sugar. All wintered equally well, and all breed alike this spring. Had all young, vigorous, Italian queens.

T. F. Bingham.—We continually hear of the wonderful workings of the bee: its skill in science, and proficiency in architecture; the hexagonal cell, etc. The truth is, bees build the hexagonal cell because they could not do otherwise; were compelled to this in order to perpetuate their own species.

Pres. Balch.—So far as my own experience goes, all insects work by instinct, not science. In wintering, I experience more difficulty in spring, the warm days enticing them away from home in search of food—than in cold weather of winter.

After further discussion, the subject of time and place for the next annual meeting was taken up. Many were opposed to

having it in connection with the State Fair—too much outside attraction to make the meetings a success. Later in the season, when the bee-keepers could command more leisure, was deemed preferable. The convention finally adjourned to meet in Kalamazoo, on the third Wednesday of December next.

H. A. BURCH, *Sec. pro. tem.*

We give below statistics, as far as ascertained, of what our bee-keepers did last season. We think the showing not altogether unfavorable, even when compared with that of the National Society. It will doubtless be observed that the "bee-disease" has not subsided altogether "out West."

For the American Bee Journal.
Novice.

DEAR BEE JOURNAL: Were we to set about picking all the flaws in friend Adair's writings and works that we could, as though we had a case to work up, and bound to show all his weak points, etc., we presume we might keep up an animated controversy all summer. Some would applaud and say, "now you've got him, Novice, he can't get around that," and perhaps an equal number would say, "Adair is too much for him, he had better twist out of it as he has a way of doing, etc., etc.;" and perhaps a few might profess a particular sympathy with each one side when writing them, and this latter class are productive of the most mischief perhaps of all. One class would become more and more settled

in their convictions that Novice was the aggressor, and the other *vice versa*; and no real good would come of it all, any more than will perhaps from further arguments at present in regard to "Queen's wings."

Perhaps Mr. Adair is 'right, and that we have not done him justice. If so, we beg his pardon and will endeavor to submit with better grace when we see reason to conclude he is right all through Progressive Bee Culture. In place of arguing as to what is on the inside page of the cover, we would ask those who have the curiosity, to read it and form their own opinion. If we misrepresented, we beg pardon, for we did not intend to, and cannot see now that we did, in substance.

Although Mr. A. has taken extracts here and there from our writings, and held them up in a way that makes one look ridiculous, and in a few places does us gross injustice, we cannot really think it best to censure him so much, for this is a common method of attack in controversies. Again, several things appear badly against us because all the facts are not known; one of them is in regard to the Peabody Extractor.

Were we to tell just how we came to recommend it publicly we should drag another person forward into a controversy perhaps, so we prefer to let the blame rest on us. With the rapid strides bee-culture has made, it has many times been hard to decide what is best, and we really must confess on looking back that Mr. Adair has some reasons for his charge respecting what we have advised.

Will he and some others remember that our opinion was continually asked and is yet, on many difficult points, and we could do no better than to answer them to the best of our honest convictions. If he ever had any such foolish belief that we are "capable of the job of regulating the whole bee world," we certainly are cured of it now. Reports of losses of whole apiaries come to us from all quarters, and under seemingly almost all circumstances, and we honestly haven't a word of advice to offer. If friends Adair and Gallup, would tell us how many colonies they had in the fall, and how many they have now,—May 29th,—we might form an opinion as to how much aid we might hope to expect from adopting their long hives and mammoth colonies. So far as we can learn, stocks made purposely of double strength in the fall, have fared but little better. Although as we have said, failures are reported when everything seemed most favorable. On the other hand, Apiaries located but a short distance away, have wintered as usual under even unfavorable conditions. Dysentery seems to have had little or nothing to do with it this spring, but the trouble seems to have been simply a dwindling

away of the bees, until none are left to care for the brood. We have never yet found a case that reported unfavorably in regard to sugar for wintering when the full facts were brought out, unless it be the one on pages 132 and 133, and we would be much obliged to the writer of that article for his full address.

It is well known, we believe, that our reverses have been given just as faithfully to the public, (perhaps more,) as our successes and we can hardly consider it fair to make an enumeration of the former only, as Mr. Adair has done, sending eggs by mail, for instance;—this we were induced to do by accepting the statements of some whom we considered trustworthy, before we had had an opportunity of verifying the matter ourselves. However we offered to refund all money sent us for eggs, as soon as we discovered it to be a failure. And by the way here comes something queer. Mr. Adair, among the rest, wrote us for eggs, saying his stock of Italians had got reduced or failed, or something of the sort, and at the convention he states that a number of queen cells were started on the inserted comb and *all of them produced queens.*"

This was the *only instance* we know of when a single queen was reared when the eggs went out of our immediate neighborhood, or so far that they could not be inserted in a hive the same day. Why should Mr. Adair class it as "vagaries," if he succeeded so well, in fact far beyond everyone else? Since we have got your ear friend A. please tell us where the "Annals" is that your advertisement keeps saying was out in Dec. 1873.

We are not yet convinced that queens on an average can use more than 20 combs, when we are, we will make hives longer. You wouldn't have a body believe a thing before they thought it was so, would you? We don't wish to appear to doubt what you and Mr. Gallup say about the capability of your queens, but those we are acquainted with frequently fail to occupy ten Langstroth frames. Shall we accept it as a fact that the very idea, of occupying a "New Idea" hive fills their little selves with the boundless ambition of being able to fill every cell with eggs in 24 or more frames?

In soberness, the bees we have known, and the ones we get letters about, do not deport themselves near up to accounts we get from Quinby, Hazen, Gallup nor Adair—begging their pardon if they object to being thus put into a "four horse team,"—and we have seen them tried in 18 or 20 frames spread out horizontally for several years past too. But we do get by far too many accounts of "blasted hopes," to decide that bee-keeping at the present time could even be considered a safe business

for anyone to embark in largely.

Our offer to make the Quinby hive 25 *per cent* less, ready to nail, should read 25 *cents* less, ready to nail.

We beg pardon, Mr. Editor, if we are writing rather dolefully, but we have no facility for invoking merry words when prospects do not seem to warrant them.

At present we have only 16 queens, and scarcely bees enough with them, for 3 good colonies. Unless Mr. Adair objects, on the ground that we have not earned the title, we would prefer to keep on as your old friend,
NOVICE.

P. S. It is no more than justice to ourselves to add that we made the remark over a year ago, that if *as much* honey could be secured in a hive of double width, as with the two story one we had better adopt it simply to avoid the laborious operation of lifting off an upper story in extracting. A trial of such hives in different localities, it seems, would demonstrate that full as much honey can be secured thus. Now the Langstroth frame was planned with an idea of a two-story hive, or at least for surplus boxes on top. Should we abandon them and spread the 20 frames out horizontally, we would have a hive much more difficult to handle than one with narrower and deeper frame; also, it would be difficult to make a cover for such a hive with a single board which can be done readily with a frame not exceeding 14 inches in depth. Mr. Langstroth suggests such a frame (see page 38 *Gleanings*) with no thought of Adair's "New Idea," and in deciding on the dimensions of a frame to be used solely for the extractor we had no idea of copying the above more than in adopting the frame which he had named the Adair frame in our classification of frames. This frame being about midway in length and depth between the extremes as Mr. Gallup partly states it, it would seem, that there would be a greater probability of its being adopted as a standard. Our reason for turning the frame crosswise is that, in using such hives in our Hexagonal Apiary they must almost of a necessity be turned so as to stand close up to the grape vine trellises, or they would obstruct our walks. We prefer the entrance in one or both ends, because in using a division board it can be adjusted without interfering with the entrances. In recommending our Standard hive to our friends we do it with no expectation of realizing any such great advantages as the advocates of the "New Idea" claim, over the two story hive. If it answers just as well we shall be pleased, because it lessens the labor of extracting; if it shall do all that Adair claims for it under all circumstances, we will most cheerfully record him the full credit of horizontal hives over two story.

Do not our readers agree that we are excusable in feeling much hesitancy in accepting Adair's reasoning? see page 129 *Bee Breathing*; and shall we clip *Queens Wings*? page 137. The former seemed to us to be only the reviving of an exploded theory so palpably erroneous as to require no other notice than to simply call it "folly". Prof. Cook has our sincere thanks for coming forward at a most opportune moment, and giving such support to our position, as could only be furnished by a skilled Entomologist. With pleasure we accept scientist's apology, and also thank him for his kind reproof.

Bees as Architects and Mathematicians.

Man is obliged to use all sorts of engines for measurement—angles, rules, plumb-lines—to produce his buildings and to guide his hand; the bee executes his work immediately from her mind, without instruments or tools of any kind. "She has successfully solved a problem in higher mathematics, which the discovery of the differential calculus, a century and a half ago, does not enable us to solve without the greatest difficulty." The inclination of the planes of the cell is always just so that, if the surfaces on which she works are unequal, still the axis running through it is in the true direction, and the junction of the two axes forms the angle of 60 degrees as accurately as if there was none.

The manner in which she adapts her work to the requirements of the moment and place is marvelous. In order to test their ingenuity, Huber glazed the interior of a hive, with the exception of certain bits of wood fastened on the sides. The bees cannot make their work adhere to glass, and they began to build horizontally from side to side; he interposed other plates of glass in different directions, and they curved their combs in the strangest shapes, in order to make them reach their wooden supports. He says this proceeding denotes more than an instinct, as glass was not a substance against which bees could be warned by nature, and that they changed the direction of the work before reaching the glass, at the distance precisely suitable for making the necessary turns, enlarging the cells on the outer side greatly, and on the inner side diminishing them proportionately. As the different insects were working on the different sides, there must have been some means of communicating the proportion to be observed; while the bottom being common to both sets of cells, the difficulty of thus regularly varying their dimensions must have been great indeed.—*Scientific American*.

For the American Bee Journal. The Bee Disease.

For three years past I have remained somewhat silent in regard to the calamity among bees termed, Dysentery, learning what I could from the bee journals and other sources; so many conflicting opinions have been expressed that I should even now be left in the dark as to the cause, were it not for the dear-bought experience I have had during these three years. I will give a few facts and let others judge for themselves.

In the spring of 1871 I took a quantity of bees to work on shares, the latter part of the season was very dry and no breeding of consequence was done. In the fall the man that owned the bees took his away. He sold some 20 swarms that I did not learn the fate of; about 60 that he retained were put in a cellar in the bank. All but two or three swarms came through in good condition. I had 110 swarms which I packed by the side of a tight board fence with straw betwixt, behind and above. Some 20 of the number were put into a cold cellar. All had the so-called Dysentery, and I lost 80 swarms before May. In the season of 1872 I increased up to 83 swarms, packed again as before in winter, not being satisfied but that was the best way yet to winter out of doors. In the spring of 1873, May 1st, I had lost 76 swarms, leaving 7, and 2 of which could be said to be in good condition; the other 5 seemed to be demoralised, killing and superseding their queens. All had the dysentery but the two swarms above mentioned, they were very strong. The swarms were a part of 14 left on their summer stand in the Badger State hive to test the quality of the hive for wintering. My neighbors again wintered his well in the cellar.

Not being entirely discouraged with my losses, I went at it again with a will. I bought some bees and worked some on shares, so that in the fall I had some 45 swarms.

Not daring to venture another Poland winter, I concluded to build a bee-house to put the pets in; I built it double-walled of wood, 8 inches between filled with sawdust, and the outside veneered with brick, made double doors and ventilated with my bees in, the thermometer indicating from 35 to 40 degrees above zero. I think it would have been better if I had seen it up to 50 as some of the very small swarms had the dysentery while all the strong ones did well, bred up and came out strong this spring; some of the stocks that I worked on shares the owner took away the last of November. I advised him to put them in a warm place but he had more confidence

in his own judgment than in mine. I saw him the first of April, "Well, neighbor," said I, "how are the pets?" "All dead," he replied. "Where did you put them?" "I put them in the barn on the scaffold over the north door. They were being opened half a dozen times a day all winter. A very little hay was put over them." This was the very worst place he could put them, unless on top the barn; well, I went to see them and sure enough they were all dead, while mine that stood by the side of his before dividing, were all alive.

With the experience I have had, I have come to the conclusion that long continued cold or dampness will produce the so-called dysentery. Weak swarms will suffer first even in the same room or out of doors. I would not say that some other causes might not produce a disease of a similar kind. I knew once some ten years ago that the bees died with a disease resembling the dysentery. The season before had been very wet, so much water in the honey collected that but little was capped over when cold weather came that winter. In the ensuing spring many bees died.

We are now brought to May 23rd. Bees came out of winter quarters comparatively good, but the long, cold spring has carried away probably one-half the swarms that were in good condition the first of April. So you see we have the blues again. I am running about 35 swarms at home. Some are in the Excelsior Hive, some in the Badger State Hive, and some in the High Pressure Hive, a combination of the two. It is so arranged that two single ones may be worked,—single at 2500 cubic inches, or combined may be made to hold five, ten or twelve thousand five hundred cubic inches. It may be worked with ten, twenty, thirty or forty frames. It may be worked two-story on Novice's plan, a long one-story on Adair's plan, with 40 six-inch boxes on Hazen's plan, with the twin hive plan of Gallup, or long boxes and little frames plan. I will report hereafter the success of each.

A. H. HART.

Appleton, Wis.

For the American Bee Journal. Do Bees Injure Fruit?

I have noticed a controversy in the AMERICAN BEE JOURNAL in regard to bees destroying fruit in which statements were made, I am sorry to say, in language that the subject did not by any means call for. We may present facts and arguments without unkind words.

I have been associated with bee culture half a century. Have kept bees and cultivated fruit together for about twenty years and will present a few facts. Langstroth

says at page 85 of his excellent work on bees, "the jaws of the bee being adapted chiefly to the manipulation of wax, were too feeble to enable it readily to puncture the skin even of his most delicate grapes." This was for me conclusive, but to the facts:

1st. Three years ago Thomas Atkinson introduced the Queen Bee Hive with a slide at each side to form an air chamber to equalize the temperature of the hive. This slide was made of paper-board nailed to a wooden frame, and the bees cut it into holes, till pints of paper dust had to be removed, and the paper-board had at considerable cost to be changed and wooden picture-backing put instead. This was the case with some hundreds of hives.

2nd. In transferring bees, to fix the comb into the frames, I tied the combs in with cotton cord, and the bees cut that and pulled it out, many getting fastened in the string and dying; they also cut out hemp twine in the same manner, and chair-seating cane is now used entirely.

3rd. Having 5 acres in grapes of many varieties, my daughter, in gathering Concord grapes called my attention to the bees alighting on the fruit on the other side of the trellis and eating the grapes; and both of the past seasons all of the family have watched the bees *alighting on perfect berries, cut the skin and fill themselves with juice*. It is so with the finer kinds of plums, pears and the thin skinned peaches.

My loss in this manner has been quite considerable. I love the bees, love to keep them, do keep them, and just so with fruit, but the facts are true and it is only just that they should be known.

Having had about 30 colonies the damage was considerable, but, then, bees are kept by my neighbors and they feast on the fruit as well as my own, and I would lose the fruit and not have any honey if I gave them up.

Whether there are differences in climate or in the want of a full amount of bee forage in St. Louis Co., Mo., it is at present hard to say. Nay, may not the instincts and habits of the bee develop, and as he finds fruit-juice more abundant and more easily obtained than the nectar of flowers, may he not prefer it?

As the season of all these fruits will soon be with us it will be a good opportunity to watch, make notes and report.

Names could be given as witnesses but facts will convince much better. Kind tones are more taking and equally as impressive as harsh, unkind words and low slang or innuendoes.

I feed my bees when they need it and never poison or brimstone them.

WILLIAM MUIR.

Fox Creek, Mo.

For the American Bee Journal.
Do Bees Injure Fruit?

In the June number of the AMERICAN BEE JOURNAL, Prof. Riley tries to sustain his position, by affirming that *he has seen bees cutting into fruit*. I have just read an article in the journal *L'Apicoltore* of Milan, Italy, (May no.) that I translate, in answer to that bold assertion.

"Being a lover of good wine, I manufacture mine with shrivelled grapes; my crop amounts annually from 30 to 40 *hectolitres** of such wine, worth an average 1 franc 75 centimes to the litre.† As my grapes are gathered, I spread them upon a mat of reed or straw, in a sunny place, in front of my apiary; where they remain to shrivel for about 15 days.

For the first two or three days the mats are covered with bees; but I do not care, for I know that they do no damage; having ascertained that they gather only the juice of the berries, rotten or damaged. As soon as the injured berries are sucked dry, the bees quit visiting the mats, for they cannot cut the skin of the berries. In any case I can say that, instead of damage, the bees help me greatly; for they take off entirely, from the bulk of my crops, the putrefied juices, which would give a bad taste to my wine." GACTANO TAXINI.

Coriano, Circ. di Rimini, February, 1874.

I think that after such testimony, the assertion of Prof. Riley is of little account. Hamilton, Ill. CH. DADANT.

* An hectolitre is equal to 25 gallons.

† Equal to \$1.40 the gallon, that price is very high for Italy.

For the American Bee Journal.
Doolittle's Article.

Our bees had but four days on which they could fly, from March 3rd to May 4th; and by the 15th of April all brood rearing had ceased in small and medium stocks, and pretty much so in large ones. On March 18th the mercury rose to sixty degrees in the shade, and bees were seen at work quite briskly on stumps of the sugar maple, but with the night it became cold and we had steady winter weather until April 15th, when they had a chance to fly again. On April 19th, 22nd, and 25th, snow fell to the depth of one foot, and lasted until May 3rd, during which time the mercury did not rise above 41 degrees, even in the middle of the day, and went down as low as 18 degrees.

May 9th it came off quite warm, and the bees began to hatch the few eggs the queen had laid, and brought in the first pollen of any account, which was from elm and soft maple. Skunk's cabbage was in full bloom from March 20th to April 18, but it

was so cold that the bees could not get to it. On the whole, we think it was the worst spring for bees we ever knew. May 4th the first day that we could really work at bees, we examined them and found some so weak that we thought it best to unite them. We did so, and now have 51, one of which proves to be queenless, so we shall call it but 50 stocks to commence the season with. Golden willow commenced to blossom May 20th, from which our bees frequently get from 5 to 7 lbs. of honey, but owing to the cold and rainy weather they could get nothing, and what was worse still, they killed nearly all the larvae: so little but sealed brood and eggs remained. May 24th it became warm again and our bees have done their level best ever since, and the hives are beginning to be quite well populated with bees. Apple trees blossomed May 29th and our strongest stocks made a gain of 12 lbs. of honey during the time they were in bloom. White clover was nearly all killed from freezing the past winter, so we do not anticipate much from that, but basswood hangs as full of buds as we ever saw it. We forgot to say we put one swarm in manure "a la Novice," and that died out-right some time during the cold weather of April. Our first drones were flying June 5th, which is nearly two weeks later than we ever knew them before. We have spread the brood once in six days, so we have our strongest stocks nearly full. What we mean by full, is brood in from 8 to 10 Gallup frames.

By the way does not Gallup and Adair get off some pretty big notes about the capacity of a queen for laying? We have had queens from nearly every breeder in the United States and the best we ever had would not keep more than ten Gallup frames full of brood, or about 900 square inches of comb occupied with brood for two months in succession. We came to the conclusion that 800 square inches of comb would be about the average, so last year built our new hives to hold but nine frames instead of twelve. As the bees will have some honey and pollen in their combs the 9 frames give us about 800 square inches of brood, or 1380 cubic inches comb space. We place 42 boxes of 2 lbs. capacity in this hive and expect to get all the honey the bees make in the boxes, but last year they stored enough to winter on in the frames.

Why does not Adair tell us how much honey he receives on an average in his apiary with those prolific queens and large hives? Let us figure a little and see what is best. 800 square inches of comb would give 40,000 worker bees every 21 days or 1,905 every day, and as 45 days is the average life of the bee in the working season we would get 85,625 bees on the stage of

action at once. 21 old stocks of the above brood capacity worked by us in 1873, produced on an average 80 lbs. of box honey, and 60 stocks worked by N. N. Betsinger, Marcellus Falls, N. Y., produced on an average 100 lbs. of box honey. Now as 4,000 cubic inches comb capacity (the amount Gallup and Adair say their prolific queens will keep occupied with brood) is nearly three times the capacity of the hive used by B. and myself, they must get the enormous amount of 256,000 bees on the stage of action at once. This would be 5,700 bees daily or that amount of eggs for the queen to lay every 24 hours. As it is estimated that, by the use of the extractor one-third more honey can be obtained than with boxes, an apiary with such queens should produce on an average 320 lbs., to be equal to that produced by us or 400 lbs. to equal that produced by Betsinger. As Gallup's hives worked exclusively for extracted honey produced in 1873 only 100 lbs. per colony (the same amount produced by Betsinger in boxes) and as it will take three times the honey to feed the brood in the large hive, we will leave the reader to tell which is best—one colony in a large hive to produce 100 lbs. of extracted honey, or three colonies in small hives with the same amount of brood to feed, to produce 300 lbs. of box honey. If friend Adair can give a better report than Gallup we would like to hear from him on the subject, as we want all the light we can get.

G. M. DOOLITTLE.

Borodino, N. Y.

For the American Bee Journal.

How to Introduce Queens.

I write with a sincere desire to benefit many a fellow bee-keeper, who, when the fine golden queen arrives will ask himself the perplexing question—"How shall I introduce her." I have been so uniformly successful since I adopted the following method that I unhesitatingly recommend it. It is certainly as safe, and I verily believe much safer than the common practise of caging, and the advantages over that plan are too obvious to need mentioning.

To illustrate—Have a new queen at hand, also two empty hives B and C, the latter should be nicely cleaned. Now open A and proceed to find the queen you wish to supersede. This over, the work is soon over. I look over the frames, guess where she is and lift that frame out first. When satisfied she is not on it, place it in B, and try another. If not found on this, the chances are, if she is a black queen, that you will have to search the corners of the hive for they are shyer than the Italians. The queen dispatched, remove A and place C with its entrance near where that of A

stood, but with positions reversed. Now replace the combs in C, first shaking off the old bees. The young ones will do no harm, and in order to confuse the bees still more, I change the positions of the frames where the combs will admit of it. These all in place, cover with the quilt, now roll up a corner at the back end, and slip her majesty in, roll back and put on the cover. Place a hiving-board in front; put the two hives (if there are bees in both,) at the foot of this on their sides, and let the bees enter A gradually, like a natural swarm, thus introducing them to the queen, who by this time is less confused and feeling more at home than themselves. The bees all in, the hive should be turned so as to occupy the exact position that A did. No bees will be lost, and my experience has proven to me that all will be well. The regular order of business resumed at once, the same as if no change had occurred.

Perhaps I ought to have said, that I usually have at hand some sweetened water scented with peppermint and sprinkle the combs slightly before putting on the quilt, and also the bees, before allowing them to enter, though I have occasionally omitted this precaution, and observed no difference in the result.

E. K. G.

Appleton City, Mo.

The Late Dr. T. B. Hamlin.

It is a painful duty to announce the death of so prominent an apiculturist as Dr. T. B. Hamlin,—one who as a friend was so highly esteemed by all who knew him. This sad event occurred at his residence, near Edgefield Junction, Tennessee, on the 24th of last May.

Dr. Hamlin was born at Red Hook, on the Hudson River, N. Y., in June, 1810. At the age of sixteen he was left with no near relatives and but little education. His prominent position and financial success in life are wholly due to his own indomitable energy and perseverance combined with his uprightness of character. At about eighteen he was foreman of the largest watch-making establishment in Albany N. Y., and probably the largest in the United States. After preparation in dentistry at Albany and while watchmaking in Lee, Mass., he commenced the practice of that profession in Virginia. While there he took an active part in the organization of the first dental association known in the world. He afterwards removed to Alabama and thence to Nashville, Tenn., where for twenty-five years he followed his profession with eminent success.

More than forty years ago the young watchmaker of Albany, shortly after his marriage in Lee, Mass., where he had established in watch-making, commenced the keeping of bees. This last named occupa-

tion was continued for many years thereafter in connection with his profession as a dentist. In 1861 his health, which had failed early in life, became quite poor, and he gave up the practice of dentistry and repaired to the sea-coast at Newport, R. I. At the close of the war Dr. Hamlin returned to Tennessee and devoted his whole attention to bee culture and the nursery business. The extensive business of the "Cumberland Nurseries" which he established in connection with Mr. B. B. Barnum—a practical nurseryman, was conducted mainly by the latter, while he devoted his attention almost wholly to the apiary. He was the first to introduce the Langstroth movable comb hive and the improved methods of bee culture in the South, and to engage in the importation and rearing of Italian bees, which he did extensively, and aided in their introduction throughout the United States. He assisted greatly in establishing the "Tennessee Apian Society" of which he was President, and also, the "National Bee-Keepers' Association," being Vice President of the latter at the time of his death. His interest and enterprise in the promulgation of apian knowledge, especially in the South are worthy the highest encomiums. His own success in increasing his bees from a few colonies to over three hundred and continually getting large returns from them, furnishes a practical proof of the reliability of his teachings. His little work on bee culture has wrought a great change in the manner of keeping bees in many localities here.

Dr. Hamlin's marked energy of character, his perseverance, his lofty aspirations after perfection and his kindness and affection as a husband, a father, and a friend are well worthy of imitation. An upright, zealous member of the Church, a prominent leader in the Masonic fraternity, held in high appreciation by the members of his profession, and an enthusiastic master of apiculture, he is mourned by a large circle of friends and relatives, who alone are comforted by the knowledge that he so lived that

"When the summons came to join
The innumerable caravan that moves
To the mysterious realms, where each shall take
His chamber in the silent halls of death.
He went, not like the young slave, at night,
Scourged to his dungeon, but sustained and soothed
By an unflinching trust in God, he approached his grave
Like one that draws the drapery of his couch
About him, and lies down to pleasant dreams."

FRANK BENTON.

Edgefield Junction, Tenn.

The bees do not deposit in the cells all the pollen they gather. Many of the pellets are taken from the gatherers as they return with laden thighs, and are consumed, to qualify the workers for secreting wax or preparing food for the older larvæ.

Sundry Questions and Answers.

CONDUCTED BY CH. DADANT.

QUESTION.

As you are in charge of the questions in the AMERICAN BEE JOURNAL, I would ask you to answer the following through the JOURNAL. I would like to import queens myself. To whom shall I send? Are the queens sent through the mails or as freight? and at what cost? What proportion usually reaches this country in safety? You could give much information to many readers on these points.
Hartford, N. Y. J. H. MARTIN.

ANSWER.

For the last seven years I have been trying to find an Italian bee-keeper able to send queens so packed as to reach this country alive. Since my return from Italy, I have received three invoicees: one containing 30 queens: 28 were dead—only two were alive. What was the matter? The Italian breeder had failed to comply with the simplest precautions that I had indicated.

In a subsequent invoicee all the queens were dead, for the same reasons.

It is impossible to imagine how queer are the ideas which can germinate in the minds of the Italian bee breeders. In an invoice of 14 queens, I found five that were put up in queen cages, very pretty queen cages indeed, with two or three workers, and all dead of course. In that invoice one queen alone was alive, after 23 days journey: it cost me more than \$50 in gold.

In his second invoicee the same man tried a second time his queen cages, in spite of my warning, and refused to replace the queens that died in them, and feared that it was impossible to send queens here alive.

Another bee-keeper sent me 16 queens, and put under the package, without my cognizance, three bottles of wine for sauple. My correspondant at Havre informed me that they were seized by the French custom-house officers, while I was here going every day to the express office, and writing everywhere to know why my bees were so long to arrive at Hamilton. I wrote to the sender to replace them, but he made his second invoice so unwillingly and so carelessly that very few queens arrived here alive.

I could narrate many more of these costly experiments made by the Italian breeders, at my expense.

In my long experience I have received but two or three invoicees which could give a beneficial result. Combs broken or loose in the boxes; too many or too few bees; too much or too little honey; sponges with sugared water; unsealed honey; sealed brood instead of honey; rough handling; boxes placed on their sides or in the vicinity of noxious matters in the steamers; too long delay

in the voyage; and moths. Ah! yes, moths! One day I received a package of 16 queens; not one live bee in the 16 boxes, but plenty of living and flying and creeping moths in every box. How good that smelled? Prof. Mona wrote to me, a few years ago, that, in Italy, it was impossible to send bees without sending moths; the winters are too mild there to kill the moths.

Never have I seen so many moths, at the same time, as in a well known and far famed apiary of Italy.

In fact, I have received but one package without moths and that invoice was the last, received a few days ago, with 8 living queens. Eight living queens out of 16, after 37 days journey. That was marvelous; but the bees were so carefully packed; the little attentions that I had prescribed had been so completely observed, together with some others so intelligent and ingenious cares, that I have at once sent to that careful breeder an order for 100 queens, to be sent in six packages, from week to week. This man lives not far from the shores of the Adriatic Sea, in one of the best bee districts of Italy. He is a very careful and successful Apiarian. I could say, the first careful bee breeder that I have found in Italy.

Many bee-keepers, of this country, after losing money in their importations, have given it up in disgust. But, in spite of the losses and disappointment, I have persevered; surely there are some conditions which would insure success. Of course I had to learn these conditions, one after another, by examining the boxes on their arrival here; the requisites of a successful journey being determined, the most difficult to be found; a man who could comply with them without varying, to do better.

The importation of bees is like gambling, with its illusions and its deceptions. When the bees arrive, I feel the same sensations as a gambler at the lottery; and too often the result is the same; loss, dead loss. But to-day I am sure to have turned the chances on my side; if the man continues to prepare the bees as he has done for his first invoice, and I do not doubt it.

QUESTION.

In your answer to H. A. SPRAGUES in the June No. of the AMERICAN BEE JOURNAL, you say that you know of no honey yielding plant, good for hedging, in this country. Will not the honey locust, (*gleditsia triacanthos*) answer the purpose? EDGAR SAGER.

ANSWER.

The honey locust would make a good hedge were not the cattle so fond of its leaves and young sprouts. I know a Frenchman who tried it, but had to protect his hedge against the teeth of his cows.

QUESTION.

I wish to know what color the pure bred Italian bees are? I purchased a queen two years ago, about two-thirds of her progeny are what I take to be pure, that is are not quite as dark as the native bee, with three yellow bands around them; the others are about the color of the native bee. I fear she is hybrid, will you please inform me upon that point.

W. F. FERGUSON.

ANSWER.

The pure Italian bees have three leather colored bands around the abdomen, *i. e.*, the first small ring which is attached to the corslet, then the second and the third. This third ring is more or less bordered with black. When the bee is empty, the leather color disappears and the bee seems to have but two yellow rings. All the bees in a pure colony have the three rings visible, in the young bees as soon as they have taken their first meal; in the old bees when they return from the fields in the time of honey harvest. Sometimes, even in Italy, there are a few black bees among the thousands of well marked, but it is not a mark of impurity.

The color of bees is not always a sure test of purity. By selecting the yellowest queens, for several generations, there are produced bees with so much yellow and so thin black borders on the rings, that a slight dash of black blood cannot be detected in their progeny. It is on that account that some queen breeders do not like the imported Italian queens, the smallest stain of black being visible in their progeny, these breeders obtain from them a less number of seeming pure queens and consequently they claim that the Italian bees are injurious. Yet this false idea is fast disappearing, for I have received lately orders from breeders who three years ago complained of the Italian queens; and who now want dark colored bees, because they are more hardy and more fertile than the light colored.

As for myself, I consider the color of the bees but a second test of purity. My first test being the demeanor of the bees, when the combs are taken out of the hive. The quieter, the purer are the bees.

If the progeny of the queen that you received two years ago was then such as you describe it, she was impure. It is more probable that, after you received her, she was replaced and that her daughter failed to mate with a pure drone.

QUESTION.

I am using the Langstroth hive—is it good? I think if there is any better, I would like to know it.

W. T. F.

ANSWER.

The Langstroth hive is good, but I prefer the old Quinby (not the new) enlarged to 11 or 12 frames. I use two sizes of hives: Quin-

by with from 11 to 16 frames 18 inches long by 11 inches deep; and the American with 16 frames 12 by 12 inches, with partition boards in both. Every year I find that there is more brood and more profit in the larger and shallow frame. If I was to begin anew, I would choose a hive with 11 frames 16 inches long by 12 high, inside; or 16½ by 13 outside. I give to the upper bar of the frames, ¾ inch of thickness, to prevent warping under the weight of honey.

For winter the brood chamber is reduced by the partition boards to 8 frames, with a dead space on both sides.

To Beginners in Apiculture.

BY PROF. A. J. COOK.

One beginner had a colony swarm last week, and though he hived them according to the rule already given, and although they seemed to take full possession, yet one thing was omitted—putting a comb of worker brood in the new hive,—and in about an hour all came out and left for a wood-land home. And thus was lost a splendid colony of Italians, worth at least \$10.

Another beginner,—Mr. B.—was following directions, but as the queen cells were not yet capped, he thought to wait a little longer, and went to business as usual. About 9 o'clock a prime swarm issued from one of the two colonies. Mrs. B. who had never seen such a thing done, but had carefully read directions, and talked them over with her husband, went bravely at work, followed directions exactly, and the result is that Mr. B. now has three fine colonies instead of two.

So let me repeat, that I may emphasise the advice, *never* hive a colony in case of natural swarming,—which will occasionally happen in the best regulated apiaries,—without putting into the hive some brood, even eggs will not do. There must be capped and uncapped brood, and the above experience makes the farther advice pertinent to all beginners who are in the bonds of single bitterness, immediately procure a brave intelligent help-meet.

Again our beginner should commence to start some more nuclei, for all the summer through, queens will be needed. If the season is good you may at least hope to increase from two to six, though if the season is not *extra good*, you must not expect much honey with such increase. You also may need to replace poor queens.

Be sure that all through the months of June and July, your bees have plenty of room, thus you will be more apt to get worker brood comb—that with small cells—and more than this, you will preclude that necessary idleness, which can never be conducive to the happiness and well being of

the “busy bee.” Every hive should contain empty cells, and empty frames, that the gatherers may have room to store, the queens to lay eggs, and the comb-builders to form their beautiful white structures. A non-observance of this advice, and the workers will hang outside the hive, the palets of wax go to waste, and, the queen ceasing to lay eggs, the colony will become weak, unable to protect itself against robbers, and moths.

We are now in the midst of the locust season, at the dawn of the white clover, and that regal season,—the bass-wood—will come very soon. So now, as seen, is the time to get our box honey, if we desire it. Simple boxes will do. They may be made from six to ten inches each way with glass on two sides and long narrow holes cut in the bottom, the top and other two sides of half inch pine, put these immediately on the frames.

During the hot weather be sure to have your bees shaded from the hot sun, not at morn, and eve, but at noon-tide. I have known bees to honey outside the hive just because they could not endure the oven-like interior. The formation of a screen, by placing boards a little above the hives, worked like a charm. Idleness was at once banished, and the happy hum of returning industry, told of a rich harvest of prospective sweets.

One new beginner has already banished veil and bee-gloves. Another was *too* rash, and was fearfully stung. It is best to use a good degree of caution and smoke, and retain at least the veil, till all show of nervousness is gone, and you have a perfect understanding with your pets. My friend, and old pupil Mr. E. Benton, now in charge of the large Edgefield Junction Apiary, writes me that the late Dr. Hamlin—whose urbanity, candor, and Christian integrity were so pre-eminent that his decease makes a sad loss in our fraternity—never used smoke and did not believe in it. He further adds that the bees were very cross. In early spring and late summer and autumn, I believe that even the experienced Apiarists had better use smoke.

If any find a queen missing before having extra queens, give the colony comb with eggs from your best queen. In my next article I will give directions for introducing queens.

Agricultural College, Lansing.

It is a common practice to rub the inside of a hive with aromatic herbs, a solution of salt, or other substance, with a view of making the hive more acceptable to the expected swarm. But the most experienced and observant bee-masters deem this altogether unnecessary, if not injurious.

For the American Bee Journal.
Feeding Bees.

I find in our bee journals considerable written upon the subject of feeding bees. I think it an object worthy of consideration and effort, to find and pursue a system that will save the necessity of feeding at all. To secure this it is only necessary to adopt a hive in which we can effectively control the swarming and limit the number of colonies to the amount of honey produced by the accessible field.

The great body of farmers do not desire to, and will not make, bee-keeping a principal business. What they do in securing the honey produced in their fields must be done incidentally, other interests of the farm claim their principal attention. I presume few will be found among them to use movable comb hives, to raise Italian queens; or honey extractors to furnish extracted honey for market. That must be done by experts in the business, whether they are farmers or not.

For them the best hive will give about 2,500 cubic inches in the breeding and wintering apartment; and as much more in small frames or boxes, for storing surplus. With such an arrangement, the bees will be very likely to make a fair arrangement with the farmer, and gather the honey in his and other surrounding fields, at the halves. If the field is very good and the season fine, they give him two-thirds, requiring only one-third for consumption. My enquiry is whether it will not be better to give this room in the breeding apartment, and save the necessity of feeding at all.

These thoughts have occurred to me now on reading, P. W. McFartridge's experience, in the May number of the AMERICAN BEE JOURNAL page 112—he gives as the product of his apiary a little over 4,000 lbs. He tells us that he has fed 1,100 lbs. of A coffee sugar, and that 200 lbs. of the honey soured a little he reserves for feeding. This leaves 2,700 lbs. of honey.

With 250 cubic inches ample room is given for storing a winter's supply for the bees, and feeding is unnecessary.

There must, however, be another condition implied to prevent danger, that is, that there are not too many colonies in the field. If there are more colonies in the field than can be supplied with winter stores, they must be fed or starve, even if each colony had a meeting-house to work in.

I find it difficult to so express my ideas upon this subject as to be understood.

1. If an apiary is located in a field yielding 12,000 lbs. of honey, and each colony of bees for breeding and winter, will consume 60 lbs.; 200 colonies would consume it all.

2. One hundred colonies would consume

6,000 lbs. and give 6,000 lbs. in surplus.

3. Fifty colonies would consume 3,000 lbs. and give 9,000 lbs. in surplus.

4. If you put 300 colonies into the field there would be but an average of 40 lbs. to each colony for both breeding season and winter, and a great amount of A sugar or something else must be fed, or almost all of them starve to death.

In the last case a few of the strongest colonies might get an early start, and live throughout the winter. Possibly some of them give a little surplus; but nine-tenths of them more or less would starve to death. Some of them would die so early that the moths, in their weakened state, would weave their webs. Some of them would wander over the combs defiling them.—Some would crawl or fly out of the hive and die, and some would try robbing to make a living. Nobody knows what the matter is. Some lay it to the moths; some to dysentery; some to robbing; and some to "don't know," while the whole truth is there are far too many bees. There might have been some cases where the bees left some honey in a part of their hive that was out of their reach in a cold spell, and it is even said, "Oh, no they did not starve to death, there was honey left."

In the case of 200 colonies having 60 lbs. each in the field, perhaps one quarter just go through the winter and only half perish.

In the case of 100 colonies they would not give 60 lbs. each but some might give 100 lbs. and some 20 more or less.

So in the case of 50 colonies, 180 lbs. each. As has sometimes been known they may range from 100 to nearly 300 lbs.

What I would urge is that 100 colonies in the supposed field is better than 200. And 200 colonies is better than 300.

Indeed the farmer had better have no bees than to have so many more than his field will supply. From 50 to 100 colonies is a full supply for the field; 100 colonies would store half the production in surplus.

While we are taught by some that "there is no danger of overstocking the field," I believe without one doubt that three-fourths of the difficulties we encounter arise from overstocking.

Woodstock, Vt.

JASPER HAZEN.

For the American Bee Journal.
My Experience.

It is some time since I have written for the AMERICAN BEE JOURNAL, but during that time my experience has been worth gold. In 1872, I lost 43 hives by dysentery, and last year, I lost 15 hives from robbery. At the end of the year I bought a beautiful \$2 queen from "Olley." This queen died last season in a strong hive, which started cells profusely. I counted

52 cells on a single frame. I Italianised my whole Apiary. I had carefully cut away all drone brood from the black bees and left my pure Italian drones to preserve the queen cells. As soon as one queen came out a black queen was killed and her body cast out.

One day I had occasion to go to the blacksmith's, on my return home, I found my whole farm on fire; in less than an hour everything was consumed except my bees, and an old potatoe cellar. I and my family took shelter in an improvised log hut for 14 days. Then I had prepared a new abode, and was prepared to put my bees in the cellar by Dec. 14th. They needed feeding all winter. Lost one, and had 31 left. Fed with coffee A sugar.

On Feb. 1st, I examined and found all in good condition.

On March 15th, I found one hive dead from dysentery, another queenless and a gallon of dead bees on the floor.

As soon as the cleansing was done, I fed them warm honey, poured in the large drone cells on one side; then that was set outside to cool, then laid it down on a newspaper, honey downwards and poured the other side full. Such frames contained from 4 to 6 lbs. Feeding was easy in that manner. I fed until the 5th of May.—April gave me one day that bees could fly. I have lost 6 swarms in all. I intend to run up my swarms this summer to powerful colonies.

I intend to experiment with the Gallup system. My frames are all 12x12, this is my standard. JOSEPH DUFFELER.

Wegnoick, Wis.

Spare the toads, but place your hives out of their reach, for they can soon destroy a strong colony if they can get near enough to the entrance to catch them, as they pass in or out. Watch the toads late in the evening and at night.

Many people are fond of bees—indeed have a passion for them; but it is not enough to be fond of them, they must be skillfully taken care of, according to certain rules, applicable in every case, but more particular in bad years. Mistaken care annoys them—niggardliness ruins them.—*Exchange.*

Hives, or the habitation in which the bees live, breed and work, have been made of different materials, and in different forms, according to the fancy of people of different ages and countries. Melissus, King of Crete, is said to be the first who invented and taught the use of bee hives.—*Bonner.*

For the American Bee Journal.

Gallup on Artificial Queens.

We have never, to our recollection, given the readers of the AMERICAN BEE JOURNAL our ideas in full on artificial queens. We have given them in Mr. Mitchell's paper, and sent them in full to Mr. King; but he was afraid that his readers might learn something contrary to his teachings, therefore did not publish it. In my opinion "Novice" and others have led many a beginner astray, by advocating that there was no difference between artificially and naturally reared queens. Langstroth, Grimm, Adair, and the late Dr. Hamlin, and others, agreed with me in full. Quinby says that there is no difference and even went so far as to accuse me of never having had any practical experience in raising queens, etc.

Now to the question. What are the conditions for natural queen raising? We have abundance of bees, consequently warmth, we have abundance of food of the right kinds, and we have abundance of young or nursing bees to prepare that food properly for the queen larvæ. Now if the novice in the business will see that he has all those necessary conditions and eggs or larvæ just hatched, whether in nuclei or standard hives, he or she will raise natural queens every time—nothing artificial about them. On the other hand, we will suppose we do as many queen breeders have done; raise artificial queens about in this manner: Measure out a sufficient quantity of bees, place them in a nuclei hive, and give them comb, eggs and honey and no pollen. Confine them for 3 or 4 days before giving them their liberty, and in a majority of cases pay no attention to the age of the bees selected, but get mostly old bees, or those incapable of digesting or preparing the natural food for the larvæ, etc. Queens raised under those circumstances are artificial, or raised under circumstances contrary to nature. In such cases queens have hatched out in nine days repeatedly, and in some instances they have been known to come out in eight days; but we never have nine-day queens, if we make up our nuclei of young or nursing bees. For the novice in queen breeding must bear in mind that bees at a certain age are incapable of digesting pollen, and preparing the necessary food for larvæ. Now we will tell you how we raise queens. If in nuclei hives, we use three standard combs and always keep abundance of nursing bees, and if they do not gather pollen enough we supply them with pollen from other hives, and we like to have them have quite a quantity of larvæ on hand to feed, at the time of starting queen cells, so that they are preparing the necessary food in large quantities, and

we raise natural and prolific queens, every time,—there is nothing unnatural about them that we could ever discover. Now, suppose, as soon as the young queen becomes fertile and commences laying, we remove her and allow the bees to start queen cells from those eggs. There is no larva to feed, as it is all sealed or hatched out, and the bees are well advanced as to age, or in other words there are but very few nursing bees, etc., we may succeed in raising a good queen, and we may not. There is no certainty about it. Thousands of queens have been sold by queen breeders that have been superseded the first or second season after being received. A good queen properly raised ought to be good for four seasons. Langstroth and Grimm know how to raise good queens, but they could not raise them for \$1 each, consequently both have quit the business.

We might have explained our ideas long ago on this subject, but we should not then have drawn out so many ideas from others. In other words, we like to have those that have received their first stock of bees give us their instructions. It amuses us hugely!

Now "Novice," would it not have been just as well to have criticised Gallup on the queen question, after you knew what his ideas were, as to criticise before you knew? Give us a clip and see what effect it will have.

I like "Novice's" grit. He gives his instructions to-day and contradicts them to-morrow, and thereby gets himself into inextricable snarls, yet he never gives up, like our friend Price, who killed himself by trying to instruct others in what he did not know himself.

For the American Bee Journal.

My Mary Ann.

My beautiful, beautiful, Mary Ann.—Yes! that same old story over again. The crow whose chicks were white. Not so fast my friend; not so fast: She is not my daughter, neither is she a blonde; but a bronze colored queen.

Well; why such an ado over Mary Ann; others have raised queens as good as she, and have made money too with bees, which is more than you have done. Let me feel joyful over Mary Ann any how.

I value money, from the enjoyment I can get from its use. What if the coffee A does disappear mysteriously. You know "my dear," we have not had a doctor in our house professionally, since those bees arrived at the express office, so strangely.

The doctor always said, exercise in the open air. How much good could I get, sweeping the side-walks with trailing skirts? You do not wear trains. I know

I don't; but when a person talks to me of taking a walk for exercise, I think of the Yankee who wanted work, and a man told him, he would hire him; and set him to pounding on a log, with the head of an axe. He tried it awhile, but soon threw down his axe, exclaiming I can't do this: I must see the chips fly.

You always scatter so. I thought you were talking about Mary Ann. You keep quiet now, while I tell of Mary Ann's wrongs.

I have already been taught to respect the advice and opinion of the stronger sex; so when Mr. Harrison recommended putting Mary Ann in the cellar, I silently acquiesced. Put those five in the cellar, they will consume less there; (I knew all the time coffee A had much to do with it).

We tucked Mary Ann, and her companions under their quilts, and carried them gently into our cozy little cellar. When old boreas raged without, how thankful I felt that these "fire pets" were protected from his blasts.

These bees flew on the 7th of Nov., and we put them in the cellar on the 10th. We carried them out for a fly, on the 2nd of Dec., returning them as soon as quiet. On the 3rd of Jan., the thermometer being at 76, at 11 o'clock, carried them out for a fly. They all flew finely, but I did not like the appearance of the combs.

On the 11th of Feb. carried bees out, finding them in a dismal state; O, those bed clothes; damp and disagreeable; no more quilts for me. Some of the colonies had quarts of dead bees. Plenty of honey, with no appearance of dysentery. As the weather was very warm, I cleaned out the hives, and placed them on the east side of the house, protecting them on all sides, except the front, with straw. Made little sacks and filled them with straw, that just fitted into the porticos, so the wind could not blow them out. Every night, and on cold and windy days, I protected the fronts in this way.

Every fine day some of these bees went a visiting, and forgot to come home. One by one they dwindled away, until May 12th I found I only had Mary Ann and a handful of bees. I caged her and filled up the hive with frames of brood and bees, releasing her the next day, after sprinkling all thoroughly with sweetened water, scented with the essence of sweet anise; she is now the adored mother of a thriving and prosperous colony.

I wintered successfully 11 colonies in the open air. Hereafter, I shall winter in the open air, as the Dutchman says "shingled mit straw," every time. I put in the cap, a gunny sack filled with straw, raising the cover slightly for ventilation.

CHICAGO. JULY. 1874.

Theories and their Advocacy.

It is during the working season that most of the theories of bee life are evolved from the apicultural mind. While the bees are busy building cells, the bee-keepers are busy building theories. There are minds that have a natural faculty for the construction of theories, even as bees have a natural faculty for cell-construction. Theories ought always to be the results of observation, and should be based on facts. But they are often like those pleasant stories we sometimes meet with, and which are headed, "founded on fact." This is generally fair notice that among what is strictly true, there will be interwoven a good deal that is purely imaginative. Imagination is very well in its place, but it must be excluded from the realm of science. It is pleasing and useful in light literature, but considerable of a nuisance mixed in with the solid and sometimes prosaic affairs of real life. Not a few of the most important of human interests have suffered from the tendency of mankind to spin theories out of cobwebs, and to go to the realm of investigation with their theories ready made. Most of the difficulties in theology have arisen out of preconceived theories, which their authors have sought to uphold, when framed, out of the Book. Bee-keeping has suffered in the same way. People have gone to the hive to get evidence in support of a favorite theory, instead of going to it without any theory, to gather facts as the material out of which to manufacture theory. A certain member of the British Parliament was frank enough to confess that he trusted to his memory for wit, and to his imagination for facts. Not a few draw on the imagination for facts, who have not self-knowledge enough to be aware of it, nor candour enough to own up about it. Theories

require the utmost deliberation and care in construction, and, like Italian queens, are not worth much until well tested.

When a theory is adopted on what are considered sufficient grounds, it should be advocated with modesty and forbearance. Haste in forming a theory is usually followed by dogmatism in contending for it. A man who is patient in constructing a theory, will be patient in urging it upon the acceptance of others. Slow in espousing it himself, he will not be surprised to find many who are slow as himself, if not slower. Impatience to get credit and honor from those to whom a theory is announced, not infrequently betrays theorists into unseemly behaviour. Some espouse theories as they do matrimonial partners, and afterwards illustrate the proverb about marrying in haste, and repenting at leisure.

Theories, if well-founded, will bear the test of criticism, and the sensitiveness of many to a dissenting word, argues no great amount of confidence in their own views. What is based on fact, can never be overthrown. It is like the "tall cliff" immortalized by a great poet:—

"Though round its base the rolling clouds are
Eternal sunshine settles on its head." [spread

We commend these general, and as we think, timely remarks, on "theories and their advocacy," to all and sundry who write for the AMERICAN BEE JOURNAL.

Bees and Grapes.

It has often been insinuated by the ignorant that bees injure fruit; and some time ago, a benighted little village in New England undertook to expel all bees from its limits because of their supposed depredations. An American naturalist of some note, not very long since brought this accusation against the bees, and recommended fruit-growers to protect themselves against these industrious insects by the use of certain recipes that would attract and destroy them. But the great majority of fruit-growers are too keenly alive to their own interests to take any steps toward the suppression of bees or bee-keeping. It is pretty certain that by collecting and distributing the pollen of plants, the bees

accomplish fructification in many cases where otherwise it would not take place. There is no conclusive evidence to sustain the suspicion of their injuring fruit. Ch. Dadant, who is now settled in Illinois, but who for many years kept bees near the hills of Burgundy, says in a recent number of the AMERICAN BEE JOURNAL, It is well established that bees are unable to cut the skin of grapes. In order to ascertain the fact, the most juicy and sugared grapes, pears, sweet cherries, plums, apricots, etc., were put inside the hives; never have the bees attacked them if they were not previously scratched. The experiment was repeatedly made; it was discovered also that the first cutting was made by a kind of wasp, or by birds, or caused by the rain falling when the fruit was ripe.

A Wisconsin bee-keeper also writing to our journal says, "Last fall I took a bunch of Delaware grapes (the most tender variety we have here,) and put it on a hive, directly over the bees, and watched proceedings; but not a single berry was opened; then I broke a few berries, upon which they went immediately to work, sucking them dry, thus showing that something besides bees does the mischief."

The idea is entertained by many intelligent bee-keepers, that where the bees have been suspected, with any air of probability, of doing injury to grapes, the skin of the fruit must first have been punctured by some other insect, thus affording the bees access to the pulp. On this point a correspondent of the *Rural New Yorker*, writing from Marcellus, N. Y., says:—"There is much complaint made in the papers of bees eating grapes in different localities, which I doubt not is true; but I wish some scientific man would give a close examination, even with a magnifying glass, and see whether some insect has not been gnawing the skin in the night; for we know that the corn worm comes at night, eats off the blade, and the snail eats holes in the young tobacco leaf and is not seen in the day time; and there may be insects flying in the night, like the lightning bug, that gnaw the grapes. Now, in this section almost every house has a grape vine, and there are bees kept in many

places all over town and this village; and I have kept bees and grapes over 30 years, but have never heard the first complaint. I wish there could be some close examination made."

Back Volumes.

Complete sets of back volumes are scarce. But few can be procured at any price. We have a set, consisting of the nine volumes (complete), which we offer for sale, either bound or unbound, for a reasonable sum. Many of the numbers we have paid fifty cents each for, to complete them.

We have several single volumes (complete) which we will send postpaid for \$2.00 each.

Several volumes, which lack only a single number of being complete, we will send postpaid for \$1.50 each.

Vol. 1, we can supply in cloth boards, postpaid, for \$1.25. Bound in paper covers, \$1.00, postage 10 cents. This volume is worth five times its price to any intelligent bee-keeper. It contains a full elucidation of scientific bee-keeping, including the best statement extant of the celebrated Dzierzon theory. These articles run through eight numbers, and are from the pen of the Baron of Berlepsch.

Beginners in bee-culture, who desire to read up in the literature of bee-keeping, are earnestly advised to obtain these back volumes. Many of our best apiarists say they would not sell their back volumes of the AMERICAN BEE JOURNAL for ten times the sum they cost, if they could not replace them. They are exceedingly valuable alike to beginners and more advanced apiarists.

A CHOICE OF SIX VOLUMES FOR \$5.—Having a few back volumes complete, and some lacking only one or two numbers each, we will give the purchaser the choice of six of such volumes for \$5.00, until they are disposed of. As only a few can be supplied, those who wish to avail themselves of this offer, should send for them *at once*.

We want several copies of No. 1, Vol. 2, of the AMERICAN BEE JOURNAL, and will pay 50 cents each for them.

The postage on this paper is only twelve cents a year, if paid quarterly or yearly in advance at the post-office where received. We prepay postage to Canada, and require twelve cents extra.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

Voices from among the Hives.

O. L. BALLARD, of Malone, N. Y., writes :—“Most of the bee-keepers in this vicinity have lost a large proportion of their colonies since setting them out this spring; but by feeding mine a little they have increased in numbers, although they have not swarmed out as yet.”

WM. PERRY, SR., Lynnville, Tenn., writes :—“Our honey harvest has been very tight the present season. There has not been much increase in stocks. The very wet spring, followed by a drought of some five weeks, has proved quite unfavorable for honey gathering.”

E. GALLUP, Orchard, Iowa, writes :—“The bees are swarming and doing finely. The spring was cold and backward, which makes them late in swarming, but the flowers all produce honey this season. They are now to work on Alsike and white clover. The basswood or linn is going to blossom very profusely; so look out for honey.”

J. H. CRISTIE, Dyersburg, Tenn., writes :—“My bees are doing well. The winter was mild, and the spring opened early, but cold and wet. Bees could gather nothing to make honey of, and many starved to death. All were put back at least a month. The poplar is our best honey food, and it is in bloom now. We have besides this, holly, maple, elm, and black gum. My bees are all of the black kind. I intend to Italianize them soon.”

JOHN BARFOOT, Wellsville, Mo., writes :—“So far this has been a good bee season. Honey dew commenced here May 22nd and it has continued up to this time, with the exception of two days while it rained. We have also had our usual supply of bee pasture from flowers. We are in the midst of swarming. The Messrs. Baldwins, since their advent here, have infused new life into bee-keeping. Hives have increased 5 pounds in a single day here lately.

L. BURDICK, Galesburg, Mich., writes :—“Our bees wintered very well last winter. But a great many were lost during the month of April, who flew out and died apparently without disease, the queens living till about the last. They laid some eggs but did not hatch, for the want of bees to take care of them. The bees might have died with old age. Any information on this subject would be thankfully received. The season here has been good for bees, up to this date.

SAMUEL LUETHI, Gnadenhütten, Ohio, writes :—“Bees wintered well in this locality. One of our Italian colonies treated to horse manure as recommended by ‘Novice.’

did not seem to derive much benefit from the process. The manure was put around the hive up to the honey board on three sides, and the front was protected by straw and a board placed in front of it. The prospect for surplus honey is poor, owing to the long continued dry weather.

FRANK SEARLES, Hadley, Ill., writes :—“I wintered 123 swarms and lost but one. I have only lost 8 swarms in the last three years. The weather for the past ten days has been very unfavorable—clouds, rain, and wind. The fields are white with clover, and my hives are full of bees. All they want now is fine weather. Swarms that I did not think good enough to sell 15 days ago are now in first-class condition. They have done finely on the locust trees, for the past few days.”

C. H. ENGLISH, Sullivan, Mo., writes :—“We have a good bee range here. The natural timber is very good. Sugar trees, soft maple, walnut, gum, and linn are among the best. They also make honey from a vine called ‘poison vine,’ wild grapes, etc. I intend hedging my farm with a kind of hawthorn, resembling sugar haws. It blooms in June. Bees are very fond of it; and it makes a good hedge, and the berries are good for hogs. Red raspberry is the best honey plant. Its leaves are dripping with honey dew. My hives are full of honey, some in boxes. I have had several swarms. I use black bees. Some day I will give you my experience.”

M. QUINBY, St. Johnsville, N. Y., writes :—“When I first read on page 106, the heading ‘A new smoker’ I thought ‘a contrivance for smoking bees’ had reference to the way smoke was applied. Instead of a new way of applying smoke, it seems that only the material that he recommends to make it of is new. He concludes by saying: ‘You can blow the smoke where you want it, it leaves no bad effect on the bees.’ Are we to infer from this that some kinds of smoke do leave a ‘bad effect?’ If so, I would like to enquire what kind does it, and in what way it does it. All bee-keepers ought to be interested, as our success in bee management depends on the judicious use of smoke. If any kind is detrimental, it is important that I know it, as I am just now recommending an indiscriminate use of what is most convenient, and am unable to detect any difference. When ‘corn silk rolled in paper’ is most convenient, I would advise using it. How to apply smoke conveniently, and effectually, without blowing the breath away, has been a long study with me. Any one that has a convenient method would confer a favor on the bee-keeping community, by making it public.”

W. M. KELLOGG, Oneida, Ill., writes :—“Bees are doing finely at present, filling their

hives with bees and honey; I have had to use the extractor to keep them from crowding the queens out of doors. Stocks in small hives are preparing to swarm, raising queens, drones, etc., while those with movable division boards, where we can give them plenty of empty comb, seem to be content with raising lots of brood and lugging in the honey for us to sling out. I have made some new stocks and soon will have some more. We are having plenty of rain, so that bees have all they want to do to tend to their knitting; but yesterday was so damp they could get no honey from the flowers, so they pitched into everything that had sweet to it, by thousands, and were so cross one couldn't touch them with a ten foot pole.

On page 142 Wm. Morris asks, 'are large hives less liable to be affected with dysentery than small ones?' With our bees that died off in the spring of '73, they did not get the dysentery till they were reduced to about a pint of bees, none of the stocks in large hives having it, till weak in bees, or the small hives either, for that matter. For my part I do not think it makes much difference in the size of the hive, if they have plenty of bees; and as to the cause of the disease here, we think it is to be laid to the long continued cold rains and winds, keeping the bees from breeding, and what few were left had to gorge themselves so with honey to keep up sufficient warmth, and then being confined to the hives, gave them the dysentery.

D. D. Palmer (page 143) speaks of the 'ingenious bent wire' that Mr. Dadant uses to secure frames at the bottom of the hive in shipping, but leaves us with our curiosity unsatisfied. Friend Palmer, can't you give us a description of it so we all can have the benefit of it? or is it a patented article? If it is, of course we'll have to pay for the use of it."

M. NEVINS, Cheviot, Ohio, writes:—"My 34 stocks of Italians are doing finely. They have worked more freely on red clover during the past two weeks than I ever knew them to do before. One swarm, from which I took 4 frames of brood in March, April, and May, has now made 50 lbs. of comb honey in the small frames, and 50 lbs. of extracted. This hive has been weighed every day since the 4th inst., and on 4 of these days has made 4 lbs. per day of comb honey, and almost entirely from red clover.

I see some inquiry is made through the different journals for a convenient plan for weighing. I have a fixture which is convenient. Take three strips of sawed stuff, 2 in. wide by 1½ in. thick, (or round poles will do) and 8 or 9 ft. long. Shave the top of each so they will fit together when the lower ends are spread some 5 ft. apart. Fasten the top

ends together with an iron bolt. Now you have a tripod. 4½ ft. from the foot fasten a cross piece from leg No. 1 to leg No. 2 of sufficient strength to bear the weight in the centre, of anything you desire to weigh. Across the centre of this cross piece attach a lever, letting the inside end project just far enough to reach past leg No. 3, fasten a cleat to rest the end of the lever on. Attach a ring to the lever about midway between the cross bar that supports the lever and leg No. 3. Take a piece of rope, tie the two ends together and you have it long enough to go under the hive double and come up on each side near the top of the hive. Tie a spreader to the rope on each side of the hive near the bottom to keep the rope sufficiently spread on the bottom of the hive. I use a leather strap over the top of the hive, and through the rope on each side of the hive to hook the steelyard into so that it can readily be adjusted by a buckle to the right length to just swing the hive clear, when the lever comes to a horizontal position and rests upon the cleat on leg No. 3. I frequently leave the hive suspended there from day to day. The outer end of the lever projects over the cross bar far enough to give sufficient leverage to raise the hive easily by bearing down on it. The ring on the lever is for the upper hook of the steelyard.

All bee-keepers will readily see the great advantage of weighing a sample hive every day so as to know just what calculation to make about supplying additional storage room etc. etc., without having to open and go through the hives, which is always an interruption to them when storing honey rapidly.

The above apparatus is a great convenience on a farm, and for many purposes aside from weighing bee hives. I once had a lot of 40 or 50 beehives on the farm, which I desired to slaughter. I made a tripod 12 ft. high with a light tackle-block attached at the top, and a pole across two of the standards near the foot with a crank on one end for a windlass. Shoot down a steer in the lot or any place where you could have a fair swing in the air, set the tripod over it and with one hand I could lift it into any desired position for dressing, or raise it clear from the ground. When dressed it could be run up out of the way of dogs, to hang over night, or a wagon backed under to take it away. This apparatus was made of tanarac poles and was so light that a man could easily carry the whole rig half a mile on his shoulder.

My hives all stand on little posts driven in the ground, one at each corner of the hive. Old broom handles, sawed off 8 or 10 in. long are sufficient if the ground is hard. Let the hive come within 2 or 3 in. of the ground. This plan affords no harbor for ants, spiders, rotten-wood, lice, etc., and is very nice. I bank up in the front of my hives with coal ashes, even with the alighting board, to keep the grass and weeds down and give the bees a smooth and easy passage.

THOMAS G. NEWMAN,
Room 27, Tribune Building, Chicago.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

The German Bee-Sting Cure can be obtained at this office. Sent by Express for \$1.00. It cannot be sent by mail. See notice.

Our subscribers in Europe, can now procure Postal Money Orders on Chicago. This plan of sending money is safe and economical.

Subscribers wishing to change their post-office address, should mention their old address, as well as the one to which they wish it changed.

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

We have received a Postal Order from Shanon, Wis., in an envelope containing nothing else. We do not know from whom it came, nor for what it was intended. Will some one inform us?

The Rev. W. F. Clarke has resigned the Rectorship of the Canada School of Agriculture. Not finding it compatible with his other duties, he refused the honor.

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Honey has been coming in moderately for the past few weeks. Honey from fruit blossoms, this spring, is abundant. The harvest of white clover honey was duly inaugurated two weeks since, in this section. The quality is excellent.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. 7 lb.

ST. LOUIS.—Quotations from W. G. Smith 419 North Main st.

Choice white comb, 25@29c; fair to good, 16@22c. Extracted choice white clover, 16@18c. Choice basswood honey, 14@16c; fair to good, extracted, 8@12c; strained, 6@10c.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 7 gal. St. Domingo, and Mexican, 90@95 7 gal.

SAN FRANCISCO.—Quotations from Sterns and Smith, 423 Front st.

We received the first new honey about June 1st; the season is four weeks late in honey. The quality, so far this season, is superior. From information derived from all sources, the yield this season will be very large, and we shall have to look to the East for a market. Comb in wood, new, and well filled, 20 @ 30 cents 7 lb; in tins, 2 lb tins, comb, \$3.50 @ 3.75 per doz. But little new strained has yet come in, and dealers are only buying small lots.

Special Notice.

During the past ten months of "Panic," the receipts of the AMERICAN BEE JOURNAL have been very light. We have cheerfully "carried" thousands of our subscribers, and now trust that they, will respond as soon as possible, as we have obligations that must be met at once. Many subscriptions ran out with the JUNE number, and now we hope to hear from them, as well as from those that expired before that time.

We shall continue to send the AMERICAN BEE JOURNAL to all our subscribers until we get an explicit order for a discontinuance, and we hope those who not wish to continue their subscriptions will notify us by letter or Postal card, either when they expire or before that time.

We have purchased of Geo. S. Wagner Esq. and the Rev. W. F. Clarke all the back subscription and advertising accounts,

AMERICAN BEE JOURNAL

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. X.

CEDAR RAPIDS, AUGUST, 1874.

No. 8.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

For the American Bee Journal. Bees, Birds and Grapes.

What the Greeks or Romans may have said or written on this question fails to come down to us in history. But we find the bee and the grape side by side, occupying the most delightful portions of our globe for ages, without threat of deadly poisons or other violence, till you come to America in the year of our Lord, 1873.

Over twenty years have I cultivated both bees and grapes, consequently my affections are about equally divided between the two. On a lot of some acres I have many of the choice fruits of the climate, with grapes in profusion.

My colonies, say 60 to 80 in number are located under Apple, Peach, Pear, Quince, Cherry, Grape and Plum trees, where contact occurs necessarily every season. Being a person of leisure, my opportunities have been good to closely inspect this question. I too like Prof. Riley and hundreds of horticulturists and apiarists have seen bees cut into small fruits, especially grapes and peaches.

I too with all my family have had our fingers cruelly stung in gathering those fruits when ripe. In years departed I have witnessed my bees swarming by the thousands on my trellises, apparently threatening the entire destruction of my grape crop, to say nothing of my pears and peaches. My neighbors too, both learned and unlearned, give their unimpeachable testimony to the same state of facts among themselves.

Surely this ought to be sufficient to convict every bee in the land, and, as the lawyers say, we might here rest the case. Now I have summed up all I care about on this side of the question, and am free to say, there is not any evidence touching the vital point at issue. Who cares what bees eat

in general. All winged insects live on something. Every barefooted boy in the land can testify to bees extracting the juice from pomice laying around a cider mill, peaches, pears or grapes that have been maimed, crushed, eaten into or broken open by some other agency. But not one living soul of all the parties to this question have seen with the physical eye, a honey bee at any time or under any circumstances pounce upon a bunch of grapes or other fruit untouched by birds or insects, perfect in all respects; and with its mandibles eat through the skin or rind and open up its contents to a free banquet! And I challenge all parties interested in this controversy to come forward through the columns of this journal, not with circumstantial or superficial evidence, but with facts bearing directly upon this vital point.

The season of 1872 visited a fearful drouth on this portion of Ohio, and the bees and birds alike were hard up for provinder and made sad havoc with our grapes. Some citizens counted their loss as high as twenty bushels and vigorously pressed the Village Council to expel the bees by ordinance beyond corporation limits. Acting on the spur of the moment they actually passed an ordinance to its second reading (repeating the Wenham farce) imposing a heavy penalty for keeping bees within said limits. In the mean time I had not been idle, but applying tests to satisfy our people of their error, I invited them to come upon my grounds and see for themselves the Robbins, Red-birds and Orioles that lay dead under my vines and fruit trees with grape seeds in their stomachs and mouths, as I had often shot them in the act of biting open the grapes as they hung on the vines.

Our bees were undergoing a test also—three hives had as many bunches of ripe concord grapes tacked to their fronts—that passing out and in, contact was unavoidable; on the fifth day they remained untouched save the bees hunting through and over them to find an open berry. Then I opened with my knife say a quarter of the berries on each bunch and true to their instinct they began taking up the juice before I completed the job. In about forty-eight hours they had taken up all the juice and

and pulp I had offered them, and four days later, when I removed the bunches, not a single berry had they opened, but were busily inspecting those that remained, doubtless waiting for some stronger power to lead in the business.

The bald hornet, both black and yellow, are experts in cutting into peaches, pears, grapes, &c. In handling fruits, I have seen them cut through the rind of ripe and tender peaches with great facility, thus leading the way for the more feeble insects to follow and take up their contents, and therein lies the great mistake with the hundreds of complainants. Birds and hornets are few indeed when compared with bees, and whilst they glide along opening up and inviting to the feast, are rarely noticed. The honest bees, tarries to appropriate for the supply of his home, and is seen by the million and condemned as thieves and burglars.

The most persistent and clamorous of our citizens, who had threatened bee-men with the law and our bees with strychnine were the first to come forward and thank me for what I had placed before their eyes, as the true solution to the whole question; for all who took the trouble, accomplished exactly the same results by the same means that I had used, and no further complaints have reached my ears to this day.

Would it not be much more commendable for horticulturists as well as scientists to keep their eyes open to facts as they exist, than to make and publish to the world their sweeping declarations, founded in error and so prolific in mischief, wherever they take root.

To Prof's. Dadant, Cook and Krushke: let us cordially thank you for the light you have shed upon this important controversy and in the mean time keep your powder dry.

Athens, Ohio.

J. W. BAYARD.

For the American Bee Journal.

Handling a Delicate Subject.

In writing to our friend, Prof. Cook, we did not intend to convey the idea that Dr. Hamlin *never* used smoke in handling his bees, as the Professor has it stated in his July article to beginners; but we meant to say that he objected very strongly to its general use and only resorted to it when absolutely obliged to do so. He was of the opinion that smoke of any sort, though it quieted the bees for a time, left them in a very irritable condition from which they would not recover for some time. He imagined that from handling his bees for a long time with the use of but little smoke, he had developed in them an extraordinary peaceful disposition. Then, too, he thought the smoke stopped the labor of every bee in

the hive and left them filled with honey, idle, and sluggish for some time after its use. On opening hives in the spring without using smoke, with the greatest possible care and when the bees were gathering honey, we frequently found that the result would be a hasty retreat and an arming with a good smudge. Simply the odor of the person while standing on the leeward side of the hive often aroused them. Surely the labor of the whole hive was interrupted. By using, as has always been our custom, just a trifle of smoke on first opening the hive and then placing it near at hand so the fumes would scent the air about the hive, those same cross bees are quite easily handled, while the danger of arousing the peaceable ones is wholly avoided. The smoke seems to neutralize the scent of the poison floating in the air as the hive is opened. When properly used we have never seen any ill-effect arising from the application of a small amount of smoke. Some stocks will require more than others on the start to subdue them, and occasionally one will scarcely ever need it, yet it is indispensable at times. The greater rapidity in the handling of stocks with smoke, is a strong point in favor of its use, even if it does not leave the bees with as peaceable a disposition. We think bees once irritated will remember the occurrence longer than they would a thorough smoking, and that, by the timely use of a little smoke, it is much better to prevent their getting once aroused than to attempt the handling of them without the smoke when there is danger of their becoming angered. In proof that the smoke does not induce an ugly disposition I would state that those same colonies that were cross in the spring on the first opening of the hives at a time when they were gathering honey rapidly, can now be handled on warm days with little or no smoke and but little danger; yet they are not gathering a drop of honey, but are persistently endeavoring to take the little sweetness accumulated by some of their less fortunate neighbors. When the smoke is used in the manner described they *always* observe a proper decorum realizing that their master is at hand.

We class ourselves as "a beginner," (Northern winters have necessitated our beginning several times,) so Prof. Cook's articles apply to us; and, though we spent some time studying bee-culture under the Professor's direction and are willing in most matters pertaining to the subject to follow his excellent advice, yet in the third paragraph of his July article he has some advice which for the present at least, we shall have to put along with the advice on queen clipping,—as a total loss upon us. He says to "all who are in the bonds of single bitterness, immediately procure a

brave intelligent helpmeet." But really after writing the sentence we have come to the conclusion that it does not include us or else we are not capable of comprehending our own condition. We never became aware that we were "in the bonds of single bitterness," but always thought it *freedom*; then, too, we have always been accustomed to consider the occupation of the apiarist as a *sweet* one so we should label the condition which the Professor evidently means to describe as *the freedom of single sweetness*. As far as bravery and intelligence are concerned we presume there are many young ladies both North and South that would answer to that description, yet were we not afraid of a "severe trouncing" (see Sept. Oct. and Nov. No's. of *Bee-keepers' Magazine* for '73,) we should be inclined to say that most of them would take but little interest in the cultivation of the "little busy bee" or as they sometimes term them, "miserable stinging things." However we should do injustice did we not mention that there is one Southern Miss who surely takes an interest in bee-culture, else she would not have ridden sixteen miles horseback through the rain and on the Fourth of July to receive two Italian queens.

We well know that Mrs. C. is an excellent helpmeet, yet we never remember seeing her in the apiary. Taking the views expressed in the above statement of the case we think the Professor ought to try and have the beginner think himself sufficiently blessed if he but procure a companion who would prove a "brave intelligent helpmeet" outside of the apiary. Besides when too many "bee-folks" are around there is great danger of one's getting "bee on the brain,"—a very bad complaint which in most cases narrows the mind down to one thing, and confines its sphere of action, thus making of what might be a *man*, a mere *machine*.

For the American Bee Journal.
A Lady's Experience.

I think as I am considerably indebted to yourself and the *Gleanings* for the degree of success I have been favored with. I will give you an account of the experience I have had, since the fall of 1872. I bought, at that time, 2 colonies of bees in Langstroth hives, for which I paid \$20. I increased them last summer to 4, and in the fall united my 2 nuclei, thus I wintered out of doors 3 stocks on natural stores and fed a little sugar syrup; I had no surplus honey, the season being poor. To say I was afraid of my bees would hardly express it. I almost laugh now when looking back over the last summer, to think how I have overcome many difficulties, and I al-

most dread to think of those nights of almost hysterical excitement; how the bees seemed to swarm around me as soon as I closed my eyes to sleep, and nothing but the continued angry buzz (as I imagined) greeted my ears day and night, and then those horrid stings. I had to go to our physician 2 or 3 times. (Now please do not laugh it is not polite you know, especially when one suspects you have been in a similar position yourself.) I asked him whether I had not better give up those bees entirely. I had not been well and he thought I needed something to draw my attention out of that gloomy state into which I had sunk. So I attended to the millers, around the blocks, and clipped the grass in front of the hives and watched them whenever I could. If work kept me in the house all day I often stole glances through the window, or when I rested and I read Longstroth on the Honey Bee in the evenings, (I did not know anything about bee journals then,) when I made these artificial swarms how I trembled, and how heated I got, and the little rascals seemed to know I was afraid of them. They came out all right last spring. I fed them a little, and opened the spread, as Mr. Doolittle recommended. You see I had the AMERICAN BEE JOURNAL to study then, it has been worth very much to me. I have an acquaintance who lives about 3 miles from us, who owns about 100 colonies; he has kindly instructed me from time to time; he has not used the extractor yet, but I presume he will soon.

Last March I bought 5 stocks in box hives. I transferred them very successfully. Some were in fine order; one was destitute of brood and honey, I think. I bought them just in time to save them. I gave them brood and honey from some of the other hives, and now they are my best stock, except one. I drummed them out and opened the side of the hive, on which the combs lay flat, with a cold chisel, borrowed from my husband's mowing machine. When I asked for it, he laughed and consented to lend it if I would return it to its place, and remarked that he supposed I would have all of his tools about those hives if he did not look after them. Of course it was duly returned, I do not like to hear men grumble especially when they are in the house. The first week in May I visited A. I. Root & Co., of Medina; the day was very warm but little daughter Edith and myself had a very pleasant time. Mr. Root certainly is a gentleman, and Miss Andrews took especial pains to show us their apiary, and I learned what I could. I fear I troubled them with questions, but as some Americans I have heard say, "I wanted to know." Mr. R. has a pleasant home, and a very nice family; especially

little blue eyes. We have a little fair-haired girl with a sunny smile, who the other day got a sting while adjusting the blocks as she had seen me do. She kept me awake that night, and the next morning Mr. M. remarked my wearied appearance, and said, "Wife. I do not think it pays to have that baby stung like that; I fear your bees are a poor investment." I had my own private thoughts and again bathed my baby's sting with amonia, and said nothing. Poor darling, she often puts that hand for me to kiss, and tries to tell me about it. Sir, I thought I was transferring bees; but I see I have wandered far away. I will tell you the result of those bees at some other time.

Elyria, Ohio.

Mrs. W. M.

Cause of Bee Swarming and Migrating to the Forests.

The period of incubation by the queen commences early in the spring. It is rapidly generative, and when the honey season approaches, the cells are well stocked with eggs, larvæ, &c. At this time, the working bees sally forth to labor day after day with untiring assiduity to stock their homes with a winter's supply of provender. During the busy season they intimate a negligence toward the royal blood by packing cell after cell with their wealth and rapidly contracting the queens domains—the cells for her deposits. The breeding space of the hive thus becomes rapidly narrowed, and, finally, the queen, having no empty cells, locates in some remote place, generally on or near the edge of a comb, and continues her deposits. The latter, on the edge of the comb, are eaten by the working bees. Thus situated, the royal influence of the queen is limited, and unexerted. The wealth of the community has unsettled the kingdom. The entire swarm seems to be dis-loyal. It presents the condition of a nation which has lost its sovereign. The working bees, powerful in wealth, construct royal residences or "queen-cells," in which they rear queens; and to be certain lest the royal blood should become extinct. The royal family consists of many queens, heirs expectant, and when these youthful queens are hatched, the old queen, jealous of her regal honors, undertakes to destroy her rival queens. Unable to succeed, as an army of workers surround and defend the young queens, the old queen abdicates her throne, and sallies forth from her late dominions, accompanied by her loyal subjects, old and young, whirling and buzzing in dire confusing. After all of the disaffected have left the hive they settle with the queen upon a shrub or bush. This is what constitutes "swarming."

In swarming, it is believed that a regular and permanent organization is not entirely

affected until after the departure of the swarm from the parent hive to cluster in a body, not unlike a mass convention. Immediately on swarming, the greatest tumult and confusion ensues throughout the ranks, at the same time manifesting a desire to alight sufficiently far from their late abode, so as not to be interrupted or annoyed while completing their organization and arrangements for their prospective home. Here we notice a striking peculiarity. All the bees that are capable of taking wing, young, middle aged and aged (except those that are employed in nursing the young larvæ, brooding over the chrysalis, or are out in the fields,) accompany the swarm to seek their new habitation.

Here is wisdom and order created out of disorder and rebellion. The Author of all things has "most wisely" fixed their dispositions so as to prevent the overthrow of the old colony. A large number of bees are absent from the fields, amassing honey, at the time when the swarming takes place. These, no doubt, amid the unsettled condition of home affairs, would join the new colony and leave the parent home unprotected and defenceless. The combs would become despoiled and ravaged by the irruption of those little barbarians—the moth family; the infant queens would die from want of careful nursing; the germ of another new colony—the larvæ and chrysalis—would be lost in the general wreck, without the protection afforded by these absentees, who, when they return, offer the necessary care to preserve the household with its interests.

When a new colony leaves the hive, and goes off without alighting on a shrub or bush, it is, as a general thing, these swarms which hang upon the outside of the hive. It is an unusual occurrence, that swarms which hang upon the outside of the hive leave until they have sent off ambassadors to select a suitable home for their future abode.

Now if bees are hived immediately after they have alighted, or before they have dispatched their agents to select a new tenement, they will not leave at all, if their new residence has been made agreeable, and clear of everything offensive to them, and sufficiently commodious. (For it is want of room that causes swarming.) Then, to secure the new swarm we recommend "artificial swarming."—From *Flander's Bee Book*.

Honey is never found in the second stomach of the bee, but only in the first. The latter contains only the Myme, being the digested or partially digested food, which passes into the intestines, and the final excreta there show that the food consists mainly of pollen or bee-bread.

For the American Bee Journal.

A Voice from Pennsylvania.

In writing for the JOURNAL, I wish more would give their experience in bee-keeping, whether good or bad, that others might profit thereby; for, as I understand it, the object of the paper is to give practical information, and not to dispute over differences of opinion, until bad blood is aroused among those who should be the best of friends. I believe there are many successful bee-keepers who could give valuable information; but I fear the great fault of humanity—selfishness—may perhaps prevent them.

Bees have not done so well here this year on account of the late and cold spring; they wintered very well, but as the season advanced I found three hives did not increase, and upon examination I found them queenless, a misfortune which I see by the proceedings of the Michigan Convention; others have met with this winter to an unusual extent. The cause may be in my case the age of the queens, for I have not had a swarm for two years. My room for stands being limited, and honey my object, I have entirely prevented swarming, by giving plenty of room for surplus, early in the season and ease of access to the surplus frames or boxes. I never clip the queens wings, and my experience is that it is entirely unnecessary. My bees are of the black, or as some call them the gray variety. I expect shortly to receive several Italian queens to supply my loss, though I am not over sanguine of great improvement, for I see upon occasions that I have visited the fields to observe, that a good many gray bees are at work on the red clover, though I do not think bees like it very well, which is perhaps the greatest reason they do not visit it more, for it secretes honey in abundance; and if some can get it, others would try much harder than they do, if they liked it.

I use the Quinby hive as described in his work on the bee, enlarged to hold 14 frames 10x18 inches inside measurement, with two dividers, making the main hive, or winter house of 8 frames, with a dead air space on each side for winter protection. By removing the dividers six small 5 lb boxes or 18 small frames may be placed on each side for surplus, or if the extractor is used, the whole hive filled out with full sized frames. The bottom board under the main hive or 8 central frames is loose and joined to the side bottoms by rabbets. The side bottoms are nailed to the hive which makes it stronger, and keeps it always square and firm. The bottom board is held in place by 2 buttons underneath.

I find this form of bottom board much more convenient than in those that are all in one, as some of my first were made.

Honey board made of 6 pieces—after Quinby. I had some with holes, but threw them away. Cap fits down over all, and rests on a loose moulding frame held in place by a screw or nail on each side, and may be left down to the bottom board for further protection in winter. Top the same as the Bay State hive and loose. Portico movable. It makes the hive easier to handle and lighter. When I commenced keeping bees, I tried wintering in the cellar and lost heavily, but since I leave them on their summer stands, I have not the slightest sign of dysentery, and loose very few. In wintering, I have never yet (except when I tried the cellar) given upward ventilation, and I am not sure that it is ever necessary; it is not the true principle of ventilation for buildings, then why for bees, besides why do they so carefully close up every upper hole and crevice—even to wire gauze put over the holes or openings in the honey board, even in hot weather? I believe the true principle—as I saw recommended some time since in the JOURNAL—would be to give plenty of open space below the combs, and not open the top and let the heat pass off.

The whole of my stock at this time are natural swarms and yet I have never had a swarm leave for the woods, or leave the hive I introduced them into, and yet I never even gave them a piece of comb to start on. I incline the hive slightly forward and mostly secure straight combs.

I am located in the rural part of the 24th ward of the city of Philadelphia, near George's Hill and the Park, and my bees have a fair field for pasture. They swarm here about the first and second week in June in favorable seasons, and I have had them as early as the 10th of May during the blossom season. Our best and largest yield of honey comes from the Tulip Poplar—the queen of honey-producing trees. It scarcely or never fails as white clover and basswood some times do. Its blossoms open successively for a long time, indeed without it bee-keeping here, I think, would be a failure, although there is considerable basswood and white clover. The leaves of the Poplar frequently yield largely of honeydew in the fall. I would like to recommend them to Novice while he is planting an orchard of honey-producing trees. They grow quite as rapidly as basswood and are very handsome shade trees. Bees will not work on flour here in the spring; perhaps the reason is that they get natural pollen from the shade-tree maple, which is so very plenty, and blossoms when the weather is at all favorable as early as February.

Being near to a good market I prefer honey in the comb and find small frames 5½ by 6½ inches in the clear, 7 or 8 to a case, and glass at each end, just the thing. They sell well, are convenient to handle, easy to

get the bees out of, when full; and when the honey season is over I join those filled and sealed ones together into full cases, and extract the honey from those partially filled, and they are worth pounds of honey the next season in starting the bees to work early on surplus, and thereby also prevent swarming. By having one full sized comb in the middle of the case, and small combs or pieces warmed and stuck fast to the frames I secure straight combs and a comb to each frame every time.

"Do bees injure fruit?" I see is now up for debate. I say, no! I have grapes hanging over and all around them, and so have also my neighbors. I have watched them closely and though I frequently see them on the ground at the broken and fallen grapes and occasionally a defective one on the vine I have never yet seen them open a sound grape. I have observed that they act in the presence of, or in going over sound grapes as if they had no idea of sweets being in their neighborhood, but break one open and they then soon go for it. Three years ago one of my neighbors did complain about my bees eating all his grapes, and he said he would not get any, the latter was really true, for he got very few, but it was because they were diseased, as he soon discovered, and nearly all fell off or rotted on the vine.

"Do king-birds eat worker bees?" is another question which has been disputed, but I say from personal knowledge that they do, and a great many of them too; while I am writing, I hear them up in the air on the top of some large maple trees which surrounds my neighbor's house. They are after bees, for I have shot a number of them and sometimes their craws were stuffed with bees, and on careful examination I found most of them to be worker bees. I have also watched them in the park, (which is full of them, as they are not allowed to be shot.) They are very tame there, and therefore I could get close to them. I have seen them leave a small twig of some ornamental shrub and dart down among the white clover, take a bee, and return to the twig, first beat the bee to death holding it in its bill, and then swallow it, and in a few minutes, go for another, I can assure you I felt very much like going gunning for king-birds about that time.

Artificial combs have been talked of in Conventions and in the JOURNAL. Has any one succeeded in getting bees to work and raise brood in them? If so, can any one inform me where to send for one, as I would like to see and try them. I have an idea that they might be made of vulcanite, such as is used in making artificial teeth, as it is put to almost every use now.

At the Centennial Fair to be held in Philadelphia in 1876 almost every interest that can be mentioned except bee-keeping has

been referred to an appropriate committee. Why is this? There are several organized bodies of bee-keepers in the United States. I thought I would call attention to it through the JOURNAL, though I know there is some objection to having bees where there will be such a large number of people and horses.

Philadelphia, Pa., J. R. WELLS.

P. S. I wish those who advertise would state price, and not wind up with *send for circular*, for bee-keeping time is often precious, queen raisers I fear sometimes forget that in filling orders. W.

For the American Bee Journal.

Fruit and Forest Culture in Nebraska.

At this time there is great interest attached to the subject of tree-planting on the prairies. It is a well settled point that the forests of the country—vast as these are—will not forever bear the enormous demands now made upon them. As trees grow rapidly in prairie soil, it is beyond doubt that the great plains will afford sites for some of the forests of the future. Not forests where for hundreds of miles there is nothing but trees; but forests, after the fashion of the old world—except that the main incident in their creation will not be to afford coverts for game—where woodland, arable and pasture alternate with each other. In Nebraska, the settler has special inducements to plant trees. The law of the State gives a bounty in the shape of remission of taxation for tree-planting; and, in four or five years, the farmer begins to reap his advantage in fuel grown upon his land, and in the fruit ripening in his orchard. The new timber law, also, will stimulate forest culture. This law, as amended by Congress during its present session, gives 160 acres of land to whosoever will plant forty acres to trees, and cultivate the same for eight years; and this without any condition as to residence, so that a homesteader or buyer of railroad land can, when there is Government land in his vicinity, have 160 acres as a gift, if he will plant one-quarter to one of the most profitable crops that can be put into the ground. Some time ago your correspondent was favored on this matter of tree-growing, with the experience of Mr. V. C. Uttley, of Nursery Hill, Otoe county, Nebraska, who has resided eleven years on a Nebraska farm, and who, before that, was a farmer in Ohio. He says that the fruit grower need have no fear in planting on the open prairie. Apple trees flourish on the highest bluffs, care being taken, by the planting of cottonwood as a wind-break, to shelter the orchard from the highest winds. Mr. Uttley has also found the black walnut adapted to Nebraska soil; and indeed, it is naturally adapted inasmuch as on the banks of our rivers and creeks

these trees grow luxuriantly. As the result of experience, Mr. Uttley commends to the tree-planters in Nebraska: black walnut, soft maple, box-elder, poplar, cottonwood, honey locust, butternut, American and European larches and all evergreens. He has experimented with most kinds of trees; and his conclusion is that these are the best for the settler to plant—and to plant in the Spring. N. A. E.

For the American Bee Journal.
Novice's Answer.

MR. ERROR:—We should like to make a mild protest against the position in which our excellent correspondent, Mr. Gallup, places Novice in his article on page 164. We believe that we should go to work to rear queens in just about the same way that Mr. G. would, and cannot think that our readers have understood us as ever having advocated queen-rearing in the manner he mentions. That many who rear queens for sale, do. 'Tis needless for us to refer to where we have narrated on these pages our experiments in rearing queens with old bees and small clusters, and how they laid eggs only a week or two, &c., for our readers certainly remember. Please, Mr. Gallup, be a little more neighborly. Although we agree perfectly on queen-rearing, we fear we do not *quite* agree on hives.

As a great deal has been said about the Gallup hive as described on page 133, we would like to add our opinion, but it is certainly respectfully tendered, and given in all candor. As to the length of the hive we have nothing further to add than what we have said heretofore, but we cannot help feeling doubtful about the double casing, and air space; on the same page, mention is made of disastrous losses where double-cased hives were used, and our friend fed on sugar syrup too. Also, the case of Mr. Elwood, mentioned by Quinby, who lost bees by dysentery when fed on syrup, was in double-cased hives, or at least something to the same effect; and without going farther, we will only mention that our neighbors, Shaw & Son., put a good colony last fall in a hive or box with double walls, filled with sawdust on top, bottom and sides, and the walls were *eight* inches thick; they died with dysentery in its worst form very early in the winter. Double-walled hives have been advocated, patented, tried, and abandoned, by bee-keepers the world over from the veriest novice up to both Langstroth and Quinby for years past, but yet Mr. G.'s plan may be a little different and it is well not to be too hasty. A colony that can cover 26 combs in February, certainly should be able to keep warm, independent of any aid from the sun in occasionally warming up the sides; but Mr. G.

also mentions wintering a weak colony thus: Was this simply because bees frequently wintered well almost any way, or was it on account of the double-walls? Please Mr. G. tell us how these hives came through the spring. We cannot understand how it is, that the long hives only build worker comb with friend Gallup, when they build drone-comb almost every time with us, Medina bee-keepers, as in fact they do from all accounts we receive of them. One of the best bee-keepers in our country who uses the Gallup frames and has followed faithfully Mr. G.'s, excellent articles from the commencement—uses division boards constantly and would not give it up "no how;" but he cannot yet make comb in large colonies, and he has bees and brood on 20 or more Gallup frames in the long hives at this present time. Now although we have had our say, it may still be that the "New Idea Gallup Hive" will cure all the troubles in wintering which we *most sincerely* hope may be the case, for if somebody don't help, we really fear we shall forever be only a Novice.

P. S. We may be mistaken in saying that Quinby has abandoned double-walls for out-door wintering, if so we are sorry—no, we mean we beg pardon. While we think of it, does any one know that the Quinby hive without boxes is a veritable "New Idea," and although 'twas given to the public years ago, no one has ever even said "thank you."

If any one should find that glass for the outer walls of the hive secured all advantage from the sun and the dead air space too, remember we inserted it several years ago, but never tried it, like lots of other "blamed good ideas that our head is always 'chuck' full of." Our 16 colonies are now 31 and are bringing in basswood honey at an unprecedented rate. We have actually got almost a barrel on this 7th of July, 1874.

For the American Bee Journal.
Ants and Cockroaches.

In my correspondence and the bee journals there is much complaint against ants in bee hives, while there is nothing said of cockroaches. I have ants enough in my apiary; but the cockroaches are ten times as troublesome. The ant does not steal honey out of the hive, nor trouble the bees to my knowledge, but the cockroaches do both. All the ants want is a warm and dry place, for a nest on top of the honey board where they can enjoy the warmth of the bees below, and this is but a portion of the year, from May to October, while the cockroaches are present the year round. When you go to open a stand with an ants' nest on the honey board, it is no small job to brush them off, and when you raise the board a great many get inside and worry

the bees very much for a few minutes. Those who will take the trouble can keep the ants away by rubbing the outside of the hive with green elders or turpentine, or corperas, but none of this will keep the cockroaches away.

I find the cockroaches very thick in my apiary all summer, and in winter they are on top to enjoy the warmth of the bees, and inside of weak stands. That they do steal honey and live on it through the winter there is no questioning. In proof of their fondness for honey, I have often set out mugs and bowls with honey and water to drown moth flies at night, but the result would be about one hundred drowned cockroaches to one moth fly. Also the sweetened water that I use in introducing queens, wintering bees, etc. I can set cups nowhere in the apiary at night but the next morning it will be perfectly clean, and cockroaches found in it.

I have tried a great many devices to get rid of them, but all in vain. The best I ever tried was to go through the hives on a very cold day, and brush off the cockroaches to freeze which they readily do, but there is an evil in this plan; it disturbs the bees which should not be disturbed in cold frozen days. I have found a still better plan. I am in the poultry business, and have put a trio of Buff Cochins in the bee yard, and trained them to follow me around on warm days, and eat the cockroaches as fast as I can brush them off. This I find to be a good plan with no evil in it. I have never had a fowl eat a live bee. I have seen fowls go to the entrance of a hive and pick up a worm without disturbing the bees. I have also seen them go round a hive looking on the sides for moth flies, and I believe this is one reason why the moth is no trouble to me.

Lowell, Ky.

R. M. ARGO.

The most complete check upon robbing bees is to place a bunch of grass or wet hay over the entrance to the hive. The bees will find their way to the entrance to their own hive, the robbers will be caught by the sentinels in passing through the grass, and soon cease their pilfering.

CRYSTALLIZATION OF HONEY.—The action of light causes honey to crystallize. The difficulty may be obviated by keeping it in the dark, the change, it is said, being due to photographic action; and that the same agent that alters the molecular arrangement of iodide of silver on the excited collodian plate, causes the syrup honey to assume a crystalline form. It is to this action of light that scientists attribute the working of bees by night, and they are so careful to obscure the glass windows that are sometimes placed in their hives. Therefore, keep honey away from the light.

For the American Bee Journal. Gallup Again.

Without doubt the Extractor has killed its thousands of stocks of bees. Now, Mr. Editor, publish the above without explanation, and, oh, horror of horrors, how Gallup would catch it. In many cases it has been used without the least particle of reason, and the bees have all died of dysentery, or that terrible bee disease. Perhaps we could illustrate better by telling of one of our mis-moves a number of years ago.—Soon after learning to drum out bees, we made a grand discovery. Mind that there were then no bee journals, or perhaps we, *Novice-like*, should have been caught giving instructions to others, when we knew nothing ourselves.

Right here, allow me to say for *Novice's* consolation, that we passed through the same ordeal that he is now going through. That is, we were very forward in giving our knowledge to others, before we had any to spare.

But to our story. We thought that we could drum out our bees in August, place them in a new hive, (we used the old box or chamber hive in those days,) and in 27 days the young bees would be hatched and we would drum them out also, and unite them with the others; they would then fill the hive and winter, and I could have the old stores, etc. This was a wonderful discovery and I, *Novice-like*, spread the news of the discovery far and near. But by the month of February these bees had a terrible disease; in fact, they all died of dysentery, (fine stocks). They had honey enough, but it was made or gathered too late in the season, consequently was not properly evaporated or matured, and the result as stated above.

Now, is it not a fact that many, in order to get a large yield of honey, extract too late in the season? They have the necessary amount in weight but not in quality. You will recollect of one person telling in the back numbers of extracting late in the fall, and their filling up and that all died with dysentery. That person requested some one to give the reason why they died, and we told him he had given the reason himself, etc. Now, if we winter bees on honey we want that honey of good quality and made in the proper season, and when the bees are raising brood rapidly, and have large quantities of bees of the right age to properly manufacture or evaporate it.

Here is another question for our consideration. The two-story hive has been lauded to the skies by *Novice*, when practice and experience has taught us and others that it is entirely in the wrong form, as the bees are not able to properly evaporate

their honey in cool weather and raise brood as rapidly and abundantly as they ought to in a hive of the proper form. In the "New Idea" form we have the brood nest always warm, consequently breeding can be carried on rapidly, and honey stored at the same time, without the animal warmth escaping into an upper story and away from the brood nest. Now, if we extract all the honey on the 15th of August in our climate (except from a few central combs in the brood nest, we have room enough for the bees to breed and store from 80 to 150 lbs of honey without any more disturbance for the season. This honey we leave in the hive until the bees begin to gather rapidly the following season, and it is stored where it is convenient for the bees to get at and still does not keep the brood nest cool or take away one particle of warmth from the brood nest. The consequence is that we have no feeding to do at any season of the year, for it is a well-established fact that a strong powerful stock of bees with abundance of store do not need any stimulation to induce them to breed early enough for all practical purposes.

Now, here is another consideration. A neighbor of mine uses box hives 14 inches high and 18 or 20 inches square, and his bees have not died or had the dysentery while the neighbors' bees have died by the thousands; he winters on summer stands. My impression is that the injudicious use of the extractor, two-story and small standard hives has killed thousands and thousands of stocks of bees. Why did not my bees have the terrible disease that has been so prevalent all over the country? There has been other causes besides the injudicious use of the extractor to kill the bees. Years ago we lost heavily at different times and at that time we were not willing to attribute our losses to our own ignorance, but it was a fact nevertheless. Whose advice is the best—the advice of those who fail, or that of those who succeed. Let the "Novices" decide for themselves.

Yours truly,
Orchard, Iowa. GALLUP.

For the American Bee Journal. Gallup and Queen Rearing.

Don't set it down too positively, friend Gallup, that "abundance" of food of the right kind and "abundance" of warmth are *all* the requisites of successful queen rearing, simply because you don't *see* other conditions present when a full colony of bees are raising queens at will. We should remember that a colony of bees are a whole—they are one individual, the same as a swarm of cords and nerves that form the human body are one, except they are separable for a short time. Taking this

for a basis, is not the whole colony the parent of the queen as well as all the offspring? We all know that animal magnetism is the essence of animal life, and that parents greatly endowed with this life-giving principle will produce the strongest offspring, other things being equal. Now, would it not be natural to suppose that a full colony of bees would be sure to produce the best queens. I believe the best queens we get are those reared in cases of supercedure when the *whole* colony remains together till the *hatching* of the queen, at least.

"Novice" says, on page 53 of *Gleanings* for May, that, "to be sure many will say she can't lay eggs, and brood can't be reared without more than eighty-two bees.—But why? Ans. A lack of "animal magnetism." Now, friend Gallup, don't accuse us of having been only six years in the business; for we see you criticise Mr. Quinby who has been engaged in apiculture much longer than you, and has had no "big farm" to take his attention either. I am no stickler for old methods and systems, nor do I believe that queens reared at will of the colony are as good as those properly reared at the will of the apiarian. I think I can show that prolificness in the mother-bee, beyond a certain limit, is of no value. The *quality* of the bees in our apiary is what we need, and not a great number *from one queen*, or a few queens.

Apiarians have dreaded the swarming impulses of their apiaries worse than the moth, and this I believe has been owing to a limited knowledge of the science. We have known how to take a profitable advantage of the powers of bees, so long as this impulse did not interfere, but when it did, we were left in the dark and our plans thwarted. When we understand how to *use* this impulse to the best advantage, we shall foster and encourage it. Then shall we appreciate the Italian bee in its broadest sense.

Now a word for "Novice." No apiarian has done more for me than he. I look upon the changes of his mind, we hear so much about, as evidences of his progressive nature. The above is simply *our* views. Let the watch-word be "onward" throughout our apiarian lines, and hence let us speak our minds freely, not for spite, but for the advancement of our pet science, and let us change our minds *publicly*, as often as we do privately, which will be often if we observe closely and experiment largely. Convictions do not come at will but are always forced upon us.

Dowagiac, Mich. JAMES HEDDON.

The bees throughout the world, as known collectively to the richest cabinets, number about two thousand species.

For the American Bee Journal.

Our Honey Markets.

MR. EDITOR:—I wish to ask through the JOURNAL whether other apiarians, who ship honey to any amount, have any difficulty in getting returns. I have had considerable, and it is only because I feel it a duty due to my fellow bee-keepers that I now make public several transactions with honey merchants. For over a year there has been an advertisement in the AMERICAN BEE JOURNAL of Baumeister & Co., wanting 10,000 lbs. of extracted honey. In answer to that advertisement I offered to buy them honey, and have their reply stating what they would pay and what commission they would give for buying. I bought considerable, and with some of the product of my own apiary, collected about six barrels, and wrote them to that effect, stating the quality of each barrel whether basswood, clover, mixed or fall honey. By fall honey I mean that collected principally from bone-set, buckwheat, fall astor, butter-weed, (or as some call it, fire-weed,) golden rod and a number of other honey plants of minor importance, all blooming at so nearly the same time as to render it difficult to say which flavor predominates in taking a sample from a barrel. At the time I wrote I also said that I had had an offer of 15 cents per pound for it in the warehouse but as I had written to them previous about it, they had the right to the first choice, and if they wished to take it at that price I would send it, and in reply was ordered to send it on. But upon their receiving it they wrote saying that the honey was not as represented. In marking the barrels I did not rely entirely on my own judgement but on the judgement of two other apiarians, to whom I can refer; but the trouble came afterwards. I looked for money but none come. After waiting a month or two I went to Chicago to see about it and found they had sent \$200 in a letter addressed with wrong initials. That being made clear and satisfactory, they faithfully promised to send me \$100 the following week, giving also a note for \$150 payable in one month, and \$20 in cash. The honey amounted to \$470. Instead of the \$100, only \$50 came and that two weeks late. The note was paid on time; but the \$50 they now refuse to pay, saying they will only give \$25; and it is three weeks since they offered that and I accepted it, but still they do not even send that.

I have given a rather lengthy account of this one transaction, as I would like to know if any others have had business with this firm, and whether they do business generally in that style.

I also sent a bill of honey to J. W. Winder of Cincinnati, amounting to \$160; he

complained of nothing but "panicky times." When the money was due I received \$75 from him, but for the last few months cannot hear a word.

I wrote to the Chicago Honey House, 360 Wabash Avenue, asking what they would give for fall honey, and stated that I had a barrel (I use 500 lb barrels) to dispose of. They offered me 15 cents, if clear. I shipped it, saying it was candied, and now they do not want it at all.

Who are the staunch men to whom we can ship honey and feel sure of having speedy returns. We can better afford to sell for 13 cents cash, than wait six months at 15 cents, not knowing whether it will ever come.

WM. W. BIRD

Ohio.

For the American Bee Journal.

Our Opinion of Artificial Queens.

DEAR JOURNAL:—Methinks your contribution from S. W., Mo., is far and few between. Last fall, I predicted that many black bees in log gums would starve. So they did. Mine (Italians) all wintered, and have made some surplus. I like Gallup's article in the July No., page 164, on artificial queens, and commend it to beginners in bee-keeping. I would like to have the line of distinction between natural and artificial queens drawn upon a little different ground. I think natural queens are those produced by natural swarming and none others. Queens that are produced from any and all other causes are artificial.

If we take the queen away from a strong colony of bees in warm weather, when they are getting plenty of stores from the field and have bees in all stages of existence, from the egg up to the field workers, we are apt to raise good prolific, well-colored queens, large size and long lived; but they should know no scarcity of food. If they need it, they should be fed daily the first eight days. Such queens as these we call artificial. Gallup calls them natural. Such queens as Gallup calls artificial, I do not take any stock in. In fact I do not have any confidence in any of those low-priced queens, and I do not believe the expert bee-keeper can afford to raise good queens (or what we call good queens) tested and warranted for \$2 and \$3. He would do better to devote his time and force for surplus honey. If those cheap queens are thrown on the market, it will have a great tendency to hinder the introduction of the Italian bee. I would much prefer paying \$5 to \$8 for a queen that was actually worth that, than to pay \$2 for a cheap one and run the risk of being totally disappointed.

I beg leave to differ with Mr. Hazen, on

page 163 of the AMERICAN BEE JOURNAL, in regard to over stocking the field. Probably we in the West are differently situated in respect to bee pasturage to what they are in the East. When we have good honey flowers here, we never have bees enough to gather all, until rain or dry weather stops them from work, and we should always be prepared with our colonies, strong and large enough, in case of failure in flowers, to secrete honey; for such colonies will live when others will starve to death, and more especially if they be Italians.

For the American Bee Journal.

Double Story Hives.

While bees are storing honey rapidly they should have more room within their hives than at other seasons. They need this both to prevent swarming and to secure from them the largest yield of honey. A given number of bees in one hive will store much more surplus honey, than the same number divided out into several hives. One of the most important rules to be observed, where surplus honey is the object, is to *keep the stocks strong*. The queen should have all the combs she can supply with eggs, and the workers as many as they can fill with honey. When the hive is in this condition, and the extractor is freely used, there is little if any danger of swarming, and an abundance of honey will be obtained.

Ordinary single-chamber hives contain about 2500 cubic inches of space. For medium sized stocks in ordinary seasons of the year, this will be room sufficient; but when the flowers are secreting honey profusely, and the queens are laying freely, twice that space should be given them.

Some intelligent bee-keepers hold that all this room should be furnished in a single-story hive. Their theory is that the workers will extend their construction of comb, and the queen her deposition of eggs, from the centre to either side, more readily than above or below, this may, or may not, be correct; I am not prepared to deny or affirm. But I have met with no difficulty in getting either the queens to lay or the workers to work in either upper or lower stories. I have had no experience with these large single-story hives. It seems to me, however, that whatever advantages they may have in other respects, they must be very cumbersome and unwieldy when it becomes necessary to move them. I should think it would also be quite difficult to contract the space within them to suit a small stock, or to winter even a full stock.

I have been using for several seasons a double-story hive, which has given me

entire satisfaction; and before giving a brief description of it, I will say that I have no "axe to grind" in doing so, as there is no patent on it, so far as I am concerned and I keep none for sale. It consists of two boxes of the same size, set one on top of the other, each filled with ten frames. It is cheaply made and easily handled. The bees are wintered in the lower story. When they become strong in the spring, the second or upper story is set on, and to induce the bees to work above, without any delay, a few of the frames of brood are put in the upper box. The work then goes on in both stories as well as in one before. No honey brood or portion of any kind is used between the stories.

My hive is modified after the Langstroth, but, I think it is more convenient and less expensive. Each chamber or story is, by inside measure, 19 in. long, 14½ wide and 10 deep. I have a J in. portico in front of the lower story, but while this answers some good purposes it is not essential. I use poplar lumber and have it dressed to ⅞ of an inch in thickness. The sides are 10 in. wide, the front end 8½ and the rear end 9½. Both end pieces are set with their tops ⅞ of an inch below the upper edges of the sides. On these ends are suspended the frames. The upper piece of each frame is made first 19 in. long, the ends of which are beveled off to prevent interference with the ends of the upper story.

The upper story is made without bottom and fits nicely on the lower. Each end of it also drops down ⅞ of an inch below the edges of the sides. The inside lower edges of these ends are beveled off so as to fit down over the ends of the frames in the lower chamber. Strips are nailed across the ends of both stories to strengthen them, and to furnish handles by which to lift them.

A cap or cover is made to fit either story, by nailing strips around and under the outer edges of a board about 18 in. wide and 22 long.

Anyone that can use a saw and hammer can make these hives, and I consider them as good as the best. I have never had a swarm of bees from one of these hives since I have been using them. This season I have had 26 in use, and have taken from them 110 gallons of honey. From one hive I have extracted 14 gallons, and taken about a dozen full cords of brood to build up weaker hives. They are all now in good condition, and well supplied with honey. I have already started 26 nucleus hives, and as fast as the queens become fertile, will build them up to ten frames. This will reduce all the double-hives down to single chambers. I do this now because the honey season is over with us. We may have a little in September, but cannot calculate with any certainty on that.

Charlestown, Ind. M. C. HESTER

For the American Bee Journal.

My Management of Bees.

My apiary is built slightly facing the southeast, in order to have the morning sun. The bee stand is built upon a post, within the enclosure, with no connection with outside parts; this prevents a direct communication to the hive, by ants and other preying insects.

Ants are sometimes troublesome—to prevent them crawling up the post, a band of raw cotton, passed around the post of the stand, will make an effectual barrier.

Hives.—I have used the common hives for years, also, common hives with surplus honey-boxes; also, the Langstroth Moveable Comb, and many other popular hives; am now using the American Bee Hive, which I think superior to any that have come under my notice, and have been taking 100 per cent. more honey from them than from any other kind. In the spring, I overhaul all my swarms, cleaning out all litter that may have accumulated during the winter, and occasionally give them a little honey, which seems to encourage them to begin their labors; and if any surplus honey has been taken the previous fall I seldom replace the empty boxes till the swarming season is over—too much room prevents swarming.

Swarming.—Artificial swarming is much spoken of, and perhaps profitably practised, but I prefer natural swarming, for I am confident that it is much better for the parent stock as well as the young swarm. Swarming usually begins in May, about the middle, and sometimes earlier; the first swarm needs little or no care, it being generally strong and vigorous, and goes to work with a will, frequently surpassing the parent stock in surplus stores. The second swarm appears about 12 days later, does not number as many, and seldom gathers more stores than is necessary for its winter use; occasionally a third swarm issues, weaker in number, and having less time to provide for themselves; they need more care than rest, though I have at times carried them for miles, where buckwheat fields are numerous, and they have turned out more than self-sustaining. I generally weigh all my hives before using them, then when occupied by the bees, on re-weighing them in the fall, I can tell whether they have sufficient honey for their subsistence. A swarm and stores, independent of the hive, should weigh at least 25 lbs.; when I find them below that weight, I always feed them during the winter. Honey, of course, is the best food, though some make a syrup of white sugar, or use sugar candy. In giving them honey, it should be placed within the hive where they can have easy access to it; if it is in the comb, where I

have a movable comb hive, I place it in the frames, but strained honey should be placed in a small wooden trough, (tin or metal will sour the honey) then at intervals I place straws so as to give them sure footing, and thus prevent them from falling in the honey and drowning. They require more food upon a bright, warm day; during the extreme cold days they are in a state of torpor.

When swarming is over, I put the surplus honey-boxes in their respective places, and take them out about the 1st of October or even earlier, taking care to leave sufficient for their maintenance during the coming winter; at times, I have taken from 40 to 50 lbs. of beautiful white honey from a single hive. B. R.

For the American Bee Journal.

Artificial Swarms, etc.

On page 148 friend Dorr gives his method of artificial swarming. We have tried that way too, but do not like it, for it breaks up the stocks so badly, it gives them too much empty space.

Here is our plan. Say you have five stocks; go to four of them and take out two frames of brood and honey from each, shaking the bees back into the hive, and put in an empty hive; then move No. 5 to a new place and set your hive filled with brood combs in its place; all flying bees from No. 5 will enter the new hive and soon be building queen cells, unless you can give them a capped queen cell, as friend Dorr says. No. 5 will soon have more flying bees, and will hardly know they have been molested, for while the young bees are hatching and eating honey, the queen will be filling the empty cells with eggs before the older bees can fly to fill them with honey. You can give each stock an empty frame or two if you like, but to give a new stock one-half of the hive in empty combs is too much, I think.

And still another one, which I think is even better. Place your empty hive where you wish it to stay; go to your four stocks as before, take 2 or 3 frames of brood, according to the amount they can spare, and shake the bees off on the alighting board of your empty hive, being *sure* you have not got the queen. The flying bees will rise and go back to the old stock, while the young bees will travel into the empty hive where the frame of brood is placed after shaking them off. Give them 6 or 8 frames of brood and honey shaking each at the front, and then if you have not bees enough to suit, take out more frames from old hives and shake off bees till you have enough, giving the combs back to old stocks. If you have a queen cell to give the new stock, all right, if not, they will

attend to it themselves. The young bees will not fight each other, as we have used Italians, hybrids and blacks all mixed together.

BEEES AND GRAPES.

Some of our hives stand close to our grape-vines, have had them under the vines and none over 5 ft. away, and we never yet saw bees touch them. It's all *bosh*. Roll up the evidence, friends, and let's "squelch" the poisoners in their infancy.

BEE QUILTS.

To those who use or are going to use quilts for their hives I would advise them to *not use cotton-cloth*, but take woolen; it is more porous than cotton and will not take fire from sparks when bees are smoked with rotten wood, etc. If you use cotton you may step out into your bee yard some day and find one of your stocks doing a land office business in the way of a bonfire.

Since June 15th we have had no rain and things are getting pretty dry, but bees are getting honey, for combs are nearly full that were extracted on the first of this month.

W. M. KELLOGG.

Oncida, Ill.

For the American Bee Journal.

Caution!

Believing it the duty of everyone to expose fraud wherever found, I herewith submit the following—my experience—to the consideration of my brother bee-keepers: Last season I obtained 1050 lbs box honey, and wrote C. O. Perrine, for the purpose of making arrangements for the sale of the same.

I gave a clear statement of the condition of my honey. In the lot there were 12 Adairs sectional boxes—14x20x5 of $\frac{1}{2}$ inch stuff, with glass on both ends. Most of it was put up in boxes 5x5x6, glass on four sides, with $\frac{3}{8}$ inch stuff for top and bottom; perhaps about 20 were of the same dimension, with glass at two sides—the other sides of $\frac{3}{8}$ lumber. The honey was about one-half Linden, the other half Buckwheat.

I stated in my first correspondence with him, that I wanted *gross* (that is, weight of boxes included) weight for all my honey. In answer to my letter he stated he would pay 27c per lb; and gross for small boxes. In my reply I stated that my large boxes contained not as much lumber per pound of honey as the small ones, and as they were as convenient for retailing, if not more so than the small ones. I wanted gross for all. No reply was made touching this point, and my honey was sent supposing this understood.

About *two weeks* after shipment, I received word that honey was received all

"O. K." (he promised to pay within a week at most, after receipt of honey) but busy times made it impossible for him to get at the tare. About two weeks after this, and after I had written stating I needed money bad, I received a check of \$100.00. About four weeks after this, I received \$60.00 through a draft, and four weeks later another \$50.00 by the same process.

He finally wrote asking if 25c $\frac{7}{8}$ lb would do me, the honey being not as bright as he supposed; and as prices *then* were, he would be glad to *sell* the *Buckwheat* for that price. I replied no, for he had but offered a medium price—honey being then, when the bargain was made—25 to 30c per lb. I stated further, he should have made this request in the first place; and that I thought I had waited long enough for my money, without being compelled to lose two cents per lb on it. He finally sent the balance. On figuring up, I found I was about \$25.00 behind; that he kept back in deducting boxes to that amount. I wrote him in regard to this, and threatened to expose him if he did not do the fair thing—I received no satisfaction.

I would advise bee-keepers to beware. Tardiness in payment is sufficiently annoying without indulging in such trickery as I have enumerated above.

If Perrine did not intend to pay me for gross weight, he should have said so, seeing I insisted upon it. "Be not deceived by imitations!" he puts at the end of his advertisement. Verily I say, beware of such imitation! Adam Grimm hit him a severe blow and I hope this addition will either make him a fair dealer or force him from lack of patronage, to shift his business into more prompt and reliable hands.

Berlin, Wis., J. D. KRUSCHKE.

P. S. Have just received a statement from Mr. Dadant to the effect that they are always paid *gross* for honey in Adair's sectional boxes.

J. D. K.

For the American Bee Journal.

Things Seen and Unseen.

WHAT I HAVE SEEN.

I have seen in the bee journals a great many reasons why the bees die. Some are all right, but nearly all wrong! I have seen bee-keepers so anxious to obtain surplus that they robbed bees in the fall, and the consequence was the bees died of starvation during the winter!

I have seen bee-keepers so anxious to multiply, they kept their stocks all the time in a weak condition; but the result was less brood and little or no surplus!

I have seen an empty comb put in between the brood combs in order to hasten matters; but I have seen it act as a division board; the queen remaining on one

side and the bees building queen cells on the other, thus causing trouble in the camp!

I have seen a ten-days queen live just as long, and proving equally as prolific as one hatched in the usual time, though the former are not to be recommended!

WHAT I WOULD LIKE TO SEE.

I would like to see bee-keepers when reporting how much honey they obtain from a single hive or number of hives, be just as particular to state the size of their hives, for in my humble judgment there *is some* difference between a hive holding ten frames and one holding fifty!

I would like to see bee-keepers when reporting how much surplus they have obtained, to give *some* credit to providence and not all to their *own skill* or particular *hive* they are using!

I would like to see every contributor to the BEE JOURNAL when he errs either in judgment or practice, to early and freely confess it! Why? Because it is noble and manly!

I would like to see a good feeling prevail amongst bee-keepers, if they do cross each other's path once in a while, and also

I would like to see the managers of the BEE JOURNAL report before the year is out, that no man (nor even a woman) owes them anything—not even a grudge! So mote it be! ARGUS.

For the American Bee Journal. Transferring Bees.

Many persons having the old box gum, and wishing to use a frame hive, are puzzled to know how to get the bees from the old gum to the new hive. It may seem to be a terrible job, but the operation can be performed in an hour, and if care is used, without a sting, even if working without a veil or gloves. The best time to transfer is early in the spring, when the fruit trees are in bloom, though it can be done any time during the summer, and the combs be soft, but you will have to feed them. All the tools that are necessary are, a hatchet, cold chisel, and a long knife. Select a room, or an out-house, with one window. Underneath the window fix a stand or table about five feet long. Take an old sheet, double it up to about the size of the frame, to lay the comb on, so as not to bruise the cells. Lay your tools along side, and some sticks, made about one inch longer than the frame is wide, and three-eighths thick; also rubber rings, such as are used on ear tickets. Fine wire or string will do to tie the comb into the frame, but not as good as the sticks. There are many ways of fastening the comb into the frame. After transferring one hive, you can use your ingenuity. Se-

lect the gum, blow smoke in at the entrance, and rap briskly on the outside of the hive for a few minutes, until they set up a hum of peace. Remove the hive to the room, and leave a box in the place of the hive, to catch all returning bees; invert the hive, and cut out the side of the hive parallel to the comb; the bees will get out of your way; lay two sticks down on the quilt, and a frame on top; cut out a comb; brush all the bees off; lay it on the frame, and cut it to fit; lay two sticks on top; spring the rubber rings over the ends; raise the comb, and place it in the hive, having it at your right hand; continue to remove all the comb in a like manner, using care that you put the combs in the new hive in the same rotation that they were in the old hive. Shake all of the bees out of the old hive in front of the new one, and they will all go in like a new swarm; or, after placing two frames in the new hive, brush all of the bees adhering to the comb into the new hive, and by the time you are through, nearly all of the bees will be in the hive. After closing up the hive, let it stand for awhile, and if the bees are still quiet, you may be sure the queen is in. If she is not, the bees will run all about the entrance and over the hive, hunting for something, as they are, for their queen. Look around for a cluster of bees, pick them up with a dipper, and put them in the hive, and if the queen is with them, all will soon be quiet. Return it to its old stand, shake out the bees in the box in front of the hive, and they will all go in. In three or four days after, open the hive, pull off the top rings, and pull the sticks out, as by that time the combs will be fastened to the frames. They are all right now. After performing the operation you will be surprised to see how easy it is, and how quiet the bees are at being thus stirred up, and you will also see the advantage of the frame hive.

For the American Bee Journal. How to Introduce Virgin Queens and make New Colonies.

Take your Queen Nursery and put into each cage, between the tins, a few cells of sealed honey in new comb, or a small piece of sponge, well saturated with honey, for feed for the hatching queens, so that they will not starve if the bees fail to feed them. Now cut from the combs as many queen cells as you have prepared cages in the nursery, and suspend one in each cage with the sealed end downwards, as found in the combs, remembering always never to jar or compress the cells in any way, and also to see that you have good, large perfect cells, and generally not cut from the combs before the 9th or 10th day.

The cages of the nursery being thus supplied with feed for the queens when they hatch, and a good, perfect queen cell in each, the doors of the cages are to be closed, and adjusted in the nursery frame.

Then remove from a strong colony one of its centre combs, and introduce the nursery into its place, to remain until the queens emerge from the cells. As they emerge, each cage containing a virgin queen, may be removed from the nursery and placed in one of the adjacent combs of the same colony, on either side of the nursery, by cutting out a piece among the brood large enough for the cages. Then each comb, separately, with the cages and all the adhering bees, is removed and placed in a new hive between two combs of hatching brood, taken from other colonies, the bees being brushed off. On the next day, near sundown, each of these new colonies so made may be opened, and the combs, bees and queens, well sprayed with perfumed sweetened water, and the queens set at liberty by opening the door of the cages, she can pass out while the bees are engaged cleaning the spray off of themselves, combs and queen, and receive her kindly, being of the same scent, and hatched in the same hive. As soon as the queens become fertilized and laying, add more combs of hatching brood from other stocks to each new colony, brushing the bees from the combs added back into their own stands, repeat these additions of brood and combs until your new stocks are complete. Thus we can raise and introduce virgin queens into new colonies with general safety. The cages can be removed from the new colonies in a day or two after the queens are set at liberty. While doing this you can see if your young queens are all safe.

If we use all black stocks in this method we can soon convert them into Italians, if we use none but pure Italian queen cells. Each comb in the nursery colony, becomes the active workers in the new ones, and the brood from other black colonies adds to the supply, until the new queen's brood begins to hatch.

J. DAVIS.

Does Bee Culture Pay?

When any new enterprise is started or any old employment of man which, in this fast age to make money in large sums, has become neglected, and the thoughtful man suggests its revival under the advancing help of science, the question is at once, "Does it pay, or will it pay?"

So it is with bee culture. It has paid all who have given it proper attention, and it pays well even those who give it only heedless care, and keeps bees more as an amusement for old, age or young girl or boy in

the family, that their attention may be sometimes agreeably taken up in watching this laborious and ingenious little worker, whose labors furnish such a luxury as honey. We give the following concise answer to this question from one of our exchanges:

"We believe that no stock upon a farm will pay better than a few good stocks of Italian bees. They provide for themselves without giving their owner any trouble whatever, and with very little attention at certain seasons of the year and with suitable quarters provided for their health, shelter and workshops, they will yield a rich crop of fine marketable honey which will always sell at a good price.

"If there is a land on earth which should flow with milk and honey it is ours, and yet owing to our own improvidence, there are very few farmers who have either milk or butter to sell, or even to supply their own wants in abundance, and scarcely one in a thousand who has honey for sale. Tell them that they ought to keep a few stocks of bees and raise honey, and one will tell you "his grandmother tried it once when he was a chap and she had no luck with them." Another will say he does not want to have "his wife and children stung nearly to death by the darned things." Another will tell you how he "knew a man who has kept bees for the last fifteen years and never made a cent from them." Another will say he has more than he can do now (raising cotton, we suppose, on all his land, and hauling bought hay and corn for his stock,) and cannot afford to "bother with bee gums."

"The management of bees is very simple, and can be easily learned. A little looking after in the morning when they fly, and in the evening when they return, a little patch of white clover and buckwheat, and a few plants suited for bee food, and a little protection in the winter, are all that is needed."

—*Baltimore Sun.*

For the American Bee Journal

Bee Keeping.

We were requested to make a statement relative to the average yield of honey procured by us, per colony, during the time we have been keeping bees, but not having kept any account of honey taken, except for the past three years, and during that time more by estimates than by actual weights, we cannot give such a report as desired, though the following estimate may be of interest:

1871. Average per colony, 40 lbs.; average sales, 22 cents per lb.; average value of honey per colony, \$10, (box honey).

1872. Average per colony, 43 lbs.; average sales, 22 cents per lb.; value of honey per colony, \$9.46, (¾ box, ¼ extracted)

1873. Average per colony, 16 lbs.; average sales, 25 cents per lb.; average value of honey per colony, \$4, ($\frac{1}{2}$ frame, $\frac{1}{2}$ extracted).

The most box honey taken any year from any one hive, 98 pounds; that was in 1871, and we are confident that twice that amount could have been secured just as well, but our bees then were all in small hives affording poor advantage for supplying them with boxes. This year promises to be a good one for a honey crop, and with our present increase in colonies, (natural and artificial) we hope to be able to make a good report for the current year.

One of the main things in successful bee-keeping is, to *keep all the stocks strong*. If you get very anxious to have colonies in abundance, send for a "bee man" who is the representative of some new-fangled moth-trap, or some other remarkable device by means of which the bees are

"happy and glorious
O'er all the ills of life victorious."

and have him divide each one of the old stands into four or five new ones, but you will be likely to pronounce bee-keeping in Kansas a humbug as your bees "play out" and leave you debating the question in your own mind whether "it is better to be born lucky than rich."

Artificial division, done in a proper manner and at a proper time, is a very good way to increase the number of colonies, but queens or capped queen cells, from strong colonies should be ready to give each divide, and we aim to improve the stock at the same time, by procuring queen cells made in strong colonies and noted for their good traits as honey gatherers, whether they be hybrids or Italians. This year we have secured a couple of cells from one of our neighbors, from a colony (and he has several colonies like it) that seems to be a cross between the Italian and an extra large gray looking bee, which kind with him gathers one-third more honey than his other bees. We make new colonies by placing three or four frames containing brood, but no old bees, in an empty hive, first placing the queen cell in one of the center ones, then we remove one of the strongest colonies, six or eight feet away on a straight line with the front and facing the same way, then we place the new one on its stand. This is best done when honey is abundant and in the middle of the day when there are plenty of bees out at work, and by night there will be a strong swarm and the hive removed not materially injured.

Thus we make a third one from two, or a third one by taking a sheet of brood from each of several different hives. As a means of strengthening weak colonies a prominent bee-keeper suggested the idea to us of exchanging the queens of the weaker ones

with those of the stronger, as with him queens not thought to be very good were generally thus rendered more prolific.

There is considerable difference of opinion in regard to the comparative merits of the Italian and the black bee. We have several of what were said to be the pure Italian, but the queens were all short-lived. As for profit in honey we doubt their superiority over the hybrids. The hybrids seem to be very excellent bees and during a year of scarcity will do much better than the blacks. Last year fully demonstrated this fact to us. It seems that almost any kind of a change from long continued in-and-in breeding, is beneficial.

Kansas.

A Visit to a Bee-Hive.

DESCRIBED BY THE FAIRY FLYAWAY.

"How doth the little busy bee
Improve each shining hour,
And gathering honey day by day,
From every opening flower?"

"How doth she, indeed?" I said to myself as I awoke one bright morning.

The thought was suggested by a noisy bee, who waked me by trying to enter my lily-bell, and I resolved that I would look into the matter. So I flew out of my lily, and to the nearest hive, to make inquiries.

Bees are high-spirited and quick-tempered persons, I know, but a fairy can make her way anywhere.

The hive was a neat building, pleasantly situated in an orchard. On one side a clover-field, full of perfume, and on the other a gay flower-garden.

At the door of the hive I was met by a number of sentinels, one of whom addressed me rather sharply, with "Who goes there?"

"A friend," I replied, "who wishes to learn something of the ways of the bees, and how they make honey."

"Your passport," said she.

"I never thought of such a thing," said I.

"Do you intend to go into the honey business yourself?" asked she.

"By no means," I replied; "I am the fairy Flyaway, and only want information and amusement."

"I will send a messenger to our Queen," said the sentinel.

The messenger soon returned with the Queen's permission to go entirely through the hive, escorted by one of her own body-guard, excepting into the royal apartment.

I then entered the doorway, where I was greeted by my guide, who gave me her name, Deborah, and ushered me, with a grand flourish of her wings, into a wide gallery passage.

In the middle of the hive I saw a long string of bees, reaching from the roof to the floor, each bee clinging to her neighbor, and remaining motionless, while other bees ran up and down, as though upon a ladder.

"What is that?" I asked my guide.

"A bee-ropé," she replied, "a short cut from the top to the bottom of the hive."

I remarked that I thought it might be some kind of dance.

"No," said she. "In the winter when there is no work to be done, we sometimes dance in the sunshine before the hive, but never at any other time. We are too busy."

This seemed to me rather sad but I did not say so.

In the gallery we saw bees hurrying about in all directions, too busy to notice us, and never disturbing or interfering with each other in the least.

"These are our workers," said Deborah.

"About how many of them are there?" I inquired.

"There are 20,000 of us all told," she replied, "one Queen, or Mother-bee, blessings on her majesty! some hundreds of drones, and the rest workers."

"They must be tired enough if they always work as fast as these do," I said.

"No," replied Deborah, "they like it. A true worker-bee is never content to be idle. Would you like to see the Nurseries?" continued she.

"Anything you please to show me," I replied.

We then turned through the side gallery into a quiet corner of the hive, where we found curious cradles or cells, of different sizes, made of the purest white wax.

"Here the eggs are laid by our queen," said Deborah, "generally about two hundred a day, but often many more."

"Then your Queen must be busy, as well as the rest of you," I said.

"No one works harder," replied my guide.

I thought of our beautiful Queen, with her delicate wings, and felt that a bee-hive was not much like Fairy-land.

"And will these eggs ever turn into real bees?" I asked.

"Oh yes," said my guide, "in three or four days they hatch into worms."

"Something like caterpillars and butterflies?" I asked.

"A little," she replied, "but in this case the young worms are worth taking care of, as the bees are valuable and industrious persons, while butterflies and idle and useless."

"You are mistaken there," I said, "they are useful to us fairies. In our long flights we could not do without them."

"Ah," said she, "I never heard of it before."

"When the eggs turn into grubs or

worms," continued she, "the workers find plenty to do to take care of them. Each little worm must be carefully fed for five days, with water, and bread, and honey."

"What kind of bread?" I asked.

"Oh, bee-bread," she replied, "nothing else would suit them. The cells are then sealed up, that is, a nice lid or cover is put upon each one, and the little worms must take care of themselves for awhile. Every worm is expected to line its cell neatly, with a silken webbing, and then roll itself up in a cocoon for a time. Ah! we are just in time to see the cells closed."

And, to be sure, there were attendants sealing up the cells, a small white worm in each. I must confess it made me shudder to look at them for I never did like worms! It is so dreadful to meet one in the folds of a rose.

But I fancied the little worms seemed uneasy at the idea of being shut up, and so I told my friend.

"Ah well!" said she, "It is the only way. We all go though with it. Before many days they will come out perfect bees.—Wings and legs all right."

"And must they go to work as soon as they are out," I asked, "and not dance once?"

"No," replied Deborah. "They are not strong enough to fly until they have been fed one or two days. Then they begin to work in good earnest."

I observed that the cells were of different sizes, and inquired the reason.

"The largest and handsomest cells," replied Deborah, "are for the young Queen bees or Princesses. The next size for the drones, and the smallest for the workers."

"Can the cells be used more than once," I asked, "or are they done with, like last-year's bird's nests?"

"The royal cells are all destroyed when they have been once used," she answered, "but the others are cleansed and the silken webbing is left to strengthen them, and they are then better than ever."

"How long does it take to turn from eggs into bees?" I inquired.

"Sixteen days for the Queen bee to become a perfect insect. Twenty-four days for the drones, and twenty-one for the workers," she replied.

"And have the attendants nothing to do but to feed the little ones?" I asked.

"Oh yes," said Deborah, "they attend the Queen, do the fighting, prepare the wax, make the combs or cells, collect the honey by day, and store it by night, and keep the hive in order. The drones lead an idle life. They will die, rather than work. They will not even feed themselves if they can find any one else to do it. And, to tell the truth, like all idlers in a busy community, they are such a bother,

that about once a year we have to kill them off."

"My dear Deborah!" I exclaimed in horror, "you can't mean it!"

"Yes. It is the custom. They don't seem to mind it. But let us look now at the store-rooms," said she, hastily changing the subject, as well she might.

In the store rooms we saw rows upon rows of cells, fitted one upon another, and every one filled with clear honey, and securely sealed.

"This is our winter store," said my guide; "pure honey, made from the white clover, and put up in the combs by the Workers."

"How do they make the honey?" I asked.

"They gather it," she replied. "We send out thousands of bees every morning, to all the gardens and fields around. Mignonette makes good honey, and so do apple-blossoms. We usually make from two to six pounds a day. The bees often fly as far as two miles from the hive, and then come back loaded with honey and pollen. Each Worker has a tongue or proboscis with which she licks or brushes up the honey, and puts it into her honey bag.

"Stop a moment" said she to a Worker who was hurrying by. "You will observe, my dear, that the hinder legs have something like baskets, on the side, in which the pollen or bee-bread is carried.

"I see it," said I "I have often watched the bees coming out of flowers, covered with yellow dust." I then took the opportunity to mention to her that I lived in a lily-bell, that I sometimes danced the greater part of the night, and that the bees were very much in the habit of waking me at an unreasonable hour in the morning.

She said she would attend to it.

"And how do the bees make wax?" I asked.

"By a process best known to themselves," replied Deborah. "It is not in my line just now, and I am quite sure that I could not describe it to you. The bees say they cannot tell how they do it, but they wish to keep the secret to themselves. The sides of these cells are the one-hundred and eightieth part of an inch in thickness. So you see we must use an immense quantity of wax."

"You must, indeed," I replied. And are the cells always made in this shape?"

"Yes," said she, "they are six-sided. The early bees fixed upon that as the best for strength and economy of space, and no change has been made since. However, Bumble-bees, she added with a slight expression of scorn as though she had said, the Beggars, "have a way which they prefer. They put it up in bags, and store it under-ground."

This was no news to me. Such a thing

has been done in Fairy-land as to "borrow" a little honey from the bumble-bee, in time of scarcity. But I said nothing.

"And you tell me workers do the fighting. Is there much fighting to do?" I asked. "A great deal," replied Deborah.— "We have many enemies, bother on them! Mice, caterpillars, moths, snails, wasps, robber-bees and other evil-minded creatures!" As she said this she buzzed fiercely and unsheathed her sting.

"Look here a moment," said she, "and you will see one of them."

And there in a corner, guarded by a squad of bees, lay a wretched snail prisoner in his own shell. The edge of the shell was covered with a strong cement, which held it firmly to the floor.

"I think we have him now, the villain!" said my guide. "His shell is fastened with propolis."

"What is propolis?" I asked.

"It is bee-glue," she replied, "resin from the buds of the trees."

At this moment we heard a low murmur of "The Queen! the Queen!" and turning, we saw passing through the principal gallery, a magnificent bee, large and more stately than any of her subject, though her wings were much smaller than theirs. The under part of her body was golden, the upper part dark.

She was surrounded by her body guard, and as she passed, her subjects politely backed out of her way, to give her room, and some offered her refreshments in the form of honey.

"What would become of us, if anything should happen to our beloved Queen!" exclaimed Deborah.

"How long has she reigned?" I enquired.

"More than two months," she replied.

"And how much longer may she reign?" I asked.

"She may outlive us all," she replied, "Queens live four years, and workers only from six to nine months. Our old Queen went away with a swarm to another hive. "But now," she continued, "if you will come back to the gallery, I will offer you some of our best honey."

This was tempting, even to a fairy, and we are considered dainty; that is, the crickets and grass-hopper call us so. I tasted some honey and found it delicious.

"This is not like the honey one finds in the flowers," I said.

"We have our way of purifying and preserving it," said Deborah.

"And bee-bread. Can you tell me exactly how to make it?" I asked.

"That is not allowed," she replied, "though it would do no harm, as no one but a bee could ever make it. It is made of the pollen of flowers, and honey and water; and it wants a great deal of kneading. But

it is only fit for the food of young bees. We old ones never eat it."

"And do the young princesses eat it too?" I asked.

"Not at all," she replied. "They are fed upon royal jelly."

"And what is that?" I asked.

"Don't ask it!" she replied. "It is the greatest secret of all. Off goes my head, if I tell you!" "And by the way," said she, perhaps it will be better to say nothing about the Drone business."

"Perhaps it will," I replied, "for I have known our fairy-queen to imprison one of her subjects in a pea-pod a whole hour, for only pinching a gnat."

"Ah! yes," said she, "not our idea of discipline."

She then escorted me to the door of the hive. I thanked her, recommended less work and more dancing, invited her to call on me in my lily-bell, and took my leave, feeling that I had really learned something of the ways of the busy bee, if not how she makes honey. The next day I sent to my friend Deborah, by a butterfly, the finest four-leaved clover I ever saw, knowing that to be the best return I could possibly make for her kindness.—*St. Nicholas*.

Entrance Holes to Hives.

The honey bee ordinarily in its wild state inhabits hollow trees, the entrances to which are either through long slits or large holes, through which it has ample room to pass, without brushing off the pellets that stick out from its sides. A worker bee can pass easily through a hole three-sixteenths of an inch high, but in passing through a round hole of that diameter the pollen would be dislodged. A drone requires a hole nearly $\frac{1}{4}$ of an inch in diameter to pass through, so that in making entrance holes to hives it is evident they should be at least $\frac{1}{4}$ of an inch high, to allow drones, as well as the queen and workers, to pass; but they should not be any higher, if we expect to exclude mice, humble bees, hornets and other enemies of the bee, larger than they are.

Now, did the bee carry its load behind it as the leaf-cutter does, a round hole of $\frac{1}{2}$ of an inch in diameter would be large enough, but the load on each side sticks out from its sides so that more room must be given laterally, even for the passage of a single bee at a time—but as, during active working, there is a constant flow of passing bees, it must be much wider. I find the width should be at least 3 in. But a single hole is not sufficient, even of that width, on account of their peculiar manner of ventilation, by which they are enabled to keep up a constant circulation of fresh air through the hive and regulate the temperature. There should be two such holes

at least four or five inches apart, but on the same side of the hive. All other openings should be closed tight. If thus arranged, the left hand hole will be used for ventilation, and the other for the passage of most of the bees.

Query: Why do bees always use the left hand hole for ventilation?—*Cor. Southern Farmer*.

Movable Homes for Bees.

It is well known that bees may be moved from place to place, and, honey-secreting plants being in abundance, they will store large quantities of honey. A contemporary, in illustrating this, mentions the following circumstances said originally to have appeared in the London Times in 1850. It will of course be taken with a large allowance for "salting" by those who know bees:

As a small vessel was proceeding up the channel from the coast of Cornwall and running near the land, some of the sailors observed a swarm of bees on an island; they steered for it, landed, and took the bees on board; succeeded in hiving them immediately, and proceeded on their voyage; as they sailed along the shore, the bees constantly flew from the vessel to the land, to collect honey, and returned again to their moving hive; and this was continued all the way up the channel.—*Western Rural*.

Honey-Dew.

Amyntas, in his Stations of Asia, quoted by Athenæus, gives a curious account of the manner of collecting this article, which was supposed to be superior to the nectar of the bee, in various parts of the East, particularly in Syria. In some cases they gathered the leaves of trees, chiefly the linden and oak, for on these the dew was most abundantly found, and pressed them together. Others allowed it to drop from the leaves and harden into globules, which, when desirous of using, they broke, and having poured water on them in wooden bowls, drank the mixture. In the neighborhood of Mount Lebanon, honey-dew was collected plentifully several times in the year, being caught by spreading skins under the trees, and shaking into them the liquid from the leaves. The dew was then poured into vessels, and stored away for future use. On these occasions the peasants used to exclaim, "Zeus has been raining honey!"—*History of Insects*.

The rule generally adopted for taking bees is for the second party to furnish hives, take care of the colonies for a term of years, and return old stocks with half of the increase.

American Bee Journal

W. F. CLARKE, EDITOR.

AUGUST, 1874.

Bees and Wasps.

Sir John Lubbock has just read a paper on the above subject at the Linnæan Society. The paper commenced by pointing out, with reference to the power of communication with one another said to be possessed by Hymenoptera, that the observations on record scarcely justify the conclusions which have been drawn from them. In support of the opinion that ants, bees and wasps, possess a true language, it is usually stated that if one bee discovers a store of honey, the others are soon aware of the fact. This, however, does not necessarily imply the possession of any power of describing localities, or anything which could correctly be called a language. If the bees or wasps merely follow their fortunate companions, the matter is simple enough. If, on the contrary, the others are sent, the case will be very different. In order to test this, Sir John kept honey in a given place for some time, in order to satisfy himself that it would not readily be found by the bees, and then brought a bee to the honey, marking it so that he could ascertain whether it brought others or sent them, the latter, of course, implying a much higher order of intelligence and power of communication. After trying the experiment several times with single bees and obtaining only negative results, Sir John Lubbock procured one of Marriott's observatory-hives, which he placed in his sitting-room. The bees had free access to the open air; but there was also a small side or postern door which could be opened at pleasure, and which led into the room. This enables him to feed and mark any particular bees; and he recounted a number of experiments, from which it appeared that comparatively few bees found their own way through the postern, while those which did so the great majority flew to the window, and scarcely any found the honey

for themselves. Those, on the contrary, which were taken to the honey, passed backwards and forwards between it and the hive, making on an average, five journeys in the hour. Sir John had, also, in a similar manner, watched a number of marked wasps, with very similar results. These and other observations of the same tendency appear to show that, even if bees and wasps have the power of informing one another when they discover a store of good food, at any rate they do not habitually do so; and this seemed to him a strong reason for concluding that they are not in the habit of communicating facts. When once wasps had made themselves thoroughly acquainted with their way, their movements were most regular. They spent three minutes supplying themselves with honey, and then flew straight to their nest, returning after an interval of about ten minutes, and thus making, like the bees, about five journeys an hour. During September they began in the morning at about six o'clock, and later when the mornings began to get cold, and continued to work without intermission till dusk. They made, therefore, rather more than fifty journeys in the day. Sir John had also made some experiments on the behavior of bees introduced into strange hives, which seemed to contradict the ordinary statement that strange bees are always recognized and attacked. Another point as to which very different opinions have been propounded is the use of the antennæ. Some entomologists have regarded them as olfactory organs, some as ears, the weight of authority being perhaps in favor of the latter opinion. In experimenting on his wasps and bees, Sir John, to his surprise, could obtain no evidence that they heard at all. He tried them with a shrill pipe, with a whistle, with a violin, with all the sounds of which his voice was capable, doing so, moreover, within a few inches of their heads; but they continued to feed without the slightest appearance of consciousness. Lastly, he recounted some observations showing that bees have the power of distinguishing colors. The relations of insects to flowers imply that the former can distinguish color; but there had been as yet but few direct observations on the point.

Consolidation.

We think we shall give pleasure to a large majority of the bee-keepers of America when we announce that the NATIONAL BEE JOURNAL is with this month's issue united with the "old reliable" AMERICAN BEE JOURNAL. The time has passed when the friends of either JOURNAL, have any points at issue, or any personal feeling in the way of a union, on the common ground of a deep interest in bee-keeping, and an ardent desire to see a JOURNAL devoted to their interests so sustained as to be worthy their support and an object of national pride.

There may have been in the past a division of interests and a difference of opinion upon patent hives which engendered strife and *seemed* to make it necessary to support two journals. Those things belong to the past, and we know that the time has come to bury the hatchet and all agree to make our one JOURNAL what it ought to be—a medium where bee-keepers of experience can exchange opinions upon both practice and theory, and also where beginners may find reliable counsel, and timely hints upon all doubtful points in their new employment.

By the union of these journals we are enabled to secure the services of all the best writers in the World upon the topics of which it specially treats. We shall also be enabled to improve it in all respects, and we are sure that we shall publish a journal which every bee-keeper will feel a pride in supporting.

There is always an increase of strength in a union of interests upon proper grounds, and this consolidation is one so manifestly wise, that we are sure to receive such an endorsement as will make us strong in our aim to issue the best periodical ever sent forth, devoted to any special interest.

We have decided to publish the consolidated BEE JOURNAL not only in Chicago, but also in Cedar Rapids, because Iowa is now the centre of the bee-keeping interests of this country. West of us, the business is being rapidly developed. Our subscribers are numerous in California, Colorado, Nevada, Kansas, Nebraska, and Missouri, while enterprising bee-keepers are found

both north and south of us. It is evident that in these new fields the best pasturage for bees on the continent is found. The State of Iowa has furnished for years some of the most progressive bee-keepers in the country, who are prepared to be safe advisers for beginners at the West.

While we are dependent upon our subscribers for the material aid which is to enable us to carry out our plans for their good, we ask it not as a favor to us, for we shall send out a journal which no bee-keeper can afford to do without at any price.

Seasonable Hints.

If bee pasturage fails at any time by reason of dry weather, it is usually in the early part of this month or latter part of July. Hives that have been gaining in weight, may now be losing daily, and except in the morning and evening, when bees are out for water and pollen, they hang idly about the hives. Rains in most localities have started buckwheat and fall flowers into growth, and if properly managed, bees will soon begin to gather fall stores abundantly. What they need now, is room near the centre of the hives where the queen can deposit her eggs, so that young bees can be reared to supply the places of those that will be used up in gathering the fall honey.

If the combs have not been emptied with the extractor, do it now; not to take away all supplies, but to make empty space for two purposes: 1st, to give the queen room. 2nd, to stimulate the bees to exertion. There is nothing like a "vacuum" to do this.

Even when there is abundant honey in a hive, it sometimes pays to feed sugar syrup or diluted honey, to colonies in which we find the queen has stopped laying, or she has ceased to cherish her eggs. We have known them to begin again, as if it were spring in 24 hours after they had been fed in this way. To use the extractor and return the combs with some honey "loose" upon them will answer the same purpose.

A good supply of water is also essential now. Springs and brooks from which they have had their supply may now be dried up. Your neighbors will complain

for the first time, perhaps, that your bees annoy them by hanging about watering troughs, drains and pump-spouts. Make a place or places, some rods from your hives, where the bees can drink safely, and keep them always supplied. It is well to toll them to their trough by putting pieces of comb, and sweetening the water at first. A little salt thrown in every day keeps the water sweet, and some claim, is beneficial to the bees.

While honey is not secreted in flowers, be cautious about opening hives, lest robbers are attracted. The morning from 7 o'clock to 11 is the time in this month to open hives safely.

Queen raising may proceed now to even better advantage than at any other season, if *care is taken* to make every *nucleus* self-supporting; by this we mean that each queen-rearing hive should have young bees, old bees, brood at all times, and plenty of honey.

Queens may be exchanged now, poor ones killed, either impure or not prolific; and young ones given to them. We never, however, take a queen from a full colony until we can give it one that we are *sure* is a better one. We would not put a queen into such a colony until we had tested it in a nucleus.

The care which we recommend, in order to keep the colony raising brood, is really the first step towards successful wintering; a subject of vital interest now to bee-keepers, and on which we shall have much to say in succeeding numbers. E. S. T.

Bees and the Centennial Fair.

Mr. J. R. Wells in his communication for this number says "nearly every interest that can be mentioned except bee-keeping, has been referred to committees preparatory to the Centennial Fair to be held in Philadelphia 1876, etc."

He is in error in supposing that the bee-keeping interest has been neglected. At the meeting of the National Society at Louisville, last December, a committee was appointed consisting of Gen. Adair, of Kentucky; Mrs. E. S. Tupper, of Iowa; and J. W. Winder, of Cincinnati; with the President of the Society, *ex-officio*; and authorised to appoint sub-committees where ever they deemed proper. The question as to whether bees shall be allowed at the Fair is still an open one, except in observation cages; but there are multitudes of other things—honey extractors, artificial

comb, choicest honey in various forms, queen shipping cages, etc., to say nothing of hives, out of which a most valuable and instructive as well as interesting exhibition may be made. This committee will report at the Pittsburgh meeting, doubtless, and receive aid and counsel as to future preparations.

Honey Dealers.

We have published the articles from Messrs. Bird and Kruschke, complaining of our honey markets and merchants, with great reluctance. We do it "under protest" hoping that no one will feel that we desire to be unjust. Our columns are open to anything that the accused may have to say, as to their reasons for the *seeming* unfair dealing.

We can say ourselves for them, that times have been hard; honey as a luxury which people can do without, has been slow of sale, and it takes time to turn it into money. We know that if Mr. Winder has made no returns "for a few months" as Mr. Bird says, it is because he has received no money from his sales, on which to report.

Joseph Duffeler writes to us that he is willing to publish a card to the effect that Mr. Perrine paid him in full for his honey, even though it was all burned, and he had no insurance on it. We have made collections of Baumeister & Co. for parties and have the promise of money from them, for others, as soon as they can pay it.

Those who send honey to market especially from a distance must remember that expense and time must be expended by the consignee to get it into market. One firm tells us that they have received 1230 lbs. of honey from California. The first bill paid by them was \$57 freight charges! Finding it impossible to sell it in bulk, they went to the expense of \$100 for glass jars and tumblers, and took the trouble to put it into them. It will sell now, and at a profit; but the consignees, doubtless, will begin to grumble before they receive their returns, and then be dissatisfied with scanty profits.

Our advice to those who have honey to sell is to sell it out-right, if possible, even if at a less price. If this is not possible, send it to dealers of established reputation, take receipt for exact weight and until returns are made, exercise charity and patience. In some places where you think there is no sale, a home market may be secured by taking the trouble to put your honey into attractive shape.

NOTES AND Queries

QUESTION.

Please inform your subscribers in your next, how far north bees may be kept with profit?
G. O. GRIST.

ANSWER.

Bees are kept very successfully in the northern part of Russia, and winter there out of doors safely. They are also kept in Canada and in the extreme north-east of Maine. In Aroostook County, and as far north as Presque Isle (Maine), bees winter well and are very profitable. Among the mountains of Colorado bees do well. Our opinion is that wherever flowers are found, bees may be kept successfully, if their owners have judgment enough to adapt their care of them to the climate and location.

QUESTION.

1st. Does the queen have a call which she constantly makes her presence known by?

2nd. What state or temperature of the weather it will do to open hives for the purpose of examining brood, etc.?

3rd. The reason why bees cluster before going to the woods?
W. M. A.

ANSWER.

1st. It would seem that she does not, from the fact that we have known a populous hive to be without a queen 24 hours without discovering her absence.

The only times we have heard the call of the queen are when she was under guard of worker bees to prevent her going out with a swarm; and again when we have confined one in our hand for a few moments. It is at times, like the first, that the noise of young queens is heard before a second swarm issues which is called "piping." Sometimes this noise is made by a queen before it hatches from its cell.

2nd. It will do to open hives and take out the comb, whenever bees are flying freely. When they are not, it is safe to leave them undisturbed.

3rd. We think the main reason why bees cluster, before leaving is, that the queen in great swarms, is unable to fly freely when she first leaves the hives, her ovaries being full. We have seen hundreds of eggs on the leaves of a branch where a swarm had settled. Swarms containing young queens fly longer and usually settle higher. They seldom show any disposition to go to the woods at first, as they have no special attraction to the young queen with them and will not follow her as they do the "mother" bee in first swarms.

QUESTION.

How long are you to write me nothing encouraging about our bee-keeping? Here

we are again at the end of our honey year almost, and still the same old story "bees doing poorly." My 48 swarms came out of my cellar in the spring in very fine condition, losing only one, and only few cases of dysentery; but the spring months carried off 10 or 12 more—some of my best stocks. "Novice" calls it by the right name—"dwindled away." No cause for these losses that I could see. Honey plenty, combs bright; everything in perfect condition. Very little use to talk about the causes of these losses, for I do not think Mr. Editor, we do not, any of us, know. After summer came, swarms came on fast, and swarmed finely; even in fine condition for the largest blow of white clover I have seen for years; and the drouth came with the clover blow; and to-day we are burnt, dried, and roasted. I have got seventy swarms now—that is bees enough. Who cares if they only make honey enough for their own "use."
R. DART.

ANSWER.

If you want more honey, do not expect to increase your stocks so much. An increase of 22 swarms on 48 is all you can expect, without looking for much surplus.

Voices from Among the Hives.

N. K. PEDEX, Mitchellville, Tenn., writes: "Bees have done very well here this season. I commenced with 9 colonies in the spring, increased them to 14; and got 750 pounds of honey up to June 10th. Since that, they have been cut off by dry weather."

JOSHUA ARTER, Crestline, O., writes:—"Basswood bloom is over. There were the most flowers on the trees that I ever saw; but the bees did not collect very much after all. White clover was a failure. There was a profuse swarming. Some hives swarmed as much as three times."

E. DEANEY, Norton, O., writes:—"I began with 24 swarms last spring, and now I have 72. Three have not swarmed yet. Some of my first have swarmed again; in fact my bees swarm nearly every day. I expect if it does not get too dry, to run up to 90 or 100 swarms, all natural swarms but one."

J. M. MARVIN, St. Charles, Ill., writes:—"My 140 old stocks have increased to 200. My surplus is five tons. A neighbor's, under my care, 8 stocks increased to 18; surplus 750 lbs. Honey superior in quality. Stocks in splendid condition, and nothing to do, on account of a severe drouth, the worst ever seen in these parts."

CHRISTOPHER GRIMM, Jefferson, Wis., writes:—"I wintered 124 swarms and lost none through the winter; but spring was very cold and wet, so that I had to unite four swarms, which got very weak with the others. I have got, at this date 67 natural swarms and all are doing finely. The basswood, or lime, are nearly through blossom in this part of the country."

M. T. EMBRY, Poplar Bluff, Tenn., writes:—"I went into winter quarters last fall with 57 colonies. They went through safely with the loss of about 7 or 8 queens. I sold two colonies. The spring was very unfavorable up to the 1st of May. Since that time we have had but three light showers. I have taken about 2500 lbs. of honey from them. Some of my bees have considerable honey yet to spare."

Special Notice.

During the past ten months of "Panic," the receipts of the AMERICAN BEE JOURNAL have been very light. We have cheerfully "carried" thousands of our subscribers, and now trust that they will respond as soon as possible, as we have obligations that must be met *at once*. Many subscriptions ran out with the JUNE number, and now we hope to hear from them, as well as from those that expired before that time.

We shall continue to send the AMERICAN BEE JOURNAL to all our subscribers until we get an explicit order for a discontinuance, and we hope those who not wish to continue their subscriptions will notify us by letter or Postal card, either when they expire or before that time.

We have purchased of Geo. S. Wagner Esq. and the Rev. W. F. Clarke all the back subscription and advertising accounts, and hence everything due to the AMERICAN BEE JOURNAL of whatever kind or nature *must* now to be paid to the undersigned.

We hope those who are in arrears will send the amounts due us, during this month, as we are in pressing need of it, to cancel obligations already given for these very accounts. Who will respond?

THOMAS G. NEWMAN, Publisher.

We have received a Postal Order from Shanon, Wis., in an envelope containing nothing else. We do not know from whom it came, nor for what it was intended. Will some one inform us?

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. P lb.

ST. LOUIS.—Quotations from W. G. Smith 419 North Main st.

Choice white comb, 25@29c; fair to good, 16@22c. Extracted choice white clover, 16@18c. Choice basswood honey, 14@16c; fair to good, extracted, 8@12c; strained, 6@10c.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 P gal. St. Domingo, and Mexican, 90@95 P gal.

SAN FRANCISCO. — Quotations from Sterns and Smith, 423 Front st.

Southern Coast Honey is coming in very freely, and the crop will be very large. We are selling comb in two pound tins, two dozen in a case, for shipping at \$3.75 per dozen. Sold mostly for the Montana and Idaho trade. Strained honey, in 5 gallon coal oil tins, 8 and 10 cents P lb. We have sold several lbs. of choice Montana strained at 11 cents. Comb honey in frames 14 @ 22 cents, according to quality.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

The German Bee-Sting Cure can be obtained at this office. Sent by Express for \$1.00. It cannot be sent by mail. See notice.

Our subscribers in Europe, can *now* procure Postal Money Orders on Chicago. This plan of sending money is *safe* and economical.

FRANK SEARLES, Hadley, Will Co, Ills., has 50 swarms of Italian Bees which he will sell for \$5.00 each, in any amount, if sent for soon.

Subscribers wishing to change their post-office address, should mention their *old* address, as well as the one to which they wish it changed.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

For the American Bee Journal. Spring Dwindling.

You may possibly find the following worth a place in your paper:

Much has been said about the dwindling down of bees this spring. I have observed the same phenomenon without finding the solution. I wintered 29 stocks of Italians on summer stands. 3 stocks died in February with sufficient honey. The balance or 26 stocks remained good and lively. I made in May and June 17 new swarms, but the bees would not increase much. Many stocks even seemed to dwindle down in June, when I found one day that a fly of a peculiar long form, caught and sucked my bees. Becoming awake to the subject I found many such bee-killers, who were very greedy on the poor bees. No book or journal speaks of them. At last, I found a description of them in Prof. C. V. Riley's Second Annual Missouri Report, page 121; all three species are there described. I found and killed a large number. At first I found watching on grass, *Evaux Barbardi* and no other. After that disappeared, a similar fly *Asilicus Sericeus* and then as *less Missouriensis* appeared. The latter two I found in large numbers on buckwheat and wild flowers. They abound at this day, although I catch with an insect net as many as possible, often 50 in an hour. I am sure these creatures have killed over 100,000 of my bees, and I am convinced, that there is no other bee enemy to be compared with these flies. The swallow's seem to be fond of them, also other birds. This fly will destroy a bee in five minutes. They pounce upon them while alighting on grass or flowers, holding them helpless with their long feet, and inserting their short but pointed proboscis into their chest, they drop with them to the lower part of the stem of a plant and sucking a little while, let their

victims fall to catch another. Bee-keepers should be awake, as there is no doubt, but this insect retards the progress of hives more than anything else. The flies are from $\frac{1}{4}$ to $\frac{1}{2}$ inches long, with a long pointed abdomen, marked with light colored wings. Wings transparent, color from yellow to brown. Feet long, strong and hairy. Proboscis (the sucking apparatus) strong, short and pointed. I give this rough description to enable every bee-keeper to recognize them quick. They fly with a short deep "hum" almost like a bee's hum, only shorter and deeper in tone.

Bee-keepers should report on this Insect.
Sigel, Ill. CHAS. SOME.

For the American Bee Journal. Some New Thing.

This has been an unusual summer for swarming. Notwithstanding I commenced early dividing them. When the swarming season came on, they went into swarming in real earnest. At first I accommodated them with new homes, and gave each swarm a frame filled with brood. All went on well but still they continued to swarm. I then came to the conclusion, as the basswood harvest was just approaching, there must be something done to keep them together, or lose our favorite supply of surplus honey; so I commenced cutting out the queen cells from the parent hives, but almost invariably failed in keeping them together. The following day, out they would come and continued day after day to come out. Finally I concluded to try an experiment something entirely new to me, but perhaps not new to our old experienced bee-keepers. As they refused to accept their old homes, I put them in an empty hive, setting them a proper distance from their first location, then proceeded to take out the frames with adhering bees; examining closely I removed all the queen cells, adding them to the new swarms, I had no more trouble with them coming out. Instead of putting the new with the old, I put the old with the new, having tried the above experiment on some 8 or 10, I consider it a success.

The early part of the honey season was poor, the white clover proved a failure. Up

to the beginning of basswood bloom they scarcely gathered honey enough to supply the young bees. There was an unusual crop of basswood bloom, which began to open about the 1st of July and lasted until the 15th. During that time the little fellows put in full time. I never knew bees to store up such an amount of honey in as short space of time. The hives now are filled to their utmost capacity, with the exception of the comb occupied with brood, leaving no place for the queens to propagate their eggs. I have thrown the honey out of 16 frames, which amounted to 65 pounds, sold in the city of Adrian at 18 cents per lb. I shall use the extractor sparingly, in order to keep them working in the boxes as much as possible. I have now 59 colonies. I calculate I could extract 1500 pounds at this time. I use the Barker & Dicer improved hives with sectional honey boxes. These boxes will stand at par with any I ever used. They can be safely shipped to any part without sustaining the least injury; the retailer can separate each section without injuring the honey, by cutting the paper at each division of the section; each section contains from $2\frac{1}{2}$ to 3 lbs. and when placed upon the table it cannot fail to please the eye as well as the taste.

SAMUEL PORTER.

Lenawe Co., Mich.

For the American Bee Journal.

The Sale of Honey.

MR. EDITOR:—The burden upon my mind at the present time is, the great disparity between the price obtained by our honey-producing fraternity for their product and the price paid by the consumer. Large honey houses in Chicago (for instance) buy up the honey in bulk at 16 cents per lb. for extracted and 25 to 30 cents for comb. Here it is put up in appropriate packages and shipped away again to wholesale dealers in other towns, who in turn distribute to smaller wholesale dealers and retailers. I presume there are none of these middle men handling honey for fun, but each one must make his profit, and the consumer pays from 30 to 40 cents per lb for extracted and, from 40 to 50 cents for comb. Now the question arises, is it necessary for the producer to pay so many shipping bills. I have not found it so in my experience. I put my honey up in attractive style for retailing and deliver it direct to retail dealers who sell it for me and retain 10 per cent of sales for their service. I use the square honey-jar made for the purpose. The smallest packages sell most readily.

My honey has netted over 30 cents per lb for extracted and 40 cents for comb for the last four years.

Cheviot, O.

M. NEVINS.

For the American Bee Journal.

Report of my Apiary.

EDITOR BEE JOURNAL:—I congratulate you upon the consolidation of the two great Bee periodicals of America. "Long may it wave," is the worst wish I have for it. I cannot get along without it.

We are having a good honey season here; the best we have had since I have kept bees, (which has only been about 4 years) but I am not going to derive much benefit from it, for I have neglected my bees shamefully all summer. I extracted over 300 lbs. on July 21st from 8 colonies of black bees most of whom had cast 2 or 3 natural swarms. I have now 19 colonies, which will all be in condition for winter before the end of this month, if all goes well with them. I put 12 colonies in a clamp last fall and succeeded in wintering them all through, but lost two in "springing," and two others were so near gone they will have to be helped in order to make them fit for winter; so that I had 3 medium stocks to commence with. I shall try to do better next year.

Nelson, Pa.

JOHN ATKINSON.

For the American Bee Journal.

New Method of Wintering.

DEAR EDITOR:—I noticed in your July number remarks upon a new method of wintering bees, by Mr. Bidwell, given to the Michigan Bee-Keepers' Convention, I believe. The manner of wintering is not given, and that is what calls me out to write this article. If Mr. Bidwell has a plan for the safe wintering of bees, he is entitled to as much honor as Langstroth has enjoyed, in giving to the public the moveable frame.

There is nothing so puzzles the bee-keeper as the successful wintering of his bees, seventy-five per cent. of the losses arising from the want of that knowledge. Any man that can show the bee-keeping fraternity a safe method of doing so, is a public benefactor, and should not hide the knowledge of the same from us. I do not charge that Mr. B. desires or is doing such a thing; nor do I expect the information gratis, if Mr. Bidwell does not wish to give bee-keepers the same. I would like to know his address, that I might buy the right. One of these two things Mr. B. should do: Either to give the public, through your journal, his mode of wintering, in season for a trial the coming winter, or let us know, through your columns, what will be the price of it. I will be willing to pay liberally for it. If this catches Mr. B.'s eye, I hope he will allow me to know his address, or that you will furnish it if you can, that I may correspond with him. If he or you will do so, I shall be

more than grateful. It seemed to be no secret to many present at the convention, and you could not find the subject that would be more valuable to your subscribers than to get Mr. Bidwell to give through the columns of the AMERICAN BEE JOURNAL his mode of wintering bees. Please give this more than a passing notice, and oblige,

C. D. HIBBARD.

Chips.

MR. EDITOR:—"Tis hot; it's more 'n hot! While the hayseeders are doing their stacking and roasting, and while my bees are pumping the buckwheat and sap blossoms dry, I'm sitting in the coolest part of the house, and enjoying and admiring the industry of Nature's creatures. How grand it is to contemplate how everything is subject to our will! We are the cap-stone of all creatures—all are beneath us! The faithful horse does our drudgery; the cow gives us nourishment, and when her milk ceases to flow in sufficient quantities, she bows her head for the fatal blow, after which we consume her very hide and hair! The tireless bee furnishes us with that sweet luxury with which we are so well acquainted. And the Granger, in his meekness, provides us with the toping-out variety. Oh, how everything is adapted to our wants! especially if we have lots of the "filthy lucre" to get what we want; which I haven't.

While in this cheery mood, I would like to run over the pages of the "Old Reliable" and stick in a few words right and left; and as Bro. Gallup likes to hear the opinion of baby bee-keepers or novices, this is written for his especial benefit.

CAN BEES EAT FRUIT?

It is often asserted by some of the best apiarists that bees cannot cut the skin of grapes, &c. Now, if they can gnaw the edge off of wood, and eat large holes through building paper, and cut through strong cotton cloth, and all this I have seen them do. Why can they not as well cut the skin of fruit, if they wish? But the trouble is, I don't believe they have a mind to; they want direct access to the juice. They will suck corn-stalks, mellons—in short, everything that is sweet; but they will not *dig* for it.

CAN OLD BEES BUILD COMB AND NURSE BROOD?

In the AMERICAN BEE JOURNAL "Adair" says old bees won't build comb or nurse brood. I don't know about the brood, but I've seen them build comb. I saw a handful of bees last week (Aug. 5,) that came through the winter queenless, and they had a piece of comb built as large as my hand.

WHAT KILLED THE BEES?

Mr. Gallup, as I expected, attributes my

loss of bees to the extractor. Perhaps he is right; but then one of my neighbors lost as many—all he had—and had never seen an extractor; didn't know one from a saw-mill; he kept his bees in a similar winter quarter as mine. To me, now, it would have been a wonder had they *lived*; it was as cold where I had them as it was out of doors, and occasionally warming them up did the work of destruction completely!

MODEL BEE MANAGEMENT.

I think it cannot be long since that "T. R.," with my "Management of Bees," ever saw the first bee journal, for it *does* seem if he had, he would not mention his hives stuck up on posts, and these wound about with cotton to keep off the ants—perhaps a balloon attached to each hive to suspend it in mid air, would be quite an improvement on his plan. We don't intend to secure a patent on this, so that that progressive(?) bee-keeper may use it if he likes. He still keeps box-hives and considers natural swarming best. Well, no wonder his article reads as if it had been written twenty-five years ago. Forty to fifty dollars' worth of honey from a *single stand*! Well, that explains the value of *his* management. Why, I could get that, if my bees were in the carcass of a lion, as we read about, provided they followed the ribs in comb-building, and these same ribs were arranged to take out, so I could swarm artificially—but read the article and learn!

DO ANTS ROB THE BEES?

Mr. Arga says: "Ants don't steal honey out of the hives." Now, that's strange; for they will steal it wherever else they can get it, and I have an opinion that they make no scruples stealing it from those that give them shelter and warmth.

WILL HONEY CRYSTALLIZE IN THE DARK.

On page 178 there are a few words, written by I don't know who, to the effect that it will not. Wonder how the "tarnal light" goes into cellars and inside of a honey-tight cask; for with me it will crystalize in this condition. But perhaps it wasn't dark enough; so I would advise bee-keepers when they think they have their honey in a sufficiently dark place to keep it from crystalizing, to make it a *little darker*!

A GREAT DISCOVERY!!!

Mrs. Tupper says: "Salt thrown into water will keep it sweet." If so, why not feed our bees with salt water, instead of sugar-syrups? But hold on, "Novice"—or any other man! I made the discovery, although Mrs. T. may have spoken of it; but I made the application above mentioned—so keep your hands off. To make sugar, all we have to do is to sweeten water with salt, boil it down, and you will get as nice

158 THE AMERICAN BEE JOURNAL

a sugar as you ever saw; for salt is so clear and white, you know. When this discovery is generally known, salt will be worth something.

HOW DO YOU LIKE IT?

How do you like to hold up a frame for inspection, with a bunch of black bees dangling on the bottom, so you can't set it down without crushing about fifty; how do you like to have a bee come at this critical moment and plant you one between the fingers? I don't appreciate this sacrifice of the "busy bee!" If I had been brought up in a Christian community, under these circumstances, I think I would swear.

Mr. Editor, there is no use trying to white-wash these honey-merchants; you can't get around their actions, "no how." Say Perrine *did* do the fair thing with some; he even paid two of my neighbors 5 per cent. interest on the money not sent on time, but that don't help my case in the least. I think I and Mr. Bird had better light our lanterns, and, like Diogenes, hunt for an honest honey-merchant.

Yours,
J. D. KRUSCIKE.

Berlin, Wis., Aug. 18.

For the American Bee Journal.

Scraps.

The old "AMERICAN BEE JOURNAL" since it lost its founder and head, the late Samuel Wagner, has been moving around considerably, though it has been in good and faithful hands. And now as it has "gobbled up" another journal we can say good bye to the "NATIONAL," but we haven't lost it, though it has married and changed its name. *I like the change first rate and wish success to the new order of things.*

Friend Argo says his chickens will pick worms off the bottom board and not touch any bees. I think ours can beat that, for besides getting what few moths there are, they will go up to a cluster of bees and pick out the flies and drones by the half-hour, and I never saw but one take a worker and he dropped it and looked as though he had made a mistake and was sorry for it. How will that compare with king birds?

To the advice to "keep bees" I would add keep *chickens*, set your hives up from the ground and snap your fingers at moths.

Friend Hester says: "I have had no experience with these large single story hives," and, "I should think it would also be quite difficult to contract the space within them to suit a small stock, or to winter even a full stock." We use the Langstroth frame, Adair size, 16 and 20 frames to the hive, and find them to work well. We had but one strong stock in the spring, a 20 frame hive. Made one new stock, bought

5 light ones, and built them all up mostly from the big stocks, and have extracted 34 lbs. of honey besides. The hive has always been full of brood, at least 16 out of the 20 frames, and is now very strong, enough bees and brood for two good swarms.

As to using them for light stocks, that is easy enough; just put in a division board, or two of them, and give them room as fast as they require it. I transferred a light stock from box hive to 16 frame hive; could get but five frames of comb out of it for them; put in the division board and now they are a good strong swarm.

In wintering you can put the swarm in the centre of the hive, with a board or wire division on each side and pack the two ends with clean straw, or shavings which will absorb the moisture and keep the bees dry and warm.

In the old directions for transferring it was always stated to put the brood the same side up as in the old hive. All of us "Novices" thought it was all law and gospel and so took special pains to do it.

We have a glass fish tank and the bees gather around it by hundreds to get the dripping water. While looking at the fish we noticed one bee who didn't seem to care about the ills of life, for she had a big hole stove in on one side as large as a pin head, the scale sticking out at right angles. The said bee came after a load of water 4 or 5 times in an hour, and we noticed her for several days. How is that for perseverance under difficulties?

A writer in the National some time ago, said in regard to the qualities of Black and Italian drones: "Don't be afraid of black drones, but let them fly if any should be out at this time. Your Italian drones know what is up. You will then have an opportunity to test the superiority of Italian drones over black ones. You will also notice that if there are any black queens flying at this time in your neighborhood, there will be a majority of them fertilized by Italian drones."

Your Italian drones know what is up! Yes, they do, "in a horn." I made three new stocks for a friend, and one of his old stocks raised a new queen. They had hundreds of Italian drones, eleven swarms in all. About a fourth of a mile from them are four of the insignificant black stocks, while in different parts of the town are about 40 stocks of Italians, and no other blacks within a mile. Three out of the four new queens *mated with black drones*, and one or two others that I know of. One of the black stock swarmed, and the new queen in the old hive mated with a black drone;—four black stocks against over 40 Italians. Superior fiddlesticks!

Wintering Bees.

On the 31st of October last year, I put in my cellar, 12 stands of bees; and before the 15th of November 120 stands. The cellar is 16x24, and dry. I took from 50 stands from one to five frames each. So ten or twelve swarms had only 3 frames left. The 50 hives had three to seven frames in each. All are 8 frame hives. I took them from the cellar March 17 and 18th, and of the 120 hives but two swarms were dead. I afterward lost 6 more, by being queenless. My bees were never in better condition than last spring. I saw little difference between those from which I took the frames and, those I did not. I would not recommend the removal of more than two frames, and think that beneficial.

When swarming began, I had 98 swarms, which I increased by natural and artificial swarming to 175. I lost several swarms which went to the woods. Swarming closed July 1st. I took with the extractor 6,000 pounds of honey in two weeks, all of which was linden or basswood. Have on hand 8,000 lbs. The crop was cut short by not less than 10,000 lbs.

Of all honey plants I have tried, the Meliott Clover is the best. The drouth does not affect its product of honey. I shall have ten acres in bloom next year. Seven years experience teaches me that it pays to have plenty of artificial pasture.

My lowest average hive, was 40 lbs. per hive old and young, the highest 80 lbs. I think the proper average should be 50 to 75 lbs. each.

My bees wintered so well in the cellar, I have enlarged the cellar to 24x58. and 7 feet high, and shall try it again.

R. MILLER.

Campton, Lee Co., Ill.

For the American Bee Journal.
My Report.

We are having an uncommon good run of basswood honey this season. In fact honey has been too plenty for those not having extractors. I have been moving about with mine pretty lively for the past week, and the experience I have had among my neighbors I think would convince the most skeptical of the usefulness of the extractor, as I have found stock after stock without an egg or young grub in the hive and every cell full of honey, except a very little capped brood. I would like to ask some of those who do not believe there is any use in the extractor, what they would do in that case without it? It is no use to give them empty frames, for as fast as a cell is built and sufficiently lengthened out to contain a drop of honey it is filled, and some

hives that I nearly emptied last Saturday (five days ago) were filled again so quick that the queen did not get in a patch of eggs as big as my hand. So much for Michigan. Now a word for the moth.

My advice to those that raise such a "hue and cry" about the moth, is to get a mechanic to make their hives. I do not mean a man that has jack-plane and scratch awl and calls himself a joiner, but a man that can and will fit two pieces of board together so that the worms cannot build a nest between them. Then let your stocks be either strong or weak and you will have no trouble with worms. I have thirteen stocks of bees and I do not think I have found to exceed three or four moth worms about the hives this season, and only one inside the hive at that. The only secret there is in it is this: I make my hives so that there is no crack or crevice in them where a worm can hide, and the bees keep them out. Now all you unbelievers come and see for yourselves. But perhaps you will think as the negro told the Irishman when he asked what made him so black: "It's the climate." Not so, my friends, for my neighbors have the same climate that I have and some of them have plenty of moth-worms in their hives. They buy cheap hives.

I very often see advertisements of patent hives with moth-trap attachments, etc. Please let me give my experience with a Buckeye hive; moth trap and all. Last month in the natural course of events there fell into my hands a stock of bees in a Buckeye hive, and also an empty hive of the same sort. Two or three days after I got them home they swarmed, and not having anything else handy, I hived them in the empty Buckeye hive (after inserting a couple of cards of comb from the other hive); and to save speculation I might as well remark that I saw the queen safely on a card of comb, and then closed the hive. They appeared to go to work all right but in about 8 or 10 days they swarmed out. I opened the hive and found they had made but very little comb, and that all drone comb. There was not an egg in the hive—pretty good evidence that they had raised a young queen. Now the question was what had become of the old queen. Time will show. I cut out the queen-cells and hived them back again and the first spare time I had I made a hive and transferred them, when I found that the young queen and the swarm were in the body of the hive, while the old queen and a little handful of bees were down in the moth trap!

That was the reason they raised a young queen and swarmed out, by my not expecting any such thing and cutting the queen cells out.

If the traps will not catch Millers, they will sometimes catch queens, so buy one by all means of the first pedlar that comes along.

How One Man Got Rid of his Drones.

MRS. TUPPER:—Your valuable favor of the 8th inst., to hand. The bees reached their home on the evening of the 23rd, in apparent good condition. The next day I noticed some dead ones at the entrance, which I removed frequently during the day with a small wire. Prompted by curiosity and with the hope of relieving the labor of the bees in bringing their dead to the door, I opened the hive in the evening, lifted all the frames out, brushed out and gave the box a good cleansing, returned the frames and bees without offending a single bee so far as I knew. I think about half the colony were dead—say one pint.

From book information, I concluded there was a surplus of drones in the colony. How to get rid of them was the question. Drone catchers were patented and what could I do. The laborers were working finely but the surplus of gentlemen of elegant leisure was annoying. With a small bit of paste-board, with a notch one-eighth by three inches long placed over the entrance, settled the question speedily. The laborers could enter but the drones could not. A little squeeze on the head settled the business for them, and to all appearances the colony is doing well. Several of my neighbors want bees and the JOURNAL, but are a little demoralized by the delay of our railroad up the Platte, and think they must wait another year.

Wintering Observations.

It has been some time since I have felt like writing to the BEE JOURNAL but now that my bees have done well, I am encouraged to take up the pen again and give my experience and observations that they may possibly be of benefit to brother bee-keepers. Trusting that the wintering question will receive the fullest discussion before another winter comes down upon us with its uncertainties and disastrous results.

I put twenty-six swarms in the cellar November 21st, all except two supplied with natural stores, and nearly all strong swarms. Now, as Mr. Quinby, on page 106, desires to compare notes in relation to temperature, here are a few facts gleaned from personal observation. The portion

of the cellar in which the bees were stored was near an outside door, and though banked with straw, during our severest cold the temperature fell two degrees below the freezing point. A few days after, the temperature arose to 40°, and two swarms, one of them upon which all early honey had been extracted leaving fall honey exclusively, showed signs of dysentery. The latter swarm was very large and vigorous, occupying a three-foot hive with Adair size of frame. We had several of these cold snaps and every time the temperature arose dysentery was developed more and more virulent in the large swarms. Until being set upon their summer stand the remainder smeared their combs and themselves in a fearful manner and froze up solid. Now, was it the honey or the cold, or a little of both that accomplished the ruin of this swarm? All of the rest wintered well whether fed on syrup or natural stores.

On the 19th of March they were set upon their summer stands. A careful examination showed no sealed broods except in a very few hives. The queens had apparently just commenced to lay. In two days after setting them out the weather changed and a cold spell intervened. Upon the next warm day an examination showed no sealed brood but the queens had just commenced to lay, the first eggs of the ten days previous being destroyed. Three times we made these examinations through the months of March and April with like results, no brood rearing and all the while a constant diminution of old bees, and eventually the swarming out fever left me, by the middle of May, with only six swarms out of twenty-six, and only two of these were strong. These had sealed brood when set upon their summer stands.

With the temperature of the cellar at 40° or 45° the bees were very quiet—about 45° would be my "standard."

During the past winter bees wintered upon their summer stands and were in better condition than those that were housed. I have also observed that during the past three severe winters, bees wintered in a neighboring village where the hives were entirely surrounded by buildings, and came through in the very best condition.

Now having lost heavily and observed closely, let us see if there was not a remedy, if it had been applied in time. Fine food and an even temperature of 45° would have banished dysentery. They would not have dwindled down in the spring if each swarm had been examined and not set out until each had capped brood. This could have been obtained by feeding syrup and supplying pollen. And here let me suggest the experiment of feeding rye meal late in the fall. Will bees work upon it at that time? If they would, a supply might be

stored and reserved until spring.

While extracting we often observe that cells of certain combs are about two-thirds filled with pollen while the other third is filled with honey and capped over. This was evidently put up for spring use. The honey being put in with it for its better preservation. We all know that pollen moulds very easily. Can we not learn something from this fact also? Several combs containing pollen could be preserved in honey. And we want to know what would give the queen the laying fever in the spring more readily than the insertion of a frame of pollen dripping with honey.

We trust these facts will receive due attention during the coming fall.

"SCIENTIFIC."

For the American Bee Journal.
Chips from Sweet Home.

DEAR EDITOR:—Ten years ago we became interested in bees by taking orders for the Thomas Hive. We handled bees some for six years and four years ago Palmer Bro's made a special business of them for two years, then we dissolved partnership and I bought *Sweet Home*. In the winter of '72 and '73 I lost all (54 hives) the bees I had. Of some 700 or 800 hives between New Boston and Muscatine (20 miles) only about 15 or 20 were alive in the spring, and last winter took the most of them to parts unknown. In the spring of '73 two neighbors and I bought 96 hives in Kentucky, I shipped them 80 miles by rail and about 600 miles by boat. I increased my share (40) to 95 hives, this spring had 35 living. I now have (July 10,) 67 hives, am running them for extracted and box honey. I use Longstroth and Thomas Hives, am 29 years old, weigh 140 lbs., have a library of books and geological specimens, have an observing hive in the parlor, the bees pass out and in through the wall, all the workings of the once mysterious hive can be seen by lamp-light or sun; it consists of one comb and glass on each side. Our apiary is shaded by a natural grove. Our Sweet Home Honey Slinger consists of a stationary tub with handles and a faucet at the side or the bottom, and a revolving frame which is run by fanning mill gearing, it is much better than a revolvable can. We carry our combs to and from the hives in a rectangular frame supported by four legs which are long enough to keep the frames from the ground; the frame is carried in front of the person by grasping the two end pieces; the combs are so placed in the frames that the ends are to and from us. If robbers are plenty we jar it as we enter the honey-room, and if a few follow us in they fly to the windows, which are made *revolvable*, so that a *flip* puts them outside.

HOW WE SAVE COMBS FROM THE MOTH.

The *we* just mentioned consists of myself and a blue-eyed boy of 21 months old, we two complete the family of Sweet Home. We have had a great amount of good comb destroyed by moths. We tried limestone, and last season we hung them on poles in the shade; the wind blew them down, damaging them, but now we have them *safe* at last in our cellar, which is 20x24 feet, having a chimney in the center with a draft-hole at the base which is continually drawing the damp bottom air out; also 2 windows on each side covered now with fine wire-cloth. Last spring we put our combs (enough for a hundred hives) in there, soon we found the moth eggs hatching, it being cold in the cellar the worms nestled closely together and we readily fed them to our poultry; but some few were overlooked and are coming out winged moths and are seen to fly to the windows where I am certain to put my fingers on them. My bee-shirts I have made as others except buttons a little closer on the bosom and elastic in the waist-bands.

While on a visit to Dadant & Son., of Hamilton, Ill., I became very much in favor of using the black-board instead of a book as I had formerly been doing; but seeing C. P. Dadant use a *slate* pencil, I thought why could not slates be used instead of boards, I accordingly procured a few school slates from which I took the frames and cut them in pieces of 2½x3 inches boring a hole in the middle of one end and hung them on nails, these slates cost me a little over a cent apiece and the cutting is readily done by any sharp instrument and a straight-edge. They are cheap, durable, writing-lasting, and always just where we want them.

For the American Bee Journal.
My Experience.

I have just noticed Mr. C. Hester's "Random Notes" in the June number of the NATIONAL BEE JOURNAL, as we live only eight miles apart, I will give you my mode of operating with my bees last winter, my success this season &c., &c. I have no cellar to winter in, consequently I winter as you may say out of doors, it's true I have them under a shed, and protected from the north and west winds. I went into winter quarters last winter with 14 colonies, at the time I put them up, there was not one pound of honey in the 14 stocks. I fed them sugar syrup, made precisely as Judge Hester did his and fed them in like manner, by pouring in the empty combs, but I fed mine at intervals through the winter, that is on warm days. I came through the winter with 10 stocks losing four, which I

am confident starved, not giving them syrup sufficient. My stocks came through in a very weak condition, the spring being very cold and backward they did not get to breeding until late, but after the weather did begin to get warm, their increase was more rapid than I ever experienced before. Seven of the ten is all I have extracted any honey from during the season, that being so nearly gone, it was all they could do to keep or get up the strength of the colony to make one divide from. I use the double Langstroth hive, and from the upper stories of the seven stocks I have extracted four hundred and fifty lbs. of honey this season, the lower stories contain sufficient honey to winter them through. I have divided to eighteen this season. I will try wintering on their own honey and if I do not have success hereafter I will try Judge Hester's plan, extract all and feed syrup. I must state how I saved one of my pet stocks after I placed them on summer stand. I went out one warm morning about the 20th of April, I noticed the bees just able to crawl from the front entrance of the hive. I immediately opened the house and found the bees on the cards just able to move and the queen on the bottom of the hive as I thought dead. I immediately got some syrup and on examining closely, found my queen with some life yet. I placed some syrup to her and she eat it. I sprinkled syrup over the mass of bees on the cards lightly. I then filled all the empty cards with the same, and in one hour I examined again, found them quite lively, during the day they removed the syrup from the outer cards to the center and this summer that stock has made one divide and furnished me over 50 lbs. of honey; in one half-hour longer the stock would have been gone. The reason of their consuming the syrup so fast was they were breeding rapidly.

JAS. R. WILCOX.

For the American Bee Journal.
Bee Notes.

There seems to be a perfect dearth of honey; no flowers, no honey-dew; nothing but pollen from corn tassels, and, whatever it is, that bees get from fruit. Hives that contained honey a month ago, now have almost none. But for the cotton blossom now unfolding, bees would have to be fed, something the fogies never think of. Bees are doing nothing in boxes, and on inquiry find it to be a general thing; a state of idle inactivity seems to reign throughout the neighboring apiaries. A good patch of Buckwheat and Alsike clover have been very much needed this year, and it behooves apiarians to see to it that the same state of affairs is not repeated next year. The golden bands might succeed in finding

honey, but our black bees have well nigh given up the game. For one, I am anxious to see an accurate drawing and description of *your* hive, and am *now* anxious to know whether or not a different style and *size* of hive (than the one you use) is best for our long and hot summers and short winters. Dr. I. P. H. B., of Augusta, Ga., could give valuable information on this subject. Can't he be induced to give an article for this paper on "The proper size of Hives for the South." I hope so.

S. C.

EDGEFIELD.

J. P. Moore, Binghamton, N. Y., says: I commenced the season of 1873 with seventeen stocks of bees, having lost four in the spring, and sold one. Ten were in fair condition by May 20; the other seven were much reduced, but by taking brood from strong ones, I was able to build up five of the weak ones by the time honey commenced to yield. The other two I run for increase or surplus queens, and was able by breeding and using my four hives of empty combs, to increase the two to eight full stocks and five half stocks or nuclei. Two of the nuclei died in the winter, and the other three are very weak, (I prefer full stocks for winter), and raised ten surplus queens. The fifteen that the boxes were put on were run entirely for box honey, without increase, as we have things so arranged now that when we have got a hive filled with brood in time to put on boxes, we can have them put all their surplus in boxes, if the queen is prolific, without the trouble of handling the brood.

Hints from Bee-Keepers.

If several days of rainy weather should succeed a warm coming off, they may die of famine, if timely relief of honey is not given them.—*Wildman*.

Queens are not equally fruitful. While some breed slowly or not at all, others will speedily increase in prodigious numbers.—*Keys*.

No true lover of bees, I am persuaded, ever lighted the fatal match that was to destroy his little innocents with livid flames and a smoke that strikes them dead with its intolerable stench, without much concern and uneasiness.—*White*.

It is commonly the practice to rub the sides of the hive with aromatic herbs, or a solution of salt, or other substance. But the most experienced bee-master deems this altogether unnecessary, as it can be attended with no advantage whatever.—*Hacher*.

Always have the cheerful rays of the morning sun fall upon *your* hives; but contrive to throw a shade upon their front for a few hours in the middle of the day,

when the weather is very hot. Such a shade will be grateful to your bees.—*Nutt.*

Bees express no more love for their keepers than for strangers, but they (the keepers) being used to them, with greater confidence venture among them, while some (more fearful) beholding, fancy that the bees respect and love them more than strangers.—*Purchase.*

Workers alone have the property of secreting wax. Scales of it ranged in pairs are contained in minute receptacles under the lower segments of the abdomen. * * This substance is produced by a particular organ, after the manner of other secretions.—*Huber.*

When Bee-Keeping don't Pay— What then?

Hogs have been sold for less than value of corn fed in fattening. Cattle brought less than cost of raising. Poultry could be had for less than value of food fed them. Yet all required as much care as if sold at a profit. We would, however, think that farmer very unwise who would quit the raising of live stock or grain, because of low prices or severe winters. If the bee-keeping farmers would use as much precaution in preparing pasturage and shelter for their bees as they do for other live stock, I doubt not that a few years of experience, backed with a comparative table of facts and figures, would convince them that bee-keeping would prove as remunerative as any business in which they are engaged.

The man who expects a large crop of fine fruit each year, without pruning or cultivating his orchard; he who hopes to harvest a heavy crop of wheat, corn, or oats, without properly plowing or pulverizing the soil; he who expects to cut a heavy swath of hay, every year, from a meadow he devotes half a year to pasturage; and the bee-keeper who expects to get a large yield of honey without giving his bees any attention whatever—are all sure to be disappointed with their business, and will declare it don't pay.—*Ex.*

For the American Bee Journal.

Successful Bee-Keeping.

I came through the winter with all my colonies, 36 in number, most of which were in good condition. The spring opened favorably and my expectations were great, but about the 1st of April the rain set in, and I think my bees only worked two days during the whole month. I fed them occasionally, but nearly every queen ceased laying and all the hives killed their drones.

The rain ceased the 1st of May, and the poplar commenced blooming at the same time, but alas! my bees were not strong enough to bring in honey as I wished them to, but to make the best of what could not be helped I commenced doubling up, putting two and sometimes three colonies together and so reduced my colonies to 22, leaving the queens and what bees adhered to one comb in the old hive with a division board on each side. These I would give room as they increased, and have made strong colonies of them all.

From the poplar I took 1032 lbs. of extracted honey which I thought doing pretty well, but when the sourwood bloomed the bees exceeded my highest expectations. From the sourwood I have taken 2004½ lbs. which makes a total of 3036½ lbs. and have increased my bees to 69 colonies all in good condition with honey enough to spare at least 500 lbs. which I will take as soon as the buckwheat commences to bloom. The sourwood makes the prettiest honey I ever saw; when poured on the whitest letter paper, you can see no difference in the color of the paper and the honey.

I think this a splendid place for bees. I have lived here a little more than two years and am highly pleased, and right here I would say to any of our northern bee-keeping friends who think of emigrating, that I don't think they could find a place more suitable. The woods are thick with poplar and sourwood besides other blooms in abundance. The water which is pure freestone cannot be exceeded anywhere. The air is pure and consequently healthy and society as good as could be desired. Lands are cheap ranging from 5 to 15 dollars per acre. We have in our midst a great many families who have moved here from the northern States, all of whom are well pleased. These families are all United Presbyterians, have built a large and commodious house for worship, have regular preaching and Sabbath school.

We have other churches near by, Methodists, Missionary Baptists and Baptists, and within a few hours ride, Cumberland and other branches of Presbyterian churches. We have built and furnished a large two-story academy, which is now under Prof. John A. Ramsey of the Indiana State University as principal. Tuition has been put down to the lowest figures and no person could find a better place to educate their children.

Any one desiring to learn more of our country can do so by addressing, Rev. J. W. Wait, Prof. J. A. Ramsey, or your humble servant,
J. F. MONTGOMERY.

Lincoln, Lincoln Co., Tenn.

Where the Linden grows.

DEAR JOURNAL: One of your correspondents (R. H. M. I think), wishes to know now far south the Linden grows. I am on the high ridge of land or "divide" between the head-waters of the Guadalupe and the Piedronalis, about two thousand feet above the Gulf, in lat. 30 deg.; and a dwarf or mountain linden grows on all the creeks that flow from the "divide" into these two rivers. It has never been seen any lower down than this, that I know of. I sent to Michigan last March for 50 linden cuttings and set them out in San Antonia (lat. 29, 30 deg., and 750 ft. above the Gulf) and they all perished though I mulched them and kept them well watered. I think the season was too far advanced and intend trying some more this fall. The "divide" is a fine range for bees. I have known one person to have as many as 7 trees at one time, standing in the forest, which he had found by coursing wild bees from water, and I obtained my dozen swarms to start with this spring for nothing.

Texas.

S. J. NEWCOMB.

Success in Wintering. Is it Attainable?

Probably no other topic in connection with apiculture has of late been the subject of such extensive experiment and thorough investigation, as the one which heads our article. In view of the heavy losses which have been sustained by American apiarians during the past three years, the interrogation—Is success attainable?—has become one of no small significance. We believe it requires no argument to convince any candid mind, that the cause of apiculture in our country must materially suffer, unless some method shall be devised that will insure more uniform success in "Winter Bee-Keeping" than has been attained during the past few years. 'Tis true that we do not lack for theory to account for these losses in wintering, and demonstrate how the way henceforth be avoided. But the simple fact that many apiaries have again been decimated by that fell destroyer, designated as the "bee disease," is sufficient evidence that there is yet abundant need of further investigation.

Sugar syrup which was announced with such a flourish of trumpets, as being the panacea, *per se*, for all our troubles, has been tried and found wanting. A uniformly warm temperature has done better, though not a specific for the "bee disease." And so of other theories; none have proved universally successful.

Please don't infer from the above, that

we intend to convey the impression that no one has succeeded. But we do say that in sections where the bee disease has prevailed many have failed, despite extra care and exertion to secure the conditions necessary to success.

Really then, is success—complete uniform success—attainable? We believe it is, *provided* the requisite conditions are complied with. But what *are* these conditions?

According to our best authorities, we might enumerate an abundance of wholesome food, prolific queens, young bees, empty comb in the brood nest, a uniform temperature of 40 degrees Fahrenheit, and ————well, "you know the rest." But are these *all*? Let us see. Bees we are told are "natives of warm climate," where polar blasts and arctic's cold is unknown; where their joyful, busy hum is heard alike in dreary January or bright July. Notwithstanding this fact, the honey bee has vied with man himself in manifesting qualities, characteristically cosmopolitan; having with him become acclimated to many an uncongenial climate. Yet for all this, a fearful mortality has ever and anon, decimated the ranks of "bee-dom" in our more northern latitude, blasting fond hopes and depleting unfilled purses. This has no doubt often been the sequence of carelessness and ignorance, though of late the destroyer has often baffled the hand of skill and science. But must these scenes of desolation be witnessed with the return of each succeeding winter? Is there no "safe retreat" by which success may be attained? Or, are the *conditions* necessary to success unattainable?

After devoting much time and thought to the investigation of this problem, we arrived at this conclusion, regarding its solution: *complete success is to be attained only by approximating the conditions which surround the bee in its native climate.* This involves a point which seems to have hitherto escaped the discriminating discernment and analytical acumen which has characterized the modern Yankee investigator; supply natural conditions and success is yours. But this is impossible. How are we to arrange our bees so that they may fly in December, January, and February where the mercury will persist in neighboring with Zero? Away with your vain tantalizing theories, 'tis impossible.

Be patient dear reader and we'll explain. We, too, thought 'twas impossible, but were mistaken; and here's how we ascertained the fact.

A friend, by name of H. (we withhold his real name and address, to save him the annoyance of "a thousand and one" interrogations) thought if he could manage to give his bees an occasional "airing" during

Southern Bee Notes.

the season of frost and snow, it would do 'em good. (By the way, no abler or more successful investigator ever graced the ranks of those engaged in apicultural or pomological science in this or any other country, than this same H.) Thinking and acting are synonymous terms with him, in matters that engross his attention. So on a clear frosty morning in December, he placed three colonies of bees in a "hot-bed," as an experiment. Presently the genial rays of old Sol raised the temperature of the interior so that a few bees came to the entrance of the hives to reconnoiter. "Surely" says the advance guard, "spring is here again; let's have a play-spell and enjoy the bright, warm sunshine." So saying they took wing and commenced buzzing around in good earnest. They were soon followed by their napping comrades(?) and in a few moments longer the "voiding room" was a scene of wonderful activity. In less than fifty minutes from the time they commenced to fly all was quiet again, the bees had had a good purifying flight, and strangest of all, scarcely a dead bee could be found to indicate the "lapse of time." This experiment, so auspicious in inception and satisfactory in results, was followed by others on a larger scale, including about 75 colonies in all. As a result, our friend says that hereafter, his bees will go into a hot-bed in November. He thinks that every colony in fair condition in October can be brought through so as to be in just as good, or even better condition, the following May. He is naturally quite enthusiastic over the success of his experiments and well he may be, for in our humble opinion, it is one of the discoveries of this age of invention, one that will mark a new era in *successful* bee-culture. For, despite cold, snow, and wind, we can give our bees an opportunity to fly almost any day in the winter and spring season, when the sun shines, which makes our success in wintering doubly sure.

But we're getting verbose again—a common fault of ours when deeply interested in any subject—and must close. At some future time we will give the details of management necessary to insure success with this method of wintering; also its effect upon early brood rearing, and other topics connected therewith.

S. Haven, Mich. HERBERT A. BURCH.

P. S. Please *don't* write us, making enquiries relation to bees or bee-culture. Our time is too fully occupied to answer such letters even at "one dollar each." If you wish our opinion upon any given point send your enquiries to the AMERICAN BEE JOURNAL for publication, and we'll cheerfully answer them to the full extent of our ability. Please *do try* and bear this in mind.

H. A. B.

Mrs. TRIPPER:—I have just received and perused the June No. of the "NATIONAL" with interest. It would give more satisfaction if correspondents would give their parish or country. I live on the same meridian as your correspondent "Y" of La., and although we had a poor yield of honey after the middle of April, we have not thought of feeding. We live on Vermillion river near the sea marsh, and have extensive forests on the southern border of an extensive prairie. "Y" may live east of the Mississippi and I should like to know his surroundings.

During March and early part of April we had a great flow of honey from willow, peach, plum, etc. The great rains, followed by drought, cut off the yield; but for some weeks my bees have revived, as have the crops, from bountiful rains. After two years impartial trial I find different experience from Robert J. Collinson. The Italians are much the easiest handled.—They are also much less disturbed by worms; they are more prolific and make more honey.

In reply to your correspondent R. H. M. page 145, I will state that every southerner knows basswood by the name of linn, the bark of which is often stripped by negroes for chair bottoms, horse-collars, etc. It grows freely here.

J. B. RAMSEY.

Abbeville, La.

Who will answer the following question? How to purify wax, and prevent its becoming of a dark color.

S. S. ELLIOT.

My bees have stored about 60 lbs. to the stand, so far this season. It is very dry at present.

EDGAR MCNITT.

Moving Bees in Winter.

EDITOR AMERICAN BEE JOURNAL:—I am 46 miles from Milwaukee, in the best honey producing portion of Wisconsin. I moved twice between the last of October and 12th of January, 1874. I moved six hives of bees four miles to the city of Milwaukee on a wagon, then 30 miles on a freight train; then 4½ miles on a half-spring wagon over the roughest road I ever saw. The bees were placed in the cellar and 14 days after I gave them a flight. The cellar is dug into a hillside, is covered with wood and gravel, and averages 30 to 40 deg. heat. The 14th of December it was about 57 deg. on the sunny side and I took the bees out

for a flight which entirely cured the dysentery of which I had discovered symptoms. I feed them warm sugar and syrup.

On the 6th of January they were again packed for an 18-mile trip on a sleigh over a rough road, and they were again placed in a cellar. On the 11th of February, they had another flight. I lost but half of one swarm which was caused by a frame getting loose and crushing them. Who will say bees cannot be moved in winter? I would risk a swarm 200 miles on an express train, if packed so as to let the heat out at the top of the hive—not in front, for then the heat remains in the hive, and the second day the bees are sick. Flat bottom hives are useless in this cold climate—too damp. I make my own, and use no patents.

From 3 swarms bought last May, I have increased to 7, and 4 nuclei, and while basswood was in bloom I could have used the extractor every three days, but I was at home only Sundays and got but half the crop. From one second artificial swarm I took $3\frac{1}{2}$ gallons of white clover honey. Now, the swarms average 60 lbs. per hive. I have sold a few queens. I am partly satisfied with Grimm's sending pure Italians but the queens 2 out of 3 were old. I have raised 15 young queens, and will put them in place of old ones. The bees have cost me \$15 per live on the stand. I will sell as good for \$12, in frame hives.

I have handled bees 18 years, 12 of which have used frames.

This morning I opened a nuclei to search for a queen which I knew was 9 days old. I saw a drone just letting loose from her, and before my surprise was over, two bees took hold of a small white string hanging from the abdomen of the queen. These drones were laid in the nuclei, by a fertile worker, which I killed last Sunday.

I can give many interesting facts relating to queens, but have not time now.

Wintering and Springing Bees.

Winter is coming on and bee keepers in different parts of the country are beginning to feel anxious about the pets. The question of all absorbing interest at this time is how shall we winter our bees without fear of a repetition of disheartening experiences of the past three winters and springs.

Now there are half a dozen men in our immediate neighborhood who keep from 20 to 80 swarms each, and have had no loss the past four years, neither have they had any trouble with swarming out or dwindling down in spring, though the two last springs have been unusually cold, back-

ward and unfavorable. All wintered on summer stands and on natural stores and none have any fear of disease or extensive losses in the future. All these parties prepare their swarms for winter upon the same general principles, but vary somewhat in their methods. We will state these variations and give our views upon them.

One plan is to remove two frames from the hive and put a partition board on each side of the remaining frames and bees, lay a blanket over the frames (after putting some sticks across to keep the blanket up sufficiently to give the bees a passage over the frames) put the cap on and pack it full of dry leaves.

It is my opinion that strong stocks thus closely packed find themselves so comfortable and warm that they keep on the move, and consequently consume much more food than they would if they had more space, more air to keep them cooler and more dormant.

Another plan is to leave all the frames in, put blanket on as before and a straw mat over this, with a stick an inch thick across the mat at each end and place the cover on the sticks. This last plan I think is a little on the other extreme as sudden and severe changes of temperature would have too direct a bearing upon the bees, rendering them less dormant, and again consuming more food than is desirable.

My own plan is the medium, thus: put the straw mat over the frames the same as a honey board, then put the cap on and put a coffee sack or any kind of a cloth that will let the moisture from below pass through readily, on over the mat. Tack bits of leather on the edge of the cap to keep cover raised $\frac{1}{2}$ of an inch, put the cover on, and a stone on top to keep it there, and they are ready for Jack Frost or any thing that may come.

Our 33 stocks wintered in this way last winter and they certainly did not consume more than 120 lbs. of food each from the time they quit gathering in the fall till they commenced again in the spring, a period of over six months, and a large force of brood reared in the time.

The most experienced apiarians in Europe and America decide that straw is the best material to keep bees healthy in winter that has ever been used for a hive. Quimby, in his excellent *Mysteries of Bee-keeping*, advises the wintering of bees in straw hives and changing them back to wooden ones in the spring. This material, being a more perfect non-conductor of heat than any other, and at the same time a good conductor of moisture serves the purpose of keeping the interior of the hive dry and sweet with the least possible expenditure of animal heat. Now by placing a well made straw mat (like the sample you have Mr. Editor) over the entire top of the

hive we secure nearly all the advantage of an entire straw hive. It is very important that all the little details in this matter of wintering should be understood and carefully observed. In conclusion I will state a little incident that came under my observation last winter, to show how a little variation (accidental or otherwise) may result in loss. And, to give a hint to some of our writers who still persist that ventilation in winter is, under all circumstances bad for the bees.

Calling on friend Muth about the middle of January I found him (as usual) very busy in the store. But when a bee-keeping friend calls, if the weather is mild, as in this case, the clerks usually have to put in extra liks enough to make his place good while the bees are looked into to see if they are rearing brood, to compare the Egyptian queen with Italian or something of the sort. We were soon on the roof and after going through five or six hives we came to one that was quite damp, the bottom board nearly covered with dead bees, and several knots of dead ones between the combs.

"I can't understand that" says Muth. "I think the cover must leak."

"No there is no leak in the cover, there are two blankets and they are stuck together."

He pulls them apart and finds on the inside of one of them a pretty nice coating of propolis which had nearly stopped the upward ventilation. The discovery was made in time, and a good swarm saved.

Cheviot, O.

M. NEVINS.

P. S. We are glad to see the JOURNAL constantly improving in interest. I don't know how any beekeeper and takes any interest in them can afford to do without it. There is not one page in all my back volumes that I have not read more than once, and still I think so much of them for reference that I would not be willing to part with them for three times their original cost.

M. N.

For the American Bee Journal. Bees and Grapes Again.

In the autumn of 1872 I had one and one-half acres of grapes mostly of the Concord variety. I also had 24 stocks of bees and there were 160 stocks in and near our town. (By the way only ten lived through the next winter, out of the 160.) Before the Grapes were ripe the bees were working on rotten apples and sound ones also when the birds picked into them; but when the Grapes ripened the birds and tame fowls picked into a great many of them, and then, but not till then, the bees were all over them by the thousands, but not once could I find that the bees opened the grapes first—only working on those already open, and I

watched them closely. There was no honey in the flowers and the bees were everywhere, around stores, cider mills, and any place where anything sweet could be obtained, no matter how much acid was mixed in. I think this is the first cause of the great loss of bees here the next winter, as forage was so scarce that they almost entirely ceased raising brood by the 15th of September, and all that were already hatched worked nearly their time out before cold weather set in, and were too old to start into winter. The honey they gathered, too, contained so much acid that it helped the cholera along. Then the unprecedented cold winter finished the business for them. But I am digressing. We had but few bees here the summer of 1873 but what there were worked on grapes again in the fall. As before I could not find that they were the first to begin, but only picked up what would spoil. I shall give my attention to it again this fall as I have the grapes yet, and a good crop too, if nothing happens to it. I do not even think they will work on damaged grapes at all if there is any honey to be gathered from flowers. We now have some 60 or 70 stocks of bees here, mostly Italians, of which number I have about 25. They did well in June and the first part of July, but since then, until yesterday, it has been very dry; and they only got enough to keep brood well going. They are at work now on buckwheat. We "bee-keepers" furnished the seed for a neighbor to sow about 10 acres and the bees are just swarming on it. I sent to Wisconsin and got the seed and it is the best variety for honey and grain also. Wishing the consolidated JOURNAL success I remain Respectfully,

J. W. CRAMER.

Knox Co., Ill.

Jefferson County Bee-keepers' Meeting.

Pursuant to a notice for a meeting of the Bee-keepers in Jefferson County a goodly number assembled at the farm of Adam Robisch, three miles north of the village of Jefferson, August 16th, 1874, for the purpose of organizing an association and discussing the different vital questions arising in bee culture. There were 15 bee-keepers present and reported that over 2400 stocks of bees are kept in the neighborhood of the village of Jefferson, but they could not report the yield of the surplus honey at the present time, because bees are not through making honey and that nearly all of the comb honey is in the hives yet.

The meeting being called to order the following officers were elected:—C. Grimm, President *pro tem* and William Wolf, Sec'y.

Moved by A. Robisch, that a committee to be appointed by the chair to present different questions to be discussed in this meet-

ing. The committee reported the following questions to be discussed. Is the Italian bee superior to the Hybrids or Natives? 2. Is artificial swarming as good as natural? 3. Is upward ventilation necessary after bees are housed in the cellar as repository? 4. Is the single hive as good as the double-story hive for extracting?

All the above questions were warmly discussed and the result to the first question was, that Italian are not superior to a good Hybrid in storing surplus honey in boxes, but are superior in gathering honey when empty combs can be given and extracted. Natives or Blacks are nowhere. The second question showed a large preponderance in favor of natural swarming, and artificial swarming or dividing should only be done when a quick increase of stocks are wanted. The opinions to the third question was general, that upward ventilation should be given to bees in damp cellars or repositories, but are not necessary in dry places. The fourth question was answered to that effect that the single story hive is preferable in a mild and cool season, but in a hard season the two story hives are better for extracting honey and handier for handling the bees when we do not extract.

Moved by Wm. Wolf, not to organize and elect officers this meeting, but to appoint a committee of three to draw a constitution and report next meeting, carried. Wolf, Fuerbringer and Roepler was appointed to serve as said committee. Meeting adjourned until the 13th day of September, 1874, at one o'clock P. M., at Wm. Wolf's residence.

WM. WOLF, C. GRIMM,
Sec'y. *pro tem.* President *pro tem.*

For the American Bee Journal.
Chips From Sweet Home.

Many bee-keepers are like ourselves—few bees and many hives and combs. How can we get a quantity of honey and a large increase?

We will tell you how we do. Many of our hives were very weak. We took from the strong and gave to the weak, till we had all strong. Then from our best queen we raised queens, and as soon as they were ready, we formed nuclei by taking two combs and cutting out brood and adhering bees, from two different hives. These we put in a new hive on the right side—as we face the hive—and put in a division board. A few minutes or an hour after forming we give them a young queen. Or another way, but a little more trouble, when your queen cells are capped—on the eighth or ninth day—put one in each comb, and leave one day to fasten; then give one of these frames to nuclei, and all or more bees than adhere to the frame and comb of cutting brood

from another hive. We mark on our slate, "Aug. 2.—Got y. q." In five or six days we look at them and if queen is seen, we say, "Aug. 7.—Saw q." If she is out of the cell, and we don't see her, we write, "Aug. 7.—Q. out." In a few days we examine and find the queen laying; we mark, "Aug. 12.—Eggs." If the weather is warm we look at them in four days, but if cool, not for six or seven days, and supply them with a comb of cutting brood and an empty comb, and write on slate, "Aug. 16.—O. K." Thus we continue, and in from two weeks to a month we make a strong colony of them. If they fill in too much honey, we sling out, so as to give the queen "elbow room." When every comb is full of brood and the hive crowded with bees, we put on our boxes; or, if we wish to sling, an upper set of combs. If for box honey, we take off boxes once a month and put those combs with most brood outside, and those filled honey, we sling and put inside—thus we keep a greater quantity of brood rearing, and consequently more honey stored. When we have tested the queen we mark on slate, if pure, "I. Q.," if hybrid, "H. Q. 1874."

Readers will remember that Sweet Home has a continual average flow of honey the whole honey season.

We wrote "Novice" about the slate, and he speaks of them in a manner to appear as though we carried a "slate and pencil" around with us, and then he refers to his "Queen Register Cards," illustrated in his number. (See *Gleanings*, page 267.) These slates are the cheapest and most convenient register we have used. When we wish to make a new entry on the slate we erase the old. Sometimes we would wish to make a note, which we could not do on the slate. If we have anything special, we can write on out side of slate—such as "Feeding or gave queen, or queen cells, Aug 4," etc.

Eliza, Ill.

D. D. PALMER.

A Proposition.

"Can the time of Swarming be controlled?"

We know if we place a queen cell in a colony of bees without removing the queen, the cell will be destroyed.

The writer proposes the following experiment to his aparian friends: Isolate one or two combs from the rest of the hive, without removing them from the hive, and so arrange the division board that the bees may retain the same scent, and let the bees make queen cells. At the expiration of eight or nine days withdraw the division, whatever it may be—whether of glass, wood, or wire cloth, or a combination of all three—and as the bees are of the same scent, it is possible the old queen may depart with a swarm.

C. C. MILLETT.

Notes AND Queries

I see noticed, in your excellent journal, that in weak colonies the queen often lays two and sometimes three eggs in one cell. Now I would like to ask what is the result? Do bees remove one of them, or do they destroy both, as only one bee can be raised in a cell?

GEO. D. SELVINS.

It is said that the bees eat their surplus eggs. We never saw them do it, and we never saw them remove them; but they probably do one or the other.

The Lindon was very rich with sweet in this part of the State. I have taken from one stock, between June 17 and July 24, over 200 pounds surplus.

L. J. DIEHL.

Good enough for one stock.

Mrs. TUPPER:—Inclosed you will find two samples of honey, one taken last fall and gathered from a species of *Coreopsis* improperly called here Spanishneedles; the other was gathered from honey dew and is as good as any of the spring honey I have ever got here.

We have generally two honey harvests in this part of Illinois during the year. The first from the 1st of May to the middle of June, the second from the last of Aug. to the last of September. The fall harvest is without question the harvest here for honey, in quantity as well as quality the bees storing it with surprising rapidity.

The spring harvest I intend to use hereafter exclusively for increasing and strengthening my colonies, letting them keep all their honey gathered in the spring until the hot and unusually dry season of July and August when it is usually all gone before the fall harvest comes on.

I know the above is not the instructions usually given but I am satisfied if a man wishes to make bee-keeping a success he must study the resources of his own locality and govern himself accordingly. The natural instincts of the honey bee are the same north or south, but the manipulations of the apiary has to be varied according to climate, honey resources, etc. I winter my bees on their summer stands. I expect that some of your readers are ready to say how improvident, but I have wintered in that manner for the last 15 years and have never lost a single colony in wintering and never saw a case of dysentery, neither do I want to; how many of your readers can say as much? I am satisfied with the results but would not recommend it to my

brother bee-keepers as a pattern, believing as I do that it is the superior quality of the honey gathered in the fall that produces the result.

Respectfully, D. M. L.

Clay Co., Ill.

The honey sent is of excellent quality, and both kinds are new to us in flavor. Our correspondent is correct in his premises and in his conclusions. We *must* study our honey resources and the season of them and adapt our management of the bees them and to the climate where we keep them. Let us hear from bee-keepers in all parts of the country.

DEAR EDITOR:—The first stand of hives I bought was two feet long, eighteen inches wide and eight inches deep, and a cap of equal size for boxes. Shall I continue to have hives made like this or change at once? These are easily and cheaply made, and if one does not intend to use an extractor, will they not do?

A swarm came from a hive like this the 1st of June. After great difficulty they were prevailed upon to settle and go into a new hive; they were not contented, and in a day or two went back in the old hive—they seemed to gather in the honey-boxes above. I then removed the honey-boxes to the new hive and placed it where the old one had stood, removing the old one ten feet away. At this time both swarms seem contented, although the old one for a time would have great clusters of bees hanging about the entrance. The old swarm seems to be making no honey in the boxes.

The new swarm has filled, perhaps, one-third of the lower chamber with beautiful, white comb, and partly filled with honey. I drove the bees from two of the boxes. I had moved and turned them upside down. The remaining box was partly filled with honey—it is always full of bees, and the honey in the cells seems to be getting dark and they add nothing to it. I fancy the queen went immediately to this box when she re-entered the old hive and is rearing brood there. This may be a very absurd idea. If so, I shan't be offended if you laugh. The new swarm certainly must have a queen or they would not work. If they have her now, they must have had her during the week that they remained in the old hive before I removed the boxes.

Mrs. VIRGINIA C. MEREDITH.

Your form of hive is as good as any can be that has no movable combs—but these are really indispensable to successful bee-keeping; because, they enable you to find out at any time the exact condition of your bees, and if anything is wrong, to apply

the remedy. Make the hive as simple as you please, but have movable frames in it. If you do not want to use the extractor now, you will soon find it a great help in keeping bees strong, and making them profitable.

You managed well with your bees, and your "fancy" that the queen went into the boxes is true, no doubt.

DEAR EDITOR:—Is there any rule about using the extractor? Would you extract all the frames in a hive but those containing brood and larval, queen cells, &c.? or would you prefer taking the outside frames?

Where you extract thoroughly, is it, in your experience, that they will fill boxes at the same time?

2. Is there any danger in opening hives after the bees leaving—say twice in a week? An old bee-keeper says there is; that they know more than we think, and finding their stores unsafe will be apt to leave. He is a man of intelligence and large experience, having made a business of bee-keeping for many years.

3. Would you expect any trouble in introducing queens to queenless stocks at the close of the basswood season? I wished to do so, but the same authority dissuaded me from it—although I should have bought them of him—saying they would certainly be destroyed. My opinion is that he is wrong. Please enlighten me.

E. LAMBE.

We have no rule about using the extractor. During a good yield of honey, would always take all we could get without disturbing brood. At other times would take only enough to give empty cells for the bees to cluster in.

We have had bees work steadily in boxes while we were extracting honey from the main hive, every third day—but these cases are the exception, not the rule. When able to use the extractor, we don't put on boxes, with our present light. Mr. Dale, a successful bee-keeper of our State, writes us: "I know that extracted honey can be produced for at least one-third of comb honey." We make even more difference than this in the value.

2. There is no danger in opening hives too often, if there is any object in it. We have opened hives to show visitors queens of special interest every day for weeks, and had them do even better than other hives seldom disturbed. One colony containing

a queen of remarkable beauty, several years ago, was opened nearly every day for the season, and we obtained that year 196 lbs. of honey from it! No bees ever left because too often handled.

3. We prefer to introduce queens late in the season. It is, for us, *the* time of all others, but there is no risk at any time, if it is done in the right way.

DEAR EDITOR:—In the June number of the BEE JOURNAL you are asked for a description of the bee quilt. I am a beginner in the culture of bees, and wish only for further information as regards the quilt. Is it to be kept on in addition to the cap? Do you recommend its use for the entire year, or for winter only? If kept on during summer, will it not interfere with proper ventilation?

MRS. R. F. GREEN.

We would keep it on the entire year, except when we put in extra frames or boxes. It is laid over the frames instead of any honey-board. It will not interfere at any time with necessary ventilation.

I am just a beginner in bee-culture, and look for you to help me along.

I started last spring with one colony of Italian bees; increased it to three that summer; two died through the winter, and left me one very strong, good, healthy colony. I looked to them in June (spring was exceedingly late here) when they had some brood, and some honey. I again looked to them the 17th of July, and found plenty of bees, a good deal of brood, but not an ounce of honey in store. What can be the matter? Is there possibly too many drones in the hive? How many drones should there be in proportion to the bees?

How long before a hive can safely be moved back again, after having been replaced by a newly made colony?

There is an abundance of lucern, alsike, red clover, and flowers around the bees, so they do not starve, and it seems unnatural that they should gather no more than what they consume.

MRS. HELENA MADSEN.

We should say that honey had not been very abundant in your locality; and bees being not very plenty in the hive, it had taken all they could gather to raise bees, and they had none to spare. A dozen drones is enough in a hive, if you can prevent the colony raising more; indeed they would do well without any, *if you could make them think it so!*

We would not move the hive back, after

being replaced by a new swarm, until another season.

Bloom may be very abundant, without yielding any honey. It depends on the state of the atmosphere. If there is honey, the bees will find it in all cases.

DEAR EDITOR:—I would like to know something more about those small frames that you use in place of small honey-boxes, to get comb-honey.

1. What shape is best to use, in order to get the bees to work in them the soonest?

2. How do you make them?

3. Do you put them in glass boxes upon sending them to market?

4. What sized boxes then?

5. Does not honey improve in flavor the longer it is in the hive above the bees, after it is sealed over?

6. Does not dark honey cause the bees to build dark combs?

Mercer Co. Pa.

PETER MOYER.

1. We do not think the bees have any preference for one shape or size over another.

2. We make the frames 6 inches deep by 9 long, as that size is as good as can be for market.

3. Make them just like the large frames.

4. We put them in glass boxes for show sometimes, but it does not pay.

5. The honey is best when it is removed as soon as sealed over.

6. Some dark honey is stored in light comb seemingly made from the same honey, but the honey from Golden Rod is very yellow in color, *if bees build any comb to store it in*, which is not always the case, as bees are loth to build comb late in the fall.

1. What is the best manner of wintering surplus queens?

2. Is box and frame honey sold by net weight, or is the weight of box or frame charged for same as honey?

3. Are hybrids from black queens as good honey gatherers as hybrids from Italian queens?

4. Has any one tried the queen nursery with a special entrance away from the main entrance to the hive? and with what success?

5. I am experimenting with a nursery on top of the hive, with special entrances to the queen cages. Has any one tried that plan? and with what success?

W. C. P.

1. We have never succeeded well in wintering surplus queens, not well enough to

give advice in the matter. All we ever brought through, except in full colonies, cost us more than their value.

2. We sell it always by gross weight, but to do this the boxes and frames must be made very light.

3. We think not.

4 & 5. We have not tried any such plans. Let those who have, report.

Will you answer through the JOURNAL these questions.

1. I have two queens that breed drones. That for the first two or three weeks their eyes are bluish white, the color of skim-milk, I never saw the like before, nor have I ever seen one word from writers, on this feature of drones. Their head is often white as well as the eyes; now if this is any mark of purity we all ought to know it as soon as possible.

2. I had a hybrid queen; her progeny were as black as any. I killed her. They built queen cells. I destroyed all, as I thought, and put in cells from a pure queen, but I had missed killing all the young queens, so one day I had the mortification of seeing a large swarm start and go to the mountains. This was a young queen not fertile. Now tell me will the swarm stay in a tree while she goes out to meet the drones? this also is a question we all ought to know. WILLIAM REYNOLDS.

Westmorland Co. Pa.

We have never seen any drones like those described. Should regard it as a freak of nature—instead of a mark of purity or impurity.

As to the young queen who went with her bees to the woods—she would probably be fertilized before reaching the tree; if not, the swarm would be affected by her uneasiness and come out when she did, flying round until she was ready to return with them.

Can bees be taken from Detroit, without honey in the hive and but little combs, and carried south to some good locality in Northern Georgia, Alabama or Mississippi—during the last half of September, and after that gather *honey and bee bread* sufficient to winter them?

Should I carry them on cars—travel with them in person—feed them, &c., on route. Please give your opinion and designate some good localities, also give address of any southern bee-keeper, and ask several to write me and send particulars.

There is no trouble in moving the bees, prepared in that way, to any point of the

country—at any season of the year ; but whether they would gather honey and be bread to winter on after arrival would depend on where you went—if they did not do it you could feed them with sugar syrup.

Will some southern bee-keepers give advice as to locality.

DEAR EDITOR :—According to promise I will let you know more of my experience about bees. When I first commenced with bees, being a professed bee-hunter, I went to the woods and found my bees, many of which went in at the root of within a few feet of the ground. I cut them off a suitable length and transferred them home and from them I obtained a good swarm. Lumber at that time being scarce I went to the linn timber and found some with small hollows and cut them suitable lengths and with thin long wedges hollowed them as thin as I wanted which should be $1\frac{1}{2}$ or 2 inches thick put on a tight head and good cap, with a few holes to communicate with the hive, and four pieces of timber nailed below, outside, for legs, to stand one or two inches from the ground, and when I had a swarm I set on the ground where it suited best, and my bees did well. As long as I used good round hives there was no trouble about wintering, and to this day I believe bees will do and winter better in a good round hive than a plank one. At the beginning of cold weather take long hay or rye straw and twist a rope and wrap your hives from bottom to top and let them stand where they summered, and I will guarantee the bees to winter without much loss. My bees have never wintered so well as in the open air in plank hives and it is essential for them to be sheltered from cold storms in plank hives.

It makes no difference how well a plank hive is made, wet and dry, cold and hot, will shrink and swell more or less, and let the cold penetrate to the bees ; and if I could easily obtain round hives, I would never put bee in any other ; for I can put frames, in round hives, with but little more trouble than square ones. For commercial bee-raisers, who want to sell bees in place of honey, artificial swarming may do, provided they can find buyers, but for those who want surplus honey, I would advise to let bees swarm themselves. They understand their necessities best ; if there is a flush honey season and fair weather, bees will always swarm in good season ; if otherwise, I would rather they would not swarm. One swarm in one season, is all I want my bees to do. If more than one swarm occurs, the old hive and second swarm, are both liable to become a prey to the moth. The only security against the moth, is the strength of the bees themselves. I have

lost no strong colonies by moths, but several weak ones. All careful bee keepers should aim to keep strong swarms ; if any are weak double them. One strong swarm, will make as much honey as two or three weak ones. A plain movable comb hive is a good thing, but an expensive, complicated hive, is what honey raisers don't want. Artificial swarms have never satisfied me, as well as natural swarms ; therefore I bid them good bye. G. TRULLINGER.

We give Mr. Trullinger's opinion of "artificial swarms," as he calls them—being always glad to give both sides of any point, but we think, if he will divide his bees judiciously, and give it a fair trial, he will come nearer agreeing with us, than he now seems to do on this point.

I have one stand of bees *numerous* and in a thriving condition. Have raised a good many young, but do not show disposition to raise young queens or make much new comb. The hive (American) being nearly full of comb which they are filling with honey. Please advise the best course to pursue and oblige

Butler Co., Kansas. C. M. HUMPHREY.

Bees will not build new comb while they have old comb to fill—they only build it when they need it.—We would, in such a case, divide the colony if early enough in the season to make it sure that both colonies would fill up for winter ;—if too late for that, let them alone.—We notice also that bees seldom swarm or make preparation to do it *while they have empty comb* ; though they often swarm when the hive is half full of comb, leaving plenty of room to build more.

We have a plant growing here called bur-weed, some call it stick-tight, which is some of the greatest honey to fallen plants in existence. It blooms from May 10th until the end of June. It makes honey of a beautiful flavor, but dark, about like buckwheat. Now if this should find room in your schedule of bee seeds ; and if you would like to invest, I can furnish it to you by the bushel. C. G. SILVER,

Mason Co., Mich.

We know that the honey from this plant is abundant, and of very choice flavor. By some it is esteemed one of the best, but we cannot advise any one to sow a weed like this, while there are other things,—like Alsike, white clover, rape, &c., that have a two-fold value.

With us, this weed is called "stick-tight." It is a great nuisance, if it does produce honey.

DEAR EDITOR:—My husband has a few stands of black bees which we manage on the old fogy plan, and I often have to hive them when he is absent. I like bees (although they sting me sometimes), so my husband has offered to give the bees to me, if I will care for them and study bee-keeping. A friend handed me the February number of your Journal to read, I am well pleased with it, and think it is just what I want.

It is a question, with the people in this country, as to whether bees do as well on a fruit farm. Some think they do better on account of so much peach and apple bloom; others think that eating so much ripe fruit is against them. Will you please give me your opinion about it? We have a large peach and apple orchard, some pears, grapes and strawberries.

MRS. D. SHELTON.

A fruit farm is one of the best places for bees. The bloom in the Spring just when they need the stimulus must counterbalance all injury from ripe fruit, of which none complain; we have never had any trouble, though always keeping bees near orchards.

DEAR EDITOR:—Enclosed please find a specimen of bees that are dying from a disease that is unknown in this vicinity; I cannot find any bee-keepers in this part of the country that know anything about it. It resembles the nit of a louse as much as anything. Whether it is a gum that they gather, or get on their feet, or a louse, or something else I cannot tell. Did you or any of your readers ever hear of such a pest. A great many bees are destroyed by it in this locality. This season has been uncommonly dry, and that may be the cause. I have 14 swarms in the Kidder compound frame hive, and every swarm is infested. All they do is to fight and carry off the diseased bee. WM. H. PAGE.

Branch Co., Mich.

We have never seen anything of the kind. If any one has noticed or heard of it, that can give any reasonable explanation, let us hear.

DEAR FRIEND:—Our only colony swarmed 15th of May; we had intended to divide them in a few days. The new swarm was very large and filled their empty hive with comb, brood and honey. In about two weeks, we then put a large honey box on the top (King's patent hive) which was also

nearly filled in about ten days, when they made a feint at swarming; came out, making a great noise, flew around, most of them lighting on a tree near by, but soon left and all went back to their old hive again.

Question. Why did they do so, and what should we have done with them? The next morning we divided them, as recommended in the April JOURNAL, only as we could not find the queen and there was no queen cell started, we put four frames of brood and honey into the empty hive, instead of two; moving the old hive to a new stand, which they soon refilled, but on examining it the other day, I found the new combs had no brood or eggs in them; nothing but honey.

Question. Is that a proof that they have no queen?

The other hive of that division is building up very slowly. I put young brood in it that they might rear themselves a queen. The hive that the swarm came out of, May 15th, we divided about two weeks afterwards, fearing they would swarm again. The hive left on the old stand is about built up, but the one we moved away is quite weak, and I think queenless. We have added young brood and empty queen cells. It looks as if a queen had hatched. How shall we strengthen it?

What shall we do to keep the bees from building crooked combs? We have waxed the frames, but for all that they will run them together. Do you know of anything that will prevent swelling from bee stings? I do not mind the hurt but I dislike the swelling, particularly when it blinds me for days. BEULAH E. BETTS.

To question first, we answer that when they swarmed and then went back, the queen for some reason could not fly. From your account of what followed, we judge that she was lost in the grass or in some other way, and that when you divided and found no queen, there was none there! Both parts therefore had to rear a queen.

As honey was being gathered fast, then, they would store a great deal before they had a young queen ready to lay, and therefore the combs would be full. We think by this time you can easily tell if they have fertile queens.

Strengthen the weak one by giving it a frame of brood, ready to hatch from one of the others.

To have combs straight it is necessary to pay attention to the hives that are building comb. Direct the bees a little by turning any piece round that inclines to be crooked.

Start them right and they keep so. When you have straight combs already, put an empty frame between two full ones, and it must be built straight. We now allow no other comb building done, except between two straight worker combs in any hive.

Cold water applied at once, will in most cases prevent swelling from bee stings. The German Bee Sting Cure, advertised, is highly recommended. After all, prevention is better than cure; and when you learn to handle bees more easily, subduing them before opening hives, you will have no trouble from stings.

I had a new swarm that came out June 14, with a queen of fine size, but it has did no good in the way of young brood. It has laid no eggs. I would like you to state the cause, and oblige,

T. H. BASKETT.

We can give no cause, and would wait no longer for her majesty, but replace her with another, or brood to rear one. As it was a natural swarm, it would seem you must have drones.

DEAR EDITOR:—I write to you to get a little information.

1. Will bees gather honey and bee-bread, and store it in the hive when they have no queen?

2. Does the queen lay according to the population of the stock?

3. When there are but few bees in the hive, and the queen two or three years old, and does not lay eggs, is it not time to have a new queen?

4. What is the best way to make bees make comb? as I see a journal says: "if any one contemplated bee-keeping, he should spend one year in raising comb, then the next year he would be prepared to make bees pay." G. D. CAPEWELL.

1. Bees will gather both pollen and honey and store it when they have no queen. At such times they accumulate much bee-bread, because that is made for and consumed by the larvæ.

2. The queen seems to lay not only in proportion to the population of the stock, but to the amount of honey they either have on hand or are gathering. They seem too wise to use up all their stores to support brood, at the risk of their own starvation. But when they have a good surplus on hand, or are bringing in freely to the hive, then the queen lays in propor-

tion to it. If there are workers enough all the eggs are cherished; if not, some are lost.

3. We would not destroy such a queen until we had given her more bees, or put her into a strong colony. Have seen a queen in a nucleus, that hardly deposited any eggs; on being removed to a full colony, make one of the most prolific queens we ever saw.

4. We know of no other way to have bees make comb, than to provide large numbers of the bees with empty space, and plenty of honey, (if they do not get it) and arrange with the "clerk of the weather" for an unusual number of hot days. The gentleman referred to should "rise and explain."

1st. What is the difference in quality, if any, in honey from flowers of a tree, and honey from the leaves of the same tree known as honey-dew?

2nd. Will an Italian queen pure in her birth—mating with a black drone, ever produce entirely black workers?

3rd. Or will a hybrid queen mating with an Italian drone produce hybrids only?

J. A. E.

1st. There is no similarity either in taste or color. Honey stored from honey dew, so far as we have seen it, is dark in color and peculiar in taste—no matter from the leaves of what tree it is gathered.

2nd. An Italian queen so mated will produce some perfect Italian workers, some with one and two bands and many genuine black workers, as black as those from any black queen.

3rd. We have seen a hybrid queen, mated with an Italian drone that produced uniformly beautiful Italian bees—we never discovered one poorly marked. This is an exception, generally, we think a hybrid queen so mated would produce all kinds of progeny.

What should be the width of a hive, from one inside to the other, to contain 9 frames, and what would be the consequence if it should be a $\frac{1}{2}$ inch or inch larger or smaller?

Mrs. G. W. CHURCH.

Thirteen inches from one inside to the other is the orthodox width to contain nine frames. If it should be half an inch smaller it would crowd the combs too much; if half an inch larger it would not matter so much, provided the frames were all kept, in the first place, adjusted to their proper distances, and the vacant space kept at one side or the other. Some bee-keepers always allow a margin in this way, to secure more care in taking out the first frame. When it is so left, care is necessary when honey is plenty, to prevent the bees filling the vacant space with comb.

Work for the Month.

Now is the time to look after surplus honey. Little or none will be stored during the remainder of the season, except where buckwheat abounds. Where there is abundance of buckwheat, it is well to empty the combs by the use of the extractor, and leave the bees to store up the buckwheat honey for themselves. They appear to like it, and to thrive on it, quite as well as on that which is more desirable for table use.

No good end is gained by leaving honey boxes in the hive after they are filled. Some think it is a protection against the moth miller, but better protection can be secured by removing them to a dry, cool cellar. Should any moth eggs hatch, the larvæ can be quickly destroyed by a dose of brimstone smoke. If boxes of honey are left in the hive, they are apt to depreciate in value, owing to their becoming dark in color, as the result of the bees running over the combs. Not infrequently,

too, the surplus honey is all carried below, to the surprise and disappointment of the overconfiding bee-keeper.

It is therefore on various accounts desirable to remove the sulphur boxes as soon as the cells are filled and sealed over.

There are several ways of doing this, but the method adopted by Captain Hetherington is as good as any, and better than some. It is as follows:—Slip two pieces of tin under the box, then remove the box with one tin, which will keep the bees in, while the other tin will keep the bees from coming up from the hive below. Now turn the box bottom up on a board and place an empty box on it, removing the tin to let the bees pass up into the empty box. Remove and treat all the full boxes in the same way, rapping on them if necessary to force the bees to go up into the empty boxes, then slip the tin under each box and place them on the hive, when both tins should be withdrawn. Any boxes in which a few bees remain may be placed in a dark room with a small window, or a tub or barrel, covered by a thin cloth, which should be occasionally turned over to allow the bees clustering on the under side to return to the hive. Paste a paper over the holes in the boxes to keep out bees, ants, or moth-millers.

There is never any difficulty about selling nice, fresh, white, virgin honey, stored in clean boxes, and look so lusciously tempting that even an ascetic might be expected to bid a liberal price for it. While broken and black looking honey goes a begging for a market, box-honey in A 1 condition is always in demand. Generally speaking, as with other products of the farm, so with this, it is well to seize the early market. But very little is gained by holding over for better prices. Often there is waste and loss as the result of delay.

When the yield of honey fails, it is well to take precautions against robbing, especially in the case of weak stocks. Contracting the entrance will usually prevent this trouble. Bees are brave defenders of their citadels, if they have a chance to resist attack. Too wide an entrance gives the advantage to an invading force. Make the entrance a Thermophylæ, and the bees will defend it valiantly and successfully,

even though the colony be not a strong one.

Stocks that have swarmed should be examined, to see if they have fertile queens. Though a sight of the queen may not be obtained, yet the presence in the hive of of eggs and larvæ may be taken as evidence that there is one. Queenless colonies should be supplied with a queen-cell at once, and, if necessary, strengthened with bees and honey. It is well to have some surplus queens on hand to give to queenless colonies, even if they are not as pure as could be wished. "Better is a living dog than a dead lion." A common stock can be Italianized another year, but an extinct stock is a dead loss.

A careful inventory should now be taken of the condition of the apiary as to stores for the coming winter. Such hives as need feeding should be marked, and preparations made to give their inmates an opportunity of laying in what additional supplies may be needed. They must be furnished with syrup or whatever food it is determined to give them, before the nights get too cool to admit of their working. To guard against robbing, which is very apt to take place during the feeding process, they should be fed in the evening, so that before morning their task of storing will be done, and no unusual stir be observed by other bees, else marauders will be attracted, battles fought, and stores pillaged. If any stocks are weak in numbers, as well as deficient in stores, feeding will have a tendency to stimulate the queen to lay, and the hives will become recruited with young bees, before winter sets in. C.

Honey Resources of the Prairie.

The question very frequently comes to us, "Can bees be kept on the virgin prairies of the West?" The impression seems to be general that away from timber there is little for bees to gather after May. This may be true in a measure; after the prairies are settled up and many cattle are kept that eat the pasture close—weeds, flowers and all. But on the new prairies there will be found most abundant bloom, all kinds of which afford honey in honey weather. Reports from those who have tried keeping bees in new sections of the West have been good, invariably. On a recent trip by stage, over a hundred miles or

more of prairie, fellow-passengers remarked "there was no chance for bees here, away from even the sight of a tree!" We called attention to the flowers on every hand, of several varieties, besides the countless acres of Golden Rod in every stage, from bud to full bloom. We did not cross one half mile of prairie that could not afford honey for 20 or 30 colonies.

In the Spring there are numerous other honey-producing flowers, giving good success throughout the season—except it may be in July.

We are of the impression that no quarter section of prairie can be found where bees may not be kept with profit by following directions often given, providing water and keeping only strong colonies.

If the country is settled up—unless clover is raised—other honey plants must be provided to take the places of those destroyed by cattle—while the prairie is new we warrant success.

The income of four or five stands of bees and the honey afforded for the family would make a most valuable addition to the comfort of the "home trade." T.

Seasonable Hints.

More of the success in wintering bees depends on their care in September than a "Novice" would easily believe. The way with many is to "guess they are all right," and let them alone, until it is too late in the season to make any changes to good advantage. As soon as frost comes the honey secretion ceases, and no more can be expected from bees for the season.

An examination of all stocks should be made before that time, as it is much easier doing it while they are still flying briskly. Some hives will be found to have a good proportion of bees and honey, and may be marked as safe for winter. Others may have bees and comb enough with scanty stores; these may profitably be fed some sugar-syrup or honey, and will then make good colonies for the winter.

If there are any hives half full of comb, and with too few bees for safety, they may be united, and two of them will make one of more value than any number of weak ones that are sure to perish during winter, unless extra pains are taken with them.

There is no trouble in uniting two or more colonies. When the bees of both are alarmed and induced to fill themselves with honey, they will unite peaceably.

Our way is: To take away the queen of one of the colonies to be united a few days before doing it; then thoroughly smoke or sprinkle the bees of both hives; select the best and

fullest combs from both, taking care to place two or more with some empty cells near the centre of the hive in which they are to remain; brush the bees from both hives before the entrance of it; put away any surplus combs for another season—and the work is done.

We do it more easily, when there is a loose bottom board to the hives, by setting the hives—first one and then another—over an empty hive; then, brushing the bees from all the combs into this empty hive, and arranging the best combs in the upper one, close all up and allow them to go up among the combs at their leisure. They will be found like one colony the next day, when the lower hive may be removed. We used to think it trouble in making bees adhere to a new location. After being united, of course, the bees of one of the hives must be in a strange spot, but we find that after such a stirring up as they get in this process, each bee seems naturally to make a new departure. T.

The committee appointed at the meeting of the North American Bee Keepers' Society to provide essays on interesting topics for the coming meeting at Pittsburg, earnestly request those who are writing such essays, or desirous of doing so, to report soon to either members of the committee. No time should be lost, as it is necessary to place the essays in the hands of the critics early in October.

There are bee-keepers in every part of the country competent to write essays full of interest and instruction. Let us hear from them. Report to either members of the committee.

N. G. MURRY, Memphis, Tenn.

E. S. TUPPER, Des Moines, Iowa.

G. S. HILL, Mt. Healthy, O.

My Straw Mats are reduced in price to \$4.00 per dozen, or 50 cents each for a less number. See advertisement. They will last many years and remain as good as new. Put them on when cold weather commences—the latter part of October—and take them off when the bees commence to gather honey, and there will be no propolis on them. The Mats are very much more convenient than cobs, leaves, &c. Sample Mats can be seen at the Chicago office of the AMERICAN BEE JOURNAL, and at the office of *Gleanings in Bee Culture*, Medina, Ohio. Mats cannot be made by the process given in the June number of *Gleanings*, that will compare in any respect with these samples. M. NEVINS.

MRS. S. E. SPAIDS, as will be seen by advertisement in another page, has removed to New York, having been burned out at the late fire in Chicago on the 14th of July. She states that she is prepared to pay cash for honey promptly.

Voices From Among the Hives.

D. A. PIKE, Maryland, writes:—"The first part of the season was good here; then it became dry, but it is now good again for honey."

"NOVICE" writes:—"Allow me to congratulate you on the consolidation of two such valuable journals as the AMERICAN BEE JOURNAL and the NATIONAL BEE JOURNAL, as our American bee literature will thus come nearer our common ground.

F. GRABBE, Wilmette, writes:—"I am glad to hear of the consolidation. The "old and reliable" AMERICAN BEE JOURNAL is conceded to be the best medium for disseminating information, contributed by the most successful and scientific bee-keepers in the world; and now with the consolidation of the NATIONAL BEE JOURNAL, will be the standard authority and CHAMPION."

DR. BAKER, of Berks County, Pa., writes that he is "very glad to learn that the old AMERICAN BEE JOURNAL is consolidated with the NATIONAL, and hopes that bee-keepers will give it that generous support that it so richly deserves."

JAS. G. TETER, Farmington, Minn., writes that "the Globe Microscope, advertised in the NATIONAL BEE JOURNAL a few times, is a fraud." We know nothing of it, but suppose it may be as he states. Due caution should always be used about such matters.

MICHAEL SORRICK, Clinton, Iowa, writes:—"Bees are doing well at present. They are gathering honey fast. The season has been fair all through. I feel glad to see the consolidation of the two Journals."

JOHN F. DIPMAN, Fremont, O., writes:—"I was glad when I noticed the consolidation of the two Journals. Bees have done well this season on Basswood, white clover being a failure, on account of dry weather."

WALTER NEWTON, Derby Line, Vt., writes:—"If it is of any interest to you to listen to our 'voice from among the hives,' permit me to say that we never have had dysentery among our bees. We winter them on their own stores, taking away their surplus in the spring. I use the Langstroth hive altogether. We pile them two hives high, in upper chambers of the house, give them plenty of air, and never have any dampness. Our old swarms refuse entirely to work in the boxes this year, so that we have to remove the frames. Our forced swarms are very heavy, with an average of 110 lb. box of frame honey. Their forage is 32 acres of alsike clover. After reading your Journal, we find we have much to learn, and intend experimenting next spring."

W. M. KELLOGG, Oneida, Ill., writes:—"I am very much pleased at the consolidation of the two great Bee Journals."

G. W. ZIMMERMAN, Napoleon, O., writes:—"Bees have done well here during the white clover and basswood bloom. They are not doing so well now. We have about 3,000 pounds of clover and basswood honey on hand, all extracted, which we are offering at 16 cents per pound."

JOSEPH JONES, Centre Co., Pa., writes:—"My bees have not done very well so far this season. Commenced with ten stocks, the season is very late and cold—June and July very dry. Increased to fifteen. No surplus honey yet. The prospects for buckwheat are good and we think we may get some surplus yet."

THOMAS G. NEWMAN,
Cedar Rapids, Iowa.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

The German Bee-Sting Cure can be obtained at this office. Sent by Express for \$1.00. It cannot be sent by mail. See notice.

Our subscribers in Europe, can now procure Postal Money Orders on Chicago. This plan of sending money is safe and economical.

FRANK SEARLES, Hadley, Will Co., Ills., has 50 swarms of Italian Bees which he will sell for \$8.00 each, in any amount, if sent for soon.

Subscribers wishing to change their post-office address, should mention their old address, as well as the one to which they wish it changed.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

We have received a Postal Order from Shanou, Wis., in an envelope containing nothing else. We do not know from whom it came, nor for what it was intended. Will some one inform us?

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c. according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. P lb.

ST. LOUIS.—Quotations from W. G. Smith 419 North Main st.

Choice white comb, 25@29c; fair to good, 16@22c. Extracted choice white clover, 16@18c. Choice basswood honey, 14@16c; fair to good, extracted, 8@12c; strained, 6@10c.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 P gal. St. Domingo, and Mexican, 90@95 P gal.

SAN FRANCISCO.—Quotations from Stearns and Smith, 423 Front st.

Our Market is weaker and stock very large. Outsiders, who do not make a business of handling honey, do not know where to sell and place it, and are selling at a sacrifice. We quote: Strained Southern Coast, at 7@10c; Comb, 12@20c; the latter figure for San Deigo, in Harbison frames.

STEARNS & SMITH.

Premium Queens.

Mrs. Tupper authorises us to say that she will still continue her offer of a tested Italian queen to be sent to anyone who procures four subscribers, and sends the names with \$8. This is a rare chance to procure a good queen at absolutely no cost, except the expenditure of time; and those acting as agents will find it easy to secure names for the consolidated JOURNAL during the approaching season of fairs and expositions. The queen will be sent promptly on receipt of names and money.

Any one ordering a Queen at the time of renewing or subscribing for the JOURNAL, will receive it and the AMERICAN BEE JOURNAL one year for \$6.

HONEY COMMISSION HOUSE.

W. M. BRACKETT.

Room 27, Tribune Building, Chicago, will take consignments of Honey and dispose of it to the best advantage, for those desiring such services, on commission. Or he is prepared to pay cash for honey on delivery.

Mr. Brackett is General Agent for the American Publishing Company in Chicago, and may be relied upon to act on the square.

AMERICAN BEE JOURNAL

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. X.

CEDAR RAPIDS, OCTOBER, 1874.

No. 10.

Correspondence.

Correspondents should write only on one side of the sheet. Their best thoughts and practical ideas are always welcome; no matter how rough, we will cheerfully "fix them up."

Kansas Association.

Transactions of the Kansas State Bee-Keepers' Association, held at Leavenworth, Kansas, Wednesday and Thursday evenings, September 9th and 10th, 1874.

WEDNESDAY EVENING SESSION.

The State Bee-Keepers' Association met at 7½ o'clock in the Mayor's office, Hon. M. A. O'Neil in the chair. The Secretary read the minutes of the last annual meeting which were approved. A committee was appointed by the chair to select subjects for discussion for Thursday evening.

The committee reported back the following which were adopted, viz:

1. Is it more profitable to keep bees for honey or to raise stock for sale?
2. How can the largest amount of surplus honey be obtained?
3. Which is the cheapest and best plan of feeding bees?
4. What is the most successful plan of wintering?
5. Can bees be wintered without bread?
6. Is a single story hive more profitable than double?
7. What is the best plan to prevent robbing?
8. The best plan to introduce infertile queens?
9. Is it profitable to keep an extract-or?

The President then read a paper entitled *The Hopes, Disappointments and Realizations of Bee-Keeping*, which touched on many points of interest.

He gave notice that an election of officers for the ensuing year would be held to-night.

Adjourned to meet again Thursday evening in the Mayor's office.

THURSDAY EVENING SESSION.

The President in the chair. The minutes of last meeting read and approved.

The special order of the evening was the discussion of subjects selected by the committee and the election of officers.

Subject: "Is it more profitable to keep bees for gathering honey or increase colonies for the purpose of making sales?"

Mr. Riling.—With me the greatest profit derived is from the sale of honey, but I am of the opinion that it depends considerably on the locality and season.

Mr. Jacot, of Douglas County.—My experience is that in my locality the profit is in the sale of bees. As the honey season does not open until the 15th or 20th of August, by that time the colonies are reduced from swarming, and consequently not in as good condition as they would otherwise have been had the honey season opened earlier, before the swarming impulse set in.

Mr. Harris.—I am unable to discover any difference.

Mr. Wolfron.—I am of the opinion that there is more profit in honey, providing we have empty combs to insert in the hive during the honey season.

O. Badders.—By a judicious management of the extracted and properly constructed hives we could obtain more profit from honey; but in my locality the two should be worked together; as the honey season opens early we can depend on honey in the spring, and after the 15th or 20th of July could divide and make sales, providing we have the Italians, as they command a higher figure than the common bee.

Hon. M. A. O'Neal.—That it was rather a difficult problem to solve, as it depended on the locality, demand and price of bees and honey.

Subject: "How can the largest amount of surplus honey be obtained?"

Mr. Riling.—Stimulate and nourish them in the spring, so as to give them a chance to increase for the basswood harvest.

A Member.—How do you prevent swarming?

Mr. Riling.—By keeping the hives cool with plenty of lower ventilation.

Hon. M. A. O'Neal.—I consider top ventilation during the summer a deceptive teaching.

O. Badders.—I am of the same opinion.

Mr. Jacot.—Considered early feeding in his locality unnecessary, as it encouraged swarming and consequently weakened the colonies so that they were not in very good condition when the honey harvest opened.

Hon. M. A. O'Neal.—I am of the same opinion; did not nourish until the middle of July, so as to have them strong for fall harvest; use the extractor.

Mr. Wolfron.—Thought that plenty of room and some empty combs were necessary to procure a good yield.

O. Badders.—Thought that we did not quite understand the size of a hive to use; considered a four thousand cubic inch hive about the right size. If properly managed, it would yield about one-third as much more as two colonies of two thousand cubic inches each.

Hon. M. A. O'Neal.—I am of the opinion that such a hive would be difficult to handle.

"What is the cheapest and best plan of wintering bees?"

Mr. King.—Have fed coffee sugar, and consider it very good. Also gave a description of feeder.

O. Badders.—I consider cream candy, inserted between the combs over the cluster, the best winter food that can be given, but think sugar syrup the best to stimulate with in the spring as the candy is a slow feeder, and does not encourage breeding fast enough in the early part of the season.

Mr. Jacot.—Have fed candy, and was astonished at the result; consider it the best winter feed that could be given, especially to colonies in a cellar or winter repository. He also gave an excellent recipe for making candy, which can be obtained by any member of the Association by addressing the secretary.

"The most successful plan of wintering."

Mr. Jacot.—I think the Quinby plan,

in the cellar, with plenty of top ventilation, the best.

Mr. Riling.—I have wintered very successfully in the cellar. To some colonies I give upward ventilation; to others only bottom ventilation; think that those ventilated only at the bottom came out of their winter quarters in the best condition, but am of the opinion that a long hive containing 5 or 6 colonies, divided by thin division boards, would be the best for out-door wintering.

Hon. M. A. O'Neil.—Have wintered on both, but am most successful with out-door wintering. Place blankets on top of the frames; fill the top boxes with hay, and place a board up in front of the hive to protect the entrance from the wind.

O. Badders.—I have wintered in a cellar very successfully, but am of the opinion that they will not increase as fast as out of doors, although a great amount of honey can be saved. I have been astonished at the result of an experiment of placing two colonies in one hive and dividing it by a wire cloth, placing the hive in a large box and packing around the hives with common print paper.

Can bees be wintered without bread or polon?

Hon. M. A. O'Neil.—I am of the opinion that they can be brought through, but would not amount to much.

Mr. Riling.—I never have had any experience in the matter, but I think it a hazardous undertaking.

O. Badders.—I am of the opinion that it could be done with success, but it depends entirely upon conditions. I think that if plenty of young bees were placed in the hive late in the fall and with a favorable early spring, so that the bees could get out to gather from maple and early bloom, so as to encourage breeding, they could be made a success.

Is a single story hive more profitable than a double?

Mr. Riling.—I always considered a two story hive with my management the best, providing the frames were shallow as they are the easiest handled and more convenient in every way, but I prefer the deep frame for rapid increase.

Hon. M. A. O'Neil.—With my experience the single chamber is the best, provided it is so constructed that the aparian could adjust it to suit the size of the swarm.

O. Badders.—I will have to acknow-

ledge that I am a convert to the Adair and Gallup theory, believing it to be the true method not to crowd the brood chamber. I have constructed a Gallup hive, and found it to do all that was claimed for it, if properly managed.

What is the best plan to prevent robbing?

Hon. M. A. O'Neil.—Wet hay thrown in front of the entrance is one of the best preventatives I have ever found.

O. Badders.—Strong colonies with entrance constructed so as to adapt them to the wants of the colony, is one of the best preventatives of moth or robber bees—that is providing the hive has a ventilator opposite the entrance 6 or 8 inches long by one deep,—also consider the small black bee the worst robber.

"The best plan to introduce unfertile queens."

Hon. M. A. O'Neil.—Cage and place in the hive, and at the end of 24 hours open the cage and place a piece of paper over the opening to allow the bees to cut through the rest.

Mr. O. Badders.—I believe in caging, but in addition would sprinkle the queen and colony with sugar syrup and peppermint mixed, then introduce her on a comb taken from the hive.

"How soon should honey be extracted after gathered."

Hon. M. A. O'Neil.—In order to have it good, it should be capped or nearly so, then immediately after extracting seal up in glass jars, in order to preserve the aroma.

The President announced that the discussion of subjects would now close, and that the next order of business would be the election of officers.

A member moved to suspend the rules, in order to add an amendment to the constitution, which was carried. The following resolutions were carried by an unanimous vote.

Resolved: That all that clause in the constitution heretofore existing in regard to the membership should be struck out, and in place thereof insert the following:

That all persons paying an initiation fee of 25 cents, and a membership fee of 25 cents a year, should be considered members in good standing.

The Association then proceeded to ballot for officers, with the following result:

President, N. Cameron, of Lawrence; Vice-President, Hon. M. A. O'Neil, of Black Jack, Douglas County; Secretary, O. Badders, of Leavenworth; As-

sistant Secretary, J. V. Randolph, of Emporia; Treasurer, J. Riling, of Leavenworth.

After a vote of thanks to the Mayor for the use of his office, and the Press for favors granted. The Association adjourned subject to the call of the Board of Directors.

O. BADDERS, Sec'y.

Hopes, Disappointments and Realization of Bee-Keepers.

A PAPER READ BEFORE THE ASSOCIATION OF THE STATE, SEPT. 9TH, '74, AT ITS ANNUAL MEETING IN LEAVENWORTH CITY, BY THE PRESIDENT OF THE ASSOCIATION.

Like almost other branches of productive industry in the west, bee-keeping is not entirely exempt from uncertainties as to results, but there is nothing to mark it as being a peculiarly uncertain branch of business.

As shown by the last annual report of the State Board of Agriculture, the whole number of colonies kept in the State on the first day of March 1873 was 14,884. No. of pounds of honey the preceeding year 135,384. No. of pounds of wax the preceeding year 3,686.

The counties in the order named reported the largest amounts of honey, viz: Leavenworth, 12,815 lbs; Jefferson, 12,611; Johnson, 11,384 lbs; Bourbon, 11,352 lbs; Atchison, 10,993 lbs; Doinphan, 9,795 lbs; Douglas, 9,384 lbs; Miami, 8,756 lbs; Jackson, 6,139 lbs; Franklin, 5,331 lbs; &c.

Although such reports are not generally very accurate yet they form a basis for calculations.

Placing the average value of honey for that year at 25 cents per pound and colonies at an average price of \$10 each we have the following estimates:

135,384 lbs honey at 25 cts.....	\$33,846
14,885 colonies at \$10.....	\$148,850
3,686 lbs wax at 25 cts.....	921

Total valuation \$183,716

In the year 1860 the number of pounds of honey reported was only 16,904 lbs. Hence it is quite evident that apiculture is rapidly growing in importance as one of the wealth and luxury-producing pursuits of the State.

So far as we have been able to learn, the past year has been an unpropitious one to bee-keepers generally, in Kansas, but in some localities bees have done very well—perhaps better than many other years. Those situated in or near large bodies of native timber and basswood groves have done the best. To determine what are the relative advantages of having apiaries situated in or near timbered districts, or on the up-lands when a good portion of the land in each year put under cultivation, is a subject worthy of consideration.

It is very evident that bees will not do well under all circumstances and in all localities, and to those who imagine that in their vicinity thousands of dollars worth of honey is annually going to waste for want of bees to collect it, we would say: be sure first that you are right and then "go ahead," otherwise if you should make much of an investment in the business and build much upon net results and large profits, you may find when too late that under the surrounding circumstances, all efforts, whether well directed or not, can only end in disaster.

But we believe that as the country gets older bee-keeping will become more certain and remunerative. A more abundant flora of other States and countries as it takes root and flourishes in soils, tempered by cultivation to its wants, along with our own indigenous varieties will furnish bees a more constant field in which to labor and will play an important part in the attainment of this result.

Too many in our state have nothing to report but their failures and the unprofitableness of the business and it would seem from this phase of the question alone, that bee-keeping is like a mirage to a thirsty man traveling on the desert who vainly follows its constantly receding form until at last he gives up from inability to proceed further. Then he arrives at the conclusion that he has been the victim of a delusion.

But there is to this, as well as to all other questions, two sides—a bright one as well as the dark one.

The present year as well as the preceeding one have been noted in the history of the State and country, dating back for the past 25 or 30 years as drouthy. The amount of rain-fall during the summer months being unpreceedently small and the evaporating power of the air being very great and continuous for a long time, the dew point being seldom reached. A consequence is, that during that time the flowers failed to furnish their ordinary amount of sweets, and the bees have had to remain idle during a time that in other years they were storing honey rapidly.

That degree of atmosphere humidity and that electrical condition of the atmosphere most favorably came to an end in our part of the State about the 20th of June, since which time the bees have done nothing; but prior to that time they did as well if not better than preceeding years.

Quite an amount of honey has been taken that was stored in the fore part of the season, and the prospects now are that bees will store enough this fall to last them through the winter, and in some localities furnish considerable surplus.

This prospect is more cheering in view of the fact that we have been visited by pests in the form of chints bugs and grasshoppers

which have made such a heavy onslaught upon vegetation that it would seem to have "played out" much of the bee pasture. But many of the plants furnishing honey in the fall months are not savory dishes to those pestiferous visitors, and hence since the heated term has come to an end the atmosphere has changed as regards the dew point the bees have again resumed their cheerful hum and returned to their natural habits of industry.

A life is made up of pleasures and sorrows; hopes and expectations; happy realizations and bitter disappointments; the bee keepers have a fair field in which to pass through all these life-phases, and to see as if in miniature the foreshadowings of all that makes life pleasurable or otherwise.

He is flushed with hopes and buoyant with expectations, as he sees in the near future the happy realizations of his dreams and very often, whether they be night or day ones, they end in happy realities and success beyond expectation. The more thorough the acquaintance with the business the more certainty there is of satisfactory results.

But very frequently, just as the prospect is brightest and most flattering, some calamity crosses his pathway and his fair fabrics totter and fall to the ground. In a great many instances the calamity with its dire consequences might have been averted.

It is the main object of such an association as this to determine what is necessary to make the business more generally successful. That many of the causes of past failures can be avoided in the future is, to our mind, apparent. A free discussion of all the known causes of past failures as well as the experiences of those who have been successful, should constitute a large part of the work of this association. In addition to this the publication of everything that will lead to the attainment of better results will place our favorite branch of business where it belongs among the leading pursuits of the State.

Bee-keepers are generally a hopeful people, but we believe that they are not prone to "hope against hope," as is sometimes the case, as manifested as an innate principle of our being.

For instance, we have seen many persons in the last stages of pulmonary consumption, and the rule has been that they were always hopeful—hopeful that some turn in the disease would prolong their life or that they would again be able to go around and attend to their affairs as they had done in the past.

But bee-keeping is not like an *ignis fatuus* that allures with false hopes and dazzles but to blind; but it has got something real tangible in its favor and will yet become a source of profit as well as pleasure to thousands more of this vast and changing west of which our own State is a fit representative. Then, as bee-keepers, let us do our duty. Let us keep up our organization, support our journals, and assist in every way in the good work, and thus not only we *ourselves* will be profited, but the State and nation will be made more prosperous and happy in consequence of our having lived and discharged our obligations to society.

For the American Bee Journal.

Bees Notes from Putnum Co., Ill.

In the spring of 1873, I lost 130 stands of bees; had fifty-five left. The loss being made up at this date, in the spring of 1874, I had 145. Now I have 283. My bees did well after May 1, 1873, so I got ninety swarms for 1873 and heavy surplus honey. In the spring of 1874, our bees came out rich and hardy. They began to make honey in April, of the best quality. They commenced swarming the 20th of May; that is, the yellow bees. The hybrids began the 10th of June, and swarmed until the 8th of July. On the 17th of June I got twenty-four swarms. They found the honey.

I live along the Illinois river bottom, where bees must do well, for they have the best of chance. They have in March the soft maple and willow. Then comes the orchards' bloom. Then the hard maple and ash, white elm and red. In May comes another willow, and quaking asp and cotton wood, which are heavy honey-producers. In June we have wild cherry, honey locust, linden and elbow bush. The 20th of July our bees have rest; no more bloom from timber, until the 11th of August. Then the wild flowers are in bloom on the bottoms. My strongest are making box honey now.

The Tulip Tree.

Since the publication of the communication in which I referred to the honey-producing qualities of the tulip tree, I have received several communications from the States and from Canada, inquiring how they may be procured, can I furnish young trees, or inform them who can, and the cost, to send cuttings by mail, etc. As I am so much indebted to the contributors of the JOURNAL who, by giving us the benefit of their experience and labor, have added so much to the cause, both of profit and interesting information, I feel it a duty and pleasure to answer communications, and give all the information I possess that may be of benefit to the fraternity; but as answering each separately takes up much time, and as there may be others who are desirous of the same information, I propose to answer all through the JOURNAL.

The tulip tree, commonly called, and in these parts, universally known as the poplar, is really not a poplar at all, though from the great height to which it grows, the large, green leaves, color and texture of the wood and general appearance, it might readily be taken for a species of poplar. In

some localities in the west it is known as white wood. The proper name is tulip tree (*Liriodendron tulipifera*), of the natural order of magnoliaceae. It is a native of the United States, and grows abundantly in the fertile soil of the Middle and South-western States, and attains a height of from 80 to 100 and 140 feet, with a stem some three feet and over in diameter. When full grown it has a grayish brown cracked bark, with many somewhat gnarled, easily broken branches; when young the bark is smooth and greenish in color, and the limbs are beautifully long and slender. The leaves are roundish, ovate, and three lobed. The flowers solitary, and at the extremities of the branchlets, and resemble tulips in size and appearance, and when first open, so filled with honey that the bees in visiting them make very little humming, as they simply alight, fill themselves and return to the hive. While the tree grows strong and rapidly, and great numbers of them come up from the seed and young roots in soil and places suited to them, yet they are very hard to propagate in nurseries, as not one seed in hundreds sprout; and it is still more difficult to grow them from cuttings. I am informed by gardeners who furnish all kinds of shade and fruit trees, that they procure them from the woods, and that they must be taken before they pass two years old, as they will not bear transplanting well after that age. The cost of procuring them here of the right age, which, of course, would be in limited numbers, would be about \$25.00 per 100, ready for shipping. Being a physician, living in the city, it is not in my line or convenient to procure them, but I would suggest to some of our southern friends that may have unusual facilities for furnishing small trees, that if they make it known through the JOURNAL they might get orders in paying numbers, and I am sure those who get them will be pleased, and greatly benefited in having both a beautiful shade and honey-producing tree. Although a native of the United States, they are found in many parts of Europe, having been introduced for a shade tree. In Britain they flower only in the southern part, therefore it is probable that in the extreme northern States, and in Canada they might fail as honey-producing trees. On the prairies of the West, once introduced, they would soon spread and become very valuable for shade and lumber, even if honey was not an object.

Some writers for the JOURNAL recommend keeping chickens about the apiary. I indorse that, for it is quite a satisfaction to see them quietly going around and under the hives, looking in every corner for worms and moth. They are also very fond of drones, and I have laughed heartily to see them trying to catch them on the wing by snapping at them; but if workers

get too thick around, they shake their heads and dodge away for fear of being stung. At the time the bees are driving out the drones, they are most attentive, and will run from one hive to another and pick up the drones that are being worried out of the hive by the workers; but I have never seen them catch or eat a worker bee, not even the cripples that are fluttering on the ground to get away from the hive. They will look at them sometimes carefully, but soon as they find they are not drones, they shake their heads and pass on, as much as to say, You will sting; I don't like you. My hives are from one foot to eighteen inches from the ground, with pieces of old boards resting on the ground and against the alighting board, and it is as the drones come rolling down these that the hens catch them.

Having been inquired of as to the price of honey here, I will state that I sell most of mine to consumers for 30 cents. Last year I could not dispose of it all that way, and sold several hundred pounds in the comb, in small frames, for 25 cents gross weight. I do not extract a great deal, but for what I do I get 30 cents from the druggists, who want it in that form, knowing it to be pure.

J. RALSTON WELLS.

For the American Bee Journal.

A Hint.

Overstocking is not as liable to occur as overloading the combs, in any hive, or apiary; let it be few in numbers, or many, it is liable to occur, and often does with a small nucleus, as well as in a doubled or trebled swarm or stock. Let a small part of the space that has been formerly occupied by the patent hive, that is seldom overstocked with any real value, be occupied in explaining why one stock is overstocked; another by its side giving the large surplus, as spoken of by the patent hive man, that does not, or cannot, say anything else but overstocking and recommending his hive; when there is location, hives, queens, bees of the different qualities and quantities, stores, too little of honey or bread, or the reverse.

Now, will that big pot hive do all the managing, to make all the conditions right for the big surplus? There never was a place seen, during a yield of honey, where bees were kept, that was overstocked with well managed stocks!! It depends on nature, controlled by the superior, and the keeper, to keep the conditions right, whether in one hive or the other.

To get honey, bees should be kept to gather it. The surplus should be kept out of the way of the earnings of the young

bees. One inch of honey stored around the brood nest, while more is to be gathered; that hive suffers for room; it makes no difference, whether there is many thousand empty cells around it, it suffers as bad as one of the large stocks, with every cell full of eggs, larva, bread, and honey.

A man that says a box hive, or bars are as good as frames, is not supposed to know how to get out the surplus honey, bee bread, eggs, brood, or the different qualities or quantities of bees, or queens; or add any one or more of the above, to make the condition right for obtaining surplus, either from the comb or in boxes, or improving the quality or quantity or stock.

J. M. MARVIN.

St. Charles, Ill.

For the American Bee Journal.

Bee-Keeping in the South.

I am pleased to see that the two important bee-journals of the United States have united, and that we are now to have one first-class paper.

I am sorry to see so few communications from the South. Most of the articles and experiments are not adapted to this locality. The difficulties in the North, and the obstacles in the way of success are no obstacles here. We have no trouble, for instance, or danger in wintering bees. We make no preparation for this. Our bees stand on their summer stands, with no change or protection, and I have not lost a swarm in thirty years. My bees frequently gather honey and pollen all winter.

I frequently receive letters making inquiries about this country as a bee country, and you will permit me to answer through your paper.

I find that the questions from different persons and different localities, amount to about the same.

1st. Is yours a good bee country?

Yes. The bees swarm well, and gather plenty of honey. I have taken from a number of hives this season one hundred pounds of box honey, and two hundred pounds extracted honey. I could have taken more with close attention.

2d. What time do bees swarm?

The last of March or first of April. The swarming season continues through April and May, if it is a good honey season. We sometimes have plenty of honey-dew in September and October, and I have had swarms in three months. We can begin to raise queens the first of March, and have them ready for sale first of April.

3d. What is your bee pasture?

Ans. Early flowers in February, from which bees gather pollen and honey; peach bloom last of February and first of March; apple, locust, and China bloom first of

April; linden, and maple, chinkopin and other trees bloom later. We have usually in April honey dew, from which our bees make honey. I have seen it so abundant as to drip from the trees. Generally found on the hickory, but at times on other trees. In some localities we have the muskete tree, producing considerable honey. The clover and buck-wheat do not grow here. The bees make honey from something all seasons, unless it is very dry or very wet.

4th. What is the price of black bees?

Ans. From two to three dollars in box hives, sometimes lower. There are plenty in the country, and any amount can be bought.

There is but little attention paid to the culture of the honey-bee. Some few Italian queens have been imported this season from A. J. Murray, of Memphis. A few are using the movable frames. I have the only honey extractor I know of, which I am using this season with great success. I am convinced this is one of the best localities for honey and rearing Italian queens to be found in the land. I am sorry your American Bee Convention meets so late in the season, as the weather is too cold for us from the extreme south at that season.

W. K. MARSHALL.

Sereveport, La.

For the American Bee Journal.
Sale of Honey.

It is very evident that the production and sale of honey as an industry in this country is still in its infancy. Nearly every staple article of food has its regular place and price in the market reports, while honey, if put down at all, will be found in the miscellaneous list, with hoop-poles, feathers, etc.

Though craved by a great majority of people, honey fails to become a staple article as a daily consumption, because it is upon the market but a comparatively short time, as a luxury, and at a high price. Furthermore the great majority of people are unacquainted with the nature of honey, and can easily be imposed upon by an adulterated mixture. This brings extracted honey into disrepute, and the consumer has to be educated in relation to its qualities and its production. At present the apiarian is striving to learn the consumers all of these facts, but instead of striving to learn those in his immediate vicinity, he too often desires to sell his barrels of honey in bulk as he would his firkins of butter, and ships it in the same manner to his commission merchant in a distant city, and in consequence generally receives an unsatisfactory price.

Now we claim that this education for the consumption of honey should commence near home, where the apiarian and the

method of production is known. Thousands of pounds could be sold in every farming community, and if a good article was sold every year his sales would increase. If the apiarian should start out among this class with a barrel of honey and exact cash, his sales would probably be slow; but let him adopt the exchange system, and take butter, eggs, etc., for pay, and his barrel would soon be empty, while the exchanged articles could be readily converted into cash. Different routes can be taken each day, and if his honey holds out, and his trips are regular, a great many will look for his appearance. Regular customers will buy their twenty-five to fifty pounds for winter use. A regular price should be extracted, a single pound should be sold for its price, and a discount be made in favor of those who purchase a quantity. If several apiaries are located near the same vicinity, one man could be kept upon the road a long time.

The general introduction of honey in this manner would suggest new uses for it in cooking and preserving of fruits. Some may object to this peddling system, but will not the difference between 15 or 16 cents, wholesale, and 20 or 25, retail, pay to put a good retail salesman on the road for several weeks?

A general introduction of honey in this manner through the rural districts would keep the market better in cities.

We are led to this course in this vicinity because in all eastern towns and cities sugared honey has been sold extensively, and anything in the form of honey in a can is looked upon as sugar syrup, sure. We trust Mrs. Spaid's, with western energy, will educate New York City in relation to this very important product, and give us a reliable market all the year round.

SCIENTIFIC.

For the American Bee Journal.
Test of Italian Purity.

Is there any fixed and certain test of Italian purity? If so what is it?

A bee-keeper of some prominence wrote me a year or two since, that he had "pure Italians" with only *two* yellow bands. He enclosed in his letter two or three such specimens of his bees. They compared favorably in color with my worst hybrids. Are such bees pure Italians?

Mr. Dadant says in the July No. of the AMERICAN BEE JOURNAL, that "even in Italy there are a few black bees among the thousands of well-marked," and he adds that this "this is not a mark of impurity." Mr. D. ought to be good authority on this point, as he has imported largely, and has had the opportunity of observing the Ital-

ian in its native land. But considering that his opinions are entitled to much credit, it is true in point of fact, that the *pure* Italian queen, *purely fertilized*, EVER produces "black" bees, either workers or queens? If this be so, then the Italian is only a mongrel species, and has no fixed marks by which it can with certainty be distinguished.

I am well aware that many imported queens, as well as many that are bred in this country and called pure, fail to duplicate themselves in their queen progeny, and produce workers of various markings. I had, until recently, in my own apiary an imported queen, one that was brought over last year by Mr. Dadant, whose worker progeny were two and three banded, and whose progeny varied from the brightest yellow to the deepest black. She was of extraordinary fecundity, yet fell far short of being what I considered a *pure Italian*. There was evidently black blood either in her own veins, or in those of the drone by which she had been fertilized. How she received this black blood in Italy is more than I can tell, but the effects of it were too plain to be mistaken.

The true characteristic or test of Italian purity, in my judgment, which is based upon close observation for several years, is the uniform and invariable showing of three yellow bands by the workers. If there is one worker in a thousand that fails to show the third band distinctly, or if there is a want of uniformity in the brightness of the bands, the mother of such workers will prove an unsafe breeder. And it would not do to trust to the appearance of old bees, or of bees after they have begun to work. It is then quite difficult to detect the impurity. The best, and in my opinion, only time when we may determine with certainty, is when the young workers are just emerging from their cells. If there is a two banded young bee on the cord it will soon be discovered; but if all the young bees are of a light milky color—none with a bluish, or dark back, and narrow light brown just behind the waist—the mother of such workers may be relied on to duplicate herself without fail in her queen progeny.

I think we may restrict the test a little further, and require it to be applied to the brood of young queens only. I have had a few queens, that, when young, produced occasionally a two banded bee, but whose workers, the second and third year, appeared to come fully up to the standard. I have tried breeding queens from such mothers, and have had to discard them as impure. I would occasionally find among their queen progeny, young queens with broad dark rings around their bodies, a very bad mark on a young queen. Such

ringed queens, if fertilized by black drones are apt to produce, more or less, black workers. My experience convinces me, that an Italian queen, whose own blood is entirely pure, will never produce a black worker, notwithstanding she may have mated with a black drone. And where an Italian queen does produce even a "few" black workers, although "the thousands" of her brood may be well marked, it may be set down that the mother of such a queen is either impure or impurely fertilized.

I am aware that the views expressed above differs from those held by several at least, of our best apiarists. It may be that I am wrong and they are right; yet I must be permitted to entertain the honest convictions of my mind, which I cannot resist until I have more and very different light on the subject. Chips From Sweet Home.

HOW TO GET THE MOST BOX HONEY.

Taking our location where we have almost a continual flow of honey from early spring till heavy frost cuts it short, we would proceed as follows: Get our hives crammed full of bees by giving no more room to the bees than they can fill; to accomplish this we use a division board and crowd one or more combs to one side, as soon as they have sufficient bees we insert an empty comb and move the partition board and continue thus to do till the hive is full of bees and combs full of brood, we then, and not till then, put on our surplus boxes. If previous to this time they gather more honey than they consumed in raising brood, we empty with the honey slinger so as to give the queen "elbow room," after our boxes have been on a month we remove them and see the condition below, if they have filled the side combs with honey, which they are apt to do, we remove them and sling the honey out, placing the empty combs in the center and those with most brood outside; give the queen room to deposit eggs; raise all the brood we can and the honey will come. The nearer the brood we put our surplus boxes the less honey will be stored below and the more in the surplus boxes.

All hives with surplus boxes or a set of frames above for slinging should be examined below once a month and in case much honey is stored there it should be slung out as it cramps the queens brood department. Many queens are called unprofitable because they have no room to deposit eggs. Keep hives strong by raising all the brood possible and the honey will be gathered.

SENDING QUEENS BY MAIL AND EXPRESS.

We have always sent our queens by mail, and expect to do so as long as Uncle Sam will permit. My reasons will be found in the difference of the following two examples. R. M. Argo sent me a queen from Lowell, Ky., a distance of 300 or 400 miles by mail which cost 4 cents, it was a week on the road. Ch. Dadant and Son sent me a queen from Hamilton, Ill., a distance of 80 miles by express to New Boston which cost 60 cents, it was over a week getting to New Boston and the express master notified me of it by mail. I had already made one trip (8 miles) for it, and the next day I got it; they were 13 days on the road. The above needs no comment. I get a different box from every breeder, weighing from half an ounce to a pound.

I will describe the box I use and the mode of putting up. The end pieces are 1 inch wide, $2\frac{1}{2}$ in. long and $\frac{3}{4}$ inch thick. Two sides are $\frac{3}{4}$ in. wide, 3 in. long and one eighth in. thick. The top and bottom are $2\frac{1}{2}$ in. wide, 3 in. long and one-eighth in. thick. We use cigar box nails, nail the two sides on the ends and then bottom, in the top put one nail in the middle of one end, which leaves it to swing open, now cut a piece of sealed honey comb 1 inch by $2\frac{1}{2}$ in. cut off the cells on one side near the base, lay this piece where the bees can clean off all the loose honey and no more, now place it in the end of your box, having the capped cells towards the inside of the box, then put in two nails through the box in the comb to prevent its moving, take the queen by the wings and slip her in the box, the cover being swung open a little, then put in 15 or 20 worker bees from the same hive and nail. Put on the sides the address with a lead pencil and a two cent stamp on the end and drop in the post office and Uncle Sam will do the rest. D. D. PALMER.

Italians vs. Black Bees.

As everybody likes to talk of themselves, and as amateur bee-keepers seem to be no exception to the rule, I will proceed to do likewise; and now as I promised in the May number of the *National*, I will give a sort of epitome of my experience, with both black and Italian bees the past summer.

I was anxious to know if this talk about the superiority of Italian bees over our blacks was *interested talk*, or a real fact; at the same time I could not believe that *all* the eminent bee-keepers of the country would so emphatically praise the Italians unless there was *some* foundation for it.

So having two Italian colonies, I bought two black colonies, and placing them side

by side, let them proceed to their level best. Previous to my purchase of the blacks (in April, I think), I had been feeding the Italians as often as the weather would allow me to open the cap of the hive (American Farmers', 12x12 inside). So I think the Italians had some the start of the blacks in that respect, though they were about equal in strength on coming out of winter quarters.

Now for the result. I divided both of the Italians and only one of the blacks, leaving the other for the surplus honey. The Italians have become as strong in numbers as the one undivided swarm of black bees, and one of them cast a natural swarm July 31st, which I wintered with a nucleus which I had started from one of the other Italians.

SUMMARY.

From two Italians I now have three very strong colonies and two average ones; total, five. From two blacks I have one average colony, and two scarcely fair ones.

As to honey, the drouth came in June and white clover was a myth, but during July and August they all held their own, gradually increasing in weight, (I have an apparatus for weighing like one suggested by Burch, I think), and since September 1st they have been carrying in "dead loads" of gold-wood and aster honey, so that I have extracted eighty pounds from the two strongest Italians, and the one strongest black colony. Further, I have been fighting the moth all summer in the two divided black colonies, while the Italians will not allow a moth to slap his villainous little pinion in sight of their hive.

I must, therefore, say that my prejudices (if you call them such), have been removed. Though I never was prejudiced against the Italians as such, but it is my nature to assist the weaker side always, and when I heard every one praising the Italians, I thought I would give the blacks an equal chance, "a fair field and no favor, and may the best bee win"; and for the future I shall pin the Ligurian colors to my sleeve and continue to say: Glorious little worker, from whom we may learn glorious things! from whom even the wise king could be instructed. Long may thy golden bands continue to flash in the sunlight of happy rural homes! Worker! with an industry that is never tiring, never ceasing; a perseverance that could teach a Hannibal lessons in persistence; a method that could teach "the art of order to a peopled kingdom"; a bravery in defense of home and kindred that even a Winkelreid could scarcely excel!

Verily, I should say: "Go to the BEE, thou sluggard, consider HER ways and be wise!"

I would like to ask some reader of the JOURNAL to describe "aster" to me.

There are fields literally covered with yellow flowers near me (Englewood, Cook county, Ill., 6½ miles south of the courthouse, Chicago). These flowers look like sunflowers in shape and color, but are from a half to three inches in diameter. My bees have been working on them since they began to blossom, about September 1st.

With a sincere wish for the prosperity of the united JOURNALS, I subscribe myself,
With respect,
P. J. COLBURN.

For the American Bee Journal.
Bees in New Zealand.

Whoever has read Cotton's "Bee Book," published in London, A. D. 1842, will remember the interesting account which he gives at the end of the book of the manner in which he packed two hives to take with him to the Pacific Island of New Zealand. His success was remarkable, when the great distance is considered—a voyage of five months. The Rev. Mr. Cotton accompanied the first Bishop of New Zealand in his missionary work, but he found time to introduce his pet bees among the islands of the Pacific, as the following account will show:

"The Rev. Richard Taylor, of New Zealand, while on a visit to England, reports that 'bees were introduced into New Zealand before Rev. Mr. Cotton's arrival, but the chief supply is derived from his stock. They are now very abundant and widely spread; in fact, the swarms which have escaped have completely stocked the woods. Bees in New Zealand work all the year, and make two kinds of honey. The spring or summer honey is liquid, the autumnal or winter honey is solid and completely crystalized. The honey is very fine, but varies in character according to the prevailing plants of the district. That of the south is in general better than that of the north, from the great abundance of plants and flowers.

"New Zealand will be a great honey country. It now sells at nine pence per pound, and soon will be less. Australia also produces some. We have a native bee which is solitary, and makes but one cell, which is in a hollow stick. Half the cell is filled with wax,* and the other half with honey."

Voice from Ontario.

Bees have done remarkably well here this summer so far, although I thought in the spring that we would get nothing, as the weather was so very unfavorable.

I had three stocks in the spring, and increased them to eight, and took nearly three hundred pounds of honey, principally extracted.

I am afraid some one will say, that fellow is going ahead too fast. Well, perhaps so, but my stocks are all very strong, and have plenty of honey. I had about empty combs enough for the whole of my increase. Some of your correspondents have been making considerable ado about an increase of four pounds of honey per day. I do not think that a very *big thing*, for I had a natural swarm on Monday afternoon, and on the Saturday following I extracted thirty-five pounds of honey from the same swarm, being at the rate of five pounds per day. Of course they had empty combs given them, and nothing to do but clean up house and go to work.

I see that Prof. A. J. Cook gives it as one of the special necessities that a new swarm should have a comb of worker brood in the hive to induce them to stay.

Now I do not wish to set myself up as an authority, but will give my experience. I have hived a great many swarms during the last seven years, and never had a swarm leave yet. I had no charm for them except nice, clean hives. I never had any trouble to get straight combs built. All the crooked combs I have seen, were attributable to the hanging of the frames in the hives. The principal trouble I find here is the wintering. Mine wintered as well as I could wish last winter, but I am already beginning to look forward with dread to the cold weather next spring. I will probably tell you how my bees have done this year, as I count the year from the first of May until May again.

For the American Bee Journal.
A Voice From the South.

The honey season in this section for this year has been an exceptionally good one—better than it has been for the past eight years. My apiary is now not a large one. I am compelled to keep it reduced to a limited number of about 12 hives, as I have but little time to devote to them on account of my occupation. I had one hive to give me four sets—(four boxes each)—16 lbs. in all, averaging 5 lbs. each, beautiful honey, during the season. The boxes being removed as fast as filled, and this, after having thrown off a fine swarm in April, the usual time of swarming; and having no unusual attention, and will go into their winter quarters with abundance of honey, as I never deprive them of honey from the main hive. I use the regular Langstroth frame hive.

A Visit to Mr. T. G. McGaw, Monmouth, Ill.

And a pleasant visit it was too, and to be placed on record in the book of memory to be recalled in after days with other recollections of our bees and bee men. I found Mr. McGaw's bee-yard by enquiring diligently, and found the bee man at his post with a bee veil tied on top of his hat in readiness for use if the war should be carried too close home, though he said he had but little use for it. I told my name and in a few minutes we were like old friends, talking of course about bees, hives, extractors, journals, and last but not least, the bee-keepers themselves.

He is a well posted bee-keeper in the broadest sense of the term, having taken his first start in bees back in Oxford, Ohio, near Rev. L. L. Langstroth, where he got his first Italian queen for a single stock of blacks, the said queen turning out to be a hybrid. There, for the first time, I saw Will. R. King's hive, the Triumph, Gal'up's and Novice's frames, with Novice's metal corners which are a good thing but costing a little too much to be used in a large apiary where cheapness is the main idea, that is 4 cents per frame.

Mr. McGaw has about 65 stocks I think, besides some he has on hand keeping for others, mostly in Langstroth hives. And by the way, he spoke about one thing in regard to getting up a "standard" frame. Why can't they who are getting this new frame into use, or trying to, take the Langstroth hive as a beginning. Just cut off the frame and run it the other way of the hive, a frame easier to handle, extractors could all be made to correspond with it, etc. See how easily the standard frame question could be settled if you but listen to our way of doing it. In the afternoon a slight shower drove us into the house and there we continued our talk of the same old subject.

I listened with interest to the account of his transactions with other bee men, those he had been to see, had sold queens to, bought queens of, etc. I think that if I were a patent bee hive man I'd give Mr. McGaw a wide berth, for he seems to have no mercy for humbugs, especially in the bee business. After the shower was over we went out to the bees again, where we spent the time in looking into and through the hives, which were crowded with honey, bees and brood, and some with nice box honey on top; inspecting the workers from imported mothers, etc. Was shown a frame he had put up for fertilizing queens in confinement, and he feels as though it would do him good if he could give the man a good licking who said queens could

be fertilized in confinement. Another one of the pet theories laid on the shelf. I did not have the honor (?) of being stung by any of Mr. McGaw's bees, though several came around us in a threatening manner and one I had to *walck* with a shingle to teach him respect to strangers.

I did not get the figures of his honey for this season, but think from what he said it has been pretty good. I brought away, as a souvenir, one of his excellent queen shipping cages, sent by mail, 1 cent postage.

Our bees are working hard yet, back-wheat most gone, but white clover re-commencing and bees working on it good, and heartsease by the acre in our corn-fields. Have had two big rains clear off with but a slight touch of frost, but are in hopes that we shall have a good honey time yet.

Observations on Wintering.

Last fall I dug a cave, or outdoor cellar, 10x14 feet, and 6 deep. Through the center was set a row of posts, and on these, and the dirt sides, rested a roof composed of poles, brush, hay, and dirt. This roof was about two feet thick, and two ventilators 4x6 inches were inserted in it, one of which reached to the floor of the cave. The doorway was large, with loose inner and outer doors, the intervening space filled with hay. In this cave thirty stands of bees were wintered from the 22d and 24th of November to the 20th and 22d of March. During the winter the temperature in the cave varied from 34 to 40 degrees. Once a week we went into the cave to see that all was right, generally raising some or all the hives to examine them. Five times, at intervals of about two weeks, fire was built in the cave, and the temperature raised to 50 or 60 degrees for a short time. Twenty-six stocks were in the Quinby hive, covered with cotton cloth, well gummed down with propolis, and with rather tight, flat roofs. To these stocks no ventilation upward was given until January 18th, when considerable upward ventilation was given, as much moisture had collected. Plenty of ventilation was given the four box hives at all times. Following Burch's suggestions, some hives were raised, on boxes, twelve inches from the shelf, some four inches, and some were set flat on the shelves.

Now for results. No signs of disease appeared in any hive, but all were bright when set out. All wintered on honey gathered in August and September, and consumed from ten to fifteen pounds per hive. Out of thirty hives nearly three quarts of bees died, but this loss was quite unevenly distributed. The box hives lost

almost none, the strongest stocks in moveable combs next least, and the weakest stocks most. Those hives raised on boxes lost more than those sitting directly on the shelves. Though it is safer to record facts than to give opinions, still I will venture one or two.

First. I think the tall upright form of the box is better adapted for wintering at a low temperature than the Quinby hive, as the bees are clustered more compactly with their stores above them, surrounded by warm air.

Second. In those hives set up on boxes, those bees which, from any cause, dropped to the bottom were chilled and lost before they could regain the cluster.

Third. For wintering at low temperature, strong colonies are safest and best.

Fourth. That Italians, being more active, are injured more by being disturbed than the blacks.

In two of my hives small patches of drone comb happened to be in the cluster, and the queens filled them with eggs, and one hive had some fine black drones on the first of April.

In conclusion, I would like to say that my cave suits me well for wintering, will hold about sixty hives, and will last several years, and the total cost, including labor, was not over twelve dollars.

P. C. TRUMAN.

For the American Bee Journal.

Philosophy and Practice in Wintering Bees.

As I have been successful in the wintering of my bees for years past, while death has blighted and destroyed thousand of colonies all over the country, and in some instances whole apiaries. I now transfer to the AMERICAN BEE JOURNAL my practice.

The philosophy of wintering bees is a right temperature of atmosphere, and a proper escape of the surplus moisture accumulating from the respiration and perspiration of the bees.

The practical feature in successfully wintering of bees, it is to pack them for winter quarters that there will be no conflict with nature's laws, or in other words, that a dry, warm temperature be secured.

How can this be done?

1. By placing the hive in a good, warm, dry cellar, or a house built exclusively for that purpose. And when deposited I always raise the lid $\frac{1}{2}$ of an inch on one side or end of the hive, partially closing the fly-hole so as to exclude mice. The mercury should range at about 45° Fahrenheit. When the proper season rolls around put them up immediately after they have flown out, or in a very few days after, and leave

them undisturbed in midnight darkness, and all will be right in the spring.

2. To secure the desired end in out door winter; if the hive is large, holding more than the requisite amount of winter stores it must be contracted to a proper size, and ventilated at the top, so as to let the surplus moisture escape and yet secure the animal heat of the bees. This is easily done. Remove the surplus frames from one side of the hive, slipping in a dividing board, filling in between it and the outer wall with leaves or straw. Cover the frames with a piece of cloth of any description, first laying a few small strips of board across the frames to give the bees a pass or passes over the tops of the frames under the cloth. Now, put the second story on and fill it with leaves, straw or some other fine warm material and place the lid on, contracting the fly hole to about one inch, and if the swarm is very strong raise the lid one-fourth inch on one side to dry up the moisture that collects rapidly on the top of the straw.

Hives should be placed near the ground and underpinned with straw, to secure the heat of the earth. Bees cannot be successfully wintered out door and empty combs prevented from moulding, where the hive is not contracted to a proper size. The arrangement is in conflict with the laws of success, and disastrous results must follow. The moisture thrown off in animal respiration is in fine particles like steam when exhaled from the lungs and never will condense into drops until it reaches a strata of atmosphere colder than the blood. When it cannot escape at the top of the hive it settles in drops at the furthest and coldest part of the hive, and when lodging on empty combs they are blighted with mildew and in a few years worthless, whereas they should last good 10 or 15 years. When the size of the hive corresponds with the size of the swarm the whole internal air of the hive is kept warm, and the particles of moisture are bourn upon the atmosphere, and condense in the top of the hive above the straw where they will never get back, leaving the bees dry and warm, in which condition cold seldom effects a good swarm.

A. SOLISBURG.

For the American Bee Journal.

A Proposition.

Would it not be well for bee-keepers of America to form clubs, or rather a joint stock company, in order to procure the best variety or varieties of the honey-bees that can be found in the old countries, by sending a competent and reliable person there to procure them? If for one would like to invest in this direction, provided others would join in sufficient numbers. I am willing to be one of twenty-five to pay one

hundred dollars each, which would make \$2,500. This sum probably would be sufficient to make the experiment. I have long been of the opinion that there are bees in the old world far superior to any that have been imported; and I hope there will be measures taken at our next annual convention, to be held at Pittsburgh, Pa., to form a company as above.

I believe if this subject was laid before the Commissioners of Agriculture at Washington they would assist in this laudable enterprise.

Ohio.

A. BENEDICT.

For the American Bee Journal.

Artificial Pasturage.

For some years past I have been giving much attention to honey-producing plants, and am constrained to believe that the catnip plant has not received the consideration that its importance justly entitles it to. For three years past I have been sowing the seed on waste places, in all directions, for the distance of a mile or more from my apiary, and I have never seen anything equal it. It commences to bloom here the last week in June, and lasts fully three months, giving a continuous yield from the time the white clover fails, till frost. It thrives in any part of our country; stands our continuous summer drouths better than any other plant, and never fails. Our bees are on it every moment of daylight there is, from one month's end to another; not even a smart rain will drive them from it. Notwithstanding it is now the driest time that has been known here for many years, the bees make a constant roaring over the little catnip field which I am cultivating. We shall plant more of it for cultivation next spring, or rather winter. January and February is the best time to sow it. Quinby says, "If there is any article that I would cultivate especially for honey, it would be catnip. I find nothing to surpass it."

M. N.

For the American Bee Journal.

Wintering Bees in Ohio.

Bees have wintered well with me this winter. I set my bees out on their summer stands the first warm day in March: I found all alive and in good condition.

Here let me say that I agree fully with Mrs. Tupper, Mr. Quinby and Mr. Dadant in regard to the loss of bees experienced by bee-keepers the winters of '71 and '72.

Permit me to relate here my own experience. The fall of '71 I had a number of small colonies that I had made quite late in the fall, and not having honey enough for wintering, I fed melted A sugar. Those that were strong enough to seal it up, win-

tered very well, but those colonies that were weak and did not seal their stores, perished with the dysentery. All bee-keepers ought to know that unevaporated, and unsealed honey will cause dysentery among bees, if they cannot get out of the hives to empty their intestines. This was the case with my bees. If I had set them out a few times for a fly-spell, they would have got along all right; but, says one, "why not leave them out all winter?" Because bees, to winter well, on their summer stands require plenty of bees, plenty of good sealed honey (or sealed sugar,) and proper ventilation. The fall of '72 my bees remained idle from the middle of July to September, and the queens did not lay to any account, for at least six weeks. So of course, nearly all the bees in the hives were old, and when buck-wheat and golden rod offered plenty of honey, the bees being no longer nurses, but honey gatherers, the hives were soon full of honey and the queens having but few empty cells, the brood was too scarce to replace the old bees, perishing every day. So when winter commenced my colonies were quite weak, and part of them perished like the others. The only way to prevent such a danger is to see that there is plenty of room in the hives, say in September, and then feed the bees, in order to have the queen laying regularly.

Last fall having profited by past experience I housed my bees in good condition the first cold snap in December. I prepared my colonies by taking off honey board, and putting on honey quilts, and then set them into my winter bee house with caps of the hives nearly closed below. The thermometer standing all winter at about 35 deg. in my winter depository.

Frederick, Ohio. LEONIDAS CARSON.

For the American Bee Journal.

How I Introduce a new Queen.

Perhaps you would like to know my plan of introducing, especially to bees that are cross, or too stubborn to receive a queen. I don't think it is new to you, but I have not seen it in the papers. I take one card of comb containing brood and honey, and all bees adhering to it. I then cut out a piece large enough to press the cage with the queen in to it in a perpendicular position; giving the queen a chance to get to the honey, and also to be among the bees and brood. Now I put them into an empty hive and add as many more bees to it, so as have plenty of bees to keep her, and shut them in. It seems that when bees are so imprisoned they soon forget all about a strange queen. In about twenty-four hours I open the hive for an hour or two, allowing some of the old bees to fly out, and after that release my new queen at once. I

find that in almost every case she is well received. I go in about half an hour to see that all is right. I now kill my old queen and leave them queenless for a few hours, or all night and let them find out that they are queenless, and then exchange places; shutting in the bees of the old colony, and opening it at intervals of half an hour or longer, according to how fast they leave for their old home. It takes several days to get all the bees back. This seems slow, but I have found it a safe plan.

My bees have been doing well till after linden harvest was over; but since that time they have not done a great deal. It seems as though they had come to a dead stop, for they don't increase in numbers, nor do they lay up stores. I am glad to learn that the two JOURNALS are consolidated, for it does one good to hear from old friends now and then. FRED BECHLY.

For the American Bee Journal.

Report from Bruce, Canada.

Last winter was very mild in the county of Bruce; and consequently the bees came out from their winter quarters in a very good condition. The spring, however, was very unfavorable. The days were clear, but the winds were cold and frosty; so that a large number of strong and healthy colonies dwindled down to mere handfuls. To bee-keepers the summer appeared long in coming; but when it really did come, it was most favorable for bees—could not be more so. From the beginning of May to the present—the end of August—the bees had but very few lost days. Blossoms of all kinds were abundant, and honey was brought in most copiously. Let me give you the yield of one Italian hive as a specimen, which was in a good condition on the 1st of May, but not extra. From it, I took three swarms, or divisions; 50½ pounds of box honey; and 82 pounds of extracted honey—making in all 132½ pounds of honey, and three hives. The parent stock, with the three young hives, now weigh an average of forty pounds each, which they are to have for winter supply. Of course some of this weight consists of bee-bread; but were I to extract all the honey they now have, as some on your side are in the habit of doing, this hive, which is situated 44½ degrees north latitude, would be among the wonders of the day. One thing, however, in favor of the young swarms, must be told: They had but little comb to make, as this was furnished them.

I see from the JOURNAL that bee-keepers are agreed respecting the cause of dysentery among bees in winter. My humble opinion is that undue excitement produces this disease among bees that have been

long confined. Bees are very sensitive, and easily excited. Too much *heat*; too much *cold*; *dampness*, or *scarcity of food* will excite them. I never yet met the disease in a hive which was freed from all these things; and it is difficult to winter a number of hives in the same building, or apartment, so as to be freed from them. For one hive may be too warm, and another beside it too cold; because the one contains nearly twice as many bees as the other. Two hives may have the same weight in the fall, and during the months of confinement the one may not consume half of its food, while the other may die of starvation; because some bees consume more food than others; and because the temperature in one hive may differ from that of another; and bees consume food according to the degree of temperature in the hive. Again, food may be in the hive, and the bees may perish from want, or by attempting to reach it. The food must be near the cluster, or the bees will get excited while selecting another place in the hive where they can reach the food; and during such excitement, or any excitement arising from any cause, dysentery is produced, and the most of the bees, if not all of them, perish.

My difficulties are connected not with the wintering of bees, but spring. Though my bees are generally confined for about five months, yet I bring them out strong and in good condition; but they are not long out when they become reduced, unknown to me and in spite of me. The colonies that have brood pretty well advanced during their confinement, do well in spring, if their queens should not die, a misfortune which very frequently meets me, and for which I can give no reason. In winding up my thoughts on these important points, for the time being, let me place my difficulties on record, and in the form of queries which may meet the eye of some who may be both able and willing to answer them through the AMERICAN BEE JOURNAL.

1st. Would it be wise, or safe to excite a colony which would be very still during its winter confinement, by feeding it, so as to cause breeding to be commenced two or three weeks before it would be taken to its summer stand?

2d. What causes so many young, and apparently healthy, queens to die in the spring?

3d. I have now a queen from an imported mother, two years old, which five times her own size of gold would not purchase; because she is the most prolific queen I ever saw. Her progeny are most beautiful in their appearance and form, extraordinary workers, and of a good disposition as ever I had; and all her queen daughters are in color and form like herself. Very near the half of the eggs laid by

this valuable queen last spring produced drones, though the eggs were deposited in worker cells; but now, and during the last two months of summer, her eggs are, and have been, all right. How is this to be accounted for? My own opinion is the following: When I first made the discovery that so many of her eggs produced drones, I concluded—though much to my grief—that my queen was getting to be an old queen. But now as she shows no signs of old age, but has all the energy and prolificness of a young queen, I am driven to another opinion, namely: That in the spring the queen's body was so small that when she was in the act of depositing her eggs in the worker cells, her body was not sufficiently compressed for the eggs to receive their vivifying influence from the spermatheca; but when the queen was more liberally fed, and her body became large, the compression was effected, so that the eggs deposited in worker cells produced workers. Is my theory correct? If not, who will explain the difficulty?

Wishing the AMERICAN BEE JOURNAL great success,

I am, yours respectfully,

Bruce, Ont.

J. ADERSON.

What Killed the Bees.

In looking over the reports of the bee disease, I am reminded of the story of two men meeting before an Inn. One on each side of the sign. One said it was black, and the other stoutly affirming it was white. After disputing over it a while they changed places, when lo! and behold they were both right, for one side was painted white and the other black.

Both cold and poor-honey may kill the bees. I will give you my reasons of the way it is done. Bees in their various tribes are the only things that live on sweets. All animals die in a short time when fed upon it exclusively. A dog fed on it will die in 20 days. Scientific analysis has shown that sugar is neither mineral, nor vegetable, but that it holds a medium ground easily changed into either, which when thus changed becomes food for vegetable, or animal life. The bee in digestion changes it to vegetable, while a little water causes fermentation, which changes it back to mineral, making it only food for plant life. Now, it is *honey* not *vinegar*, that is food for bees. Since, honey, or syrup, so readily unite with water, causing it to sour, it can be easily seen why dampness in the hive is so fatal.

I come now to consider the cause of dampness in the hive. 1. A hive left out will remain dry so long as all dampness

forms into ice. But carry it into the cellar in this condition, and the ice will melt, producing dampness that will prove fatal, while if it had been left out so ventilated as to carry off the water as it melted it would be dry and safe.

2. Close top frames, retain the moisture (in the cellar.)

3. Open top frames, closed below, retain the moisture.

4. A hole in the top with lower ventilation creating a draft, causes them to eat so much, as to pass it in a liquid form, arising in part from the dampness and stench arising from the dead bees at the bottom. Hence it will be seen that the difference in the frame makes it necessary to make a change in ventilation to keep it dry. Hence the difference in the various reports. Honey gathered late, thin and watery, will sour.

This is the other side of the sign. *Good honey kept dry and warm will winter bees every time.* But vinegar will not. Cold is the prime cause, with improper ventilation of producing dampness, which united with the honey or sugar syrup producing the mischief.

It remains now to determine how to winter bees so that they shall have good food, be kept warm and dry. Here I will simply suggest that the open top frame, covered with a quilt, *thin* enough to let the dampness escape, thick enough to stop a draft with lower ventilation, with the frames raised several inches from the bottom board in a dry cellar, kept so by a tin pipe connecting the bottom of the cellar with the stove pipe, would be in fair condition to winter if it was warm enough. I have known bees to winter in '72-3 buried 3½ feet under ground, packed in straw, *below*, at the *sides*, and top, so that the straw absorbed the *moisture*, while every body's bees died through the county. They were box hives set upon corn cobs, that is raised about one inch from the bottom board. Two three inch ventilating tubes, this secured dryness and warmth. It is no small study to learn how to ventilate so as to keep the bees dry under all circumstances in all kinds of hives.

Dr. C. M. JOSLIN.

BEE OR WASP STINGS.—Spread over the part stung, a plaster of salad oil and common salt; if oil be not at hand, the salt may be moistened with water or vinegar. Another remedy is to keep the part constantly moistened with a rag dipped in sal-volatile and cold water, as strong as can be borne without raising the skin. Another antidote is everywhere available, for it is nothing more than common soil applied to the wound. This remedy has often been tested with complete success, and can be implicitly relied upon. The soil should be wet before being applied.—*New Facts.*

CONDUCTED BY CH. DADANT & SON.

For the American Bee Journal.

How a Swarm Hangs to the Branch.

There is not a person who, when seeing a limb bending under the weight of a swarm, has not wondered how the bees that are fastened to the branch can support the weight of the swarm. The question is asked and an answer sought for, but many remain silent before that problem.

Here yet is one of those marvels that the works of nature offer in such large numbers to our admiration.

It seems, indeed, contrary to all the physical laws, that an insect be able at will, to walk or remain still on a polished surface in an upturned position.

Such is however the case with flies, for they can walk on the outside of an horizon-glass-pane.

This adhering capacity is so powerful in bees, that a swarm weighing several kilogrammes is supported by a few hundred bees who are fastened on the underside of a branch, without their being visibly tired by the weight. Nature shows us there, an application of the physical laws, the existence of which man has discovered only after many centuries of researches.

It is hardly 200 years since the discovery of the power of a void space or vacuum that is, the cessation of equilibrium in the weight of the atmosphere on a determined surface, give us the explanation of this fact. It was in 1650 that Otto of Guericke from Magdebourg invented the pneumatic machine.

But for generations, children in play have repeated too simple and conclusive experiments on the force of a vacuum. The first consists in taking a hollow key and inhaling the air that it contains, thereby holding it suspended to the tongue or lips. This play is common with school boys especially during school hours.

The second is not so easy. They take a round piece of leather a few inches in diameter and fasten a string in the center of it taking care to leave no room for air. They wet it and then press it against a heavy and flat body, such as a flat stone, then by pulling on the string they can lift the stone. How can it be done, since there is no adhering substance between the leather and the rock? The explanation is of little moment to them; that which they know is that by pulling a soft membrane from a smooth body they encounter a resistance which is capable of lifting a considerable weight. Let us suppose this leath-

er adhering to the ceiling, and it will support the same weight that it has lifted from the ground. It is exactly the same thing which takes place at the extremity of the bees legs when it fastens itself to the ceiling.

Enclose a bee in a box with transparent glass lid; then examine her with a good lens when she remains still with her claws fastened to the glass. You will see a hollow circular membrane that works exactly like the wet leather with which children play; only in a place of a string the bee has in the center a horny substance that she can draw at will, and that the weight of her body maintains in the proper position, so that she can sleep in this posture. They are like real cupping glasses, and when once stretched they adhere strongly without any exertion on the part of the bee. The heavier the bee is, the more the membrane is stretched. It explains the fact that a swarm weighing several kilogrammes, and heavy enough to bend the limb to which it is attached, adheres to the branch only by a small number of bees, who support the weight of the rest, although in a reversed position. Modern science has even calculated the weight that can be supported by a vacuum in a determined space. It amounts to 1 kilogramme and 33 grammes on a square centimeter of space. The membrane of a bee's claw enlarged 60 diameter would cover a surface of over one centimeter. Each bee having 6 claws, 10 bees would be sufficient to bear the weight of 1 kilogramme.

It is easy after that, to understand how a swarm, however heavy, can remain suspended for hours without fatigue.

DR. BOURGEOIS.

Translated from L Apiculteur, June 1874.

RAPIDITY OF BEES' FLIGHT.—Murray says that, connected with the transmigration of bees, is the question of the extent of their flight. He believes that two miles may be considered as the radius of the circle of their ordinary range, though circumstances will occasionally drive them at least a mile more. Judging from the sweep that the bees take by the side of a railroad train in motion, he should set down their pace at about thirty miles an hour.

VARIETIES OF THE BEE.—Don Felix d' Azara, a Spanish traveler, describes several species of bees found in Paraguay, South America. One is double the size of the bee of old Spain, and the smallest only one-fourth the size. But few had stings. The honey of the large bee was not good; that of another intoxicated; and another produced violent pains and convulsions, lasting sometimes thirty hours, without serious consequences.

AND Notes and Queries

"I have had two swarms, nice large ones, from my bees, at this late date, Aug. 3. What shall I do with them? Of course there is no prospect of their filling their hives. Please advise me through the JOURNAL?"
BEGINNER.

It is probable that your swarms *will* fill their hives and prepare for winter, if they are large ones as you say, though it all depends on your fall honey resources and the season. In the West, there are many localities where the best pasturage of the year, for bees, comes after the first of August. We, in our early days of bee-keeping have had swarms the latter part of August, and one year, we remember as late as the 10th of September that filled empty hives with both comb and honey, and wintered well.

In this, as in every other particular connected with bee-keeping, you must consult your own locality and also decide whether bees are more of an object to you than surplus honey. If you want an increase of stock, even if an early frost comes and your swarms do not fill their hives, you can strengthen from other colonies or feed so as to make them safe for winter.

If you do not care for more stocks, and prefer the honey, such swarms may be easily united with another colony, by following directions often given in this JOURNAL.

DEAR EDITOR:—My bee enterprise has been truly an uphill business. Last year was so rainy that no honey could be gathered. Consequently I had to feed my bees through the summer, fall, and winter. About the middle of February last, the swamp maple and the peach were in full bloom, and I flattered myself that there was a good time coming. But March set in with cold and rainy weather, which has continued so within ten days of the present time; hence slow progress has been made. About the 20th ult. the weather culminated in a four days storm of rain, wind, and lightning, which produced such a flood in this state as we have no record of since the days of Noah. The damage done to railroads, bridges, and farms, is incalculable.

I have this spring discovered a fact that

I have not seen mentioned in the books. It is this: that if a few days of cold or wet follow after forming a nucleus, and giving them brood, could they fail to raise a queen? The reason I suppose to be, that they cannot gather the proper food for her embryo majesty until the larvæ is too old for the change. During the past unsettled weather, I have had to supply a nucleus with brood comb three several times before they succeeded in raising a queen. Since the weather has been fair they succeeded in every instance with the first comb given them.

Query. Will it do to take comb frames with adhering bees, from different hives and put them together to form a new stock, or would a frame with the adhering bees be put safely into another hive to strengthen it?
J. APPLEWHITE.

You can take frames with adhering bees from different hives, putting all into a strange hive, and it is safe. Reason, bees are all away from home—all discontented and nothing to quarrel about—but if you take a frame from one hive and put it into another hive, even one containing a weak colony, and every adhering bee will be killed, unless you first seriously alarm and disturb the bees with which they are put. The best way to strengthen a weak colony from another, is to put in a comb of sealed brood, nearly ready to hatch.

DEAR EDITOR:—We have had a very good season for honey so far. I don't say this particularly to praise the season, but I notice the majority of the writers to the JOURNAL complain of a poor season every year. The spring was very backward, cold and rainy; we did not fairly get to breeding bees till June; most stocks, however, came through the spring well in this section, although many were reduced to a mere handful. Since the honey harvest opened, it has been all the apiarian could desire: bees have swarmed immoderately, black bees in box hives have swarmed 3 or 4 times each. We have had some trouble to keep down the swarming propensity in our apiary, but we have had but one that has made the second attempt. We have taken off 40 lbs. each of box honey, from several stocks. Our best stocks have put upwards of 100 lbs. each in boxes at this date; and have basswood now just opening. We would like to know if other box honey producers have the same difficulty in getting the very gentle, light colored, pure Italians to work in boxes. Our hybrids will put 100 lbs. in boxes while the pure pets are putting in 40 lbs. The pure ones are prolific, they keep their hives full

of brood, but fail to work in boxes to any satisfactory extent. We have one or two of the pure ones, out of quite a number, that have done well; but that is not enough to reclaim the race. We conclude they require black about them, to make good workers in boxes. We have queens so bright and yellow that you cannot discover any difference in color between the hip and upper part of the abdomen. When they are laying to full capacity they are prolific and very gentle; their hives are full of brood and bees, but they fail in the most essential point, that is working in boxes.

They will reproduce themselves in queen progeny, as we have bred queens from quite a number. We dislike to kill them, because we have been trying to raise such queens for 2 or 3 years, and have killed good hybrids last fall to make place for them. We think they would be just the thing for extracting honey. Would these queens, had they been fertilized by pure black drones, been worth more to us today than they are now?

The black bees have failed in my immediate neighborhood, so I have had no opportunity to try it the past year.

We believe those gentle ones are the pure Italian, and dark colored ones, that some breeders claim to be so smart, have just a dash of black mixed in; and if such is the case we can get some black drones and mix them in.

J. P. MOORE.

Binghampton, N. Y.

We have never given our Italians a chance to show what they could do in boxes until this year, because we do not believe it pays us or any bee-keeper to sell honey in the comb. This season, being sick through the best of the honey harvest, we were obliged (having no one to manage our apiary for us) to put on the boxes and let them do as they would. We certainly have no reason to complain that "Italians will not work in boxes." They have filled many for us. Let us hear from others who have tried it.

Please state whether refuse hops from a brewery are injurious to bees. There is a brewery located but $\frac{1}{4}$ of a mile from my apiary; and I see many of my bees working on them. What do they get from them?

E. RIEBSAMEN.

We do not know what they get, or if it is injurious. Who can tell?

Query. How shall I prepare sugar syrup so that it will not grain?

A. D. SEWARD.

A little good cider vinegar, say a tea cup full to a half gallon, will prevent the syrup from graining. We prefer this to cream of tartar which some use.

Can you tell me what is the method of "hooking together the frames" in the Adair Hive, and how it is done? I want to try 3 or 4 in my own apiary. If not too much trouble I should be pleased to learn the method.

W. NEWTON.

The sections and frames in Adair's hive are hooked by means of an ingenious, though simple wire clamp. It is impossible to describe it, but sections and wire, both, can be sent by mail by applying to Adair. See his advertisement.

I had a long confab with a lady, to-day, on the bee question, an idea she advanced made me think her beside herself as far as the knowledge of the bee went, she said when a bee-keeper dies, his or her bees will not prosper but die also; what do you think of it?

A. McMILLAN.

This is a very old superstition, but as foolish as false. Yet we have in this nineteenth century, in our own house, seen a woman take a candle down into the cellar among the bees, and coming up, inform us that "the bees were all right, she had told them the dear little babe was dead! They would stay contented now."

1. Will it be best to house bees during winter here, where the mercury rarely descends below zero?

2. How do you think it would do to cover the hive on its summer stand with hay or straw, so as to keep out the effect of warm sunny days?

3. How many inches should a hive contain, when the design is a plain box with upper and lower departments same size?

4. If we hang the sash across the entrance, will it give better ventilation than to hang it lengthwise.

D. A. SHELTON.

Logan Co., Ky.

1. Bees are housed to advantage even in such a climate as you describe, because it prevents their being excited by warm days and the consumption of honey is less. A friend in Kentucky writes: "My bees have been by your advice placed in a frost proof case for three winters and have paid me a hundred fold for the trouble it has cost me."

2. If you have no frost proof house or cellar they will do well on their summer

stands, if each hive is covered separately with straw or hay; the entrance being left open so that they can come out if they will. Always put a mat or bee-quilt over the frames whether left out or in.

3. 2,000 square inches inside is the right size when two apartments are to be used, one above the other.

4. We can see no difference.

I have one swarm of Italian bees in the Buckeye hive, which I have had only six weeks, being my first experience in bee-keeping. They have already filled all the combs with honey leaving no room for the queen to lay. There is plenty of sealed brood but no eggs to be seen. As I have but one swarm, I do not wish to get an extractor this season, so I wish to ask through the columns of your journal, if there is any way in which I can extract the honey from a few combs, having brood in the centre, without the use of a patent extractor.

My bees are beginning to work in the small frames for surplus, and honey seems to be abundant yet, as the bees work every day.

WINONA WASHBURN.

Big Thompson, Col.

We know of no way to extract the honey without an extractor, but you can remove one or more frames from the centre and put in empty combs if you have them; if not, empty frames.

DEAR EDITOR:—Is it natural for bees to die this time of the year? I discover when the nights are a little cool bees drop to the bottom board. Some nights quite a number die or are crippled, and during the day some came out of the hive in a crippled state, attempt to fly, but failing to raise off the ground, tumble around for a few minutes and die. What can be the cause of all this? Is it natural for them to die off in this way, this time of the season? I noticed that last season my bees died in the same way. Bees did well in this section of the country up to the 15th of July. Since that time it has been too dry. Bees are consuming more honey than they now gather. I have 84 stocks of bees, and winter in the cellar with success. Last winter I lost one out of 63. I would like to know where the Rocky Mountain bee plant can be had. I want some seed. Please answer in the next number of the JOURNAL.

Hagerstown, Ind. S. N. REPLOGLE.

We have never seen an instance of this kind and can give no information as to cause. Will some one answer who has seen it, and has a reasonable solution of

the question. You can get all necessary information about the Rocky Mountain bee plant from H. A. Terry, Crescent City, who advertises in our columns.

Flax Cultivation in Nebraska.

It was once supposed that flax would only thrive on the sea shore; and hence Holland had what may be regarded as a great monopoly in the growth of flax, and the manufacture of linens. But the plant flourishes in Nebraska; and the soil is too rich for even this exhausting crop easily to affect it. The cultivation of the crop is therefore yearly increasing—at present with a view to the oil expressed from the seed, though (as there is now no linen manufacture worthy of the name in the State,) it may be ultimately to provide fibre for the mills. Certainly the people of Nebraska may look to this conclusion; and settlers in the State ought not to forget that flax may be made a profitable crop.

At a recent meeting of the Farmers' Association, of Lancaster County, held at Lincoln, (the county-seat and capital of the State,) a discussion took place on the probabilities of a flax crop for this year, and it was stated that some Eastern gentlemen had offered to build an oil mill, if the farmers would guarantee a sufficient quantity of the raw material. The correspondent who sends this item of information in the interests of farmers moving West, says that in Ohio the flax crop used to be a most profitable one. Half bushel of seed to the acre would produce from ten to twenty bushels, worth \$1.50 per bushel. Taking the yield at ten bushels, the seed was worth \$15 per acre; and allowing \$8 per acre for expenses, (which included the delivery of the seed to the mill,) the net profit to the farmer was \$7 per acre. The straw also was worth \$6 per ton; and the yield was half a ton to the acre. Nebraska is more suitable for flax cultivation than Ohio; and farmers who migrate to this promising State, where the land is virgin, rich and cheap, may wisely keep this subject in view.

A speculative Scotch gentleman, wanting to dispose of some bees, to attract purchasers, printed the following placard: "Extensive sale of live stock, comprising not less than one hundred and four thousand head, with an unlimited right of pasturage."

REMEDY FOR BEE STINGS—A bee keeper says: "I have made one discovery, that a preparation of *Ledum palustre* (Labrador tea) homœopathically prepared, is a sovereign remedy for bee stings." But he does not tell us how to prepare it.

Voices From Among the Hives.

JOHN DIVICKEY, Aurora, Ill., writes:—"Our bees have not done quite as well as we expected this spring, on account of the drought. Although they have paid me 100 per cent. I have now 43 good swarms."

E. MANGOLD, Cincinnati, O., writes:—"Hon. ey harvest poor. In the spring of last year I lost 16 out of 36 stocks, and had the bad weather continued one week longer this spring, I might have again lost as many. I lost but one, but the rest were weak. I hope time will overcome our wintering and springing difficulties."

B. G. FORBUSH, Algona, Iowa, writes:—"This is my second season in bee-keeping—began one year ago last April with twenty swarms. Have now about seventy stands in splendid condition. Basswood season was short but rich, and now we have host of prairie flowers and buckwheat."

After twenty-five years of toil in the medical profession, 'tis a rare luxury to feel that I live at home, where my chief care and pleasure is my bees as I watch them.

'From every side, from earth and airs,

To the old man's ear sweet music comes,

As the busy millions bring their loads
Of treasure to their neat, white homes."

MYRON JOHNSON, Hamilton, Ont., writes:—"I cannot get along without the JOURNAL. I have nearly every number from 1868 to July 1874, and I find them very convenient to refer to. With us this has been a poor season. A cold, late spring, and no flowers since the 1st of August near the city. I have 54 stocks, some of which I am feeding up to the proper weight for winter."

G. T. W., writes:—"Bees doing splendid this season, what there was left. Nine-tenths of the bees in this county winter-killed, the past three winters."

MR. M. M., is a beginner with one year's experience, has only one swarm in a Langstroth hive, and has taken from it, this year, 12 boxes averaging 9 lbs. each of comb honey.

Well done for the first year of "bee-ing!"

S. W. STEVENS, Ridgefield, Conn., writes:—"The season here has 10¢ been first rate for honey, yet I have taken an average of 43 lbs. surplus to the stock, and have increased from 21 to 38 good strong stocks."

MARTIN TERRY, Mo., writes:—"I have long since known that the large wood or bald hornet destroys bees, especially in cool, damp weather. I stood by a hive the other day and saw six hornets catch as many bees and wound others."

JAS. B. WILSON, Des Moines, Iowa, writes:—"I am sorry to learn of others losing bees, in winter, and being troubled with moth worms in their hives. I have kept bees three years, and have wintered them on their summer stands, and have not lost any bees, either by freezing or disease, or been troubled by moths, in the least. I give the reason all to the kind of hive I use, I make it myself, and it is dry and warm in winter and cool in summer."

L. F. ABBOTT, Wilton, Me., writes:—"The season has been very poor for honey in this section. Spring was cold and backward, and bees swarmed but little and late. But few bees are kept in this part of the state and the increase has been less than 50 per cent. Old stocks, and first swarms issued previous to

July 20 have generally put in stores enough for wintering. What surplus honey is taken is stored in boxes. The "extractor" era not having reached here yet, think I shall make the experiment another season if the honey harvest should promise fair, provided my bees don't "go up" this winter."

IL. H. B., writes:—"I commenced the season with 46 colonies, some very weak ones, and had an increase of 80 colonies, 126 in all. That will average 75 lbs. of honey per hive. I have taken 3,500 lbs. with the extractor and 2,000 of box honey, 5,500 lbs. in all. I have sold 63 queens, 12 @ \$5 each and 51 @ \$1.50. I call this good for local trade. I have also sold 100 hives for \$1.50 each; no margins on hives. I have shipped 4,000 lbs. to Chicago. This season has been the driest ever known."

MRS. W. HARRIS, Buffalo, N. Y., writes:—"I have taken the JOURNAL ever since its first publication and cannot do without it while I am able to take care of one colony of bees. For the past 23 years I have kept bees, and my delight has been to take care of them, but age and infirmity tell me that I must soon rest from my labors, as I have already lived my appointed time (three score years and ten). During the past three years I have been disposing of my bees, thinking I would keep only a few colonies for my own family. This spring I had five colonies, and from them I have now 15 new ones, making 20. I have taken off 59 six pound boxes, and there are some 23 more that are nearly ready to take off. My health is so poor that I have never tried to use the extractor, and therefore I did not get as much honey as I should, had I used it; but I am satisfied. I was the first to use the Langstroth hive in Erie County. I have used it 19 years, and still use it. I have had other forms of hives, but the Langstroth is good enough for me. Bees have done well in this vicinity, this season. My best wishes for the lasting prosperity of the AMERICAN BEE JOURNAL."

Kansas Pacific Railway.

From Kansas City to Denver and the famous Rocky Mountain Resorts, passes through Central Kansas and all its important cities and towns; through the finest Farming and Grazing Lands in America; reaches Colorado, with its Charming Climate, its celebrated Hot, Warm and Cold Soda, Sulphur and Chalybeate Springs, Perpetual Snow-Capped Mountain Summits, 14,000 feet high; Magnificent Waterfalls and Cascades; Pleasant Days and Cool Nights. Colorado has the most desirable climate for invalids, in summer and winter, in the New World. Its climate is a sure cure for Asthma, &c., and has a wonderful effect on those predisposed to pulmonary affections. Colorado produces the finest Beef and Flour in the United States; has valuable Gold, Silver, Copper, Lead and Coal Mines; plenty of Hunting and Fishing, Fine Roads, Good Hotels, &c.

Only line running Pullman Palace Cars to Denver.

Circulars and all information cheerfully sent, by addressing General Passenger Agent Kansas Pacific Railway, Kansas City. *

A Disappointed Bee-Keeper.

A correspondent of the *New York Tribune* gives his experience in bee-keeping in the following dolorous communication:—

"Eight years since, when I began farming, deceived by the stories I had heard of the enormous profits to be made from bee-keeping, I purchased four skips of common bees of a neighbor, and three skips of Italians of Mr. Quinby, in movable comb hives. I constructed a number of Langstroth hives, and in due time divided my Italians, and as the black bees swarmed put in the new swarms into the Langstroth hives. I made a bee hat, and rolled up a quantity of tobacco in old muslin. I frequently examined the bees in the frames, by first partly stupefying them by blowing smoke from the rolled tobacco into the hives and then lifting the lids. The common hive I left alone. On the approach of winter the hives were scarcely half-filled, and

not a drop of honey was in the boxes. I made a room in the cellar, where I deposited them. The next spring all the honey was consumed, and but three living swarms were left; the combs were mouldy. At the beginning of the next winter I had four living swarms, which by purchase I increased to six. I left them on the stands all winter and in spring five weakly swarms were living. Hoping to obtain some surplus honey, I did not allow them to swarm; but not an ounce did they give me. Thus for five years I continued giving them constant attention, without receiving any surplus, and generally in the winter loosing all the increase of the swarms. That fall I had three weak swarms left, to which I applied the match, obtained a few pounds of honey, and abandoned the business in disgust. In certain favored localities bees may be profitable; but that they, on the majority of farms, can be made as profitable as certain venders of patent hives try to make us believe, I absolutely deny. Like everything else, they are attended with great risk. There is no royal road to wealth. One thing well tended is better than twenty half tended."

The above narration is a very suggestive one, and a few comments upon it may prevent others from becoming similarly disgusted with an important and profitable branch of rural industry.

In the first-place, it is a proof of reprehensible gullibility for any man to be "deceived" into bee-keeping by the lure of "enormous profits." It is only speculative lines of business that ever pay enormously, and the instances of wonderful success are the exception and not the rule. For one who makes a fortune by speculation, there are dozens if not hundreds who lose fortunes in that way. The pursuits of honest industry are worthy of being followed, if they pay fair profits on capital and labor. This they usually do. Something is hazarded in every undertaking, but as a general rule, the investment of capital and the bestowal of labor in industrial pursuits, proves remunerative. Hence men are encouraged to persevere in these directions, notwithstanding occasional and exceptional drawbacks and losses. Bee-keeping belongs to that class of human occupations which

promise fairly paying returns for the money and time embarked in them. This is the representation uniformly made of it by all intelligent and practiced apiarians, who with one voice are prepared to warn beginners against the expectation of "enormous profits."

Furthermore, bee-keeping requires to be learnt. It is both a science and an art, and no one need anticipate success in it, who does not acquire a competent knowledge of the business. The *Tribune's* correspondent does not tell us what means he took to qualify himself for the task he undertook. He bought four common hives of bees and three Italians to begin with. This was a very risky thing to do. A beginner should not attempt to manage more than one stock the first season. If he will thoroughly attend to that, and take every opportunity of making himself familiar with the habits and wants of the busy little workers, he may, by and by, venture to keep more. In bee-keeping, as in every thing else, it is well to heed the couplet:

"Little boats must keep near shore,
Larger craft may venture more."

Our disappointed apiarian does not inform us what system of management he pursued. He got a bee-hat, a very wise precaution; he smoked the bees with tobacco fumes, which was very foolish, as they stupify the bees instead of taming them; and he "lifted the lids," a necessary step in order to examine the interiors of the hives and perform the requisite operations there, but whether he did anything after the lids were lifted, and if so, what, he does not tell us. We suspect that, like many more who try bee-keeping for a little while only to abandon and speak ill of it, he supposed the bees would take care of themselves, leaving him nothing to do but watch their movements, and pocket the "enormous profits" of the business. His ignorance and incompetence are sufficiently evinced by his winter mismanagement. The bees were stowed away with a meagre supply of honey, owing probably to over-

multiplication of stocks. They do not appear to have been artificially fed, a most essential precaution when the store of food is insufficient. He had known enough to feed his stocks that first winter, they might all have been kept alive and vigorous, in which case, the second season would have had a very different record, and a prosperous apiary might have existed where now a few deserted hives, redolent of sulphur, proclaim the owner's incompetence and failure. No wonder the business was "abandoned in disgust." But the "disgust" ought to be awakened in view of the want of common-sense and practical skill painfully conspicuous throughout the whole affair. Let no one think these strictures unnecessarily severe. Only failure can be looked for under such circumstances, and it is too bad that an important industry capable of bringing in millions of national wealth every year should be brought into disrepute, by the negligence and incapacity of people who undertake a task they do not know how to perform, or as the Westerners forcibly express it, "fence in more land than they can till." We have a shrewd suspicion that our disappointed friend is inwardly conscious his failure is largely his own fault, from his concluding reflection, "one thing well tended, is better than twenty half-tended." To which we beg to add, that in agricultural pursuits twenty things well tended are twenty times better than only one thing well tended. A system of farming such as is known by the name of "mixed husbandry," includes the culture of grain, stock-raising, fruit-growing, dairying, poultry breeding, and, last but not least, bee-keeping, is in the majority of cases the wisest one to pursue. If several branches of profitable rural industry are kept going, it is not likely all will fail. The season that is bad for one branch will be good for another, and thus, from year to year, the operations of the farm will pay.

It is as well to remark, in conclusion, that all localities are not equally suit-

able for bee-keeping. We believe there are few farms on which bees, properly managed, cannot be kept with some profit, but there are neighborhoods, and multitudes of them, peculiarly suited to bees, where perhaps hardly any hives are kept. What we contend for is, that bee-keeping deserves to rank side by side with the other economies of the farm; and we maintain that while "enormous profits" are not to be expected nor cases of failure prevented, there are few investments of time, trouble and outlay that will pay better, if indeed so well, as those connected with a rightly managed apiary.

C.

Timely Suggestions.

The cold nights of this month should remind bee keepers that rugs, mats or quilts are needed on all colonies. Even the strongest are the better for this comfortable provision, and the safety of the weak ones absolutely depends on it. Examine and be sure that no hives have combs of sealed honey in the center. If there are any, an exchange may be profitably made between the empty combs of one colony and the full ones of another. The entrances of all hives may be contracted and mice absolutely shut out. Though the danger is less now than in the spring, still it is best to prevent it.

All necessary feeding must be done now, and enough may be given in two or three days to any colony to prevent starvation. We have taken a hive filled with combs without one ounce of honey, put in a good swarm of bees feed them 20 pounds of sugar syrup in three days, had it all taken into the combs and sealed over, and no colony could winter better under any circumstances than did this one. We do not advise this way, as best by any means; but suggest it as possible to those who have colonies that will starve in their present condition.

If a colony has too few *bees*, it is useless to feed it unless it be kept in a

warm place and fed regularly a small quantity at a time to keep it increasing in number. This involves trouble, and may not pay, but it can be done.

Be sure that you have a queen in each hive. It is not well to disturb bees in this month, except when they are flying freely on their own accord. Always select such days to open hives, and do it quickly as possible. The less they are disturbed, the better, after the working season is over. T.

Premiums at County Fairs.

The manner of offering and awarding premiums for bees, queens, honey, etc., etc., at some of our County Fairs is amusing to those acquainted with the business. Look at the following, for instance, which we cut from a premium list.

Best Italian queen bee, caged...	\$10 00
2d best.....	5 00
Best black queen bee, caged...	8 00
2d best.....	4 00
Best collection Italian drones, caged.....	4 00
Best collection black drones, caged.....	2 00
Best collection Italian workers..	6 00
Best collection black workers....	3 00

How much the judges can tell about a queen bee by looking at her caged, any bee man or woman can tell you. She may or may not be prolific, she may be a drone layer, (the very best looking queen we ever saw never produced a worker bee!) How are the judges to decide by her looks whether she is worth the \$10.00 premium or is one of the kind which Novice describes as dear if sold three for five cents. We have little doubt that one of the worthless ones would look better to the judges than a pure prolific imported queen.

It is often the case that a beautiful bright queen raised from a pure mother is fertilized by a black or hybrid drone, yet this does not effect her looks in the least.

Can our judges decide this matter by looking at her in a cage?

We think further comment on this

head unnecessary. The premiums usually offered for honey are generally of like character. Some who have taken no pains with their bees may have a box of honey that will please judges better than the honey on exhibition by a bee-keeper who has taken unwearied pains and succeeded in making his bees pay big profit. We have seen this.

Until some way is found to remedy this injustice there is little use in bee keepers competing for premiums, although it may, and doubtless does, pay those who wish to make sales to advertise their bees, hives or extracts by exhibiting when such advertisement is not too expensive. T.

Honey Markets.

CHICAGO.—Choice white comb honey, 28 @30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. P lb.

ST. LOUIS.—Quotations from W. G. Smith 419 North Main st.

I am overrun with inquiries for the sale of honey and asking what I will give for honey, etc., and I wish you to say through the JOURNAL for me, once for all, that I do not buy honey at all. I have sold a great deal of honey for parties where they have sent me samples and I have sold from the sample, which I will continue to do and will insure prompt payment for all honey on delivery here, and as the prices are low now I would advise patience to all who have honey to sell as the market is very dull for extracted here. Now, nice box will command 30 cents, and very good sale, and extracted slow at 12 to 16 P lb. for good to choice.

W. G. SMITH.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 P gal. St. Domingo, and Mexican, 90@95 P gal.

SAN FRANCISCO.—Quotations from Stearns and Smith, 423 Front st.

P Strained Southern Coast, at 7@10c; Comb, 12@20c; the latter figure for San Deigo, in Harbison frames.

STEARNS & SMITH.

Back Volumes.

Complete sets of back volumes are scarce. But few can be procured at any price. We have a set, consisting of the nine volumes (complete), which we offer for sale, either bound or unbound, for a reasonable sum. Many of the numbers we have paid fifty cents each for, to complete them.

We have several single volumes (complete) which we will send postpaid for \$2.00 each.

Several volumes, which lack only a single number of being complete, we will send postpaid for \$1.50 each.

Vol. 1, we can supply in cloth boards, postpaid, for \$1.25. Bound in paper covers, \$1.00, postage 10 cents. This volume is worth five times its price to any intelligent bee-keeper. It contains a full elucidation of scientific bee-keeping, including the best statement extant of the celebrated Dzierzon theory. These articles run through eight numbers, and are from the pen of the Baron of Berlepsch.

P Beginners in bee-culture, who desire to read up in the literature of bee-keeping, are earnestly advised to obtain these back volumes. Many of our best apiarians say they would not sell their back volumes of the AMERICAN BEE JOURNAL for ten times the sum they cost, if they could not replace them. They are exceedingly valuable alike to beginners and more advanced apiarians.

P We want several copies of No. 1, Vol. 2, of the AMERICAN BEE JOURNAL, and will pay 50 cents each for them.

P It will be a source of gratification to us if all those in arrears for the AMERICAN BEE JOURNAL will settle the same as soon as possible. Our increasing circulation vastly increases our regular monthly expenses for paper and printing. "A word to the wise is sufficient."

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

The postage on this paper is only twelve cents a year, if paid quarterly or yearly in advance at the post-office where received. We prepay postage to Canada, and require twelve cents extra.

P Let every one writing this office make all Postal Orders, Drafts or Checks, payable to THOMAS G. NEWMAN. Address everything of whatever nature to

THOMAS G. NEWMAN,

CEDAR RAPIDS, IOWA.

"Winter Bee-Keeping."—A New Method.

A PAPER READ BEFORE THE MICHIGAN BEE-KEEPERS' ASSOCIATION, AT KALAMAZOO, MAY 6TH, 1874.

BY H. E. BIDWELL.

When cold weather comes on in the fall, bees collect together in the hive to keep warm. As the cold increases, they pack more closely, and resort to the consumption of honey to preserve the heat. This increases the action of the respiratory organs, which exertion creates an unusual waste of the system, more than the perspiratory organs can throw off; this collects as faeces, and necessitates flying out to remove it. This waste of the system calls for the consumption of bee-bread, which contains much foreign matter, and further increases the necessity of flying out. If prevented, these accumulations clog and weaken the perspiratory organs, and sooner or later admonish the bees to leave the cluster, when they become chilled and perish. This gradually diminishes the number of the bees, so that by spring, if the colonies are not wholly reduced, they are weakened so that much valuable time is lost in regaining their strength.

If the honey is thin from the want of sufficient evaporation before sealing, or if the perspirations are not removed from the hive, as is usually the case in damp cellars or moist weather, the excretions become thin, and dysentery follows. This augments the necessity of flying out.

Having bought some bees last winter, which we were anxious to fly before putting them in the cellar, and having near at hand some empty hot-beds—which had been dug out in the fall for the purpose of filling early in the spring—we thought perhaps a swarm might fly in one; something risked, something gained; so we put one in. The beds were roomy, 6x12 feet, so that four sash 3x6 feet would cover them. The depth was about three feet, with a slope to the glass of one foot. In about twenty minutes after putting on the sash

—it being mid-day, with a clear sky—the temperature arose within to 70 degrees, and the bees commenced flying briskly and voiding freely. At night we found *every bee had returned to the hive.*

The next day being clear, we put in two more; the next four; and the next eight. These all returned so well to their respective hives, that we next put in eight more, two deep. Being so well satisfied with the result, and having six of these large hot-beds dug out, we flew 111 stocks, as occasion required, until spring.

The only caution I would suggest would be not to fly them too often, which can be readily prevented by covering the sash with boards.

Occasionally the bees will alight on the hives or collect on the glass, if the atmosphere gets hot and close within; they can easily be dispersed by sprinkling straw on the glass to shade the bees and cool off the bed. A similar occurrence frequently happens out of doors, on a warm, close day, after the bees have been confined some time in their hives; they alight on everything, and remain until cold or hunger reminds them of their home.

The advantages accruing to this method of wintering bees are—you can safely fly them at your pleasure; none are lost in the chilly winds or snow, or on the cold ground, which increases their value in our estimation two-fold.

ED. JOURNAL:—Some one asks for Mr. H. E. Bidwell's method of wintering bees, as it was given at the Michigan Bee-Keeper's Convention. The following letter was received by me just too late to be presented at the Convention.

SOUTH HAVEN, Mich. April 30th '74.

FRANK BENTON, Sec'y:—

DEAR SIR:—Please add to my remarks on wintering bees as follows;

The temperature of the beds on cloudy days, or when covered with boards on clear days, ranges from forty to fifty degrees, while on clear days with the sun-shining in, it is from seventy to eighty degrees under the glass. When the temperature is suitable outside, the sashes can be removed.

As far as my observation goes from fifteen to twenty days is often enough to fly and soon enough to go to their stores for removing honey to the clustering bees.

These facts ought not to be overlooked. Sunshine purifies the air, and exercise preserves the health of the bees.

Yours respectfully,

H. E. BIDWELL.

Mr. Bidwell certainly deserves thanks for his valuable paper and if his method should prove a success generally we are sure the bee keepers of the North will give him proper credit. We would like very well to try the experiment of wintering some bees under sash, but just now we are chuckling over the idea that we'll not be "tinkering" our pets to death in the "Sunny South." Quite comforting!

Edgefield Junction, Tenn.

FRANK BENTON.

Bee Report.

My bees have not made as much honey as in summers past, owing to the white clover being winter killed. They have swarmed more than usual and laid up winter stores, and made some honey from buckwheat and other flowers.

I have been led to ask what has caused such a mortality amongst bees the few years? Have we not varied from nature's path, in various ways? The Creator placed them in hollow trees in the forest, and this is why they incline to go there in swarming time. It seems they winter there better than in our hives. How rare is it that a tree is found with bees all dead or mouldy comb? this has led me to think that we have strayed from their original mode of living.

They have no upward ventilation, and but one place of egress and ingress, and need but little air; and had it been needful, no doubt divine wisdom would have caused it to be so, for he made all things perfect. The atmosphere is different in the forest; the sunshine does not start them out until the air is warm enough for them to fly, and when they swarm they do not go to some apiary, but look for another hollow tree in their native home. But the art of man has brought them to our doors, and now comes a change of climate. The sunshine is more severe, storms and winds much harder, and winters more blustering. This makes it necessary to vary in management.

I think now that I gave my bees too much ventilation, and shall try different ways next time; part upwards and part other ways, and see which is best; and I wish that others would do the same, some out of doors, some in the cellar. We had

better luck in old box hives, in the spring than now we have with all our improvements.

The Italian bees are making headway here and will soon be a majority.

Marcellus, N. Y.

A. WILSON.

Bee-Keepers' Meeting.

The Utah Bee-keepers' semi-annual meeting was held in the City Hall, Oct. 8th, President A. M. Musser in the chair.

Six counties, viz., Salt Lake, Davis, Utah, Juab, Iron, and Tooele, were represented.

Mr. Chas. Monk, from Utah Co., stated that he and his son had attended in his own apiary 135 stands. The average increase in honey per hive was forty pounds, valued at thirty-five cents per pound. He had owned bees five years, had the moth miller or bee moth there. But no fruit in Spanish Fork was wormy as yet.

Vice-president J. Morgan stated that the committee on correspondence had prepared each month an article for publication as requested. There was a great difference between the bee moth and the codling moth. He had taken from eleven hives 460 pounds of extracted honey and 120 pounds of capped honey, in surplus honey boxes.

Geo. Bailey, of Mill Creek, reported his bees doing well and in excellent condition for wintering. He had considerable loss last winter and spring, but had replenished his stock, and had taken 1,640 lbs. of honey. He recommended those who owned bees to take a bee journal and attend to their own bees, for it was a nice study, and all could learn a lesson from the little honey bee, who was in the United Order. It was not the bees that bred the codling moth.

Mr. Samuel McKay stated that bees in his neighborhood had not done well this season.

Mr. J. Barlow, of Davis county, said that owing to ill health he had only done tolerably well with his bees, but he could have done better. He had taken 500 lbs. of honey from thirty colonies. He recommended to sow seed for pasturage and to keep the bees as purely Italian as possible. He thought the business profitable.

D. Miller, of Farmington, said that he lost several hives last spring by a cold east wind, and that indoor wintering required considerable care and a suitable dry cellar. The white or sweet clover, was a good honey plant, especially for late honey.

Mr. C. Merkle gave his experience in bee culture.

Mr. T. D. Shodder, of Juab Co., stated that he wished to help his bees, and from four hives last spring, they had increased

to ten, and he had taken 205 lbs. of honey. He took a bee book and attended his own bees.

Mr. Rydaleh, of Toole Co., said that the disease called foul brood had been in one of his hives last spring, and in dividing and swarming, had spread it into other hives. His bees had not done well.

Mr. I. Bullock, of Provo, gave his experience with foul brood.

Doctor Crockwell recommended a solution of one ounce of carbolic acid to a gallon of water as a disinfectant for hives that had contained foul brood.

Mr. L. Root, of Iron Co., stated that his bees had done well. He had taken 150 lbs. of honey, and had doubled his stock.

Motioned that Chas. Monk be added to the publishing committee. Carried.

Motioned that Messrs. I. Bullock, J. Morgan, C. Monk, and G. Bailey prepare an article, on foul brood, for publication. Carried.

Prest. A. M. Musser stated that in the southern settlements they accused the honey bee of sucking the juice from the grape, but it was proved that the wasp or yellow jacket punctured and broke the skin of the grape, and the bees worked upon the broken fruit, but not upon the sound. He said that Mr. J. E. Johnson, of St. George, had done remarkably well with his bees in increasing of them. He urged it upon the members to be diligent, to learn all they could, and to make bee culture a successful branch of home industry.

Dismissed by J. S. Tanner. Adjourned *sine die*.

GEO. B. BAILEY, Sec. *pro tem*.

Voices From Among the Hives.

HENRY BOSSHARD, Highland, Ill., writes:—"This year, all around, the harvest in honey very rich. Spring and autumn good for our bees. Honey @ 25 cents $\frac{7}{8}$ lb easy to sell."

DAVID BROKAW, Maple Work, Wis., writes:—"I am going into the bee business quite extensively, raising queens etc. I expect the coming winter to get some new subscribers for the JOURNAL. We have mostly black bees all in old box hives, and am urged to bring a better hive and bees into this county; which I can do without patent rights. My report for this year, in short, is this: I commenced with 13 stocks last spring. Increased them to 46, now in good condition for wintering. In box honey, about 800 lbs., which has paid me about 500 per cent. I expect to transport some 20 stocks of my best Italians to my new home. My family is now there and I am

here at Oconomowoc, Oct. 26, 1874, preparing my bees for shipping. Success to you in keeping up a good Bee Journal, filled with facts and not theories merely."

S. H. BLACK, Sciota, Ill., writes:—"Bees have not done well here this season. From 40 colonies I had 7 natural swarms; the season being too poor to divide them. The white clover failed, but bees filled up from heartsease, this fall, and stored some in boxes. My bees are Italians. Black bees nearly all starved here last winter. I am well pleased to know that two of our Bee Journals have been consolidated. Will try to send you more subscribers."

E. OTIS, Batavia, Ill., writes:—"One year ago I put 50 colonies of bees in winter quarters. They all wintered well. The spring was very cold. I lost ten, and the rest were very weak. I increased them to 97, and took 2,600 lbs. of extracted honey. My bees are Italians; they are the bees. My hives were full combed."

N. D. WEST, Breakabeen, N. Y., writes:—"Bees done well in this vicinity this season. I use a hive which contains 1,740 cubic inches, inside of the frames, and like it well. I think it large enough. Is it not more profitable to use two hives this size than to use a hive twice as large, when with the small hive it gives me the most honey and swarms, and are much more convenient to handle. I winter with success in the cellar."

THOS. PIERCE, Gansevoort, N. Y., writes:—"My bees have done better the past season than for five seasons before. I started with 16 colonies. I have had over 30 natural swarms; have over 500 lbs. of box honey. I shall start this winter with 30 swarms and if they live through the winter, I hope to have a good time next season. This has been a very cool season, and very backward; but the fall has been very favorable, and my bees made over 100 lbs. of white honey. My bees are all black; I have tried Italians, without success. Success to the AMERICAN BEE JOURNAL."

WM. REYNOLDS, Lexington, Ill., writes:—"I have had from 40 to 80 colonies every season since 1868, and have lost none, except a few that were queenless in the winter of '71 and '72. Honey season in '74 very short, in consequence of the drouth, yet I obtained 953 lbs. extracted, and 250 lbs. box honey from 45 colonies, last spring, (sold 15 in May) and now have 47 in good condition to winter. I do not anticipate any loss from wintering or springing (unless queenless) at any future time, as my success, for six years past, is fully demonstrated. I do not

winter bees in the cellar, nor out of doors but in a brick house, expressly for keeping bees both summer and winter, where the mercury varies from 20 to 40 during winter. I would prefer to winter bees below than above 32, when protected from sudden changes."

N. P. ALLEN, Smith's Grove, Ky, writes:—"I send you six new subscribers with the money. I am pleased with the consolidated Bee Journal and will work for its success. Our honey harvest has been the richest we have had for years, and the cultivation of the honey bee has taken a fresh impetus, in consequence. I have an apiary of 42 Langstroth two story hives, with 20 frames. I succeeded in taking from one hive 423½ lbs. of honey, from another 365 lbs., and from 16 stands 3000 lbs.; all extracted. I have R. R. Murphys extractor it runs with ease, and I like it very much. I hope to be able to attend the Annual Meeting of the North American Bee Keepers Convention and to meet many of the prominent Apianians of the world there."

H. GOODLANDER, Leesburg, Ind, writes:—"Last April I had only one queen and 15 workers. I purchased one weak stock of black bees, put my Italian in, and I now have 13 good colonies. I have on hand 39 gallons of honey. Shall winter on summer stands this winter. The hives placed in a box, filled with saw dust; entrance open and free. My reasons for so doing is to try to spring them better."

If Mr. Replogle will send me his address, I can give him some Rocky Mountain seed.

NORTH AMERICAN BEE-KEEPERS' SOCIETY.

OFFICERS: Seth Hoagland, Mercer, Pa., President; Abner J. Pope, Indianapolis, Secretary; J. S. Hill, Mt. Healthy, O., Treasurer; D. L. Adair, Hawesville, Ky., Cor. Secretary. With one Vice President in each State, Territory and Province.

The payment of \$1.00, annually, entitles to Membership, and a copy of the Transactions, when published.

The Fourth Annual Session of this Society will be held in Pittsburgh, Pa., in the Hall of the GERMANIA SAVINGS BANK building, 4th floor, corner of Wood and Diamond streets, on the

Second Wednesday of November

next, (11th day,) at 10 o'clock, A. M., to continue three days.

HOTEL ARRANGEMENTS.

We have arranged with the following Hotels to entertain members of the N. A. B. K. Society at the prices named, which is from 50 to 75 cents per day below their regular terms:

ST. CHARLES HOTEL, corner of Wood and Third streets, *Harry Shirts* proprietor, will charge \$2.50 per day. Can entertain seventy-five persons.

ST. CLAIR HOTEL, corner of Penn and Sixth streets, *J. N. Anderson*, proprietor. Can accommodate 100 members at \$2.00 per day, or \$1.50 to those taking rooms with two beds.

HARE'S HOTEL, on Liberty street, near St. Clair. *Samuel Hare*, proprietor. Can keep 100 members at \$1.50 per day. This is a regular Farmers' Hotel. Mr. Hare has stabling for 100 horses, and can accommodate those who come with teams.

MANSON HOUSE, No. 344 Liberty street, *G. Bennett*, proprietor. Terms to members, \$1.50 per day. Can keep sixty. This house is situated near the Union R. R. Depot.

CENTRAL HOTEL, on Smithfield street, between 2d and 3d avenues. *J. G. Barr & Son*, proprietors. Will entertain forty members, at \$2.50 per day.

RAILROAD ARRANGEMENTS.

Arrangements with the following named Railroads have been made, and orders received to procure tickets to pass persons who wish to attend the meeting, to and from, at usual excursion rates. They are signed by the Superintendents of the roads, and require the ticket agent at all the stations on the roads, to sell to persons who present them, a ticket to attend the meeting at usual excursion rates. Within the coming ten days, one of these orders will be sent to each of the old members, as well as all others who are known to contemplate attending the meeting. Those wishing to attend, who do not receive orders by the 1st of November, will notify the undersigned by letter, when a Ticket Order will be promptly forwarded:

Pennsylvania Railroad.

Philadelphia & Erie.

Northern Central.

Erie & Pittsburgh.

Allegheny Valley.

Pittsburgh, Cincinnati & St. Louis, including Indianapolis, State Line and Chicago on the West, and Cincinnati and Dayton on the South, and all points between those places and Pittsburgh on the line of these roads as far as and including Steubenville on the East.

Cleveland & Pittsburgh.

Baltimore & Ohio.

Pittsburgh & McConnelsville.

Negotiations are making with other Railroads to obtain similar grants, with an expectation that they will be conceded. Those sending for Ticket Orders will please name the roads they wish to travel over to Pittsburgh.

All persons interested in Bee Culture, and those wishing to become so, including ladies, are invited to attend this meeting. Able speakers will be present, and animated discussions will be had on practical Bee-Keeping.

Those having valuable improvements in Bee-hive, Honey or Wax extractor, or any other improvement in Bee-culture are invited to bring them along for exhibition, as a room is provided for the safe keeping of such articles in connection with the Hall, and an opportunity will be given to show them.

The entrance to the Hall on days of meetings will be marked by a display of Honey and the Stars and Stripes.

SETH HOAGLAND, President,

N. Am. Beekeepers, Society.

Mercer, Pa., P. O. Box 167.

Oct. 17th, 1874.

For the American Bee Journal,
Pink-Blossomed Milk Weed.

In "Notes and Queries" in your JOURNAL of September, W. M. Page, of Branch county, Mich., wants you to tell him what is the matter with his bees. My explanation to him is this: It is caused by work on the large Pink-Blossomed Milk Weed, growing on wet ground or sides of ditches in wet marshes. I have cut down acres of this weed in August last. His bees are not fighting; only carrying from the hive, bees that are affected by working on this milk weed, with their feet gummed up from the sticky substance, and pollen of this weed. It seems impossible for the workers to remove this from their feet. The workers will carry them out as often as they attempt to enter the hive. Finally you find them lying around on the ground with their feet stuck together, and the bees dead. It yields a large amount of honey, and bees will go miles to work on it. Many bees are found sticking fast to the blossoms. My stocks were suffering badly from work on this weed. I hunted out its location, and cut down all of it within two miles of me, and the cure was complete for this year. It is in full blow here from the 25th of July to the middle of August.

For the American Bee Journal,
Bees Swarming.

Why do bees go to the woods when they swarm? This question has been asked by several, in the BEE JOURNAL, and answered by others; but my views are different from most of them in some respects. There are many kinds of bees created, and the Creator has given them the faculty to perpetuate their race. He has provided them a home according to their need. Some, it is said, live in the ground, but those amongst us, the Creator placed in the forest. He caused trees to leave hollow places in them for a home, and he has caused some kinds of trees to have gum issue from them for the bees to obtain it and wax the inside of their homes; and endowed them with the instinct to build one kind of comb for raising drones; another for worker bees; another for raising queens, and another for storing honey, and has caused trees and vegetation to produce honey and pollen for their food; and after they have increased and become numerous, He has given them the inclination to divide, and the signal is given for a part to leave. It is supposed that the queen gives the orders, but how many are to go, no man can tell, until after they leave; but it is

evident that a certain number are called, and they take a portion of honey and pollen to eat on the way, and until they have a home of their own. Of those that are to remain, a part are in the field and a part are at home taking care of the young. Those that leave, go to another tree and form another colony.

The art of man has brought them to our doors, and it would seem that they were intended for our use, for they often lay up more than they need for their own use, and the overplus can be taken away; and when they swarm, there is no confusion or disorganization about it. The Creator has ordered that a part should leave and form a new colony, and they leave in regular order, according to the instinct given them; and if not hived in regular order, they go to the forest, their original home, where the Creator first placed them. This is why they go to the woods when they swarm.

My bees have swarmed plentifully, but have made but little box honey, owing to the scarcity of white clover.

Marcellus, N. Y. A. WILSON.

♦ ♦ ♦ ♦ ♦
Honey Men of Oneida, Ill.

Several of the bee-keepers of Oneida clubbed together, and sent to Wisconsin, by I. W. Cramer and bought eight bushels of buckwheat, which they gave to Mr. Dater, who sowed nine acres of ground with it, just east of town. It has been in bloom for some time, and consequently there is a lively time just now among our bee-keepers. There are two honey extracting machines in town, W. M. Kellogg's and I. W. Cramer's, which throw the honey out of the comb, leaving bee-bread, etc., in the comb and returning it to be filled again by the bees. Following is a list of the bee-keepers, number and style of hives, and amount of honey taken for the week ending Sept. 12, 1874.

By W. M. Kellogg, for P. Mohler, 7 Kellogg's Improved Langstroth hives, 176 lbs.; Dr. D. W. C. Bacon, 4 Langstroth hives, 70 lbs.; A. S. Curtis, 3 I. W. Cramer's hives, 42 lbs.; Dr. D. D. Martin, 2 Cramer hives, 20 lbs.; E. J. Peterson, 1 Kellogg hive, 40½ lbs.; D. Hamilton, 2 each Kellogg and Cramer hives, 45 lbs., and at Kellogg's own yard, 7 hives, 245 lbs. By I. W. Cramer, for T. Parsons, 2 Cramer hives, 36½ lbs., and at Cramer's own yard, 200 lbs., 12 hives. Mr. Cramer has run his yard more for queens than for honey. If we are favored with the continued fine weather, the yield of honey will be doubled. 875 lbs. of honey at 20 cents per lb., is the snug little sum of \$175, for one week's work with the little stingers.—*Galesburg Reporter.*

For the American Bee Journal.

A Visit at Sweet Home, and What I Saw There.

Sweet Home is located in Illinois, county of Mercer, twelve miles south of Muscatine, and seven miles north of New Boston. The Apiarian is a man of about twenty-five or thirty years old, weighing about 140 pounds, and in opinions either religious or hygiene, is radical. We were a little surprised to find the family consisting of only two, Mr. Palmer and an active boy, of two years old, both of whom are very fond of honey. They can eat $1\frac{1}{2}$ lbs. per day. He calls the boy Honey. Why? Because that's his name.

Mr. Palmer's house is quite peculiar and handy. The observing hive we would never tire of looking at. For a young man, he has quite a collection of books and a cabinet of specimens of various kinds. He is making bees and fruit his business. The bee pasturage of Sweet Home consists of (before August) lynn, white clover and a variety of minor sources. About the first of August or the middle of July his bees roam the Mississippi bottom, which is four miles wide and twenty miles long. In autumn it is one bed of flowers. Sweet Home being on the bluff over-looking the bottom, is well situated for both up-land and bottom range. Up to this time (Aug. 10th), his bees have been idle only three days this season. His apiary at present consists of 75 hives, in Longstroth and Thomas' hives; being an increase of 40 hives, and has about 1,200 pounds of slung honey and 400 pounds of box honey. He thinks by time of frost that he will double that amount of honey, and increase to 100 hives.

He increases as follows: He raises his queens from the best queen; he puts his queen cells in a nursery until hatched; then as soon as out of cell (he examines twice a day), he introduces by putting in honey a few hours after forming. To start a hive, he takes two combs of brood *cutting out*, with adhering bees, and puts in the hive next to one side, then puts a division board close against them. As soon as the young queen is fertile, and has supplied the two combs with eggs, he puts in two combs, one empty and one of cutting brood. This he repeats once in three to six days, owing to the weather and strength of colony.

He, like others, has been trying to raise queens from eggs sent him by mail; he got some of Dadant's imported stock, and succeeded in getting two queens, after five days on the road. He tried eggs from "Novice's" queen, but failed.

He keeps a record of his hives on *slates*

about $2\frac{1}{2} \times 3$ inches. Take common school slates and cut each in six to twelve pieces, according to size; cut by straight-edge and any sharp instrument; drill a hole with a pod bit, and hang on a nail; drive the nail a little downward, so that winds will not blow the slates off; write with a slate-pencil, and it will be plain for a long time. To erase such writing, it is necessary to use water and friction, so storms will not affect it.

He told me of one of his neighbors having a swarm of bees hang on a tree for seven days, when they were taken down and put in a hive, and are now at work.

ON THE WING.

For the American Bee Journal.

My Italian Bee Experience.

Bees have done well here this season; I think the best in twenty years that I have kept them. I wish to tell my experience with Italian bees.

Seeing an advertisement in the JOURNAL, I sent the price for two; they came all right, and were introduced to two of my best stocks. Then I commenced feeding them, it being very dry here. One of them commenced laying, and in about four weeks they had brood flying. She was a hybrid, having bees from no bands to three. She died in the hive in February, leaving a fair swarm, which I put with the other one. They did not raise a bee till March; I watched them with much interest. They soon had them capped, some cells being longer than others, all mixed under the brood. They hatched out in due time a fine lot of little drones as ever need to be. That queen could not keep the colony up; she died or was displaced by the bees in July. I wrote the man, I think, in April, sending the price of another, and asking him to replace one of them. He wrote me back, saying he would send them as soon as he could raise them. I waited till August, then I wrote to know why he had not sent them. He returned no answer, but sent a dark colored queen, which I introduced to a black swarm. She raised a mixed brood. Drones are black. I have three queens raised by her; they are black now. I call that a black queen fertilized by an Italian drone. Now if those are Mr. Alley's best queens, how long would it take to Italianize an Apiary? My loss by the transaction is, two good swarms; two queens, at \$4.00, and one at \$2.25. The last one was very prolific; she filled two hives with brood, then led off a swarm. I filled the second hive with comb.

My best wishes for the consolidated JOURNAL.

C. A. SARGENT.

South New Berlin, N. Y.

The Folk-Lore of Bees.

This subject is far from being exhausted by the interesting paper which appeared in the *Gardeners' Chronicle* for June 20, and it seems worth while to supplement it by a few additional details, which I find entered from various sources in my "folk-lore" note-book. It seems to me that "J. F. R.," is a little too severe upon superstitions, which, although "foolish and ridiculous" from a strictly common-sense point of view, are at any rate harmless in themselves, and which doubtless have their bearing, even if we do not at present see how, upon the former history of the ethnology of Great Britain. However, my object is rather to add fresh matter than to criticize, so I will not dwell further upon this point.

A mediæval tradition regarding bees may worthily occupy a foremost rank in our list, as it is still current in Cornwall, and has been elegantly versified by the Rev. R. S. Hawker, vicar of Morwenstown. This tells us how a woman, finding that her bees did not thrive, obtained a consecrated Host and placed it among them, having been told that by this means they would be rendered more fruitful; and so it proved. The bees thrived apace, and when the woman in due course went to take the honey, she found in the hive "a chapel built by the bees, with an altar in it, the walls adorned by marvellous skill of architecture, with windows conveniently set in their places; also a door and a steeple with bells. And the Host being laid upon the altar, the bees making a sweet noise, flew round about it." This legend, in various forms and with different details, appears to have been very popular, and is found in various religious works as late as the seventeenth century.

The notion that bees will not thrive if purchased is prevalent not only in many English counties, but also in France, and I notice that the French bee superstitions generally correspond very closely with those of England. A hive of bees may, however, be exchanged for another object; just as in Cornwall they are transferred from one owner to another with the tacit understanding that a bushel of corn or in other places a small pig (which is fair equivalent) is to be given in return. Both French and English bees are so possessed with the spirit of honesty that they will not thrive if stolen; indeed, the French bees will find their way back to their lawful owner. So discriminating are they, that should they come in the possession of a person of bad reputation, they will desert their hives and seek a more worthy master.

The very general English custom of

announcing a death to the bees, likewise prevails in some parts of France. The announcement of death in many English villages, and even in the classic town of Oxford, is, or was, made by tapping three times on the hives with the house-key, saying at the same time, "Bees, bees, bees, your master is dead, and you must work for—" the future owner. Nor is this all; for the bees are also invited to the funeral, at least in the Sheffield district; and it is considered that they will die should this compliment be omitted. In Devonshire, too, a correspondent of *Notes and Queries* says: "I once knew an apprentice boy sent back by the funeral cortege by the nurse, to tell the bees of it, as it had been forgotten. They usually put some wine and honey for them before the hive on that day." Another funeral bee custom, formerly very general in Devonshire, was that of turning round the hives belonging to the deceased at the moment when the corpse was taken out of the house. It is a sign of death not only when bees settle on "dead wood," but also when they desert their hives and die; and in Cumberland if they rise and do not stay during a critical illness, it is a certain indication of death.

Bees have a great aversion to quarrelling, especially between man and wife, but in some parts of France are supposed to attack those who swear, and on this account children are warned not to use "bad words" near a bee-hive. They also understand what is said to them, and are not slow to avenge any insults offered to them. It is a mediæval superstition that bees would not live in Ireland; and another tradition of the same period tells us that a sorcerer, if he should eat a queen bee, would be impervious to any torture which might be practiced upon him. A humble bee in the house denotes the approaching visit of a stranger. In the east of England, if a red-tailed bee enters the house, the stranger will be a man, if a white-tailed a woman. The entrance of a humble bee into a cottage is sometimes regarded as a sign of death. The value of a May swarm is referred to by Tusser, who says:

"Take heed to thy bees that are ready to swarm.
The loss thereof now is a crown's worth of harm."

In Warwickshire the first swarm of bees is simply called a swarm; the second one from the same hive is known as a cast; while the third is termed a spindle. In Hampshire it is a common saying that bees are idle or unfortunate at their work whenever there are wars. Borlase says that "the Cornish to this day invoke the spirit Brownyn when their bees swarm, and think that their crying

Brown, will prevent their returning into their former hive, and make them pitch and form a new colony." This use of the word "brown" may, however, be no invocation of a spirit, but simply an apostrophe addressed to the bees; just as in Buckinghamshire the death of the master of the house is announced to the hives in the words: "Little brown, little brown, your master's dead."

When bees stay about near the hive it is regarded, and rightly, as a sign of rain; this generally diffused notion is given by Virgil in the *Georgics*; and hence there is a proverb, "a bee was never caught in a shower." When many bees enter the hive, and none leave it, it is also a sign of rain. They were formerly used in medicine, as we learn from Purchas' Theatre of Political Flying Insects (1657) where we are told that "bees powdered cure the wind collick. Take 12 to 14 bees powdered in anything every morning," etc.

B. M., in *Gardeners' Chronicle*.

For the American Bee Journal.

Changing the Pasture of Bees.

The practice of moving bees for the purpose of obtaining a succession of forage, is not confined to Egypt. It was the practice in Italy in Pliny's time. He says: "As soon as the spring food for bees has failed in the valleys, near our towns, the hives are put into boats and carried up the river in the night, in search of better pasture. The bees go, and return to the boats, regularly. This is continued till the sinking of the boats to a certain depth shows that the hives are full enough, when they are carried back home and the honey taken from them."

This practice is still followed on the river Po, the same stream Pliny spoke of. Bees were also transported from Achaia to Attica, from Euboea to Scyros, and from Sicily to Hybla, for the same purpose. In Scotland, bees are moved to localities where they can gather the honey of the *heather* when it is in bloom. In California, bees are sent up the Sacramento to get a succession of bloom, and in France hives are carried in carts from one section to another. Thirty to forty hives are placed on one wagon. If the weather is very hot the wagons move only in the night, and they move slowly, always choosing the smoothest roads. Sometimes, says the author of *Natural History*, ten or a dozen wagons thus loaded with hives, may be seen at once, in company.

Much has been said and written about how far bees will fly, and the number of trips they make, etc. Reaumer says if the total number of excursions be divided by total number of bees in each hive, the

average would be five or six. But says another—half of the bees are employed at home, so that the average number of excursions will be ten or twelve; and if the average length of each excursion is one mile, each bee would fly twenty or twenty-four miles, daily. Kity says that the quantity of matter thus transported exceeds a hundred pounds. E. A.

For the American Bee Journal.

Answer to Mr. Bird.

I notice in your August number, a very unjust complaint from a Wm. W. Bird, in which he complains that he shipped a bbl. of honey to the Chicago Honey House, and we would not buy it, and asks who are the staunch men that he can ship honey to and get speedy returns. The facts in that case are these: Mr. B. wrote to the Chicago Honey House, saying he had a barrel of nice honey, and asked what I would give for it; and I answered that I was paying 15 cents for good—or that I would pay 15 cents, if good—I am not sure which, as my copy book is burned, but could not have made any other kind of an answer without knowing what the honey was. As soon as I examined the honey, I found it was very dark, vile stuff, made from fire-weed, such as I could not use at any price, and immediately wrote him, requesting him to direct me to turn it over to some other person, which he did. I turned over the honey to the party named, instead of using it and then forcing him to take its value and giving him cause to complain. I think Mr. Bird will not find any party "staunch" enough to suit his manner of doing business.

MRS. S. E. SPAIDR.

The Bee in Southern California.

The home of the bee is in the mountains. There they seem to thrive, and ranging over the great surface common to all the choicest flowers, immense quantities of honey are gathered by the industrious workers. There is little difference between San Diego and Los Angeles, as far as the prosperity of the bee is concerned, but undoubtedly the above named places—especially the mountain regions—are not surpassed by any locality on the globe for successful bee culture. As the invalid comes here he cannot turn his attention to a lighter and more remunerative vocation. While the vast amount of honey is yearly going to waste, let us endeavour to furnish the means to collect this precious substance and turn to account what otherwise would be lost, and thus be numbered among the list of public benefactors. A. H. ARNOLD.

Size of Entrance Holes to Hives.

The honey-bee has, on each hind leg, a spoon-shaped cavity, studded around by stiff hairs, in which it packs the pollen and propolis—the hairs holding the pellets in place when clasped down on them. The leaf-cutter bee gathers and carries pollen also, but has no such baskets on its legs. It has a mass of stiff hairs on the under side of its tail, among which it fastens the load. Here we see the same end accomplished by different means, and it requires but little observation to see why. The leaf-cutter bee has to pass through a round tunnel or gallery but little larger than its body. If it should attempt to do so with the pollen mass on its thighs, as the honey-bee carries it, it could not do it without pulling off its load. Consequently it does not impede the passage.

The honey-bee ordinarily in its wild state inhabits hollow trees, the entrances to which are either through long slits or large holes, through which it has ample room to pass, without brushing off the pellets that stick out from its sides. A worker-bee can pass through a hole three-sixteenths of an inch high, but in passing through a round hole of that diameter the pollen would be dislodged. A drone requires a hole nearly one-quarter of an inch in diameter to pass through, so that in making entrance holes to hives it is evident they should be at least one-quarter of an inch high to allow drones, as well as queens and workers, to pass; but they should not be any higher, if we expect to exclude mice, humble bees, hornets and others enemies of the bee larger than they are.

Now, if the bee carry its load behind it as the leaf-cutter does, a round hole one-fourth of an inch in diameter would be large enough, but the load on each side sticks out from its sides, so that more room must be given laterally, even for the passage of a single bee at a time—but, as during active working, there is a constant flow of passing bees, it must be much wider. I find the width should be at least three inches.

But a single hole is not sufficient, even of that width, on account of their peculiar manner of ventilation, by which they are enabled to keep up a constant circulation of fresh air through the hive and regulate the temperature. There should be two such holes at least 4 or 5 inches apart, but on the same side of the hive. All other openings should be closed tight. If thus arranged, the left hand hole will be used for ventilation, and the other for the passage of most of the bees.

Query: Why do bees always use the left hand hole for ventilation? L. F.

For the American Bee Journal.

A New Idea Hive.

In the way of a novelty, we have a swarm of bees in the top of the First Presbyterian Church. Those familiar with Cincinnati will remember it as being surmounted with a hand, the index finger of pointing above, and in this metal hand is the hive, 285 feet high, being one of the highest steeples in the country. They were discovered by accident a few weeks ago. No one knows how long they have been there. They may be new comers; it may have been their home for years. It is so high that we have to use a glass in order to see them. We shall watch for them next spring with a good deal of curiosity. If bees can winter up there, and in a metal hive, too, it will be a wonder. I am giving my bees their fall examination now, preparatory to going into winter quarters. I have no doubt a good many bee-keepers throughout the country tried the mats last winter. It would be interesting to hear the experience of some of them; it is a grand success with us.

R. L. CURRY.

Cost of Fencing in the United States. —Economy in Nebraska.

The heaviest item of expense in farming—the heaviest, considering the profit accruing, is probably that of fencing. In many cases fences cost more than the lands. The fences of the country are valued \$1,800,000,000; and year by year, nearly \$100,000,000 are expended to keep the fencing efficient. In Illinois not less than \$2,000,000 have been invested in fencing; and not less than \$175,000 are annually expended to keep these “metes and bounds” in repair. If stringent fencing laws had not been adopted in the State of Nebraska, the settlement of the country would have been much retarded. But a law adapted to the needs of the country has been wisely adopted. This law relieves the settler, at the time when he needs all his money for other improvements, for the necessity of investing a large sum in the construction of lumber fences. The law throws upon every owner of live-stock, the onus of keeping his stock from straying on the cultivated lands of his neighbors. The farmer need not build fences around his cultivated fields, for horses, cattle and sheep are “fenced out” by law. The stock when pastured have to be herded; but the cost of herding is not a tithe of what fencing would be. Fencing goes on, of course, in Nebraska; but it is live and not dead fences which are constructed. All through

the settled portions of the State hedge rows are appearing, and thriving. The hedge plants most used are the honey locust, the osage orange and the white willow. In some places long hedge-rows of peach trees, from which, frequently, good crops are gathered, may be seen; and the peach seems to make as good a fence as the white willow.—*Correspondent.*

For the American Bee Journal.

Bee-Keeping in General.

For years I have had a desire to engage in the bee business, and now have fully determined to do so, next spring, if I can find a suitable location.

I lately made a visit to Mr. Hosmer, who has a large apiary, only a little distance in the country. After some desultory conversation, we sallied out to the apiary, and sat down at the side, or rear of the hives to watch the "little busy bee," while Mr. Hosmer gave me much valuable instruction.

Mr. Hosmer evidently understands the honey bee, and how to make the most out of its labor. He took out the frames, one after another, from a number of hives, to show me the honey comb in all conditions, and answered my various questions. In this way we spent about three hours, and at the close of the interview I felt that I had learned something about bees, and how to keep them.

I should have said that Mr. Hosmer uses but a trifle of smoke, and his bees seem to understand it as well as he does. He holds the smoke on the wind side, and lets it strike across the top of the frames, after taking off the top cover, and the bees, which were on the top, would immediately go inside, and the rest would seem to be paying little or no attention to being handled about and set outside for a time, and then put back, and all the time keep at work.

Mr. Hosmer is not working his apiary so much for large quantities of honey, as for increasing his bees and raising Italian queens, the present season.

This has been a good season for bees in these parts. Mr. Durkey and Mr. Dolley, of this town, are among the foremost of bee-keepers, and appear to be meeting with success.

I saw by the August number of THE JOURNAL, that Mrs. M's little child got stung with bees. Oh, how I pitied that dear little thing, when I read about it, and to think how much it must have suffered, gives me an uneasy feeling even now; and then I thought how easy it would have been for that mother to have given her little one immediate relief, if

she had only been prepared, and had known just what to do.

Now, although I don't give this recipe to the public, for the present, yet for the benefit of Mrs. M., I will send it to her, for it will do a great deal to disarm any one of that nervous fear, to know that they have something at hand that is effectual in killing the virus of the bee-sting.

If Mrs. W. M. will send to a Drug Store and obtain a vial filled with pure Spirits of Turpentine, (not Benzine, which is a cheap preparation, and sometimes sold for Spirits of Turpentine) and keep it ready for use, and in case of a sting, first see that the sting is all removed; then drop on the fluid as fast as it is absorbed and taken into the circulation for a short time, and then a palet of cotton may be laid on to the place and kept well supplied with the remedy, and in ten or fifteen minutes the pain will be gone. I have found nothing equal to this, and in no case can it do any harm.

Minneapolis, Minn. R. D. BUCHANAN.

For the American Bee Journal.

Handling and Quieting Bees.

Many persons say to me, and I've no doubt others who have read my articles say, you speak about bees as if they did not sting, and oftentimes the results are bad. Of course bees will sting, but if properly handled, will not sting at all, though some persons say that if they go within one hundred feet of a hive they will be stung. When they say that, I feel like telling them that their habits are bad. Bees dislike bad odors, especially whisky and tobacco, and when such persons visit my apiary, I first give them a veil to put on, and warn them to keep their hands in their pockets, for I know they will be stung. The most successful bee-keepers are men of good habits, for they can go among their bees at all times without fear of stings. Ladies are very successful bee-keepers, for they have no bad habits, except a few who will soil their mouths with filthy snuff—a habit more repulsive than tobacco-chewing in men—as they are the purer sex, we expect to see all things pure about them.

Bees, before swarming, fill themselves with honey to carry to their new homes, for the purpose of making comb, and while thus filling, they are very good natured, and seldom sting without they are hurt. We can take them down from their swarming place, turn them over, and hunt for the queen, or perform any operation we wish. When thus filled with honey or syrup, they are quiet, and this is the whole secret of the charms, secrets, &c., of bee-charmers.

Many years ago, a celebrated bee-

charmer in London, exhibited his prowess before the king—carrying bees in his hat, breast, and having them to swarm on his hand and arms; bees flying away and returning to his hand. The secret was this: he knew the bees would always stay with the queen; he had her caged, and wherever he placed her the bees would remain. He fed them on sugar syrup. He was considered a charmed person. He died keeping his secret, though by discoveries since his charms have been found, as the same can be done at the present day, and has been done at some of the county fairs, and seems wonderful to the unknowing ones. The whole art of taming bees is in the following:

“A honey bee, filled with liquid sweets, will not sting of its own accord. Bees, when frightened, will generally fill themselves with honey, and if given liquid sweets will invariably accept them. Bees may be frightened thus: by blowing upon them the smoke of buffalo chips, (dried cow manure), punk, tobacco, or cotton rags. By confining them to the hive and rapping the sides of it lightly with a small stick; at first the bees will try to get out, but finding that impossible, (first closing the entrance), they will rush to their stores and fill themselves with honey.” (Hamlin). And when this is done, you can do anything with them. Before opening a hive, blow smoke in at the entrance, to alarm them, and in a few minutes they are as good natured as a man after a good dinner. During Spring and summer, bees are less irritable than in the fall. If they are rich in stores they are harder to control; and also on cloudy days. When handling bees, always select a clear, sunny day; always use care; make no quick motions; and if the bees rush out on you, stand still; don't fight them, as they are very pugilistic, and will always strike back. Beginners, I would advise to have a veil made of black bobinet, fastened around the hat and on the shoulders. The rim of the hat keeps it away from the face. The black bobinet, unlike the white, does not tire the eyes, and interferes but little with the sight. With the above hints, no one need fear to perform any of the operations I have already spoken of.

A. J. MURRAY.

Michigan Bee-Keepers' Association.

The seventh annual session of this Association will be held in Kalamazoo, Mich., on the 16th and 17th of December, 1874. This Association has long been favorably known for the practical character of its proceedings; and arrangements are being perfected which will render the coming session fully equal to

its predecessors. Kalamazoo is one of the finest villages in the U. S.—is easily accessible by rail from all portions of the country, while ample arrangements have been made for the free entertainment of all apiculturists in attendance from abroad.

We trust that every Michigan bee-keeper, who takes an interest in improved bee culture, will be present, and endeavor to make the coming session mutually interesting and instructive; while we extend a hearty, cordial invitation to those residing in adjoining States to meet with us.

HERBERT A. BURCH, Sec. *pro tem*.
South Haven, Mich.

Bees and Orchard Houses.

A Scottish gardener of Berwickshire, Scotland, practices this novel but entirely practical method of securing a good set of peaches in the orchard house under his control. The method of course may be applied to the fructification of any fruit under artificial cultivation by means of glass:—“Into his early house, as soon as the flower-buds begin to open he introduces a “skep” of bees, and although they are in a semi-dormant state, the heat of the house soon brings them into activity, and in a very short time they are all over the house, and the result is generally a first-rate set. In looking over the trees a short time ago, it would be difficult to point out one that had missed. In giving air, care must be taken to have the opening covered with netting, to prevent the escape of the bees.”

For the American Bee Journal.

Reports from Northern Kentucky.

The weather has been very dry and hot the past summer in this section. The honey harvest closed July 4th, since that date bees have done very little at honey gathering, and consequently, but little at brood raising. From July 4th to 20th no eggs were laid in my hives, a few from July 20th till Aug. 10th when egg laying stopped again, was resumed for a few days early in September but the weather continued so dry that very few eggs were to be found Sept. 20th. Honey was very abundant in May and June and of fine quality. Dr. Martin extracted from two colonies, black bees, 380 lbs. Mr. Culbertson from 10 colonies mostly hybrids in spring, got 850 lbs. extracted, 100 lbs. box honey and 4 swarms. Pelham & Cobb transferred 10 colonies in spring, 700 lbs. and doubled the number of colonies. In my own apiary we started with 16 colonies, blacks, extracted 1350 lbs., took 75 lbs. frame honey,

bought 13 colonies in frame hives and one box hive colony, July 20th, and now have 50 colonies in the yard.

The 14 colonies purchased July 20th were, except two, Italians and hybrids. During the summer while the blacks were doing almost nothing, the Italians and hybrids filled up with honey and brood, and, Aug. 12th or 15th, began to swarm. One swarm left the hive, clustered on a tree for a few minutes and left for parts unknown all before nine o'clock A. M. They were first cross hybrids.

Having tried a number of bee-sting remedies with little or no effect, I at last found that tobacco soaked in whisky would, if applied immediately, stop the pain in 20 seconds and in most cases prevent swelling. A half-ounce vial half full of tobacco and then filled up with whisky, is handy to carry in the pocket during the working season. In my case the pain and swelling are worse just in proportion to the length of time elapsing before the remedy is applied. My neighbor Mr. Cobb, on the other hand, can take 50 or 100 stings and enjoy the fun, feeling no ill effects whatever.

Maysville, Ky. Wm. C. PELHAM.

For the American Bee Journal.
Over-stocking.

A few more weeks will conclude my 84th year; and my efforts, for my own interests or the interests of others, soon must cease. I wish to state a few facts connected with and relating to the subject heading this article.

1. There is a very great difference in the amount of honey produced in different fields in the different sections of our country and in the world, varying from the barren waste to its most productive fields.

2. Every field from the most barren to the most productive is limited in amount of its productions.

3. There is a great difference in the seasons for the production of honey, the same field producing double or treble the amount one season that it will in another.

4. In swarming hives, the increase will be from one to four new colonies per annum.

5. If we commence with one colony, and have one new swarm from each colony per annum, the first year we have 2 colonies, 1 old and 1 new; the 2nd year 4; 3rd year 8; 4th year 16; and so on to the 10th year 1,224.

6. If we commence with one and have two new swarms from each old one annually, the increase will be 3, 9, 27, 81, and in ten years our stock will amount to 59,149 colonies.

7. If we have 3 new swarms from each stock the increase will be 4, 16, 64, 256, 1024, and in ten years the amount is 1,048,576.

8. At four new swarms, as allowed sometimes to be given, both by Quinby and Langstroth, it will be annually, 5, 25, 125, 625, and in ten years will amount to 9,765,625 colonies of bees.

9. Somewhere along in these years the figures will get a little above the capacity of the field; the strongest swarms will give some considerable surplus. The weaker ones will, some of them, be robbed in the struggle for life. Some of them will be too weak to resist the moth, and will succumb; but with feeding and nursing they almost all get through pretty well.

10. Another spring has a fine opening, an abundant flora, the colonies double their numbers they have increased to double the number, that but just squeezed through the preceding winter, and now they die half, two-thirds, three-fourths, and sometimes all of them. Was the field overstocked? Oh no! they say.

11. Perhaps some of the bees straying over, daubed up and besmeared the comb. Oh it was the dysentery. Or they might have reached the sides of the hive and frozen to death leaving a little honey at the edges of the comb, and frozen there, leaving that evidence against overstocking.

12. I have never occupied a field where 30 colonies were safe to pass through the winter without starvation. Twice in my short experience (having commenced my business at three score years of age) I have had almost my whole apiary perish from starvation.

13. But why should we talk about starvation? An apiary that will give half to two-thirds of the honey produced in the field to the keeper; should not be reckoned unsatisfactory.

14. Neither should a bee-keeper be satisfied with a hive that cannot be made strictly a swarming hive at the pleasure of the keeper, or changed to a hive capable of receiving surplus honey boxes in most intimate connection with the breeding apartment, of the capacity of 100 lbs., thus giving such room as would form the colony the disposition to swarm.

14. It is not the principle object to procure bees but honey. We should think that the increase at the rate of doubling every year, one new colony from every old one, would give in ten years, in each town six miles square, 1224 hives; and in 15 years 39,168 hives. But instead of reaching this number, so many would perish from starvation that the business

would be relinquished by almost, if not quite, all of the citizens.

15. Instead of this place one or two colonies in non-swarming hives on each hundred acre lot and each might furnish one or two hundred pounds from each hundred acres. This result might be proved 15 or 20 years with no trouble but to place the surplus boxes in order in their season, and remove them when filled. So much difference may be proved by experiment on a larger or smaller scale.

Woodstock, Vt. JASPER HAZEN.

For the American Bee Journal.
Bee Prospects.

In looking over our bee journals we often see reports that read something like this: "We have commenced scientific bee-keeping and are very successful. We are trying to induce our neighbors to use the movable frame hive and to do away with the sulphur match, etc. But they say we don't want any of your new fangled things, they are humbugs."

Now, brother bee-keepers, if this is the case I believe it to be your fault and not that of your neighbors. Although I am a novice, my experience has been different. I have kept bees for many years but never made it profitable until the last three years. I saved six swarms from the great bee disaster of the winter of 1872. Transferred them in the spring into the Pallace hive (which has the Langstroth frame with the Johnson sectional honey box). During that season, increased to 13 by artificial swarming, sold \$120 worth of cap honey. In the spring of 1873 I commenced with 13 swarms (lost three during the winter on account of their not being strong enough in the fall) increased to 26 swarms and sold \$300 worth of box honey. Started this spring with 26 swarms, increased by artificial swarming to 61, have taken off 160 boxes of honey which weigh 12 lbs. to the box, or 1,920 lbs., which we sell at 24 cents Pb . Have extracted 500 lbs. and sold it at 18 cents Pb . Sales of honey amount to \$550.-80. Considering increase of stock, 35 swarms at \$6. P swarm amounts to \$204. Total amount for apiary \$754.-80. Paid for material for hives and honey boxes \$72.50, leaving a profit of \$652.30.

Now, to return to my subject. My neighbors have been watching my progress with an unflinching eye, and

the moment you prove to them that there are dollars and cents connected with the business, that moment they are ready to take hold.

The result is that over 25 of my neighbors are using the same kind of hive that I do, and if you should visit them in the summer, you would see them armed with a bee hat and busily at work with the little harvesters. And almost daily some one is visiting my apiary with observing eyes and attentive ears, to learn what they can. I am always glad to impart knowledge such as I have, for I like to do all the good I can. I believe that the era of bee-keeping has just begun, and the time is not far hence when tons of honey will be sold where only pounds are sold now. I think our locality here is as good as anywhere. We have early in the spring plenty of willow, elm, soft maple and many other spring flowers. Then comes an abundance of fruit blossom, which lasts until the white clover begins to appear. The white wood (*Liriodendron tulipifera*) comes on about this time, which our bees do excellent on. We have basswood or linden in abundance. A good deal of buckwheat is raised. In the fall we have a great crop of bonaset, we have a good many species but the most common and most profitable to bee-keepers is the *eupatorium perfoliatum* in our locality it yields a quantity next to linden. The last bloom that we have in the fall is the golden rod, and some other plants belonging to the composital order. But no matter how good a locality we have, I believe there is yet something for bee-keepers to do to aid nature.

I believe we should make the honey plant a study, and those of us who have the time and means should experiment and find out which are the best and most profitable for the bee-keeper and farmer.

I think by the cultivation of such plants we can get a far better yield of honey than with natural advantages alone. I should like to hear more through the JOURNAL about the growth of honey plants.

It is through the JOURNAL that we must become posted and up with the times.

W. L. PORTER.

West Ogden, Mich.

The sting of a bee is a barbed spear, projected by the insect in defence from real or supposed danger.

For the American Bee Journal.
A Kentucky Apiary.

Wishing to keep my bee yard as small as possible, I have studied considerably how best to arrange the hives so as not to be too crowded and not spread them all over the place. For two years I have had nearly all of my hives in rows running east and west, nine in a row, as follows: Two joists or timbers 20 ft. long, 10 or 12 in. high, are placed on the ground, 18 in. apart, my Langstroth hives rest across these, facing north and south alternately; under the rear end of each hive a strip 2x2x14 in. is nailed to the joist that tilts the hive about enough to suit me. At one end of the row a hive is placed fronting east. Over this row is a roof of rough boards, about 6 ft. wide, 22 ft. long, sloping down towards the south, and just high enough for me to work under. The roof is nailed to scantling which rest in forked posts set in the ground. It is light enough for two men to carry, and when the hives are set out of the cellar in March the roof is set down on the ground at the west end of the row, to break off the cold winds and let the sun shine on the hives, until May. When placed on the posts again it is secured by wire loops from danger of being moved by the wind.

In opening a hive I stand behind it, set the cover on a hive at one side, and turn the honey board up edge-wise against an adjoining hive with the lower edge of it on the side of the hive I am working. In a very short time the bees that may be on the honey board run down into the hive, so they are not in the way when the honey board is to be replaced. If they are black bees they rush back into the hive in a great hurry.

The rows of hives are placed about 20 ft. apart, or may be only 16 ft.; taking care, if they are near a fence, to leave a passage near the fence. I would prefer my honey room in the centre of the bee yard if there was good shade. It is now at one side.

I have experimented considerably in making bee-brooms or brushes, but have found nothing to equal an eagle quill-feather with the barbs trimmed off about half an inch from the shaft. My uncapping knife I want to be very thin and hard tempered, with the handle parallel to the blade, and not an angle to it as most of them are made. There are several little

conveniencies in use that I will describe for the benefit of beginners. A pan, to hold caps and trimmings when extracting; made of tin, 16x30 in. and 6 in. deep. Two inches above the bottom is a movable false bottom of galvanized wire cloth, and in one corner at the bottom is a hole with a thimble soldered in, and cork to fit, so the honey that drains from trimmings can be drawn off. Across the top of the pan rests a square stick, supported by a block at each end, with the edge next to you, rounded off for the comb frame to rest upon, and edge from you, sharp to scrape the honey knife upon.

A box to carry combs in is indispensable. Mine is made very light and honey tight; it holds six combs, is 9½ in. wide inside, with upright strips tacked in each end to hold combs apart, and handles on each end to carry by.

I go to work extracting as follows: One man works the slinger and uncaps, one carries combs and handles hives. One comb box is set down by the table at slinger, with five empty combs in another box, I go to a hive, open it, remove the comb, the frame slides down in the space in my box like a window sash in a frame, put an empty comb in the hive and take another for the box. Thus I take five combs, spread a cloth over the hive, carry the combs to the extractor, take up the empty box and get the other five combs from the hive; by the time I carry them to the extractor the first five are empty, so they are returned immediately to the hive and it is closed up.

Working in this manner two men will extract from 300 to 500 combs in a day. W. C. P.

A Frenchman has discovered a method of taming and removing bees, and securing honey by tapping on the sides and top of the hives. We remember trying it in our youthful years, before we had heard of the Frenchman. We tapped on a hive belonging to an old farmer one night, and the bees came out first-rate, but we didn't care to stay to remove the honey somehow. It seemed to us almost any place in the world would be desirable when compared to the vicinity of that hive. In this experiment, as in the one conducted by the Frenchman, the bees possessed all their usual activity and vigor. So did we.—*Utica Herald.*

Bee-Farming in Broome County, N. Y.

A Binghamton *Times* reporter has been investigating the manufacture of honey as carried on in the vicinity of Binghamton. He reports that:

The principle apiaries in Broome County are located, one at or near Chenango Bridge, some $5\frac{1}{2}$ miles from Binghamton, up the Chenango river, west side, and belonging to Mr. J. L. Schofield. The other two belong to Messrs. J. P. Moore and L. Beard, the former living about a mile below Binghamton, south side of the Susquehanna, the latter still half a mile lower down, on the same side of the river. They are all practical farmers. They are about the only men in Broome County who may be called scientific bee-farmers, or who are eminently successful in and make the business profitable.

He visited Mr. Moore first, and found him among his favorites, arrayed as he would be for any farm work, face, hands, and neck bare. He was drawing some large cards of honey from the centre of a hive, a hundred bees darting about his head, and with a large feather, was as coolly brushing the crawling insects from each card as though they had been so many wingless ants. A high picket fence surrounds his bee yard, inside of which are 24 full stocks of bees and 13 nuclei. The yard is well shaded with young apple and pear trees, and grape-vines running over trellises, from which hang in profusion rich cluster of grapes.

Twenty of his stocks are in a bee house, built about a year ago expressly for the keeping of bees. Entering this house Mr. Moore lifted the covers from several of the hives, exposing to view the many boxes and cards of honey already filled and partially filled, over which and through which the bees were crawling in countless black legions. The most of Mr. Moore's bees are the Italians, a few hybrids being still left among his colonies. The house is $8 \times 12\frac{1}{2}$ ft. inside, walls double and filled with sawdust. Under it is a cellar 5 ft. deep. A system of ventilation is so arranged that the temperature of the house in summer may be kept as low as desired, while the sawdust walls keep it sufficiently warm in winter, so that the bees are never moved from the house. The hives used are the Langstroth, with a slight modification. These hives will hold 32 three pound boxes next to the brood comb and 12 boxes on the sides. From one of the hives he has taken 50 boxes this season. The 50 boxes will weigh 165 lbs. Another hive has 50 boxes nearly full. He had a stock last

season from which he took 175 lbs. of honey. He states that during the honey season—which in clover lasts about 30 days and in buckwheat about 25—a strong stock will store from 10 to 15 lbs. of honey per day. He keeps the temperature of his house, when the bees are at work, at from 75 to 80 degrees. When they are not working it stands at about 70. During the winter it is kept from 35 to 40, with an occasional rise to 60.

During the whole visit Mr. Moore kept up a running explanation of his management of bees and their habits. His first effort is to prevent swarming as much as possible, by which he keeps his bees at work constantly storing honey during the honey season, instead of devoting a part of this valuable time to swarming. This he does by giving them plenty of room to store honey, and keeping them at a comfortable temperature by shading or otherwise. He succeeds in preventing from two-thirds to three-fourths of his stock that are out of doors from swarming, and all that are in the house.

A stock that does not swarm will make twice (and sometimes more) as much honey as one that does swarm, hence the importance of preventing swarming.

Mr. Moore started last spring with 23 colonies of bees, but one of which has swarmed, one of the out door stands. From these he has already taken 1,500 lbs. of box honey, and will take at least 500 lbs. more. Besides, he has extracted nearly 600 lbs., which gives him a little more than 100 lbs. of honey per stand. This is not as well as he did last season. He last year averaged from 15 stocks about 135 lbs. He has now 12 nuclei swarms, with which he is raising queens. These will be put together before winter, and reduce to 5 or 6 regular stocks for wintering.

After looking over the bees of this yard Mr. Moore accompanied the reporter to the residence of Mr. Beard, half a mile further down the river.

Mr. Beard started with 22 stocks in the spring, and will winter 33 or 34 stocks. His bees are all Italians but one stand, which are hybrids. They are in the Langstroth hive, and are all kept out on the ground, but well shaded with apple trees. He manages his bees very much the same as Mr. Moore's are managed, and his product of honey will vary but little from the product of Mr. Moore's yard. He has one stand that has made this season about 160 lbs. of surplus honey. His surplus honey is all stored in boxes, with four glass sides, and weighing $3\frac{1}{2}$ lbs. each.

Mr. Schofield's yard was visited the next day. He started in the spring with

35 stocks, all Italian. He has now 44 full stocks, with 54 nuclei. They are nearly all in the Langstroth hive. They are summered out of doors, on the ground, the hives standing some eight or ten feet apart, and well shaded by apple trees. Through the winter they are kept in the cellar under the residence. They are put in the cellar in December, and removed as soon in the spring as the weather will permit, which last spring was in March. The surplus honey is all stored in boxes of 3½ lbs. weight, except four stands, in which frames are used instead. Two frames hold just the same amount of honey as one box. His 31 stands in which boxes are used have averaged him 91 lbs. of honey the present season. But one of the four stands in which frames are used has had a fair chance to test their merits. Five cases, each containing from 45 to 48 lbs. of honey have been taken from this stand the present season, and another is already partially filled, and will be quite filled if the present weather holds a week yet. Mr. Schofield puts the weight of these five cases of honey at 225 lbs., which is their minimum weight. He thinks that with these frames his yard would have averaged four cases, or 180 lbs. of honey each. One other of these four stands of frames has filled four cases. He has a Bay State hive, a late patent of Henry Ally, near Boston, in which he put a new swarm the 2nd of July last. This stock has filled the body of the hive, holding about 35 or 40 lbs., and has also filled 24 boxes, weighing 3½ lbs. each, which amounts to about 120 lbs. of honey.

After visiting this yard, Mr. Schofield accompanied the reporter to Port Crane, where is a yard owned by Mr. D. D. Winn, but which is managed by Mr. Schofield. This yard was mostly transferred last spring to their present quarters in the Langstroth hive. He uses the frames exclusively. He had 8 stocks in the spring, which have increased by swarming to 10. The yard has averaged fully 100 lbs. per stock. He has one stock which has filled four cases, or 180 lbs., and has partly filled another.

These bee-keepers all send their honey to New York City, where they realize an average of 25 to 30 cents per lb. Their extracted honey is all fed back to the bees, by whom it is converted into the best of box honey. They are men who read bee journals, in which they are well posted, and who are thoroughly alive to the importance of their occupation. From the results of these apiaries it will be evident to all, that bee-farming is a growing industry of Broome County.

For the American Bee Journal.

Test of Italian Purity.

ANSWER TO MR. HESTER.

In the last number of the AMERICAN BEE JOURNAL, Mr. M. C. Hester asks:— Is there any fixed and certain test of Italian purity? If so what is it?

I answer: yes! All the truly pure Italian bees have three yellow bands. During the five weeks that I have spent in Italy, I have visited many hundred apiaries, I have seen several thousand colonies and I was unable to detect one single bee with but two yellow rings. It is true that I have seen, here and there, a few bees seeming black; but it is not a proof of impurity, for as far as I could judge, these bees were young, full of feces, and that matter could be formed of dark or even black pollen; for there exists in Italy some plants, such as the red poppy, very abundant in the field, whose pollen is quite black.

Every bee-keeper knows that the three first rings of the Italian bee are transparent. Suppose that the abdomen contains a black matter, her wings will be as black as those of a black bee, yet this dark colored worker can become a very bright yellow bee when full of light colored honey. I have seen, sometimes, in my apiary among my best workers, some young bees darker than their sisters, but afterwards it was impossible to detect these bees among the regular workers, their dark color having been replaced by a brighter yellow.

In the fall, bees eat dark honey, the result is that they are darker than when they find plenty of spring honey in the fields.

It is therefore but natural to find some bees seemingly black among thousands of well marked workers, and I contend that such exceptions are not a mark of impurity. Yet, if these black bees were very abundant in the hives, and above all if they were visible among the regular workers such a colony could be considered impure; for it is not so with the bees in Italy, the number of these seemingly black bees in a hive is very small when compared with the entire population of the colony; may be one or two to every thousand, yet I thought that it was my duty to say exactly what I have seen, to prevent complaints from those who could mark such accidents in their hives.

Mr. Hester, adds that he has received an imported queen, *that was brought over by me last year*, and whose worker progeny were two and three banded. I did not go to Italy last year; further more, I did not sell a single imported queen last year,* my importation having given me

only two living queens, which I have preserved for my own apiary. Besides I have never sold any queens to Mr. Hester. If he has received this queen from another party, she was not of my importation, and if she was not a bogus imported queen, she came from Tyrol, or from Germany, or elsewhere, not from Italy; for, from the Rhetian Alps to the point of the peninsula it is impossible to find a single bee with but two yellow rings, when full of honey. These yellow bands vary somewhat in width according to the districts, but I am sure, and I guarantee that, all the Italian bees that I have imported and will import, will breed all their workers with three yellow rings around the abdomen.

The queens, daughter of the imported queens and drones, will vary; some being quite dark, but the workers will be all alike in every hive. I vouch for it, having seen the bees in their native land, and having, for seven years, tested in my apiary, queens coming from more than ten different breeders of Italy.

Hamilton, Ill.

CH. DADANT.

* I am mistaken, I sold an imported queen to Mr. Hollett, this queen was from the previous year's importation. Last year having received but two queens alive out of 30. I have refunded the money to many bee-keepers, among whom I can name M. M. Root, Benedict, Argo, W. Cary, Salisbury, etc.

For the American Bee Journal.

The Superiority of the Italian Bee and Safe Wintering.

I have kept bees for thirty years, but found I knew but little about them until I took the BEE JOURNAL in 1870; at that time I had five hives. In 1871 I bought two queens of N. C. Mitchell. In thirty days I had two hives of nice three-banded bees, but lost them the next winter. In 1872 I bought a queen of Baldwin & Bros. of Sandusky; from her I have some thirty hives full blood and ten half breeds. In 1871 and '72 I lost twenty-seven hives with disease I have now fifty-five hives all in first rate condition. In 1871 I bought of N. C. Mitchell a Rough and Ready hive and the right to make. Last fall I had twenty three light and heavy. I prepared them and put them away for winter. All came out this spring in good order. For experiment in Aug. 1873, I divided two Italian hives and made six hives of them, three racks in each. This spring one of them filled their hive and swarmed on the 1st of July. In three weeks filled their hive and boxes, and swarmed the 25th of Aug. and now have their hive full.

Last fall I prepared twenty-three hives. I took off the honey board and covered it with a piece of carpet, then made a box

five inches high, the size of the top of the hive; nailed on carpet for bottom, filled with cut straw or hay, and put on the hive. That keeps the bees warm, as their breath goes through both carpets in the straw. I have a room made in my barn 12x20 feet with double doors and packed partitions, so that it is above 35 degrees through the winter. I went every week or two and lifted up the box of cut straw, and found it warm between the two carpets, although some times wet on top of the straw with their breath. In this manner prepared there will be no bees lost, and they don't eat over half as much as out in the cold. I have got a large amount of honey this summer and a very large increase in Italians.

D. A. SHERMAN.

A Bee Parasite.

I hasten to send a little insect, apparently a red spider, which I took off one of my queen bees. She had been dethroned to make room for a Ligurian, just sent me, and was released in a queenless hive into which I had introduced her on Saturday last. I opened the hive to find out whether she was alive and well, and found her with this little creature on her back. For a long time, I was unable to remove him, as he was quite indifferent to the pokes I administered with a little piece of grass, and hid himself under her wings; so I was obliged at last to capture her majesty, and in the safe retreat of my study remove this too faithful attendant with a pair of tweezers. I found only two grubs in the royal cells. Probably the presence of the spider and the cold weather had interfered with the breeding.—*Bligh*.

[The insect was sent to an eminent authority connected with the British Museum, who writes: The insect sent is the bee louse of Europe, and in some parts of the Continent is not uncommon; in fact it is a nuisance, as many as 50 to 100 being sometimes on a single bee in Italy, etc. It is a wingless dipteran, allied to the forest fly, "Hippoboscæ;" it is named *Branla cava*; the young are said to be produced in the pupa state; it lives by sucking the bees. No doubt more are to be found in the hive whence the specimen sent was obtained; if so, a specimen or two would be acceptable for the Museum collection. It is not frequently found in England, except in imported swarms of the Italian bee.—*British Bee Journal*.

Foreign Department.

CONDUCTED BY C. H. DADANT.

L'APICOLTORE.

L'Apicoltore is an Italian periodical published monthly by the Central Association of Milan, for the encouragement of bee-culture.

It is edited by Count Miscounti di Saliceto with an able corps of contributors. The September number is now before us. It is as usual replete with good articles on bee-topics.

On the first page we find a document that may be worth reading; it is a letter from the well known revolutionary General Garibaldi. We quote:

The President of the Central Association having heard that General Garibaldi is interested in bee-culture, had sent him a copy of the journal *L'Apicoltore*. In answer he has received the following letter which he publishes with pleasure.

Caro Signor Presidente:—Your journal *L'Apicoltore* is a precious treat for me. Bee-culture is now my favorite business.

I am gratefully yours,

G. GARIBALDI.

Caprera, Aug. 17th, '74.

The second article in this paper is by F. Clerici. It is one of a series of articles describing and classifying the honey yielding flowers of Italy. Mr. Clerici has so far classified and described in the *Apicoltore*, 185 different honey-yielding plants, with occasional engravings. This same writer is the engraver of the 30 anatomical chromos describing the external and internal organs of the bee, queen and drone, which had been drawn from microscopical studies by Count G. Barto.

The third article is a letter from P. Grassi on the question of foul brood. In this article we see a description and engraving of the insect (*Phora incrassata*) that feeds on the diseased larva. It is there represented in the three stages, larva, chrysalis and perfect insect. There is also an engraving of a fungus engendered on a foul brood (*melittis melittophorus*.)

We see a little further an article on honey employed in the manufacture of wine; then a question and answer department. But the best department of this paper is undoubtedly the department of "new publications of bee-culture" under the direction of Dr. Dubini. In this department, we find every month, translations from bee-papers in all parts of the world, Germany, Switzerland, England, France and America. There the Italian bee-keeper can find all the new ideas or new discov-

eries abroad, faithfully reported. Dr. Dubini searched everywhere and nothing escapes his search. And many of our American writers have been published abroad unawares. The names of Gallup, Novice, Langstroth, Doolittle, Adair, Mrs. Tupper and many others, are seen by the side of the names of Berlepsch, Dzierzon, Hurschka, Leuckart, Mona, and even Hamet.

In the present number we find translations for the *National Agriculturist and Bee Journal* from the *Apiculteur* of Paris, from the *British Bee Journal*, from the *Rucher du Sud Ouest*, and from the *Bienenzeitung*.

L'Apicoltore is doing a good work, it is stepping towards progress. Long may it live!

A Proposition.

I see readers of the AMERICAN BEE JOURNAL have asked more than once for some plan to keep syrup from granulating, honey from candying, or either from souring. I bought a receipt for just such a purpose and can dispose of it as I please as there is no patent for it; and as I paid \$30 for it in full, can do as I think fit. Now I am willing to do all I can for bee-keepers (as far as my means will allow) and if any one will raise money and send me a fine imported Italian queen, of this season's importation, I will give this receipt to be published in the AMERICAN BEE JOURNAL. The queen to be sent in a nucleus hive, well stocked with bees and honey for to do them two weeks. This receipt I can vouch for, for I have given it a thorough trial and never failed. Should any of the bee-keepers send the queen (a fine one only will be received) I will make it public, and it is worth \$5 to any man who keeps honey, as it adds greatly to its sale. DR. W. B. RUSH.

Simpson's Store, Pa.

Granulated Honey.

The Jews of Moldavia and the Ukraine, prepare from honey a sort of sugar which is solid and as white as snow, which they send to the distilleries at Dantzic. They expose the honey to frost for three weeks, where sun nor snow can reach it, and in a vessel which is a bad conductor of caloric, by which process the honey becomes clear and hard, like sugar.—*Bevan*.

A Request.

Will the contributors to the AMERICAN BEE JOURNAL please mention what patent hive they use, and oblige,

S. C.

EDGEFIELD.

NOTES AND Queries

You speak of using the straw mat in wintering bees. I would like to know how they are made. Perhaps you have answered this question but I am a new subscriber and have not had the benefit of it. Will it be best to remove one frame from the centre of my hive or extract the honey and return it? I have never used the extractor; this is the first season I have had bees in the movable frames. I think there is too much honey in my hives. The frames are all full of honey, with but little brood. I have the Langstroth ten-frame hive. R. A. CALVIN.

Send to Albert N. Draper, or C. F. Muth of Cincinnati, for a mat as a sample. Both advertise them. We use quilts instead of mats, but dare say the latter are best. We fear your hives are too full of honey. If so—remove one or more frames from the centre of each, to give room; moving all the other frames a little further apart. Put on quilts or mats at once.

It would have been better to extract the honey, and return the combs, but it is late now to do this, unless you keep the combs twenty-four hours in a very warm place before using the extractor.

DEAR EDITOR:—Ought newly formed colonies that have gathered no honey, on account of the drouth, to be fed now, or wait until later? Does feeding stimulate breeding? Do you think bees can gather enough honey from this time to keep them through the winter? What do you think is the best bee food?

J. G. STREET.

Syrup made of sugar and water, is the best bee food. The earlier in the season that bees can be fed the better, after frost kills the blossoms. If they have insufficient stores in this month (November) they must be fed on very warm days or taken into a warm room to feed.

DEAR EDITOR:—J. Davis tells the readers of the JOURNAL on page 184, Aug. No., how to introduce virgin queens and make new colonies, but he does not tell them how to construct the queen nursery he uses; will some of our veteran bee-

keepers give the younger ones a little light on the subject, if the article is patented or not, if patented where can it be had. Please answer in the JOURNAL.

Metamora, O.

N. B. SEBRING.

There are several queen nurseries patented—one of them by Mr. Davis. We have tried several of them with very indifferent success. If you apply to some one who advertises them you may get the information that will aid you in understanding the principles on which they are made.

DEAR EDITOR:—I am a beginner in bee-culture. Bought 4 swarms of black bees last spring. Have 12 young swarms from them in movable hives. I have Quinby's and Langstroth's bee books. Have not had any trouble in summer management by following their directions. Will you please give the best mode of burying bees, in the JOURNAL. Is there any better way than to put them in clamps as Mr. Langstroth describes in his book. If I can winter them I think I am all right. Most of the bee-keepers about here trust to luck and chance. I asked one man if he wanted to sell his bees. He said, no. Asked him if he took any bee-paper. He replied, no. Asked if he would like to subscribe to one. No, was the reply; and that is about the way with most of of them. They will not trouble to inform themselves nor sell their bees. It has been a good season for breeding bees here, but there has not been a large amount of surplus honey made, as there was a whole week of windy, rainy weather during the linn harvest.

Randallsville, N. Y. E. D. CLARK.

There is no better way to bury bees, than to put them in clamps as Langstroth describes. Some report good success in that way. We have not sufficient experience to warrant us in recommending it.

DEAR EDITOR:—I have two swarms of bees that are full of drones, both large and small, the small ones are regular dwarfs. I suppose they were raised in worker cells. There are plenty of worker bees, old and young, in both colonies. My opinion is that they have a fertile queen and fertile workers also. They are in hives that I cannot take the frames out to find out the cause. Please give me a full explanation, and oblige,

CHARLES E. SWEETSER.

It is probable that there is a quantity of drone comb in your hives, and honey

being abundant this year, much of it has been filled with drone brood. When the season is poor, the bees are slow in rearing drones.

The fact that there are young worker bees in the hive, as you assert, proves that they have a fertile queen, and we have never heard of an instance where a fertile worker, much less a drone-laying queen was tolerated in a hive with a perfect queen.

If you could examine the hives, you would find, we think, that in the centre of them there is much drone comb. The small size of some (the drones) indicates, we think, that part of the brood was fed too little—not more than enough for workers. This is frequently the case where too much drone comb in the centre of the hive is found. We don't know but we guess that the bees get tired of feeding many drones so bountifully.

If any one can explain our correspondent's trouble any better than this, let us hear from him. Did any one ever know of a fertile worker in a hive that contained a fertile queen?

DEAR EDITORS:—On June 6th, I took off a box of honey with brood enough in it to fill a Langstroth frame. On September 8th, I put this in a hive and it all hatched out alive, having laid in the cellar three months and two days. Have you among your correspondence any case similar? Such authority as Mitchell and Zimmerman, think it impossible.

NAPOLÉON, O.

G. M. LE VAN.

We should also pronounce it impossible, unless you are certain there is no mistake. Did you see the young bees hatching? Is it not possible that the bees removed this brood, it being dead?

Was the brood left in the cellar without any bees about it?

We would be glad of all the particulars of a case, which seems to us at variance with all natural laws. What would be thought if we should assert that we have taken eggs nearly ready to be hatched from under a hen, put them in the cellar for months, and then put them again under a hen and then hatch. The cases are not parallel, because insect life is not like that of the fowl, but they are similar, and

will serve as a comparison. Has any reader of the JOURNAL seen instances, where the hatching of brood has been suspended in this way?

DEAR EDITOR:—Please answer the following:

1. Is the black bee more apt to store surplus honey in boxes than the Italian?

2. Will a hybrid queen mated with a black drone produce hybrid drones?

3. I had a swarm of bees this summer that had a queen who begun at the bottom of three honey boxes to fill them, and did fill them. What was the matter?

4. How will it work to pack a double walled hive with sawdust, to stand out of doors all winter?

Bees have done very well here this season. The largest amount of honey that I ever heard of being taken from one swarm, was one belonging to my neighbor; a young swarm that made 56 lbs. of surplus honey.

S. Stockton, N. Y. L. N. SHEDD.

1. We have never seen any difference in the two varieties of bees, in regard to their working in boxes. If honey is plenty and the colony large enough, and boxes are put on early, any bees will work in them.

2. We do not know what the drones would be called in that case—"hybrid" we suppose.

3. There was nothing the matter. Bees often fill boxes in that way, especially if the bottom of the box is very near the comb below, or if the top of the box is too smooth.

4. We have never tried a double walled hive, packed with sawdust, and cannot advise it; but if you put a dry goods box six inches larger than the hive, over it and fill the space between with straw, hay, or chaff, covering the top of the hive also with straw and putting on a cover, leaving the entrance of the hive a little way open. Your bees will winter well out of doors. We would protect double walled hives in this way, as well as single. It is not much trouble, if it does take some words to tell you how.

DEAR EDITOR:—I have a colony of bees (Italians) that have not yet disposed of their drones, at this date, Oct. 15th. Can you account for it? What shall I do?
A SUBSCRIBER.

Examine the hive and be sure they have a queen. The unseasonable appearance of drones sometimes indicates that there is no queen. If they are all right in this respect, do nothing about it. The cold nights that are at hand will dispose of them. When honey is plenty, bees tolerate drones in the hive until they die a natural death.

Another season be sure you do not have too much drone comb in the hive.

ED. JOURNAL:—Why does some of my honey granulate while others does not? Is there any remedy? How can I restore it to liquid form?
INQUIRER.

We cannot tell why honey granulates. If any one can, let us hear from them. We only know that some honey in some seasons granulates very quickly, while other seasons the same quality of honey apparently remains liquid.

Some tell us that if no particles of comb are left in the honey it will not granulate. If this is so, why is it? What can the comb have to do with granulation?

Others tell us that if kept air-tight, in the dark it will never granulate; yet we have had it in tight oak barrels become as solid as tallow. Certainly the barrels were "air tight" and in them the honey was in the dark!

We find Linden honey almost sure to granulate. Honey from the fall flowers we have had no trouble with. Can any one tell us why this is so?

If there is a remedy we do not know it, will the "doctors" answer this question.

To restore it, requires heat. We place it in shallow pans over steam—and it melts readily. If not done in this way there is danger of burning it. It melts before it reaches boiling heat. Many people prefer to use it in the solid state, but as a rule it does not sell until melted.

Some honey dealers refuse to purchase honey of strangers unless in this state, reasoning that they are "sure of its purity when granulated, for none of the imitations of honey will harden." Another

merchant advises putting acid in the barrels of extracted honey to prevent granulation. We would give no such advice. Put honey into clean sweet barrels, or kegs, letting it settle a day or two first, and straining carefully; if it hardens melt it, but add nothing to it, selling pure honey just as it is thrown from the combs.

ED. JOURNAL:—Shall I break up my nucleus hives, or can I keep them over winter in any way? If I cannot, what shall I do with the young queens in them? A little information on this point will be valuable to us.

Can weak colonies be wintered over, and how?
J. E. R.

Olmstead, Minn.

We have kept nucleus hives over winter, but always found it cost too much time and care. To be safe, they must be kept in a very warm place, nearly at summer heat and often examined as to their condition, and if neglected you find them dead, and all past trouble with them thrown away. We kept a pint of bees, one winter in a small hive, and in the spring built it up by June to a 15 frame colony, full of brood, from which we made two other strong colonies and took some surplus honey. But we were satisfied by the experiment that it could be done and since then have never tried the same experiment. It was a costly one.

We hardly know how to answer the question as to wintering weak colonies, because it is so hard to know what you mean by weak colonies. Hosmer winters only colonies that are what he calls "small ones." He does not believe in wintering too many bees, but he keeps them in a very warm place and knows just how to manage them in spring. He is one of our most successful bee-keepers, and we have no doubt his theory is a correct one. Yet he said to us on one occasion, "I do not like to have you say too much about my method of wintering; it is so hard at a distance to explain just how many bees go to make up one of my little colonies; or to tell just how I prepare them for winter. People misunderstand me, and then when their bees die call me and my method "humbugs?"

Our advice to beginners, and indeed to

all ordinary bee-keepers, is: Winter none but strong colonies; be sure they have plenty of bees, and enough honey to last until April, (that should be at least 20 lbs. if weighed in this month) and plenty of empty room for the bees to cluster. Give space between each comb for air to pass at top, putting on quilts over the spaces; nearly close the entrance. These rules apply equally to those who protect on summer stands.

Our way of breaking up the nucleus or small hives is: Put the frames of two, three or four together in a full sized hive, and shake the bees together at the entrance. If all the queens but one are taken from them a few days before, they will unite peaceably. Then we take the queens from No. 1 and No. 2, (perhaps from No. 3, if the nuclei are not strong) and leave No. 4 with its queen. A few days after, have a full sized hive in readiness, put all the best combs, with enough honey in it, shaking off what bees you can at the entrance, (if some are left on the combs it is no matter). All the bees will go in, and all being in a strange hive, have no disposition to quarrel. The first cold night will find them comfortably clustered together, and they are to be treated like any other hive.

Unless colonies with two little honey have been fed before this month, they had better be united in the same manner.

What to do with the surplus queens, you must decide for yourself. If they are pure Italians, give them to some hives that have poorer queens. They are few apiaries where some queens may not be found that are worthless or nearly so, and this is the best of all reasons to replace them if possible.

Mr. Rogers, a subscriber in Nebraska, reports a singular circumstance. On examining one of his hives containing a choice queen, wings clipped, he found queen cells, indicating a determination to replace the queen. He destroyed them; but in a few days found others, which he also destroyed. The hive was not opened again for two weeks; when a young queen was discovered, just emerging from

a cell. Not seeing the old queen, Mr. Rogers supposed her to be killed.

The young queen became fertile, but on opening the hive again, some time after, to his surprise he saw the old queen, and on the same frame with her young one. Several times since, he has seen both old and young queens apparently living in peace.

We have twice seen a young and old queen together in the same hive, but believe such instances are very rare,

Bee-Keeping.

The following is the report of the committee on foul brood:

SALT LAKE CITY,
Oct. 9th, 1874.

Foul brood is a contagious disease among bees, affecting the young bees in the larva state before and after they are capped; they die in the cells and become putrid, emitting a stench, easily detected several feet from the hive.

On examining the frame of brood, the caps over the diseased larva are depressed or indented and of a darker color than the healthy brood.

Bee-keepers have been unable to assign a cause for this disease, neither have they found a remedy, but to destroy all the comb containing brood by burying it. Comb containing honey can be put into an oven at night, when there are no bees about, and melt out the honey which may be used in the family, but must not be fed to bees; after it is melted, let it stand until cold, when the wax and all impurities will be found on the top, which must be taken and buried.

The hives with the frames must *not* be used for bees again, nor put where they can get at them.

We would advise all bee-keepers to examine their bees at once, and if foul brood is found they must follow the above instructions and rid the Territory of this terrible disease.

I. BULLOCK,
J. MORGAN,
C. MONK,
G. BAILEY,
Committee.

The philosophy of wintering bees is a right temperature of atmosphere and a proper escape of the surplus moisture accumulating from the respiration and perspiration of the bees.

Seasonable Hints.

There is nothing to be gained by disturbing bees in cold weather. Let them remain clustered together as quietly as possible.

If they have been examined, equalized, and those fed that need it, while the weather was warm, there is nothing to do for them until the time for putting into winter quarters. Any time this month it is safe to put them away. We always choose a night following a warm day, when they have flown freely, if we can, and move them as quietly as possible.

We do not like to leave them out until the combs become frosty.

If necessary to move bees any distance, before putting them in a cellar or house,

we would set them down after moving, and leave them until perfectly quiet and compactly clustered before putting them in.

A moderately warm time is better than a cold one, to move bees, because, when it is very cold every bee that is made to leave the cluster by the disturbance becomes chilled.

Some upward ventilation is necessary, but if quilts are placed over the frames, enough air is given at the top and yet there is no draught of air through the hive.

Nothing is gained by putting bees in a cellar that freezes. If they are to be exposed to cold below freezing point, let it be out in the open air.

We would never feed during winter. Be sure each hive has food enough to last until spring, then let them alone and save your feed for March and April.

We like to have a space between the bottom of the frames and the bottom board of a hive, two or more inches deep, *in winter*, that the bees that die may drop below the comb, and the bad air have room also to fall. After bees are put away, let them alone. Be sure they are comfortable and then forget them. You can make hives for next year now, read the BEE JOURNAL and write your experience for it, and be prepared to make your bees "pay" next season.

Profitable Business for Women.

One of the most profitable as well as interesting kinds of business for women is the care of bees. In a recent agricultural report it is stated that one lady bought four hives for \$10, and in five years she was offered \$1,500 for her stock, and refused it as not enough. In addition to this increase in her capital, in one of these five years she sold twenty-two hives and 430 pounds of honey. It is also stated that in five years one man, from six colonies of bees to start with, cleared 8,000 pounds of honey and fifty-four colonies. When properly instructed, almost any woman in the city, as easily as in the country, can manage bees and make more profit than in any other method demanding so

little time and labor. But in the modes ordinarily practiced few can make any great profit in this employment. It is hoped a time is at hand when every woman will be trained to some employment by which she can secure to herself an independent home and means to support a family, in case she does not marry or is left a widow, with herself and family to support.

Bee-Keepers' Re-Union.

Mr. Hoagland, President of the Bee-Keepers' Association, sends us particulars of arrangements made for the annual meeting at Pittsburg. Our readers will see that he has done his part well toward making the meeting a success. We hope for a very full attendance and a profitable session. Our friends in that part of the country have been for several years desirous of having the meeting at Pittsburgh, and we are sure much will be gained by every one who attends the meeting.

Let all the members of the Society make an effort, and a sacrifice if necessary, to attend. We are sure that all who attend will find pleasure as well as profit in the interchange of experience.

Let all go determined to impart all they can as well as to gain from the relations of others.

These meetings have been in the past, re-unions of great interest, and we expect the one at Pittsburg to be a grand success.

Honey Crop of San Diego.

From the San Diego *World* we learn that the honey crop of San Diego for 1873 was 119,000 lbs., and it is expected that this year it will be equal 200,000 lbs. J. S. Harbison has five apiaries in that county, comprising over 2,000 hives of bees. R. G. Clark has two, comprising over 800 hives. These are the most extensive bee owners in the State.

The bees begin working in that country about the first of February, and the season for storing honey lasts from June to September.

The finest honey is made from the flowers of the sage plant, which grows

here in such abundance. This is the true sage, and must not be confounded with the sage brush of Nevada and the northern counties. The flat-top or "buckwheat" greasewood also affords excellent honey. The bloom of this plant closely resembles that of buckwheat, hence the name. The flowers of the sumac is another source, and the ice plant, which covers so much of the country, is likewise sought by the bees. This latter plant makes a very white honey, but it is liable to the objection that it turns very quick to sugar, or candies, as the honey men say. The bee-keepers therefore try to avoid it.

The bulk of the honey will find a market in the east.

The honey made in San Diego is very white and handsome, and of excellent flavor, commands a good price and finds a ready market wherever offered.

In the October number we should have acknowledged the receipt of a nice lithograph of the Hexagonal Apiary, from Mr. A. I. Root. It is a nice thing and shows how an apiary could be systematized and carried on for both pleasure and profit.

H. A. King & Co., have removed to 75 Barclay Street, New York, and there publish the Magazine, and National Agriculturist. This latter publication, came out for September with a new and elegant heading. It is published at \$1. a year. Send for sample copies.

Particular attention is called to the advertisement of Mrs. S. E. Spaid's New York Honey House. The address before inserted was a mistake. It is correct as found in this number of the AMERICAN BEE JOURNAL.

We will send the AMERICAN BEE JOURNAL six months for a copy of Volume 2, No. 1. We want it to complete a set. Who will trade with us?

Let every one writing this office make all Postal Orders, Drafts or Checks, payable to THOMAS G. NEWMAN. Address everything of whatever nature to

Correspondence.

For the American Bee Journal. Western Bee Plants.

DEAR EDITOR:—I believe I promised in a former communication to give you the result of my experiment with the Western bee plants, *Lophanthus Anisatus* and *Cleome Integrifolia*, in this locality. I am not aware of any previous effort to introduce them, though others may have tried and perhaps with better success. As you remember I wrote to H. A. Terry of Crescent City, Iowa, for seed in Sep., '73. The seed came promptly (after your forwarding mine to you) and though then the middle of Dec., was sown immediately; in soil previously well prepared, in drills three feet apart. But being sown so late the plants did not show themselves until the following spring, and then only very sparingly—here and there one—showing that the locality or time of sowing did not suit them.

The, perennial, *Lophanthus Anisatus* only started some dozen plants, with a single stem or stock, which grew 12 to 18 in. high. These produced one or more flower stems somewhat resembling catnip blossoms in appearance, but with the unmistakable anise fragrance. Though continuing in bloom for several weeks I did not notice a single honey bee upon them. The seed ripened in Sep., and was carefully gathered for replanting.

Cleome Integrifolia, the annual, came up much more promptly and evenly. It made a growth of from 2 to 5 feet in height, sending out many branches, and blooming abundantly by the 1st of July. I watched its growth closely but the bees found the bloom first, and began work upon the very first blossoms. They seemed to enjoy it exceedingly. It was no small gratification to see them as if vying with each other for the coveted luxury. For two or three hours each morning its sweet fragrance and the buzzing of the busy little workers were alike interesting. But after the warm sun had evaporated the moisture of the dew, its

agreeable odor disappeared, the bees forsook it and only the dazzling beauty of the finely shaped little shrub or plant, with its multitude of flowers remained. It continued to bloom for six or eight weeks and would probably have continued much longer but for the appearance of a striped little bug, in great numbers, destroying the foliage and in a short time killing the whole plant.

Thus you see our experiment has not been so satisfactory as we might have desired. But it has not left us without a keener interest and hope for another year. We are greatly in need of something to fill a vacancy in the honey harvest during the mid-summer; and we still hope these plants may serve to help us through. Bees have done so poorly here for two or three years that many have become completely discouraged.

Many persons lost all their stocks who had kept bees for over forty years. We kept ours through, by dint of untiring watchfulness and care. Though we had buckwheat and clover we still had to feed on sugar syrup; and frequently united the weak stocks. Late in the spring, however, they began to live up, and when the poplar or tulip bloomed they filled their hives in a little time. We had been so discouraged with long continued failure and losses, as to be taken quite by surprise to find them so heavy, and getting ready for swarming. The extractor was soon put in readiness and used to excellent advantage. Since then the season has been favorable. The autumn harvest from wild flowers has been good. We have had to watch closely to prevent filling up the brood chamber. Empty frames of comb placed in the centre of the hive would be filled with honey almost before the queen could get a chance to deposit eggs in them. It has given us an excellent opportunity of testing the advantages of the moveable frame hive and the extractor.

As beginners in apiculture we have read your JOURNAL with great pleasure and profit. We are quite pleased with the union of the two leading bee journals. You have our best wishes.

New Garden, N. C. A. E. KITCHEN.

For the American Bee Journal.

Packing Bees for Winter.

DEAR EDITOR:—As I and a friend of mine had excellent success last winter in keeping our bees, we will here give the plan we adopted. Suppose you get a box for each hive, four inches larger each way than the hive and 20 in. deep; have a bottom in the large box. Before nailing on the bottom, make an entrance for the bees to fly out, when weather permits. This we call the front of hive. Now on the back, exactly over the entrance, cut a **A** shape, one inch long, and just small enough to keep out mice. Now put in a long box a false bottom, leaving a crack 1 in. wide, from front to rear. Now put in your hive, and by looking through the entrance, you have a passage 1 in. wide from front to rear. Now put a strip of board over this passage, front and back, to prevent packing from closing it up. Then put on quilt, mat, carpet, or anything woolen to keep the bees in, and pack the 4 in. space between outer hive and hive proper, with chaff, stuff it well and fill the box until full; now put on cover to keep out all storms, and keep perfectly dry. Arrange a door step and the job is done.

The bees wintered^d in those boxes to perfection, and did not dwindle down like those wintered in cellars, but came through the bad weather in May and April without loss, and each one of them contained double the number of bees in April and May, that those did that came out of the cellar. All those swarms were nearly a month earlier than those from the cellar. The reason we think was this: the packing in the large box prevented every little change of weather from being felt by the bees, and consequently the bees never left the hive until it was warm enough for them to fly and regain the hive again; but those wintered in the cellar every time the sun came out and struck it, the hive would be on the wing, and not one-fourth of them ever returned to their hives again.

Probably a great many bee-keepers may think this too much trouble. But when we remember that some swarms will pay us a net profit of \$40 in one season, we think we can well afford about 40 cents for a box, and an half an hour's time to pack them for winter. We manufacture a straw mat for each hive, on the plan recommended in *Gleanings*. We put on next to the bees a woolen blanket and the mat on top. We think the mats O K.

Do not remove the outer box until all

bad spring weather is past. Brother Townley wintered 50 swarms last winter in this way to perfection; he did not use the mats, but woolen and cotton cloths; but the mats I am delighted with.

The past season was a fair one, although we got but little white clover honey; we got plenty of basswood and fall flowers. We started the season with 33 colonies; 20 good, and 13 quite weak ones. We have at this date 54 swarms and 2,200 lbs. of honey in glass boxes, and about 350 lbs. of extracted, besides a considerable amount in large frames, not in marketable shape; but it will come in play next spring in pushing colonies along and starting new ones. J. BUTLER.

Jackson, Mich.

For the American Bee Journal.

This Year's Honey Season.

FRIEND EDITORS:—I wonder what some of your correspondents that report such long honey seasons and large yields of honey would say if they had my location and season? I used my extractor for the first time this year on the 12th of June and on the 24th of June I used it the *last* time. I took over 200 pounds from ten hives in that short time; one hive giving me sixty pounds. My principal pasturage is white clover, and the extremely dry weather this summer cut that so short, that from the 1st of July till the 1st of August, the bees did not make enough honey to live on. About the first week of August the smart weed, of which there was an abundance, and the buckwheat commenced blooming, and by the middle of the month the bees had so far recruited their hives, that some few in the neighborhood cast swarms, but as flowers can't secrete honey out of sunshine, and especially as hot as it was about that time, all hopes of surplus honey, and an increase of stock, had to be abandoned.

I am using the two story Langstroth hive, and Winder's new Queen City extractor; two things that are as essential to success in the bee business, as plenty of flowers, and a favorable season.

I found very good sales for my extracted honey at 40 and 75 cts., when put up in one and two pound jars. To put in the corks I used a lever that was fastened to the wall just the height of the jar. After pressing the tin foil cap on with my hand, as well as I could, I fastened one end of a twine string to the wall and tied the other end around my body; then by sitting down on a chair I could lean forward to give slack enough to the string to give one turn around the neck of the

jar; then by leaning back I could draw the string as tight as I pleased and by rolling the jar towards me I could press the cap on nicely and quickly.

If I had nothing but the black bees to work with, I would quit the business; it almost makes me mad to open a hive of them and have all the little *cowards* run to the bottom of the frames just as if they were crazy. I have one hive that when I examined it for winter, Oct. 1st, I found a nice Italian queen that had been hatched about two weeks and plenty of drones. As she was hatched so late in the season I came to the conclusion she did not become fertilized, but all of my queens quit laying about that time so I had not the opportunity of knowing for a certainty. I will know what is the matter with them next spring.

I very seldom use smoke or a veil to work with my bees (unless they get too awfully cross), for the first is a bother and excites the bees too much, and the latter shuts up the road to my mouth. I would rather take a few stings than to do without eating honey. I use no remedy and can stand 15 or 20 stings a day tolerably well. When I commenced the business one little sting would swell more than a dozen doses now. I suppose "the hair of the dog is good for the bite."

For the American Bee Journal.

Pure Queens Working in Boxes.

MESSRS. EDITORS:—The JOURNAL is just received, and in looking over it I find your correspondent from Binghamton, N. Y., complains that he has not succeeded in getting his pure yellow Italians to work in boxes. The difference in localities may make the difference; but be that what it may, my experience is just the reverse. I have never had any trouble to get the golden beauties into boxes, for the reason that, as he correctly states, they are prolific and fill their hives with bees, and as soon as mine fill up with bees they go at the boxes with a vim not excelled by the best hybrids, which are certainly good for honey—equal to, but not better, than the pure yellow boys. Such queens as he describes would be a very valuable acquisition to any apiarian in any State, that rears queens for sale, as such queens are in demand. I would give two good hybrids, and perhaps two more, for such a queen that will duplicate herself every time in her queen progeny. I have had almost all kinds of queens, and but few such that invariably duplicate themselves in queen progeny. I find it difficult to

get such queens, and have had imported and homebred of the first order, and yet comparatively few such as he describes, the difference, again, probably being in locality. I am satisfied that success in apiculture varies in different localities; so, likewise, do the color of queens, etc.

Melrose, Pa.

R. W. HARRISON.

Old Harry's Report.

DEAR EDITOR—Many bee-keepers have had their say in the journals in regard to wintering; and their theories are as various as their pens. Instinct teaches the bees to build comb and fill it with honey; when circumstances place the comb all ready there, instinct teaches them to fill that comb and keep it full. Now by taking advantage of that instinct we may empty that comb a thousand times and a thousand times will they fill it; but as cold weather has come I will stop on that train of thought.

Soon all will be silent around the hive. Don't let that hum be silence forever; don't let the bees perish in the icy grasp of old boreas. They have worked hard for you the past season, charged you nothing and boarded themselves. Their product has added to your purse. Now study their nature, their habits, and their instinct, and afford them protection accordingly, but as you value their living, don't try to make them conform to some pet theory on ventilation, or some patent clap-trap ("ventilated,") mis-called a beehive, or they will be sure to suffer. They require but little air in the winter and that little they want to keep warm for comfort, now, with your ventilator, you are continually drawing the warm air off, that they much need. As it is continually being drawn off, they must be continually heating more, which exhausts them, and they die before they see the warm sun of spring. They die from over work, trying to keep warm. But it is all right, their tombs are patented, and the "hard winter" is to blame. Then nature teaches them to plaster up every crack and crevice except their passage-way. They do it in order to save as much warmth as possible. If you interfere with this, they will almost be sure to die.

Protect the outside of their home from the cold blast, pelting rain and sleet. Keep their hive dry out side; then let them alone, and they will take care of the inside. Bee-keepers, study the nature and instinct of the bees and conform your operations to that and they will place you on the royal road to wealth.

Honor to whom honor is due. We

Annual Meeting of the North American Bee-Keepers' Society.

Pursuant to notice, the above named Society commenced its annual meeting in the hall of the Germania Saving's Bank Pittsburgh, Pa., on Wednesday morning, Nov. 11th, at 10 o'clock. About fifty members were present, which number was increased to seventy-five or eighty by new arrivals in the course of the day.

President Hoagland occupied the chair. Organization for regular business was deferred until afternoon, and the rest of the forenoon occupied in suggestions of topics for discussion, and informal conversation or matters pertaining to the success of the meeting.

Rev. W. F. Clarke moved that a temporary committee of three be appointed by the chair, to prepare business for the session. Carried and W. F. Clarke, H. A. King and Mrs. Tupper were appointed said committee.

A motion was also adopted providing for the appointment of a committee of two, to act with the Secretary, Abner J. Pope, of Indianapolis, in preparing the proceedings of the session for publication.

The meeting then adjourned until half-past one o'clock p. m.

The following abstract of the proceedings is partly made up from the reports of the Pittsburgh daily press, and partly from the notes of our own reporter.

AFTERNOON SESSION.

The Society was called to order by President Hoagland, and the proceedings opened with prayer by the Rev. W. F. Clarke, of Canada, after which the President made the following

OPENING ADDRESS:

Ladies and Gentlemen of the North American Bee-Keepers' Society.

Not being present at the last annual meeting, Louisville, Ky., I would embrace the present opportunity of thanking you for the honor you have conferred upon me, in selecting me to preside over your deliberations. Any errors I may commit, I hope you may attribute to the right source—the head, and not the heart.

Bee-keeping, although not so popular a pursuit as many others, is none the less edifying and profitable. The honey bee is almost the only insect that has been domesticated by man, and aside from its giving us wealth and a delicious luxury, it possesses many charms, and is a study for the naturalist. This is only the fourth session of a continental society in our land for the purpose of investigating and learning of the wonders of this little insect.

For ages past, organizations have been effected by our best men to develop the various agricultural resources of the land. And during the same period the most industrious bees of our continent have been consigned to the ignominy of a death by fire and brimstone.

If apirians had given the time and attention in selecting the males and females of the largest and most industrious, prolific and docile colonies to breed from, with the same care, shrewdness and attention that has been practised with horses, cattle, sheep, hogs and poultry, we would not be under the necessity of importing queens from Italy, but would have a race of bees much superior to the Italians. Man can not obtain labor from any other source as cheap as from the honey-bee. They work for nothing and board themselves, only requiring house rent free.

According to the census returns of 1850 the amount of wax and honey produced in the United States was 14,853,790 pounds; in 1860, 126,386,855 pounds. With the increased attention given to the pursuit, together with the increase of colonies, we have no doubt but the present returns will show a vast increase of product.

Possessing, as we do in America, a genial climate and a fertile soil, susceptible of the production of richly varied honey-producing plants and flowers, with a due degree of knowledge and enterprise, the bees could be increased to an extent that the profit arising therefrom would pay all our taxes and supply our tables daily with one of the choicest luxuries of life.

Many of the best men of our land are now employed in acquiring practical knowledge of the nature and habits of the honey-bee. The science is advancing steadily, and the future is big with developments in apirarian pursuits.

The reading of the minutes of the last session was dispensed with. They having been published.

REPORT OF THE BUSINESS COMMITTEE.

Mr. King, from the temporary business committee appointed at the morning session, submitted the following report:

1. That the election of officers be deferred until to-morrow, to take place at a time to be designated by the Business Committee.

2. That the following topics be discussed at the afternoon session: First—"Advantages of Bee-Keeping." Second—"How is the queen produced from the Worker Egg." Third—"The Sting of the Honey-Bee." To be introduced by President Hoagland. Fifth—"Adulteration of Honey." To be introduced by a paper from Rev. H. A. King.

The report was adopted.

THE ADVANTAGES OF BEE-KEEPING.

The first topic on the list was taken up, and was introduced by Mrs. E. S. Tupper, of Des Moines, Iowa.

She said she could not imagine why she had been called upon to open the discussion on this topic, unless it was for the reason that females are supposed to be always ready to say something, whether they can talk to the point or not. She then proceeded to state some of the advantages of bee-keeping, and claimed that it was not only profitable, but that the presence of bees in and about orchards and vineyards tended to increase the yields from vines and trees. In support of these Mrs. T., who is a fluent and pleasant speaker, referred to observations made by herself. She also claimed that bee-raising was specially advantageous

to ladies, who were thus afforded, not only pleasant and profitable occupation, but also gave them out-door work, and thus benefited their general health. She spoke briefly on the question of profit, and claimed that there was no other business which offered such strong inducements to those who wished to make money on small capital.

There was further discussion of the topic, by Messrs. Hoagland, Zimmerman, Chapman, King, Clarke, Anderson, Rush, Pope, Benedict and others.

PRODUCTION OF THE QUEEN-BEE.

Mr. Alfred Chapman opened the discussion of the topic, "How is the queen-bee produced from the worker egg?" He contended that the egg of the queen was the same as that of the worker; that in some cases the larvæ was taken by the bees and put in the queen's cell, and that the drone also was hatched in the queen's cell.

Mr. A. Benedict said that he had this year noticed a drone in a queen's cell, but it was the only one he had ever seen there, and, it was twenty-four days from the egg.

Further discussion followed, which was participated in by Messrs. King, Zimmerman, Chapmau and others.

Rev. W. F. Clarke was called upon to deliver an address upon the next topic, and responded as follows:

THE STING OF THE HONEY-BEE.

A painful rather than a pleasing interest attaches to the subject now proposed for discussion. Possibly this may account for the fact that so little is said about it. In most minds it awakens disagreeable memories or unpleasant apprehensions. We incline to be mute on distressing themes. In looking through an agricultural library, one is impressed with the idea that there has been a sort of avoidance of this subject. You can readily find ample details concerning the honey-sac, the pollen basket, the wax works, the wings, the eye, but marvelously little about the sting.

Kirby and Spence, in their excellent treatise on Entomology, devote a paragraph to "insects which attack man from revenge or fear," and remark, "these all belong to the Linnæan order, *Hymenoptera*, and the tremendous arms with which they annoy us are two darts, finer than a hair, furnished on their outer side with several barbs, not visible to the naked eye, and each moving in the groove of a strong and often curved sheath, frequently taken for the sting, which, when the darts enter the flesh, usually injects a drop of subtle venom, furnished from a peculiar vessel in which it is secreted, into the wound, occasioning, especially if the darts be not extracted, a considerable tumor, accompanied by very acute pain. Many insects are thus armed and have this power." Prominent among them are mentioned the ichneumon, the spider-wasp, the honey-bee, the wasp and the hornet.

Mr. Quinby has just eight lines on this topic in his valuable work entitled "Mysteries of Bee-Keeping Explained." They are as follows: "The sting of the bee, as it appears to the naked eye, is a tiny in-

strument of war, so small, indeed, that its wound would pass unheeded by all the larger animals, were it not for the poison introduced at the same instant. It has been described as being composed of three parts, a sheath and two darts. Both the darts are furnished with small points or barbs like a fish-hook, that hold it when thrust into the flesh, the bee being compelled to leave it behind."

The only full and scientific account of the bee's sting we have been fortunate enough to find is embodied in a communication to the August, 1870, number of the *American Bee Journal* by J. R. Bledsoe, of Natchez, Mississippi. Four cuts illustrate the appearance of the various parts of of this warlike implement, as seen under a powerful microscope. One of them, which shows the point of the sting, is a truly formidable-looking object—a weapon of war well calculated to intimidate an enemy or appal a victim. Mr. Bledsoe was led to this microscopic examination of it from certain peculiarities of experience connected with a sting he received, and it is not surprising, when we look at the terrible pictures drawn by him to find him saying, "I certainly dread bees more now than before my investigation." The pith of Mr. Bledsoe's interesting paper partly condensed, and partly quoted, literally is as follows: He observed in extricating a sting from his person, that a portion of it remained in the wound, and that the part still fixed in the flesh was extremely fine in size; finer, indeed, than the portion removed, and fully as long. It also appeared to be a tube pulled out of the main sting, much in the manner of the working of a telescope. A microscope view showed however, that it was not a perfect tube; neither does it work with telescopic action. The bee's sting is a complex instrument, being composed of three distinct parts, of which the sheath forms one. These three parts join near the edges and form a tube, which, viewed sectionally, has the shape of a triangle, the angles being rounded off. The sheath near its point is narrow, but grows wider towards its base, where it gradually embraces the remaining parts, thereby keeping them in place in their working. Near each edge of the inner or hollow side of the sheath runs a ridge which fits a corresponding groove in each of the outer parts. Near its point, which is rounded rather bluntly, it is armed with two feeble sets of barbs, numbering as many as four in each set. The base of the sting or sheath is large, being broad and somewhat flattened, with an oblong hollow, which constitutes a receptacle for the poison just previous to injection into the wound.

The other two parts constitute the sting proper, and in a sectional view are semi-circular, the upper edge being thicker than the lower ones, and squarer, one of the edges having a projection extending along the under or inner portion of it, thereby forming a rabbet along which the opposite part freely moves. The under or inner edge of each of these parts, tapers down to extreme thinness, while near the termination of the edge, there runs a minute groove which corresponds with the ridge mentioned in the description of the sheath, and along which the parts move freely. Each of these parts proper, tapers down to an exceedingly fine point. Near the point begin the barbs, which, in some stings, number as many as ten, extending along the sting near-

ly one-half its length, and are well deflexed.

The parts are of a horny consistency, of a deep red color, and transparent; they are also hollow along the greater portion of their length, intended, perhaps, to combine lightness and strength.

The two chief parts of the base of the sting gradually assume a nearly round and tubular form, each terminating beyond the base of the sting within the body of the bee, and having an arm attached to it at right angles, which forms a part of the muscular mechanism by which their movement is effected.

Also, to each of the chief parts, and located in the cavity formed at the base of the sheath, is attached a plano-convex valve, the convexity of which is adapted to the inner side of this receptacle, and they occupy about one half of the space therein. When the sting is in action each of the chief parts are thrust out and withdrawn alternately; so that when working its way into a wound the valves, by their action, force out the poison which fills the cavity and which is received from a sac situated apart from the base of the sting. The poison readily passes along the tube, (which is a continuation of the cavity,) and finds its way into the wounds with great facility, owing to the peculiar formation of the sting.

It often happens that one or both of the chief parts of the sting are left in the wound, when the sheath is withdrawn. These being very minute, are seldom perceived, the person stung congratulating himself at the same time that the sting has been extracted. Additional pain and swelling result from leaving any portion of the sting in the wound.

In common with all the doctors who prescribe for the bee-stung patients, Mr. Bledsoe advises the immediate removal of the sting, but there is a touch of grim irony in the advice, when it is added, "it continues its working motion for several seconds after being torn from the body of the bee, and thereby buries itself so deep as generally to make it impossible to withdraw all of it."

The peculiarity just noticed, probably accounts for the severity of the consequences resulting from bee stings, in certain cases, in which highly sensitive parts of the body are attacked: but in view of the fact that the extremely fine point of the sting is armed with a number of barbs, may it not be questioned whether anything but the outer sheath is ever got out of the wound inflicted by this instrument?

Leaving the scientific paper of Mr. Bledsoe, and indulging in some general remarks, the celerity and force with which the sting is propelled cannot fail to indicate a remarkable endowment. It has been styled a weapon of war, and such it is, always ready and highly formidable. Is any other creature, in proportion to its size, so thoroughly equipped for martial purposes as the bee? It has been remarked that if man were as good a jumper, according to his size, as the flea, he could clear the dome of St. Paul's at a bound. In like manner, if he were armed proportionally as perfectly as the bee, he would be a terrible warrior indeed. The bee itself, if it had human depravity, would be an insect so intolerable that, spite of the sweet honey it brings us, we should be compelled to go in for its extermination.

Fortunately, however, the bee is pacifically disposed. It is armed for the preserva-

tion of peace, and not for the prosecution of war. It maintains "an armed neutrality," and must be stirred up or interfered with in some way, to show sign of menace or threat of attack. The common idea seems to be that the bee resembles the devil, who goeth about seeking whom he may devour. But the foraging excursions of this industrious insect are for other purposes than to find victims to sting. The stings of the bee colony are undoubtedly meant to defend their stores, and if bees were as harmless as flies, very little honey would ever find its way to the market or the table. Hence, the idea of some time or other bringing apiculture to such perfection as to breed a race of stingless bees, is as unwise as it is utopian.

There can be no doubt that fear of being stung is a very great hindrance, probably the greatest, to the extension of bee-keeping. Nor is this at all surprising, when you consider what serious and even fatal consequences result, in some cases, from being stung. It is no mark of wisdom to despise a bee-sting. To do so is to display ignorance, inexperience, or foolhardiness. No person who has been stung in a highly sensitive part of the body, when the poison injected has been peculiarly virulent, will pool-pool the affair. One such sting is enough to teach a lesson of caution that will last a life time. The wise course is to look a danger in the face and guard against it. Precaution can easily be taken if the habits of the bee are properly understood. A bee will sting only under two conditions exasperation or pressure. The second of these conditions would almost seem to render stinging involuntary. If you press the body of a dead bee, you will find that the sting will dart forth with astonishing celerity and force. Squeezing a live bee is very much like touching the trigger of a loaded gun at full cock. A discharge is the inevitable and immediate result. There are a few simple rules the observance of which will reduce the danger of being stung to a minimum if not remove it altogether.

1. The first is to completely master the emotion of fear. No person should undertake to handle bees who cannot maintain a perfectly calm, self-possessed, cool and determined bearing, under all circumstances. Bees know by some subtle discernment, whether you are timid or courageous just as a spirited horse knows whether timidity or courage has hold of the reins. A show of fear is pretty sure to exasperate bees. They seem to resent being meddled with by a timid hand.

2. Gentle and quiet movements alone are safe and proper among bees. They are excessively nervous and irritable, and should be treated accordingly. All rough ways, all sudden jars, all hurried motions are to be carefully avoided. Just as you would make everything as pleasant and soothing as possible to a nervous and irritable human being, so should you act among bees. Especially should this rule be observed in opening out a hive, and performing any manipulations on the interior. To insects accustomed to a dark, perfectly quiet habitation, with everything firmly fixed and in a most orderly state, it must be a rude interference at best for a hive to be opened, flooded with sunshine, and put completely out of kilter. If they can reason, they should be made to do it in this wise: "Man is our liege lord, he has a right to control us, he means us no harm, it will be all right." In all but rare

and exceptional cases, they succumb to firm and gentle treatment, and soon form a habit of acquiescence in the bee-keeper's will.

3. It is well to avoid meddling with bees, when from any cause, known or unknown, they are excited. Sometimes it may be necessary to subdue them under such circumstances, but these cases are unfrequent. In any necessary interference with them, choose a time when all is serene, and they are pursuing the even tenor of their way.

4. When, from any unavoidable causes they become exasperated, a steady, decided course is absolutely indispensable. Stand your ground. Have smoke at hand and ply them with it until they become pacified. It is like a controversy with a passionate, self-willed child. If you give in, worse contests will follow, and the hive, like a spoiled child become unmanageable. Now and then a hybrid colony will have an ungovernable temper. If it cannot be subdued, it is better to sentence it to death at the end of the honey season, than to have the nuisance of an untractable stock on hand. Such cases are, however, extremely rare, and are generally the result of bad management. Spoilt bees, like spoilt children, show bad training.

5. The utmost care should be taken never to crush a bee, if it can possibly be avoided. Some bee-keepers are very careless in this respect. With a strong colony numbering thirty or forty thousand, what signifies the loss of two or three bees? Well, the slaughter of a single bee will sometimes infuriate that whole colony. To crush a bee is, as we have seen, to necessitate the thrusting out of the sting and the consequent emission of the poison. No sooner is the odor of that poison detected by the colony than the tone of their music changes from a peaceful hum to a warlike strain, their tails are elevated high in the air, and from every tail the poison odor at once emanates, which rouses and lashes up the war spirit, until the entire army is ready and anxious for the fray.

6. Whatever style of hive is adopted, it should be such as to facilitate operations among bees. The simpler the better, if it only answers all necessary, practical purposes. Complications and nice adjustments are to be avoided as far as possible. A hive easily opened and closed, giving ready facilities of access to all its parts, without much danger of crowding or crushing the bees, is the one best adapted for the purpose, whether it be covered all over with patents, or entirely free from that style of ornament.

7. Precautionary measures in the way of personal defense, and taming the bees, are worthy of adoption by all inexperienced bee-keepers, and by all, however experienced, who know themselves to be obnoxious to bees. Inexperienced bee-keepers are apt to make slips, to have accidents, and to lose presence of mind, so that however anxious they may be and usually are to prove their skill by handling their bees without protection, it is advisable for them to use a bee veil and gloves impervious to stings, for a time at any rate. In regard to the other class of bee-keepers, it is a well known fact that bees, as well as human beings, have their likes and dislikes. There are those who are bee-loved and there are those who are bee-hated. The sense of smell is very acute in bees. By this they are guided in the recognition of the fellow-occupants of their own hive, and in the rejection of the natives of other hives. There is little doubt that it is their keen sense of

smell which leads them to take to certain persons, and to turn against others. The law of affinity which guides these little insects is not well understood, but that there is such a law is indisputable, and we must conform to it. Those bee-keepers are to be envied who are favorites with the busy little workers, and it is these who should feel called to go largely into the business, but those who are bee-hated need not on that account forego the pleasure and profit of keeping bees. They must prosecute bee-keeping under difficulties; but after all, some of the eminent apiarists have overcome greater obstacles than the dislike of their bees. Witness Huber, the father of modern bee-keeping, who made such wonderful discoveries in apiculture, and yet was a blind man. The wearing of a veil and gloves is an inconvenience, but it must be submitted to by those who have the misfortune to the objects of dislike to bees. It may be added that the use of smoke as a means subduing bees, will often enable bee-hated persons to handle their hives without protection. Much judgment is needed, however, in the employment of smoke, as an overdose of it, or an injudicious use of it has a tendency to irritate the bees.

8. Finally, a word remains to be said concerning antidotes for bee-stings. It would be a long detail to mention all the remedies that have been suggested by way of curing bee stings. In a general way it may be stated that almost any alkaline application is good, though antidotes do not always have the same effect on all persons. Bee-keepers must judge for themselves, after trial of various remedies, what are most effectual in their several cases. Without having any interest in it except a benevolent interest in the relief of suffering humanity, I strongly recommended the German Bee-Cure advertised by Mr. Hawley, of Utica, N. Y. I can testify, along with many others, that the relief it gives is well nigh instantaneous, not only relieving the pain but preventing the swelling. Of course, like other antidotes, it may not operate alike on all persons, but thus far I have heard of no exception to its curative efficacy. I would suggest whether it might not be well for this Society to take means to have the remedy just named thoroughly tested; for assuredly, if we could say to the public here is an application which will take away all the pain and prevent the swelling from a bee-sting, we should present one of the strongest inducements to embark in bee-keeping that can possibly be held out. Take away the fear of being stung, or provide a perfect antidote, and many would become bee-keepers who now, acting on the principle that "discretion is the better part of valor," give the business "a good letting-alone."

Secretary Pope, of Indianapolis, said he had always been hated by bees, and yet he did not fear them.

The discussion was continued by Messrs. King, Benedict, Chapman and others.

SECURING SWARMS.

This topic was introduced by President Hoagland, who exhibited a wooden box, perforated with holes, and elevated on a pole. This, he said, had been used with great success in securing swarms.

Mrs. Ellen S. Tupper, of Iowa, took

ground against swarming. Greater yields of honey were obtained by the non-swarming system. Swarming could be prevented by the use of the Extractor, by keeping the bees well supplied with empty comb between the brood and the entrance, and in other ways familiar to bee-keepers who use large hives. She could not obtain half as good results from bees that were allowed to swarm.

An address on the "Adulteration of Honey" was expected from Mr. H. A. King, of New York, but that gentleman stated that he had mislaid his manuscript, and would therefore have to defer reading his paper till another session.

BUSINESS FOR THE EVENING SESSION.

The following committee was appointed to prepare business for the evening session: Rev. W. F. Clarke, H. A. King, Mrs. E. S. Tupper, D. L. Brown, A. Chapman, A. Benedict and J. W. Winder.

On motion, adjourned to meet at 7½ o'clock P. M.

EVENING SESSION.

The Association reassembled at half-past seven o'clock, President Hoagland in the chair.

Rev. W. F. Clarke presented the report of the Business Committee, as follows:

1. Queen-raising and drone preservation, and best mode of introducing queens into movable frames and box-hives.

2. Adulteration of honey. To be introduced by a paper from Mr. H. A. King.

3. Moving bees to other localities for wintering, or pasturage, suggested by the question, Would it be practicable and profitable to ship bees in the fall, by boat, from Eastern Ohio, to some point on the Mississippi, in Louisiana, to remain, say, until May, returning by rail in time for clover-bloom?

4. Best method of inducing bees to breed late in the fall. Is it wise to resort to it?

5. Bee-forage, with the special inquiry, Can bee-keeping, as a business, be successfully prosecuted in a locality producing a large amount of white clover, but no other source except locust and fruit bloom in the spring?

6. Wintering bees under glass.

7. Prevention of honey candying.

8. Suggestions to Business Committee of time and place of next annual meeting.

QUEEN-RAISING AND DRONE-PRESERVATION.

The discussion of the first topic was opened by Mr. Benedict, who was followed by Mrs. Tupper, Messrs. Chapman, Zimmerman, Anderson, and others giving a variety of views upon the subject under consideration.

Mr. King was not present, and the second topic, "Adulteration of honey," upon which he was to deliver an address, was passed over.

MOVING BEES.

The third topic, "Moving bees to other localities for wintering," was taken up.

Rev. Mr. Clark said he could not speak on the subject from personal experience, but he knew that bee-keepers in Europe moved their bees from one locality to another, in order to give them the benefit of favorable climates.

Mr. Chapman said he had no experience in moving bees South in winter. He did not think it would pay.

Mrs. Tupper gave the experience of a friend (Mr. Brown) who bought 100 hives in Mississippi during last winter. As soon as the summer harvest commenced the bees were brought back to Iowa in good condition.

Mr. Brown said that bees wintered in the South consumed more honey, but they would breed a month earlier. Mr. Mitchell had transferred a lot of bees from the South last spring at a small cost.

Mr. Pope—At a loss of about \$400.

Mr. Benedict said that bees required more honey in the South than in Canada.

Mr. Clark thought that by keeping them in a semi-torpid state during winter they would do better.

Dr. Rush said it was not a good plan to feed bees, as they would consume twice as much honey as they would if permitted to help themselves.

BREEDING IN THE FALL.

The fourth topic was, "Best method of inducing bees to breed in the fall."

Mrs. Tupper recommended the introduction of a new queen in the hive. This was a good method, as applied to her locality (Iowa). There the Italians are so eager to gather honey that they will fill every cell, and the queen has no room for breeding. When fall comes we have all old bees and no young ones. At this stage the combs should be emptied with the Extractor, that the queen might have room for eggs. It would be well to introduce a young queen in the fall, so as to get more brood.

Mr. Chapman said in his experience it was good to exchange old queens for new ones.

Mrs. Tupper, by permission, read a letter from J. P. H. Brown, a prominent bee-keeper, of Augusta, Ga., containing some excellent suggestions in regard to the organization of associations. It was referred to the Business Committee.

Mr. Clarke moved that intervening topics for discussion be passed over, and that the last, "Suggestion to the Business Committee as to time and place of holding the next annual meeting," be taken up. Carried.

Mr. Clarke said that wherever these annual meetings were held the attendance was largely local. It seemed impossible to get a fair representation from all sections. He was in favor of a reconstruc-

tion of the Association, on the basis of branch or auxiliary societies, which branches could annually, or at less frequent periods send representatives to the National Association. For the next annual meeting he was in favor of Chicago.

Dr. Rush said he would withdraw his suggestion of St. Louis, and unite with his friends on Des Moines.

Mrs. Tupper, of Des Moines, said that though she would be glad to welcome the Society to Des Moines, she feared the expense of going there would be too great for most of the members.

After considerable discussion of the subject, the matter was handed over to the Business Committee.

Adjourned till Thursday morning.

SECOND DAY—MORNING SESSION.

The following Publishing Committee was appointed: Mr. Pope, Dr. Rush and Mrs. Tupper.

The report of the Business Committee, giving topics for the morning discussion, was presented, the first being the question of "Adulteration of Honey."

Upon this subject Mr. King, of New York, read a paper, from which we extract the following concerning the effect of adulteration upon the honey producing interests of the country.

"A leading honey merchant of New York, who bought largely of the comb honey of Mr. Harbison's great 100,000 pound honey crop, said (and I have it from his own lips) that he refused to purchase the extracted honey, because he could furnish a better article by making syrup of white sugar and adding to flavor the mixture, one gallon of honey to every seven gallons of this syrup, costing only eight or ten cents per pound. He said if the syrup was heated to the boiling point, so as to dissolve all the particles in the sugar, the mixture would not granulate. Others claim a secret of their own by which they prevent granulation.

"But what will be the effect upon the price and sale of extracted honey when the dealer increases every 1,000 pounds to 8,000 to flood the market? If one-third of the 300,000 pounds referred to be treated in this way 100,000 pounds would be increased to 800,000 pounds, which would no doubt glut the market and greatly reduce the price. But this is not the worst feature in the case. Dealers in New York and Chicago have resorted to the use of glucose as a substitute for sugar syrup, as others have done in the manufacture of golden syrup. Glucose is a liquid which is often made as clear as water, and of about the consistency of honey, though less sweet than even cane sugar.

"Messrs. A. Boyer & Co., whose address is Auberville, per Paris, France, are large manufacturers. Glucose is found in the juice of several kinds of fruit, but it is usually manufactured from starch or dried grapes. But will the evil stop here, or will glucose, which costs from six to eight cents per pound, soon become too expensive, and acids be used in its stead? They will extract white-clover honey go begging for purchasers, and even buckwheat honey, though darker, and therefore commanding

a better price, will be of dull sale, as these ingenious dealers can color their mixtures to look like the darkest buckwheat honey."

As to a remedy for the evils complained of, the speaker said:

"Perhaps apiarians will conclude to dispense with the extractor and think to remedy the evil by raising and selling only bad honey or comb honey in the frame. But these dealers have already found a remedy for such a contingency. They now sell most of their—how shall I call it—no, their mixture in glass jars, with one or more narrow strips of honey in the comb, which occupies the little space in the jar, but looks well, and sells the mixture with which the jar is filled.

"I can suggest no remedy but education. We must educate the people, and thus qualify them to judge between a pure and impure article. Apiarians must write on the subject, not simply for their journals, but for the city press, both secular and religious. While earth remains in its present state, evil men, as the Apostle says, shall wax worse and worse, but when Paradise is restored, that land flowing with milk and honey, these honey adulteraters shall go into their "own place, and trouble us no more."

Mrs. Tupper stated, after the reading of the paper, that she had frequent letters from Honey Dealers, wishing to purchase clean white comb.

After some further discussion, Messrs. King, Hoagland and A. Benedict were appointed a committee to draft resolutions expressive of the judgment of the association against the practice of adulterating honey.

The next topic of discussion was "Bee-Forage" and was debated at some length. Some of the members expressed themselves as in favor of buckwheat, others white clover, Mr. Hoagland, thought the forest was the great home of the bee. The richer the soil the greater would be the amount of honey extracted from the flower. The discussion as to the value of various flowers for "bee forage" was continued at some length, and was quite interesting. The sunflower, sassafras, the purple aster, and any quantity of flowers had their respective merits as honey plants thoroughly demonstrated.

The third topic reported by the Business Committee was "The wintering of bees under glass." This was discussed at some length, and the experience of different members of the Convention related.

"The best method of preventing honey from candying" was next discussed at some length, after which the Association adjourned till 2 P. M.

AFTERNOON SESSION.

The Society met at two o'clock P. M. The first hour of the session was occupied in the exhibition of patent bee-hives, honey extractors, and some fine specimens of honey.

ELECTION OF OFFICERS.

At the expiration of the hour, the Pres-

ident said that the election of officers had been made the special order for three o'clock to-day.

The Society on motion, went into an election for officers, when the following gentlemen were named for President: W. F. Clarke, H. A. King, Seth Hoagland, Aaron Benedict, Abner J. Pope, J. W. Winder. The balloting resulted in no choice. Mr. King, who had the second highest vote, moved that the President be authorized to cast the vote of the Association for W. F. Clarke of Canada for President. The motion was carried unanimously, and Mr. Clarke was thereupon voted for and elected.

Next in order was the election of a Vice-President from each State and Territory. The following persons were chosen: Pennsylvania, Seth Hoagland; Ohio, A. Benedict; West Virginia, A. Chapman; New York, M. Quinby; Tennessee, M. Benton; Indiana, A. J. Pope; Illinois, F. Grabbe; Iowa, Mrs. Ellen S. Tupper; Ontario, Dr. Thorn. In the States not represented at this meeting, the present Vice Presidents will hold over.

Dr. L. Brown, of Indianapolis, was elected Recording Secretary, and E. S. Hill, of Ohio, Treasurer.

Mr. H. A. King was elected Corresponding Secretary.

The reports of the officers of the Association for the past year were read and approved.

Mrs. Tupper, from the committee appointed to make arrangements for a display at the Centennial in 1877, reported that the committee had arranged for space, &c., at the Exposition, and that everything bid fair for a successful display. On motion, Seth Hoagland was added to the committee.

The Association adjourned till 7 o'clock P. M.

EVENING SESSION.

The Association met at half past seven o'clock, and Mr. Seth Hoagland, the retiring President, delivered his valedictory address, in which he said that he left the chair of presiding officer not in sorrow, but in a joyful mood.

Mr. W. F. Clarke, of Ontario, Canada, President elect, was then introduced, and spoke as follows:

Ladies and Gentlemen of the North American Bee-Keepers' Association:—I thank you very sincerely for the honor you have done me for the second time in electing me to the Presidency of this organization. As the retiring President observed, in the brief remarks which he made, the times are stringent and there have been unusual difficulties in getting up this meeting, and in view of the difficulties which the retiring President has experienced in this respect I hope we shall draw up a resolution at some later stage of our proceedings ex-

pressing our appreciation of his course and our thanks. I am not vain enough to suppose that I owe my elevation to the presidency of this society to my knowledge of apiculture or to my unprecedented success as a bee-keeper. I think I owe my present position to two causes. First, that I have taken an interest in the Society from the outset, and secondly, that I have not had any particular selfish interest in connection with this Society. This Society in its start encountered peculiar difficulties, which rendered it rather surprising that it should have weathered them all and come out into smooth open waters, as it has done.

It is true that this is a day of small things in this organization, but we have made considerable progress. We have, I think, escaped the greatest danger that menaced us at the outset—the danger of the Society being made use of for other than broad disinterested purposes. Bee-keeping has made considerable progress during the history of this Society. It has advanced out of what might be called the "slough of patents." Many lessons have been learned about patents which will never be forgotten.

Every business is likely to be traded upon by King Humbug. P. T. Barnum has said that mankind like to be humbugged. Whether they like it or not, they submit to it.

An educated physician once met a quack and said: "How is it I have so small a practice and you have so large a one?" "Well," said the quack, "how many people who go down street are really wise people?" "Well," said the educated physician, "perhaps one in fifty that pass our office are wise people." "Then," replied the quack, "you get the one and I get the forty-nine." [Laughter.]

Whether the same philosophy does not apply to a good deal of the quackery we have had in connection with bee-keeping I leave you to judge. We have some principles pretty well established, which I think ought by this time to be pretty well understood. Leaving the movable comb principle and the air chamber, and one or two other conditions of successful bee-keeping out of sight, the rest is not of much account. Those who like complicated hives with all sorts of fixings, can have them. We know bees are not particular, and will store honey in rough hives properly constructed as well as in the most finely adorned palaces ever constructed. We have learned a good deal about moth traps and other things, and those who have traded in this kind of apiarian Empyrean articles have shrunk away, and our society has done much to consign them to the grave they have chosen. Empyrean patents have been ignored, and this society has done much to spread abroad throughout the land the fundamental principles of apiarian culture. Although the society has not done as much as some hoped for it, it has done much. It has brought bee-keepers together and awakened an interest in the science of apiculture, but what we want in this society is to gather together all the intelligent apiarians of this country and make this a grand institution in the diffusion of a correct knowledge of apiculture. To do this we must find some means of bringing together our best apiarians.

I do not undervalue the influence of this society in the place when it meets from year to year. In all the different cities where its various sessions have been held an interest has unquestionably been awakened. But we want to do good upon a large scale.

This society shall embody the wisdom of all of our apiarists upon the subjects submitted to us. Some measures ought to be taken by which we can accomplish this result than by organizing auxiliaries to this society in every county, State and neighborhood. Pecuniary difficulties operate undoubtedly against our having as full a representation as we should have at the meetings of this society. There are many to whom apiculture is a sort of side business. Some go into it because of the interest they take in the subject. I have never been so situated that I could keep bees with an eye to profit. Yet, I have been well paid for my trouble in the interest in the pursuit. Let an interest be awakened in the minds of the public by lectures and all other legitimate means.

In conclusion, the speaker said the society had a great work before them, and it could be accomplished if they only did their duty. The rubicon had been passed, and this Association had a great future before it, and the speaker could only say that in the position he had been selected to fill, he would, with the assistance of the society, endeavor to promote the interests of apiculture on the North American continent.

RAISING QUEENS.

The first topic of discussion for the evening was then taken up. It was: "The Selection of a Place to Raise Queens."

Mr. A. Chipman had had the subject on his mind for some time, and thought it was worthy of notice.

Mr. Benedict thought the way Queen raising was now carried on was very uncertain, and more attention should be paid to the subject.

The topic was then discussed at considerable length, the details of taking care of queens and managing them as shown by the experience of a large number of persons being given.

Dr. Rush read a recipe, which he had in his possession, to prevent honey from candying and souring.

THE NEXT MEETING.

Mr. King, from the Business Committee, reported in favor of Toledo, Ohio, as the place, and the first Wednesday of December, 1875, as the time for holding the next annual meeting. The report was adopted and the time and place fixed accordingly.

The following committee was appointed to report on the question of breeding pure Queens and stock: Messrs. King, Benedict and Mrs. Tupper.

The Association then adjourned.

FRIDAY MORNING.

A discussion was held on the spring management of bees. This necessarily involved the subject of wintering, it being generally agreed that stocks well wintered, could be brought through the spring with comparative ease. Some advocated cellar wintering, and others out-door wintering, but the importance of having

strong colonies, was admitted on all hands. Warmth, stimulation by feeding, to make them strong early, were considered the chief points of spring management.

The subjects of extra combs and a standard size of frame were discussed together, a paper being read by Mr. King advocating the adoption of a standard frame. After several had spoken on these topics, it was resolved to lay the matter of a standard frame on the table until next annual meeting, then to be taken up at an early part of the session, and that papers be solicited in regard to it.

A paper sent by Mr. A. J. Murray of Memphis, Tenn., was read by Mrs. Tupper. It consisted chiefly of extracts from Purches's work on bees, published some 300 years ago, and was calculated to show that more was known about apiculture by that old author, than is known by many modern bee-keepers.

A communication from J. P. H. Brown of Augusta, Ga., recommending certain experiments in bee-culture to be made under the direction of the Society, was referred to the Business Committee, who reported recommending that such experiments be conducted by individuals rather than by the Society, which report was adopted.

ADULTERATION OF HONEY.

The Committee on Adulteration of Honey presented the following report, which was unanimously adopted:

WHEREAS, It has come to our knowledge that certain honey dealers in New York and Chicago are using large quantities of sugar syrup, and glucose, with which they mix a small quantity of honey and sell the whole for pure honey, thus making 1,000 pounds of honey sell for from 3,000 to 8,000 pounds; and

WHEREAS, We, the North American Bee-Keepers' Society, in annual session assembled, believing that the adulteration of honey can tend only to the ruin of the honey producing interest of the country by overstocking the market, reducing prices, ultimately lessening the consumption, and dishonoring our calling as well as their own; therefore,

Resolved, That we hereby express our unqualified condemnation of the course of these dishonest dealers, and hereby notify them that they must cease to adulterate honey and assure us of the fact, or for self-protection, we shall be compelled to publish their names and expose them to deserved contempt. The Committee advise honey producers to sell no honey to dealers guilty of adulterating. The Committee recommend the appointment of a Standing Committee authorized to communicate with honey dealers, and take such action as they may deem necessary to carry out the spirit of this resolution.

H. A. KING,
E. S. TUPPER,
HOAGLAND,
BENEDICT,
W. F. CLARKE,
Committee.

The Chairman of the Business Committee

reported the following resolutions which were unanimously adopted:

WHEREAS, This Society has sustained a great loss since its last annual meeting, in the death of the late Dr. Hamlin, of Tennessee, one of its Vice-Presidents; we desire to put on record the high estimation in which the deceased gentleman was deservedly held by his fellow agriculturists for his thorough knowledge of the science and art of bee-keeping; the zealous interest manifested by him in this organization, from its inception up to the time of the annual meeting, showing before his death, at which he worthily presided in the unavoidable absence of the President; and finally for his upright character, urbane manners and kindness of heart. Honor to his memory, and peace to his ashes!

Resolved, That the thanks of this Society be, and are hereby presented to Ex-President Hoagland, for the interest shown by him in the prosperity of this organization, and for his efficient, courteous, and praiseworthy occupancy of the chair.

Resolved, That the thanks of this Society be tendered to the railway companies and hotel keepers, who have encouraged attendance at this meeting by a reduction of their usual rates.

Resolved, That this Society, having received in every city where it has met, the most polite and kind attention from the local press, is pleased to find the members of the fourth estate in Pittsburg not a whit behind the fraternity elsewhere: and for their patient attendance, courteous behaviour and excellent reports of our proceedings, we desire to tender them our best thanks.

Resolved, That any and all of the officers of this Society are hereby authorized to organize auxiliary or branch societies, membership in which shall carry membership in this society; provided always that the membership fee shall be one dollar annually, and that one-half thereof shall be payable into the treasury of this Society.

A communication was read from the firm of Jesse H. Lippincott & Co., of Pittsburgh, claiming to deal in genuine, unadulterated honey, and inviting beekeepers to deal with them.

A standing committee, consisting of Messrs. King, Benedict, and Mrs. Tupper, was appointed to arrange a system of premiums for Italian queens and full colonies, for the next annual meeting.

A committee of local arrangements for next meeting was appointed, consisting of the Secretaries, Messrs. Day, Zimmerman, and Smith.

After some routine business and informal discussion on one or two points not thought necessary to be embodied in the resolutions, the subject of publication of the proceedings of the Society was taken up. The Secretaries could not engage to prepare a report in time for the December Bee Journals, and as Dr. Rush volunteered to furnish an abstract of the discussions in time for the December journals. The Dr.'s generous offer was thankfully accepted, and the Society adjourned to meet in Toledo, O., on the

first Wednesday in December, 1875.

☞ Since the foregoing Report was "in type," we have received another from Dr. Rush, Simpson's Store, Pa. From it we select such portions as was not elaborated in the former Report.

This annual meeting is reported as one of unusual harmony and interest, which must result in good, not only to the members present, but to the bee-keepers at large whom they represent.—T. G. N.

QUEEN REARING, DRONE PRESERVATION
AND BEST METHOD OF INTRODUCING
QUEENS.

Mr. Benedict—I generally have a hive that holds a half barrel, such a hive keeps a great many drones, though large hives keep drones until late or very cold weather, while small colonies will kill them as soon as the honey season is over if they have a fertile queen. I am generally successful with this kind of a hive and they fly out strong and seem to enjoy themselves and fly finely. Large hives also raise drones two weeks earlier, and they are better ones and more active. To introduce queens, put them right in. I sometimes wait a day and sometimes wait longer. I make no difference between a frame or box hive. I use a drum box, take old queen out and kill her, take essence of cinnamon in my mouth and wet them completely and put the queen in the top of the hive and let her go down among the bees. Sometimes I cage the queen and put her between the frames and leave her twenty-four hours, then I go to liberate her. I see whether the bees are inclined to sting her, and if they are, I shut the hive and go back the next day again, and they generally are all right.

Mr. A. Chapman—I generally introduce same way as Mr. Benedict does; but another way is to put her in a wire cage and put in a cork of comb, not very thick or loosely, cut a comb the size of the hole in the cage and stick it in, they find the queen caged and loose her by eating the end out and liberating her. I never loose one queen in this way.

Mr. Zimmerman—When I introduce her I take her to, and put this comb and honey in the end of the cage and to make it more sure, put in a lot of strange bees at the same time; and thereby disorganize the colony and they are less disposed to kill the queen.

Mr. Chapman—I take a comb of bees from another hive with brood in it, and a strange queen from another and put them together and they do well.

Mrs. Tupper—Queen raising in the most important of all. Each one must understand it well, the way I take is one that any one can follow. Take the best queen you have, a good hive and queen, put her in a good colony in the fall for spring operations, stimulate by feeding early, have them strong in the fall and spring both, also feed in the fall; no difference where, so it seems to come from the outside of the hive. Go to the colony (early in the spring,) take out the queen, put her in another hive, disturb them as little as possible, put in frames in another hive with enough bees to keep them warm, get four frames in another hive, move the hive and put it in the place of the old hive, and if too many leave the old hive change them and continue; in this way you can get ten nuclei, and as soon as it is warm you will have queens. As soon as one comes out, put in another cell and continue this rotation, cage or change queens between ten and two o'clock and you can have from ten to sixteen nuclei all the time without much care. Mark the entrance for queens before they fly.

Mr. Benedict—Those large hives, I would say, which have drones, that they fly early in the day, stop in the drones early, and put in a teaspoonful of honey in the big hive to feed and excite the bees and drones. Open the hive about five o'clock and liberate the drones and young queens and they will come right out and fly finely after all the rest of the drones are done flying.

Mr. Chapman—I keep my hives large and strong, and in the spring of the year take out a few drone combs and put them in two hives that have no other comb in their hives and kill all the drones except those in the two hives. I killed all my drones in this way last spring. Have practiced this for a long time, and my best success has been with large hives to keep drones.

Mr. J. S. Hill—I have introduced queens and have been successful; lose one once in a while. I do not like the method of wintering bees, they do not clean off or the queens either. When you want to change queens catch the old one, put her in a cage, raise the bottom or open the hive, put the old queen in the cage, on the bottom of the hive, and in two days if they are quiet, change the old one for a new one, and put her in the same place, stop the cage with bits of comb, getting your comb from uncapping honey. In two days after, examine to see if she has been liberated, if they have not let her go, then uncage her.

Mr. Benedict—I would have my queen to breed from, in a good strong hive in

the spring and as soon as the weather is warm enough, change her to another good hive and on the 9th day I would cut out the queen cells, get a nucleus hive and put in it frames of honey and brood capped, with a few bees, next day put the nucleus in the place of the old one, have plenty of drones in the old hive.

Mr. Anderson—When I raise queens I do the same way, but when I put my cells in (as soon as they are capped) I put them in a wire cage and leave them an exit.

Mr. R. B. Price—I first catch old queen and kill her and put her in the cage with the new queen and succeed well, keep them in twenty-four hours. As soon as the bees find their queen dead they will readily accept the new one.

Mr. Hill—I generally have bees two weeks before I disturb them after introducing a queen.

Mr. Zimmerman—I have lost queens by being killed after they had been liberated two days. To make doubly sure I would take out the bees and put the queen in, and then let the bees go in slowly and they think it a strange place.

Mr. Sweitzer—I cannot succeed in that way.

Mr. Benedict—Be sure and conquer the bees first, by smoking them well, then kill old queen, put the new one in a cage with comb stopper. In forty-eight hours see if she has been liberated and if not let her be in the cage one week, then pull out the cork and let her go.

Dr. B. W. Rush—I have tried the plan with a comb stopper and have succeeded well.

BEE FORAGE.

Can bee-keeping as a business be successfully practised in a locality producing a large amount of clover, but no other source except locust and fruit bloom in the spring?

Mr. Chapman—I will give an idea how to get honey from clover. I have been a farmer. Take a field in a good state of cultivation, sow it in clover, and when it has fairly covered the ground it will draw a moisture from the surrounding land. I do not plow it, but add more to it; this field will deposit much more evaporation than the surrounding, or poorly cultivated fields.

Mr. Hoagland—I don't think I am prepared to express myself, we cultivate from 20 to 60 acres of buckwheat of the black variety. The gray superceeded the black, and then in three years I got the silver quill. Two years ago it produced more than it has since. Sometimes clover is the best for honey and sometimes basswood, but now clover is the honey resource as basswood has failed by being destroyed. I wish to say that buckwheat

is not so exhausting as some think. I had a new field in for 16 years, and an adjoining field only two crops, then sowed with timothy, and clover grew finely. Buckwheat does not exhaust the soil as it draws most of its dampness from the air.

Mr. Benedict—In my locality they do well on clover and locust; the idea I would go on would be to select a locality where it is good to secrete honey. Our honey ceases at the end of clover time, the season lasts about five weeks. Linn is the best that we can cultivate—easily transplanted—I set out a great deal of it last spring, it did well; set out as soon as the frost is out of the ground; blooms last of June with us.

Mr. Zimmerman—I discover in my experience more honey along the rivers, and bees do better on bottom timber. We have clover and basswood. I would recommend that all would cultivate catnip. Basswood is abundant in my grove and I cultivate some of it, it is next to fall flowers. Boneset, golden-rod (three kinds of it), the low sort is the best. Use extractor in summer, and get winter stores from fall flowers, and sometimes when these begin I make three hives of one.

Mr. N. N. Betsinger—Asked if sowing two acres of catnip will pay.

Mr. Zimmerman—I think it will.

Mr. Benedict—I think it will pay better to sow white clover where the ground is moist.

Mr. Betsinger—Two years ago I sowed Alsike, and it came on last June. In passing through the Alsike clover, saw bees swarming on it, (sowed it on low damp ground) while white clover did not do near so well.

Mr. Zimmerman—Which does the best?

Mr. Betsinger—Alsike is my experience.

Mr. Benedict—Bees work equally as well on Alsike as on white clover, think Alsike will secrete more honey.

Mr. Abner J. Pope—I went to the Shenandoah Valley, Va., was there from June 21st to Oct. 30th. I saw "blue thistles" in bloom, and some told me it was their best honey source; some fields were full of it, and was troublesome; in another field by the side of it I saw white clover. Thistle is the best honey source and does not hinder cultivation, it enriches the soil and never fails to produce honey. I also saw it in Maryland.

Mr. Clarke—I would say that there is a Canadian thistle and you are welcome to all of it.

Mr. J. W. Sherif—I notice growing a species of clover, it grows 3 ft. high, and I saw as many as twenty bees on a flower, both black and Italian bees. Blooms last of August.

Mr. John Stevenson—I planted sunflower for ornament and my bees done well on it this summer.

Mr. Rush—I planted plenty of it and never saw a bee on it only for pollen.

Mr. J. Winder—A friend recommended it highly for honey.

Mrs. Tupper—We need a locality which has locust, clover and fruit bloom. This year my bees did well on fruit bloom, but it does not occur one season in ten. We should arrange to have our bees ready for the honey harvest. I would begin to rear brood freely, early. I would give them empty comb in the middle of the hive and get brood in it, and have the hive strong, and may have as high as two bushels of bees; continue to feed and keep the queen going. Everyone should study their locality. When I use empty comb I keep them from swarming.

Mr. Betsinger—What kind of a hive do you use?

Mrs. Tupper—I use a plain box hive with frames 12x12. Alsike clover when sown in a good locality is the best I have, better than white clover.

Mr. King—I think if I should go into the honey gathering again I should look to fall plants, such as golden-rod and aster, the golden-rod is rather yellow but aster is much clearer honey. All through Ohio we don't have much fall blooms, and even east of it.

Mr. Chapman—I am of the opinion of Mrs. Tupper. I can control swarms by giving empty comb.

Mrs. Tupper—Many persons have more fall pasture than they think they have, if they would take the honey out and give them a chance of gathering it.

Mr. Replogle—What is the difference of the same kind of flowers in different localities and same climate?

Mr. Betsinger—Where I am located now in Onondaga Co., N. Y., we have all kinds. I saw basswood so plenty, that if you would shake a tree it would fall in profusion and daub you with honey, it lasted one week each year. Last year I got all my surplus honey from teasel. It is not best to raise over three acres of it, it is a valuable plant, and I would give up bees if I had nothing better than clover.

Mr. J. E. Moore—I think, with me it would pay to keep bees on white clover, near Rochester, Pa. I got 107 lbs. from one hive from May 20th to July 4th.

WINTERING BEES.

Mr. Benedict—I have a plan better than glass. I have a box made square to put on top of my hives and the bees go up in the top of my hive to fly and fall back on the frames, have a quilt over the frames

the box a foot high, when feeding it is necessary for bees to fly and discharge their fozces.

Mr. Zimmerman—My experience at Cleveland, Ohio, was, put the bees in a room and place a mosquito-bar between them and the window, so as to keep them from the glass, give them light in the room by the window and they cool off, fall down and go back, do not put them in until after a cold spell in March, and then take them in a room and feed them up. I intend to continue the experiments, the one made was in 1873.

Mr. Benedict—I can feed my bees by taking them in a room.

Mr. D. L. Browne—How many times have you tried the experiment? we never put them in winter quarters or even in a room.

Mr. Benedict—I think it a good plan, I have had bees cured of the disease in that way, received them when they had the disease mildly and they recovered, and came out in good condition from the room. I can fly a good many in that way, if the weather is cold for a long time, I bring them in for a flight.

Mr. Stetsers—Will your bees keep quiet.

Mr. Benedict—When you put them in they will take their flight and fall down (in the top of the hive) and crawl back and do not seem to be much uneasy.

Mr. J. W. Parker, Chicago—A friend keeps his bees in a room, well warmed and ventilated, and they consume a good deal of honey and he expects to loose money.

Mr. Rush—Mr. Benedict, what do you cover hives with, what you put on your hive to give them a flight?

Mr. Benedict—I cover the boxes with screen wire.

Mr. Rush—If you put on glass they will fret too much, and if you put on wire its too cool and besides they will worry to much to get out. I put on a good article of muslin (brown) and they have plenty of light and cannot see out and thus save them so much uneasiness to get out.

Mr. Zimmerman—My musquito-bar keeps the bees from coming in contact with the glass.

Mr. Rush—It's too open and they see out too much.

Mr. Harrison—Mr. Benedict; will not the bees fall down and get daubed on the frames?

Mr. Benedict—A few times it may occur, when I let them fly in February they don't daub themselves, but in some days in March they will daub themselves some, I let my room cool off gradually, to induce them to go back. I have fed up my bees in the fall, fed on white sugar syrup.

Mrs. Tupper—I don't want the idea that we are to winter bees this way, but must feed up in the fall and you have no more trouble, this talk is only applicable to weak colonies which have been neglected.

PREVENTION OF HONEY CANDYING.

Mr. Pope—I took honey out and put it in a cold place and it would candy, bring it back and it would become fluid again. Keep it in a warm, dry, dark place and it will keep a long time.

Mr. Chapman—That is my experience.

Mr. McLane—What causes honey to become thin.

Mr. Clarke—Souring or ferment causes it to become thin.

Mr. Betsinger—My experience in keeping comb honey is this. I keep it in the cellar and it would get thin and run out. I moved in a thin walled framed house, with tin roof, and when the weather gets cool I build a fire in the room and the honey becomes thicker instead of thinner.

Mr. Zimmerman—I had a few barrels of honey, some were air tight and some not, the one air tight did not candy and the other did.

Mr. Betsinger—A neighbor extracted some honey and bunged it up tight and in two months it was solid.

Mr. Zimmerman—We extracted a barrel of honey, bunged it tight and left it some time, opened it and took out some and it was all right, shut it up and looked in a month and it was solid.

Mr. Betsinger—Will honey air tight, keep longer in the dark than in the light.

Mr. King—I understand that there is a man here who has a receipt for keeping honey, will he make his receipt, and I see he has offered to, in the AMERICAN BEE JOURNAL?

Mr. Rush—I have been experimenting with the receipt and it has succeeded well so far, and as soon as the terms are complied with in the JOURNAL I will let up.

Mr. King—Some one sitting by me told me to ask for it, but I see the joke comes on me for the queen.

THURSDAY AFTERNOON.

Pres't Hoagland—There will be one hour given to exhibition of articles pertaining to the apiairy.

Mr. J. E. Moore exhibited his sectional hive.

Mr. King exhibited Barker & Dier's sectional honey box and added a few words on their hives. Also exhibited Mr. Quinby's bee smoker for quieting bees; it works by a bellows.

Mr. J. W. Winder, Cincinnati, Ohio, exhibited his honey extractor No 3 *Queen City* with stationary can, also his No 1 with revolving can, and gave manner of using both.

Mr Hoagland exhibited annual herb called "Blue Thistle," same as Mr. Pope referred to.

Mr. Geo. Hardesty exhibited his "*ne plus ultra*" hive, very empirically and his remarks and hive attracted a good deal of notice, and criticisms were freely offered and the hive condemned because of the unnecessary space between end of frames and hive.

SELECTING QUEEN RAISING LOCALITY.

The advisability of selecting a locality where queens may be raised by a committee appointed for that purpose, and save importation.

Mr. Benedict—There is so much risk in raising queens and so many queens are impure. I believe there are impure bees in Italy, in some localities, but in others they up the standard of purity. I do not like to say much on this subject.

Mr. Brownie—I am called on, but cannot say much; will wait to hear from others.

Mr. Hoagland—I think it would be better to appoint a committee to take the matter in charge, and after due consideration report at our next meeting.

Mr. Chapman—I agree with Mr. Hoagland and put it to get the mind of the Convention.

Mrs. Tupper—I imported queens ten years ago by Colvin at a cost of \$50 each. I imported by Dadant and lost heavily. I have imported since through friends and have done better. But I think we have better queens in this country than in Italy. I sent queens to a man in Germany and he replies that they are better than those he gets from Italy. I think there is danger in importing of getting a taint of black stock as they may have mixed some of the Egyptian blood in them. It is like importing cattle and sheep, they have improved so that they are sending them back to where they came from. I have got fine queens from both North and South Italy.

Mr. Chapman—I would earnestly recommend, that in sending queens, you put in comb from the hive from which the queen was taken.

Mrs. Tupper—There is not the least difference to me.

Mr. Chapman—I think they should not take old comb, that is, comb long out of the hive.

Mr. King—There are persons advertising queens of both imported and home bred as breeders of the same, and at the same time do not own a hive of bees. I travelled in Europe and stopped in a German apiary and found no pure stock, and that same man was sending queens to this country. I stopped with another man and found five stocks

of blacks. In Italy I visited another apiary and one that advertised largely in Europe, and had not a pure colony. It is a shame, a burning shame. We ought to issue a diploma to the old queen breeders who have long been successful, and those who have a good locality, the one who has thorough experience, the one who keeps his bees all right. Select a number of queens and raise queens from them, and select queens to rear drones from only. In raising queens, as I pass over my apiary, I find drones just hatching in a comb, and place this comb in a hive which has a young queen in and *vice versa* with the queens. To keep drones in working with my bees one day, late in the summer, I found a hive with no queen, and the drones when drummed out came back in large numbers; and if they are excited they will attract others—throw the bees out, raise the excitement and you will have a fine lot of drones.

Mrs. Tupper—This is a free country and everyone has the liberty of buying where he wishes, and no diploma will control the queen trade.

Mr. Anderson—If our stock continues good we keep it, if not, we turn it off, some queens are more prolific and workers more industrious, and when we find a good producing hive keep them, and if we find them poor, kill the queen; but how to get good drones is the question.

Mr. Clarke—Believe giving diplomas impracticable. Let every one get their own diploma. If this subject is brought up to the right pitch we must pay a good price for queens.

Mr. King—Every one knows that premiums have been paid all over the country. Give premiums to persons for extra queens. I move that a committee of three be appointed to get up resolutions in regard to it. Premium should be given.

Mrs. Tupper—I have attended my State Fair, and it gave high premiums for the best black and Italian queens caged. What did it amount to? They could tell nothing by the queens; they must see their workers. It is the wrong time of the year to handle bees, when the Society meets.

Mr. King—I can tell a good queen anywhere.

Ex-President Hoagland, in the chair.—There are many present who wish to hear Dr. Rush. I understand that he has some means or a recipe for keeping honey or syrup. I am informed that the Dr. has consented to favor us this evening. Will he please to do it now.

Mr. Rush—I have a recipe for keeping syrup from souring or granulating, also to keep honey from souring. I cannot say that it is a certain specific; not at

all, but can truthfully say, that as far as I have experimented with it, it has not failed a single time. I believe it will succeed in a majority of cases. I have given it to Messrs. J. S. Hill and G. W. Zimmerman to be tested, and given them special directions, and if they succeed with it, in a majority of experiments, then I expect pay for it, and will leave each one to be guided by conscientious duty. If it fails I do not want anything for it.

The following is the recipe: "Flavoring Extract of Lemon," "to one gallon of syrup or honey add one teaspoonful of the extract" more may be added with safety. Do not add until syrup or honey is cool. It gives a fine flavor. Stir gently.

BEST METHOD OF SPRINGING BEES.

Mrs. Tupper—Best way to keep bees through spring is to winter them right. One says he went through finely on my plan. I take my bees out of the cellar in the night before I expect them to fly, and about the time I want to commence to stimulate, bring them out quietly. If you take them out on a sunny day, they come out and fly too sudden and many are lost, when it is warm enough I begin to feed and as soon as safe I examine them and generally find brood, also feed rye meal as long as they will take it and as soon as they have plenty of brood. I open the hive and give an empty comb-place in the middle of the hive, keep quilts on hives so as to protect the brood. I would rather have bees out than in a cellar, if not frost proof. But to keep them out doors, set a store box around your hives and fill in with chaff or manure and leave the entrance open. Bees that are in a cellar must not be disturbed at all and left until time for setting out in the spring for when they are disturbed they consume more honey.

Mr. Benedict—Bees consume but little honey from 1st Dec. to 1st of Feb. but after that they consume a good deal, for brood rearing requires much more feed.

Mr. Chapman—I cool my cellar before I go into it to see my bees and do not disturb them, I carry them out in March to fly, and if the weather gets too cold I carry them back. I feed syrup warm and get water from a brook to make syrup with, also feed rye meal.

Mr. Betsinger—Let your bees be quiet in their winter quarters. I have had experience in feeding syrup, and find comb honey the best to winter on. I winter on summer stands, I find a cluster of bees 4 inches thick will not freeze. I open a hive on a cold day and out come the bees quite active to meet me. I put a quilt on the frames first. I put on a paper about 1st of April. As soon as warm enough and brood commences, I put

in empty comb in middle of the hive and soon find plenty of brood. I find we must keep them dry.

Mr. King—Read a paper on the coming "Frame."

Mrs. Tupper—I never have any trouble in securing comb when I have plenty of bees, and the weather favorable. Put a frame in the middle of a brood chamber in the night when honey is plenty, sometimes put in 3 in a day. I don't think it pays to build comb, I would not build it for less than \$5.00 per comb, 12x12. I am in for a standard frame and that they be 12x12.

Mr. Benedict—I breed queens for sale and not for honey. I put frames in middle of the hive at night, and have got 3 frames of comb in a day. I attach great importance to a tight fitting frame and have them fit tight on the sides of the hive.

Mr. Rush—I obtained 4 nice frames of comb by feeding syrup just at the close of the honey season. Feed 10 lbs. of sugar, one of sugar to one of water, feed in the evening.

Mrs. Tupper—I tried some 20 times by feeding to get comb and did not succeed but 3 times, and then they would soon cease taking the syrup.

Pres't Clarke—I think square frames good in the north, in the south a shallow one. In Canada we need a deep frame. I have no experience with shallow frames. I find extreme difficulties with light fitting frames in the fall of the year, and I cannot use a Quinby Hive, find it produces a bad temper among the bees, I would give up something else in place of tight fitting frames.

Queen Committee recommends each one to conduct private experiments.

COMMITTEES.

Committee on Arrangements—G. W. Zimmerman, A. Benedict, J. L. Parker.

Publishing—A. J. Pope, W. B. Rush, D. L. Brown.

Centennial—Mrs. Tupper, W. F. Clarke, H. A. King, Seth Hoagland, J. W. Winder.

Queen raising—Mrs. Tupper, H. A. King, A. Benedict.

Adulteration of Honey—H. A. King, A. Benedict, Seth Hoagland, W. F. Clarke.

What Killed Replogle's Bees?

In the October number of the JOURNAL, I see an inquiry from Mr. Replogle of Indiana, wishing to know the cause of "bees dying at this time of year," (August and September?) I have been watching affected hives closely for three years to ascertain the cause. If Mr. Replogle's bees are affected like mine, and if he has noticed closely he will have observed that

it is only the young bees that are diseased. They crawl out of the hives and die for weeks, until the ground is black with them, making attempts to fly, but not one in a hundred can rise, the very few that do fly have no power to guide themselves, cannot keep a straight course, but zig zag about and fall.

With me, this commenced with my bees in August and continued till towards the last of September. I have satisfied myself that this condition of things is the result of an attempt on the part of the bees to rear more broods than the amount of honey in the hive, or to be obtained in the fields, will support. The brood in the larvæ and chrysalis state, may be said to be put on *short rations*—the short supplies being equally divided among *all, none have enough*, and when the brood is old enough to seal, *there is not food enough deposited in the cell to properly mature the bee.* My reasons for believing this are,

1st. That it occurs when the bees are gathering but little honey, and in stocks that have not much honey on hand.

2nd. In a majority of cases the affected hives were such as had been queenless for a time (either by having thrown off a swarm or otherwise) and consequently were more disposed to rear brood largely.

3rd. The affected stocks were invariably black bees, the Italians at the time, being able to gather from red clover were better supplied.

4th. About twenty days from the time the bees commenced gathering honey from the fall flowers, the mortality ceased.

We have in this latitude a honey dearth, from about the 15th of July to about the 5th of September, during which bees gather very little honey. They commenced gathering from the fall bloom this year and last, the 5th of September, as my books show. Bees were gathering honey freely by the 15th of September, but the young bees in my two Black Stocks continued to die. I predicted to my bee friends that they would cease to die after the 26th, it proved to be so, all the eggs had after the 5th of September (the time the bees began to gather supplies) produced healthy bees. Those having bees in a similar condition the coming season, will please notice in regard to the supply of honey, as I did not think of short supplies being the cause of the mortality, until after they were gathering freely, when an examination could not have proved anything, bearing in mind that bees *may* be found dying as described, with honey in the hive, from an unwillingness on the part of the bees to consume their sealed stores largely on brood rearing when gathering

little. I have found it necessary heretofore, to unite with others, stocks affected in this way, being all old bees, they would, sometime in the winter or early spring, show signs of dysentery, (caused by the reduced size of the cluster from the old bees dying) which would disappear after uniting. I thought of writing to the JOURNAL on this subject last September, but supposed old bee-keepers were familiar with what was a new idea to me, and it would be, with my limited experience with bees, like landmen attempting to teach sailors navigation.

Russellville, Tenn. W. H. RIGGS.

For the American Bee Journal.

Death of Doctor L. J. Dallas.

Prominent among those who have done much to advance the apicultural interests of the State, was Dr. L. J. Dallas the subject of this sketch, whose long illness terminated fatally this month (October) in the 63rd year of his age.

Since 1859, when he removed with his family from Ohio to Kansas, his best energies have been given to the development of our young State.

Securing a farm near Baldwin City, he put it under a high state of cultivation, and practiced medicine, also, during the same time. He left the farm in 1864, and moved into town that he might the more successfully prosecute other branches of business.

He was a strong advocate of the cause of temperance; As a physician he ranked high among his professional brethren;

As a friend of education he manifested that same indomitable perseverance, characteristic of the man, that overcomes difficulties which to common minds would have appeared insurmountable.

With the taste for all the embellishments and adornments of civilized life, he made his home a paradise of beauty. With christian fortitude he withstood the storms and contentions of life, which all men like himself, born with positive ideas, have to encounter. With due regard for his family of children, he gave each of them a good education, thus qualifying them for the various responsibilities and duties of life. He was a man of great general information,—a member of the Methodist Church and for a long time one of the trustees of "Baker University" located in the same city where he had his home at the time of his death. He evidently lived with a determination to leave the world better than he found it.

During the 15 years of his residence in this state he kept bees. The last nine years, he lived in Baldwin City and turned his attention largely to this business.

He was a strong advocate of the King hive, though he used, principally a modified form of it, having the hives made larger every way so as to accommodate several tiers of frames. He claimed that such a hive was more profitable with him than the others, as he depended mostly upon the Extractor for honey. At the time of his death he had about 80 colonies—all bright Italians and descendants of queens purchased several years ago of Mrs. Tupper. He was a strong believer in the superiority of the Italians.

His colonies were arranged in his backyard, in the rear of his dwelling in a very pleasing manner, beneath the shade of cherry, peach, apple and other varieties of trees, with paths, walks, and avenues between, reminding one of a miniature city sequestered among shady bowers.

For several years he was a zealous advocate of in-door wintering, and he built a house for that purpose, which was quite roomy, having the sides made double with saw dust filled between. His bee house was ventilated at the top, and he could maintain any degree of temperature that he desired. He also had wire cloth ventilators in the tops of his hives during their stay in-doors. But he did not succeed very well winter before last; many of the combs became mouldy and the bees nearly all manifested signs of dysentery. So last winter he resolved to not house them as heretofore but to try and make them comfortable during the winter on their summer stands. He accordingly procured rough clap-boards, which by using corner posts, he weather-boarded up into boxes, one for each hive and each having a slanting roof. After placing a quilt on the top of the frames and filling in with hay or straw on the top of it and under the cap, he placed one of the large outer coverings around each of his hives and packed between them and the hives with straw or hay, leaving an opening in front, which in severe weather he closed with a bunch of prairie hay, on top of which he placed a rough board with one end of it slanting against the box.

By this plan he claimed that his success was perfect, as his colonies were all vigorous and strong in numbers in the spring, having no signs of dysentery and no mould-combs.

For two years he was President of our State Association and made a very efficient officer.

The last meeting of the Association, at which he was present, he delivered a very able address, in which he gave us a summary of all the modern ideas and improvements and pointed out the relative value of each to apiculture in Kansas.

His energy and enthusiasm infused life into this as well as into every thing to which his attention was directed.

In his death, the Society has lost a friend, and the bee-keepers have lost a wise and experienced counsellor—one who was always wide-awake and progressive in his ideas.

M. A. O'NEIL.

BLACK JACK, Kansas.

For the American Bee Journal. Toads and Bees.

In this locality (7 miles northeast of Saratoga Springs) it will not do to have the entrance, or alighting board of hives nearer than 9 or 10 in. from the ground, on account of toads. Neither will it do to have a board leaned from the ground to the entrance. Toads are numerous and trouble bees most, early in the summer. Later in the summer, fleas, bugs, and other insects are more numerous, and bees seem to be disturbed less by toads. During the day the toads are quiet under bee-hives or boards, or somewhere out of sight, but in the evening and during the night they are out in force. I have, in the evening, passed in front of hives without a lantern, when the alighting boards were from 4 to 6 inches from the ground and there was from one or two toads at the entrance of nearly every hive catching bees. I have seen them when the hives were raised higher from the ground hop against the edge of the alighting board, and fall back. I have also seen a toad hop up an inclined board to the entrance of a hive, when the entrance was 15 inches from the ground.

Early in the summer, as the weather gets warmer and bees more populous, there are usually bees at the entrance all night. A toad will set on the alighting board and should a bee go within 2 or 3 inches of it the bee will disappear so quickly that it is almost impossible to see what becomes of it. Where toads have access to bees they usually in the morning contain from 2 to 8 bees each, and they do not eat dead bees either.

Cat birds are very attentive around bee-hives in June and July, but I have not proved them guilty of catching bees, or even drones. They are often immature bees, and moth worms.

Saratoga, N. Y.

S. RUGGLES.

It is estimated there are two million bee-hives in the United States. A hive yields on an average a little over 22 lbs. of honey. The average price at which honey is sold is 20 cents a lb., so that the revenue from bees is \$8,800,000.

For the American Bee Journal.

What Shall we Report?

DEAR EDITOR:—Are there not too many that have nothing to report but their failures, after trying to keep the Italian bees pure? A free discussion of all the known causes of past failures as well as the experiences of those who have been successful, we think, in order. Will our learned friend W. M. Kellogg please state the condition those four insignificant black stocks were in at the time his Italian queens became fertile, and by so doing will undoubtedly explain to beginners, for us. He says "one black stock swarmed and the new queen in the old hive mated with a black drone." Was not this stock in precisely the same condition we recommended for beginners to have their Italians in when rearing queens? We are very sure that there were black swarms in the above condition at the time his queens became fertile. We repeat only what we know for the benefit of those that wish to keep pure Italian bees. Allow those stocks to rear queens where your Italian drones are, at a time when there is no black stocks rearing queens in your vicinity if possible and you will not be troubled much with black drones. We are glad W. M. K. has a good opinion of chickens, for we are very fond of them ourselves, but prefer them stuffed. He says they will go up to a cluster of bees and pick out flies and drones by the half hour. What kind of bees has K. got? We are sure flies do not cluster with our bees, and if they did, woe to the chicken that undertook to pick them. By the way, would it not be well for beginners to keep a chicken inside the hive, for protection? I see that some writers find a great deal of fault with C. O. Perrine. I sold him a part of my crop of honey this season and found him a gentleman to deal with. He was the only man I could find in Chicago that would pay cash for honey. He buys at his own price, of course, as there is no competition. Is there not room for another honey dealer in Chicago?

We are aware that some of our queen breeders have recommended Palace hives, with a great number of drones. A barn full of drones would not answer us, though we could open the door and bid them fly when we wished, unless queen rearing was going on in the barn; in which case verily we say your drones know what is up.

Carson City, Mich. H. M. Roop.

Length of Flight of Bees.

An Irish paper has the following:—"Three men were at work the other day in the neighborhood of Bullingery, some three or four miles beyond Inchigeela, when suddenly a swarm of bees appeared. The men pursued the swarm, but two of them finding their exertions were of no avail, were unable to continue. The third however, persevered over hills and vales, brakes and brambles, after the runaway insects for the enormous distance of eight miles, until at length they alighted on a heath stalk, convenient to Gougane Barra, on the borders of Kaemaneigh, com-

monly known to the tourist, when their pursuer succeeding in effecting a capture, and brought them home in a hive. This uncommon race was run in less than an hour."

Michigan Bee-Keepers' Association.

The seventh annual session of this Association will be held in Kalamazoo, Mich., on the 16th and 17th of December, 1874. This Association has long been favorably known for the practical character of its proceedings; and arrangements are being perfected which will render the coming session fully equal to its predecessors. Kalamazoo is one of the finest villages in the U. S.—is easily accessible by rail from all portions of the country, while ample arrangements have been made for the free entertainment of all apiculturists in attendance from abroad.

We trust that every Michigan bee-keeper, who takes an interest in improved bee culture, will be present, and endeavor to make the coming session mutually interesting and instructive; while we extend a hearty, cordial invitation to those residing in adjoining States to meet with us.

HERBERT A. BURCH, Sec. *pro tem.*

GOV. CARPENTER'S ENDORSEMENT OF ANDREAS' IOWA STATE ATLAS.

STATE OF IOWA,
EXECUTIVE DEPARTMENT,
DES MOINES, OCT. 28, '74.

To whom it may Concern:—I have examined the proof sheets of the Minnesota Illustrated Historical Atlas, by Capt. A. T. Andreas, of Chicago, and I regard it as a work of superior merit, and it seems to me any citizen of Minnesota could hardly do without it. I understand from Mr. E. T. Phelps that Capt. Andreas is now taking the preliminary steps preparatory to publishing a similar Atlas of Iowa, with such improvements as past experience in this business naturally suggests to his mind. Having known Mr. Andreas intimately and well for many years, I have no hesitation in assuring all who may read this that he will do all he proposes, and that the public will find his work fully equal to the promises of his circular and advertisements.

Seasonable Hints.

This month is peculiarly the season of rest to the bees. Whether housed or on summer stands, they should remain quiet and be undisturbed. No colony in its normal state has either brood or eggs in the combs now, and the queen is small and appears to receive little attention from the bees, even if you stir them up by a light or too great a degree of heat. It is always best to have them in good order before this time and then leave them undisturbed.

Even if you have colonies in a doubtful state no good comes from interference now. Let them take their chances, until a month or two later, and then they may be fed and stimulated. (Of course this advice does not apply to those who are wintering over queens in small boxes or nuclei. If any one are doing this, they no doubt understand how to do it.)

The question whether it was necessary to allow bees a flight in winter was well discussed at the Pittsburgh meeting. Mr. Benedict described a cover made of wire cloth or musquito

netting, with which he covered his hives; and bringing them into a warm room allowed them to fly within it after which they settled back quietly into the cluster.

Mr. Zimmerman also stated that he had treated his colonies in a somewhat similar manner, after they began to be affected with dysentery, and it was effectual.

Though we have no doubt of this, our advice still is, to have bees put away in the dark, where they are comfortable and leave them so.

If for any reason they have been fed or unduly disturbed, so that they feed themselves freely, it will no doubt be well to bring them to a place where they can fly and discharge the fecal matter. But we do not advise beginners to try any experiment, especially in the winter.

During these long evenings, we may all find time to study our business; see where we have failed in the past and plan for the future.

There is nothing in which forethought and care will pay better than in this. Decide how your hives shall be made, and make them. They will cost you much less now than later. Read the JOURNAL and during this holiday season endeavor to procure one new subscriber, if no more, and remit for them while renewing your own subscription.

We mean to improve it, in all possible ways; but you must bear in mind that we can no more do this without money, than the bees can make wax when there is nothing for them to gather. Remember, too, that our income is all made up of small sums; just as the bees pile up their great wealth—little by little.

The article on Bee Prospects, in the last issue, should have been signed S. Porter.

The extreme length of the Report of the Annual Convention has crowded out our "Notes and Queries" and "Voices from among the Hives." They will appear in the January number.

Auxiliary Societies.

Mr. H. A. King, Corresponding Secretary of the North American Bee-Keeper's Society, calls attention in the *National Agriculturist* to a resolution authorizing any of the officers of the association to form local bee-keepers' societies, auxiliary to the North American Bee-Keeper's Society, on condition that the members pay an annual fee of one dollar, half of which shall be paid into the treasury of the National Society.

He says: As Corresponding Secretary of the North American Bee-Keeper's Society for the coming year, it is my duty to solicit correspondence, and render the aid I can in the formation of such auxiliary societies. We know your needs, and shall endeavor to do our part in providing for the same. Some have suggested the advisability of paying \$25 per lecture to some person to travel and form such local societies; but we could not give our vote to have money spent thus lavishly upon any person, even if he had uncommon gifts as a lecturer, for the hard-fisted, honest bee-keepers of the country can be better served by some one of their own number who will volunteer to deliver lectures in and near his county, where bee-keepers are ready to organize, and will pay the lecturer's traveling expenses. We will print a list of names and addresses of lecturers free, and pay them a good cash commission on all the subscribers they obtain for our periodicals, and furnish as many copies of December Magazine, containing Report of North American Bee-Keeper's Society, as may be desired for their use and no doubt friend Newman and other publishers will do the same. Then let us hear from all without delay.

1st. Let all who will volunteer to lecture or talk on bee culture and assist in the organization of local societies, send us their name and address at once, and we will publish them in a list, giving postoffice and county address of each, so that those who wish to organize a local society can have a choice of lecturers and know who lives nearest them. Of course each lecturer will have a right to ask pay for his time, if he choose, when he

has to spend more than half a day to reach the place of meeting; but we cannot agree to publish any lecturers' names in the list without charge, unless he agrees to charge nothing except railroad and hotel expenses, for his services within his or adjoining counties.

2d. Let us hear from bee-keepers who wish to form a local society in their midst, and we will render all the assistance in our power.

H. A. KING.

Of course we will cheerfully do as Mr. King suggests, but we do think some lectures would be cheaper at \$25 than others at one cent. It is quality we need, if anything. If Bee-keepers want scientific research and practical knowledge embodied in a lecture, it will cost money to obtain it, besides railroad and hotel fare! But few men can afford to give their time for gathering up interesting facts, elaborating personal experience, and delivering lectures, without some remuneration.

We learn that at the Annual Meeting Mr. King intimated that Mr. W. F. Clarke might be prevailed upon to take the lecture field for a few months. Now if this can be done, we think it would be of great advantage in developing apiculture and helping local societies.

There are others, doubtless, who could do good in this line, but we mention Mr. Clarke, because he was spoken of at the meeting in question.

We shall expect to hear from both societies as well as available lecturers in time for our next issue. T.G.N.

Premium for Rearing Queens.

At the late meeting of the North American Bee-Keeper's Society a committee was appointed, consisting of H. A. King, Mrs. E. S. Tupper, and A. Benedict, to make arrangements and offer premiums for best results in rearing choice Italian queens and bees. Mr. King remarks: that the committee expect to offer several first

premiums—one for best nucleus stock with the best colored drones. A first premium (perhaps a gold or silver medal) for best queen and workers, etc., etc. It is not yet determined what premiums to offer, or what entry fee to charge. Some plan must be devised to secure money enough to offer valuable premiums, and the committee ask the advice, assistance and counsel of local and State beekeepers' societies and all interested before we publish our plans.

Close of the Volume.

This number of THE AMERICAN BEE JOURNAL closes Volume X. During the past year we have endeavored to give our patrons reliable bee intelligence and able discussions on the various topics of interest to apiarians. How well this task has been accomplished we leave our readers to determine. During the next year we shall endeavor not only to keep up to our present standard, but also to vastly improve the "old and reliable" AMERICAN BEE JOURNAL.

Selections from the bee publications of Europe as well as able correspondence from the most reliable and experienced apiarians of our own country, will be given. We shall also increase the quantity of reading matter, by using type two sizes smaller, but having a large face, that can easily be read.

We ask our patrons to assist us, by procuring new subscribers among their friends or neighbors, and thus increase the usefulness of the JOURNAL. By getting two new subscribers you can get all three for the year 1875 for \$5. This may be divided among the three, or you can get your own copy for \$1. Larger clubs would make your subscription still less. See club terms on page 291.

Our beautiful Chromo "Just One" will be sent to all who pay in advance

for 1875, before next January 1st, whether sent in clubs or singly.

In order to assist our friends in procuring new subscribers, we will send specimen copies to those that they intend to call upon, if they will send us their names and addresses. It will take but a little time to get parties to subscribe when they see our paper. There are thousands of bee-keepers all over the country who take no bee journal and consequently are uninformed concerning scientific bee-keeping. These should all be solicited to take THE AMERICAN BEE JOURNAL, and the thousands who now read and prize the JOURNAL can easily reach them. Will they not do it? Every one who reads this is specially solicited to act as an agent, and present the claims of THE AMERICAN BEE JOURNAL. We feel assured that they will do it. A few hours time from each, devoted to the interests of THE JOURNAL will add thousands to our list.

To any person sending us a club of ten, with \$14, we will send a copy of the AMERICAN BEE JOURNAL one year free, and also the Chromo. To any one sending us a club of twenty with \$25 we will send a copy of Worcester's Unabridged Dictionary in addition to THE AMERICAN BEE JOURNAL and Chromo.

Now who will devote a few hours to benefit themselves and also extend practical and scientific knowledge concerning bee-keeping? We shall see.

Address all letters to Thomas G. Newman, Cedar Rapids, Iowa, and make postal orders payable to

THOMAS G. NEWMAN.

John McAlister & Co, are our authorized agents for the ILLUSTRATED JOURNAL, at Room 27, Tribune Building, Chicago, with whom any business may be transacted with our approval, and be promptly recognized by the manager of this paper.

THE

AMERICAN

BEE JOURNAL.

FOR THE YEAR 1875.

“——— To Us, both field and grove,
Garden and orchard, lawn and flowery mead,
The blue-vein'd violet, rich columbine,
The wanton cowslip, daisies in their prime,
With all the choicest blossoms of the lea,
Are free allowed and given.”—PARLIAMENT OF BEES, JOHN DAY, 1607.

VOLUME XI.

CHICAGO, ILLINOIS:
PUBLISHED BY
THOMAS G. NEWMAN.
1875.

AMERICAN BEE JOURNAL,

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. XI. CEDAR RAPIDS, JANUARY, 1875. No. 1.

American Bee Journal.

W. F. CLARKE.
MRS. E. S. TUPPER, } EDITORS.

Bees and Flowers at Sydenham.

The following interesting paper is from the editorial columns of *The Farmer*, (English), of September 14th, 1874:

Tuesday was the first day of the exhibition held by the British Bee-Keeper's Association. The attendance at the Crystal Palace shewed that the bees, the botanical show, and the revived comedy of *Wild Oats*, in which Mr. Lionel Brough appeared, could draw a numerous crowd to Sydenham even in September. Suburban masters who keep bees, as they plant flowers, for the graceful adornment of their leisure, were present in numbers. The Beekeeper's Association proposes to its members this mission, and in one particular it specially recommends the co-operation of neighbours or the assistance of superiors. A honey-extractor is the most expensive machine in the beekeepers' plant. It is usually dispensed with, and the consequence is that from certain combs very pure virgin honey is got by the slow progress of straining; from others nothing can be obtained without relentless crushing of the cells, and the consequent vitiation of the honey by wax, bee-bread, and the bodies of undeveloped bees. The cheapest honey-extractor priced in the Association's catalogues is £2, 10s., and it is fair to presume that the best, which obtained the prize, and has no price affixed to it, is dearer. In a few minutes the extractor empties all the combs of the hive, and therefore it is not necessary for every cottager to keep one. But the village might subscribe for one, or some benevolent person might lend it. Lady Burdett-Coutts has already led the way in supplying swarms of bees gratuitously to labouring people on the sole condition that they shall pass on a swarm to their

neighbours when the profitable insects increase after their kind.

The principal apiarian operation of which examples were given by Mr. Abbott and Mr. Cheshire, and explained by Mr. Hunter, Mr. Hooker, Mr. Symington, and other members of the Provincial Committee, was the driving of bees, which includes a great many minor processes. A few puffs from a pipe caused the bees to retreat among the combs, and the hive was then gently inverted. Above it the new and empty hive was placed with its open end towards the former base of the inverted hive. Then the chief bee-master drummed with his fists upon the lower hive and waited for the rush. At the first disturbance the provident creatures, always (though their life in summer is but six weeks) in fear of a poverty-stricken old age, had hastened to fill their bags with honey. Thus they were heavy and good-tempered, and those who escaped through the gap between the two hives forbore to sting the unprotected face and hands of the bee-masters. In a few minutes a rushing sound was heard, the bees had begun the ascent; the queen passed up, the remainder was sure to follow her. It was now safe to incline the top hive backwards so that the spectators could see what was passing inside. Like soldiers swarming up the walls of a beleaguered city the bees were observed hurrying up in thousands, climbing over each other's bodies several deep, without paying the least attention to the facilities for escape which the open hive gave them. Then the combs were taken out of the old and deserted hive and put in frames into the "slinger" or extractor. A handle is turned and the comb flies rapidly round. Centrifugal action drives out all the honey from the cells; it drops to the bottom of the vessel, and passes thence into the jar placed to collect it. The next thing is to tie up with tape the old combs, some emptied of their honey, some remaining full, in new frames and to place them in the new hive. In twenty-four hours, or, at most, in forty-eight, the fastenings of the tape will become unnecessary, for the bees with cement and wax will have built the combs into the new frames and

will quickly proceed to fill them with honey. By thus making use a second time of the old combs the time of the bees is saved; and they give to honey-making precious days of summer which would otherwise be devoted to the building up of fresh waxen cells. The whole process which we have described lasted less than an hour.

The stationary exhibition of the association was scarcely less interesting. There were some bees here, but they were imprisoned closely within their glass house or observatory hive. Mr. C. W. Smith exhibited, and obtained a prize for, the most beautiful breed of Ligurian bees a queen accompanied by her progeny. There are fifty different kind of bees known to exhibitors, but the bee of the Maritime Alps which gained this prize is the most highly valued of all for its fine appearance, good temper, and reproductiveness. It is the "yellow-banded bee," of Tennyson, and is used to improve the strain of the common black bee. There are also exhibited here, the detached glass frames following each other like the leaves of a book, the frame hives as originally constructed by Francis Huber. The blind naturalist flourished at Geneva in the last century, and all his experiments were made with the eyes and hands of his assistant, Burnens, guided by the master's judgment. The frame is the key-stone of modern hive-building. The whole show is the development of the discovery of Huber. In the modern hives, bars of wood are laid across the top of a box, little slits are made in the lower side of the bars. In these slits wax is inserted. When the bees are admitted they find the wax, attach their combs to it, and these are thenceforth formed in straight lines, and are thus more convenient for the use and observation of man than the spoke-like and irregular arrangements which otherwise are made by the insects. Mr. F. Cheshire took the prize for the best hive frame with moveable combs. For the best cottager's hive on the modern principle the prize was awarded to the untiring Mr. Abbott's 3s. hive. Mr. J. Lee gained another prize in this class for a tall and handsome house of three stories, each story forming a super to the stock hive, or a new stock hive. There were in these classes innumerable ingenious combinations of detail and whimsical varieties of pattern. The bars are kept apart by pins in some hives, by notches in others. Some hives are made to imitate houses, others are like iron safes. One is a humble imitation of the great Palace of human industry and amusement in which it is exhibited.

The "run" honey which was shewn, varied in colour from the purest shade of primrose yellow to the darkest brown. It is well known that the hue depends upon the food of the bee, white clover producing a comb as white as snow, and primrose honey, while hives which stand near the sycamore will give a fluid as dark as punch. Mr. A. Ferguson, whose bees feed probably upon the clover fields of Ayr, the Hon. and Rev. H. Bligh, of Henley-on-Thames, and Mr. Abbott tied for the largest and best harvest of one stock of bees. The Rev. G. Raynor had the best exhibition of super honey from one apiary. The weight is not declared, but Mr. W. B. Carr competed in this class with a gross weight declared by him to be about 100 lb. Mrs. W. H. Clark exhibited the best straw super, probably about 40 lb. In a similar class the prize was taken by Mrs. Pagden, widow of the Sussex bee-master, who has told how he made £70 a year by his bees. In similar classes the name occurs of Mr. Cowan, who recently informed us that he had 700 lb of honey in the season from twelve stocks of bees; and we are struck with the frequent repetition of the name of Anderson, an Ayrshire family, one of whom came up from the neighbourhood of Stewarton, of honeyed fame, with thirty-four specimens of his own and neighbours' growth, and lost not one super by breakage or otherwise in all that journey.

In the cottagers' classes, open only to those who work for daily hire, there were twenty-two entries, and Mr. Withnal, Mr. Ferguson, and Mr. W. Martin were the most successful exhibitors. Mr. Cheshire obtained extra prizes for several ingenious inventions. With five pins he formed a little trap for keeping bees out of a hive where they are no longer wanted. The pin bisects the little hole left for egress, making a valve which may be lifted on going out but bars all return. There is a drone trap of different construction. Another invention is a nucleus hive. Where a queen is desired for adding to the stock, Mr. Cheshire puts in the hive a bar which can double up. When brood cells are attached to the bar he takes it out, and puts it into the nucleus hive. The bees transferred find themselves without a queen, and set to work to feed and house one of the young in such a way that it develops into a queen fit to fly abroad and become the mother of many bees.

Complete sets of back volumes are scarce. But few can be procured at any price. We have a set, consisting of the nine volumes (complete), which we offer for sale, either bound or unbound, for a reasonable sum.

Notes AND Queries

I wish you to answer through the JOURNAL if I had not better put my Italian colonies in hives with open bottoms; then in early spring, set them on other hives filled with empty combs, and have them work down through them. I use a double-hive, similar to the Langstroth. Will that not be the best and easiest way to have access to early brood, for queen raising, and disturb the arrangement of the colony less, than any other way? S. EMMONS.

Pottawattamie, Kan.

The way you speak of has been tried often in our own apiary, but we do not recommend it as being a good plan in early spring. Instead of that, we would keep the hive as tight and close as possible, with quilt, carpet, or mats on the top of the frames. As fast as two frames are tolerably well filled with brood, move them far enough apart to admit of placing an empty comb between the two, and repeat this in a few days. If a colony has a prolific queen and plenty of honey and bee bread, they will increase very rapidly in brood, if managed in this way. Later in the season a comb full of unsealed brood may be taken away every three days, and yet the colony keep strong.

After the weather is warm, if you do not care to have swarms, you can put a hive filled with comb under another hive to good advantage. We have had both hives in this way, filled with brood in July, and secured large amounts of box honey from them.

MRS. E. S. TUPPER:—I read in the proceedings of the Annual meeting of the Bee-Keepers' Society, that you have said that there is danger, in importing, of getting a taint of black stock; as they may have mixed some of the Egyptian blood; as I am just now holding, in the bee world, that there are no hybrid bees in Italy. I would be glad to know whether you have ever received tainted queens from Italy, and the name and address of the bee-keeper who sent them. Hoping to receive an answer from you, I am respectfully,

CH. DADANT.

We said no such thing as is reported of us at the convention. During the remarks on that point some one asked if the impurities which Mr. King and others were complaining about, might not be caused by a cross with the Egyptian instead of the black bee. We replied that it was not probable, as we had never heard that Egyptian bees had been at any time taken to Italy. Our remarks were all directed to the importance of taking more pains with the stock we have

already brought from Italy, and keeping it pure, while it would be improved by the influence of climate and new pasturage—the same as experience demonstrates, cattle, sheep and horses are improved.

Which is the best and cheapest mode of transportation, express, freight, or mail? Some bees have been received here by mail, all right. I suppose that is the cheapest way—cheaper to feed them than to have the whole hive sent by express. Is this idea correct? Is it fully settled that the Italians are the best bees on all accounts?

Colorado. N. A. B.

We are sure you are mistaken about "colonies of bees being sent by mail." It cannot be done. Queens with a few bees accompanying them are often sent by mail safely, and it is perhaps as good a way as any to send them, if it can be made lawful to send them. At present the rules of the Post-office department forbid it. We have sent bees to Colorado safely, both by freight and express. If only one hive is sent at a time it would go better by express. If a number are sent together we would quite as soon risk them by freight.

It is fully settled by the vote of a large majority of those who have tried both varieties, that the Italians are best on all accounts.

As nearly as I can come at it, there are somewhere in the neighborhood of 80,000 stands in N. C. This is probably below the mark. But the losses of the two years past have been very considerable. Enough to reduce the round average by several thousands.

New Garden, N. C., A. E. KITCHEN.

We had no idea that so many bees were to be found in North Carolina. When improved modes of keeping bees are introduced there, with all the advantages they possess of soil and climate, we have little doubt that as large results as are reported from California will be obtained.

I send you a conundrum—one I cannot guess, if as you teach there is but one queen in a hive, and that every swarm that comes off has a queen. I had last May (the 25th) a nice swarm from one of my hives; saved it all right; two hours after, another swarm nearly as large came from the same hive! No mistake about it! I hived them both myself. How do you explain it?

Southern Illinois.

C. G.

It is not hard to explain. Your hive had, in some way, lost its old queen; she may have died, but from the fact of there being so many bees in the hives we judge that she came out with a swarm when you did not see her, was lost in some way, and the bees went back. They waited until the young queens in the hive were perfected and then swarmed. A young queen leading each swarm.

If there had been bad weather for a few days previous to the occurrence, it is possible that the swarm had been kept back so that a young queen hatched the same day the old queen left with the swarm.

This second solution is, however, not as probable as the first. Either may be the true one, however, without conflicting with the teachings of any practical bee-keeper.

Do you think my bees, prepared as you have advised for wintering, need water towards spring? I have left the caps on, with quilts under them over the frames. Have they sufficient ventilation?

Blair, Pa., F. M. G.

They need no water. Do not disturb them in any way until you set them out in the spring.

As to ventilation, we have always left off the caps from the hives. Others report good results, who have left them on, just as you described. We are inclined to think that when the quilts are on, they need less ventilation than we supposed formerly.

We saw a hive last spring on the top of which (the quilt being on) another hive had been set, and remained so all winter, cutting off entirely any upward ventilation. We thought it would be ruined, but it was to our surprise in good order; bees lively, and combs free from mould, with some brood in them. The quilt, however, was as wet as if it had been wrung out of water. Our inference is that, it would have been better, had the cap been on that hive. In that case the quilt would have been dry; but it shows also that there is air enough in a cap for all premises.

Mrs. TUPPER:—I am indebted to you for the information I have, and shall give; for if I get my bees safely through the winter, it will be entirely due to the advice I have received from your writings. All I see from your pen seems to be to the point. Too many connect their advice with the advertisement of a patent hive, or something else, and it sounds too much like the old Deacon who said "he knew there was a reality in religion as well as he knew he had flour to sell at four dollars and a half a barrel." In describing my bees, I forgot to mention one thing which I am not certain about, and that is, I have stopped the entrance nearly up—so close that a bee cannot get out with a view to stop a draft of air. The theory which I have adopted, after reading your articles in the Bee Journals, is, that there should be upward ventilation to let the moisture escape, but if it is left open below the heat of the bees will cause the air to ascend, and cold air rush in below, and in order to keep up the necessary heat, will make an increased consumption of honey.

O. B. BURROWS.

Close the entrance except a passage for a bee or two at a time, just so they know they can get out, if they wish. Then with the quilts on there will be no draught.

Our great want here is a plant that will produce honey from the 1st to the middle of June. For two seasons now I have had to feed in June. It looks to me like the wrong time of year to have to feed strong stocks.

Riverton, Iowa. ED. WELLINGTON.

While we lived in Washington county, we always sowed buckwheat as soon as possible in the spring. It would bloom in time to just fill in that time of scarcity which is a trouble in many parts of the West. Some years it is true, there seemed little honey in it; other seasons, it was very valuable.

We are told that rape and rapp may be made to bloom early in June. We have not tried it. Will some suggest a plant that blooms at that season.

If bees are not gathering honey from 1st to 15th of June, it "pays" to feed them then, above all other times. You will then have them in good condition for the best honey yield, which comes late in June, lasting until the middle of July.

Is there any way to evaporate honey that has been extracted before capping?

I have heard of setting it near a fire, where it will keep warm, in a wide mouthed can or jar with netting tied over it, but this seems a very slow way.

I have heard, also, of evaporating in shallow pans in the oven; but when we have one or two thousand lbs. to evaporate, this method is impracticable, it is said, also, that heat destroys its flavor. Is this correct? How would it do to put it in a large but shallow kettle, and heat it up almost to the boiling point, and let it stand there for—how long?

There would be some danger of burning it, I suppose. Here in Texas the time saved in uncapping is a great desideratum; we have no expert cappers here; and a good hand opening can keep two of our best hands capping.

B. H. IVES.

We have no experience in the matter and cannot think it pays to take honey from the hives until at least, it is ready to be sealed over. Others may know more about it than we do, and to them we will leave this correspondent.

Cincinnati Industrial Exposition.

CINCINNATI, Sept. 29, 1874.

To the Board of Commissioners:—

GENTLEMEN, Being appointed jurors in Department B, Class 21, we have examined the different entries for competition, and report as follows:

Best Apiary of not less than 50 hives. *Silver medal.* J. S. Hill, of Mt. Healthy, Hamilton Co., O.

Best Apiary of not less than 10 hives. *Bronze medal.* Jos. A. Savage, Ludlow, Ky.

Best Honey Extractor. *Bronze medal.* Henry W. Stephenson, Cincinnati, O.,

Best Display of Honey in Comb. *Bronze medal.* James H. Anderson, Hillsboro, O.

Best Display of Extracted Honey. *Bronze medal.* Chas. T. Muth, Cincinnati, O.

RICHARD L. CURRY, } Jurors.
HOWELL GANO. }

Foreign Department.

CONDUCTED BY CH. DADANT.

Who is there that would not have followed with interest the discussion on the copulation and laying of the mother bee, that had been begun at the Saltzbourg meeting? At the receipt of each number of the *Bienen Zeitung* I thought that the minds of the opponents were becoming more excited, but I was mistaken. Mr. Collin abandoned the battle field and withdrew from the stand, so that Mr. Huber remained alone. Later the *Bienen Zeitung* published several articles on this question, but nobody treated it in a complete manner, so that the question remains as it was in the beginning, when taken in a practical view.

I write this essay to conduct the novice on the track, through which he will be able to form an opinion, helping it with experiments and observations. In order to ascertain at what age the heat begins in the young queen it is necessary to know at what time she has left the cell.

Generally, a mother bee becomes developed into a perfect insect within 16 or 17 days from the time when the egg is laid, if properly attended to.

If properly attended to, the larvæ is developed in three days.

In well stocked colonies and during an abundant harvest, I have seen the larvæ hatch after after two days and 4 hours. In a temperature of 32 to 33 degrees (centigrade) I have seen the larvæ hatch after 2 days and 6 hours. In artificial swarms made with brood combs, in which the brood was but thinly covered with bees, the larvæ often hatched on the 4th or 5th day after being laid.

In a colony that had suddenly become weak, some of the eggs did not hatch for for a week until this same colony had become strong again and the bees were able to attend to their hatching. I will simply mention the fact that bee-eggs that have been deprived of sufficient heat are still capable of becoming developed after 10 or 12 days.

As the egg needs no nourishment but requires only heat to become a living being, the duration of time in which the larvæ becomes developed in the egg depends on the brooding, that is on the degree of heat that the bees produce in the brood chamber. We can assert that, as a general rule, the larvæ leaves the egg in three days.

In too high a temperature all organic life ceases. There is undoubtedly also for bee-eggs a maximum of heat that can-

not be exceeded. Bees do not produce in the interior of the hive such a degree of heat that the eggs lose their capacity of becoming developed; I think that the highest temperature in which they still become developed is 37 to 38 deg. (centigrade—98 to 100 Fahr.). This supposition is based on the observation that such a heat is about the highest that can be supported in the hive when the sun strikes it. I made the same observations on butterfly eggs. Such experiments cannot be tried with bee's eggs as the wax melts. These eggs assuredly would perish rapidly in a temperature of 50 deg. fah.

It results from the above remarks that it will always be impossible to establish in every case the length of time in which the larvæ becomes developed in the egg. Generally, the royal larvæ lives 5 days and 12 hours in the open cell.

If it is not a small affair to establish the length of time during which the egg becomes changed to larvæ, it is yet much more difficult to determine positively the period during which the larvæ lives in the open cell. Let the reader make minute observations on the subject and publish them in this paper, for it is precisely on this question that there is least known. Francis Huber, of Geneva, says that the royal larvæ remains in the open cell for five days. According to my observations which differ but a few minutes from those of Van Berlepsch, the royal larvæ remains in its open cradle 5 days and 12 hours, supposing that the temperature is regular and that the larvæ is amply fed. When I removed the comb containing the uncapped royal cells once an hour for two days to inspect it, I found that these royal cells were sealed over only 5 to 8 hours later. Afterwards I removed from the hive some combs containing royal larvæ, I removed the bees and placed one of these combs in an empty hive for 24 hours. I obtained in this hive a temperature of 23 to 26 deg. by means of heated bricks. After this time, I returned this comb to the colony and those cells were sealed 14 hours, and in several cases 15 hours, later than they should have been if in normal conditions.

It results from these experiences, that the royal larvæ becomes developed more slowly and are therefore sealed more tardily, when the necessary attentions have been interrupted and when food is given them after a prolonged interruption. It is known by everybody that royal larvæ requires more than the usual time for their development when raised in an artificial swarm that cannot produce the necessary heat for the brood.—*F. W. Vogel, in Bienen Zeitung.*

The Hen and the Honey-Bee.

(AN APOLOGUE—FROM THE GERMAN OF GELLETT.)

BY JOHN G. SANE.

A lazy *Hen*—the story goes—

Loquacious, pert, and self-conceited,
Espied a *Bee* upon a rose,
And thus the busy insect greeted :

"Say, what's the use of such as you,
(Excuse the freedom of a neighbor!)
Who gad about, and never do
A single act of useful labor ?

"I've marked you well for many a day,
In garden blooms and meadow-clover ;
Now here, now there, in wanton play ;
From morn to night an idle rover.

"While I discreetly bide at home ;
A faithful wife—the best of mothers ;
About the fields you idly roam,
Without the least regard for others.

"While I lay eggs and hatch them out,
You seek the flowers most sweet and frag-
And, sipping honey, stroll about, [rant,
At best a good-for-nothing vagrant !"

"Nay," said the *Bee*, "you do me wrong ;
I'm useful too, perhaps you doubt it,
Because—though toiling all day long—
I scorn to make a fuss about it !

"While you, with every egg that cheers
Your daily task, must stop and hammer
The news in other peoples' ears,
Till they are deafened with the clamor !

"Come now with me, and see my hive,
And note how folks may work in quiet ;
To useful arts much more alive
Than you with all your cackling riot !"

L'ENVOI.

The *Poet*, one may plainly see
Who reads this fable at his leisure,
Is represented by the *Bee*,
Who joins utility to pleasure ;
While in this self-conceited *Hen*
We note the *Poet's* silly neighbor,
Who thinks the noisy "working-men"
Are doing all the useful labor !

For The American Bee Journal.

Handling Bees.

I commenced helping my father handle bees in the summer of 1818. I have handled them in the old way, most of the time. I have a few gums of my own getting up, that I can go to, and in one minute, have them open, lift the frames, and give them a thorough examination. Long since I found that one should move slow around the hives, and if the bees should surround him or even come within an inch of his nose, he should be composed. If he should get angry the bees will know it and reciprocate it, and so will they know if you are at ease with them. When you open the hive, if they seem angry or are disturbed a few puffs of smoke will entirely subdue them, and you can proceed with your examination. J. FROST.
Gillespie, Ill.

For the American Bee Journal.

Success in Raising Honey.

We have often spoken of the business of bee-keeping and raising honey as one of certain profit when conducted as it should be.

An apiarian should have a taste for honey raising, he should have a practical knowledge of the business to go into it on a large scale, so as to make a business of it. It is very easy to keep a few hives, but to conduct business on a large scale requires a person of mind, for the study of the habits of this little wondrous creature is a most truly interesting and at the same time a most gratifying one, and when understood, the business can be made very profitable.

The largest apiaries in this state are at Sandiagio and at Los Angeles, the southern countries are very favorable for the raising of bees and making honey, as many wild flowers and bee feeding trees, shrubs and plants are found there in great abundance.

Very recently we had an interview with Mr. J. B. Harbison, the well known apiarian, formerly of Sacramento, but now permanently located at San Diego, where he is carrying on a very large and very successful apiary. Mr. H. was in this city with three car loads of his honey destined for Chicago and the East. Mr. H. had already sent six car loads, and anticipates sending six car loads more this season, thus making twelve car loads of honey from one apiary, this looks like business.

We remember well the early days when Mr. Harbison began the bee business with a very few hives, brought here via the Isthmus, at heavy cost, at a time when a hive of bees sold quick at \$100 to \$50 each.

Mr. Harbison has now at San Diego two thousand hives of bees, these are principally the Italian bees, as they are much superior to the black bee.

In addition to the large amount of honey raised by Mr. H., and it is about 100 tons, Mr. H. makes 1,000 lbs. of beeswax. Mr. Harbison went East with his late shipment, taking it in his own charge.

A. G. Clark, Esq., formerly a partner of Mr. Harbison, has also a large apiary, nearly as extensive as that of Mr. H.

For a person of the right turn of mind and a very little capital, we know of no occupation or business more interesting, or one more certain to make good returns than that of raising bees and making honey. There will always be a market for good honey here, and a certain fair return for it when shipped abroad. All that is needed to insure a complete success is a little capital, intelligence, a willingness and readiness to be industrious as the bee, and success is sure.

We would commend our lower counties, San Diego, Los Angeles, and all along that line of country.

We can always give valuable information on this subject, as we are practically in it in this city, where bees do remarkably well, as we can show.—*California Farmer*.

A FIFTEEN-YEAR-OLD SWARM OF BEES.—Early in July, 1859, I put a swarm of bees in a common box hive made of rough hemlock boards 12 inches square by 15 inches high. From this hive has issued a swarm every year until now. SOL. CRANDELL.
Chatham Village, Col. Co., N. Y.

For the American Bee Journal.

Eccentric.

Now Mr. Editor: did you ever? The old reliable AMERICAN BEE JOURNAL has had it's "Novice," "Amateur," "Tyro," "Foggy," "Beginner," and many others whom we don't recall; and now here comes another *non de plume* in the way of an "Eccentric." Well, it takes all sorts of people to make a world, they say, and we don't know of any good reason why the bee-keeping world should not have an "Eccentric" as well as other people. So please don't laugh at our queer ideas and awkward movements, lest we become embarrassed here we become waywised in our new relation, for, to tell you the plain truth, we must confess to feeling a little shaky in the *role* of newspaper correspondent. We realize our own limited attainments while in the company of the brilliant, racy writers of the old A. B. J. and really are not sure that we'll be seen at all amid so many great lights, whose brilliancy outshines all smaller luminaries. But, pleading our youthful years in extenuation of mistakes and blunders, we'll try and behave properly, doing the best we can.

By the way, what has become of all our old writers who used to entertain us so often and well? Where is Gallup? Has he engaged in the production of corn so extensively, (that yields honey the whole year 'round) that he can find no leisure to tell us of his big feats in bee-keeping? Or has he found a problem in that big, long, hive which he's unable to solve?

And Novice. He too, used to amuse "us little folks" with his funny stories, and numerous experiments. We suppose he's *cleaning* the fields of Medina Co. and really has no time to tell us of what he's doing. Or it may be his "mission in life" has been accomplished, now that the "patent-right fellows" have subsided.

And where is Quinby with his plain practical ideas and large common sense; Adair, with his ponderous, jaw-breaking names and brilliant "new ideas;" Dadant whose extensive, accurate knowledge and terse, vigorous sentences were always read with avidity; Argo who always had something good to say, and knew how to say it well; Burch who once wrote regularly, and usually to the point; and many others, "too numerous to mention." Can't they be induced to resume the pen once more? We trust they may.

We notice that some of the Journal's correspondents have been bothered in getting the pay for their honey. To toil and sweat through the hot summer months to get a nice pile of honey, trusting that the proceeds in the fall, from its sale, will remunerate us for all our hard work, and then be cheated out of a portion or all of our money, by a dishonest honey merchant, may be a nice thing for the latter gentlemen, but we don't exactly appreciate it. In fact it's a transaction that is becoming so frequent that some means should be devised to put an end to it. What we, as bee-keepers, need to-day above everything else, is, some good, sure market for our honey at a fair price, *in cash paid on delivery*.

The cold and chilling winds of spring may decimate the ranks of "bee-dom;" heat and lack of moisture may cut short the summer pasturage. This we can and do bear uncon-

plainingly. But to lose what honey we do get, through the dishonest, thieving propensity of some city dealer is a little too much; it's the one step from the sublime to the ridiculous. This may be considered plain talk, and we are inclined to think so too. We always try to speak intelligibly, ever aiming to tell the truth. Now, we by no means wish to be "understood that we demean all men (and women) who solicit consignments of our honey, as belonging to that class of people who wish to avoid paying for what they buy. Not at all. But there are people of this class, and we would denounce them in unsparring terms. We know of no better way to make them honest, than to advise people to avoid them altogether. In this connection we would caution all our readers about selling to a New York honey house "on time," unless the parties who run it have a little more regard for their dealing than a Chicago honey house, you'll be apt to lose by it. We've been there and "know how it is ourselves." And "Eccentric" isn't the only person who has lost money by dealing with these same parties.

The season just closed, has been rather a dull one in our locality. Bees came through the winter in poor condition, faucity of numbers being the rule; while the fearful months of April and May, just did a sweeping business in the diminution of the remnants of what once were, powerful colonies. June was warm and balmy, but the avidity of the atmosphere "played smash" with our honey prospects, though our little "baby colonies" increased in stature with such celerity that with the advent of the linden blossoms on the 8th of July, they were "forty thousand strong" and ready for conquest. Ah! yes, they were ready, but the linden hadn't any idea of being pumped of its delicious nectar; and after "making believe" for sixteen days—days of anxious, weary waiting for the good time a coming, ever waiting, but never appearing—doffed its millions of tiny, pendent blossoms, and bid farewell to honey and 1874. And thus it was during the remainder of the season, save that bonest furnished us with enough liquid for colds, croup and catarrh, the concomitants of Northern winters. (By the way have our readers ever investigated the medicinal properties of the various kinds of honey? If any of you are ailing, we'd advise you too.) And so we've got but little honey, and as honey is low and dull we've surely got less money; but we have got a few bees left to die off next winter when old boreas and the "bee-disease" make their annual appearance.

Mr. Editor: we said honey was low, and the probability of it commanding still lower prices in the future, stares us squarely in the face. Now, as consumers of honey pay just about as much money for the article as formerly, we'd really like to know what's the matter. Isn't the solution of the problem to be found in the fact that honey dealers are constantly endeavoring to depress prices so as to purchase from the producer at the lowest possible figures. By keeping the price to the consumer up to the old figures, of course the profits of the business are augmented. Now what earthly use is there in giving all the profits to some honey houses why not adopt the Granger's principle of selling direct to the consumer, and save our hard earned shillings, while the consumer will be benefitted by lower prices

and a purer article? Of course, if we raise numberless tons of golden nectar, it may be necessary for us to secure the aid of the "middle-men," but make him do the business, on not extortionate principles. We said that the consumer would get a purer article at a lower price. Of course we can afford to sell at a cheaper rate than the consumer has usually paid, and at the same time, sell him something besides sugar and glucose. It seems to us that there should be a distinction between the products of an apiary and a honey-house. Consumers should note this point; for, while the former represents the delicious nectar of nature's laboratory, the latter conveys a strong impression of the conglomeration of a variety of saccharine substances, of which honey forms an insignificant proportion. In recently passing over the Michigan Central R. R., we stopped off at Dowagiac to visit Michigan's rising apiarian, Mr. James Heddon. We were much pleased with his apiary and its arrangements; and also were particularly impressed with the correctness of his ideas upon the above subject. He thinks that extracted honey is having a hard time of it, when compelled to compete with the sugar works of New Orleans and the glucose factories of France. We are glad to add that he, is doing good work in redeeming the good name of extracted honey, by furnishing the consumer with a neat, pure article at living prices.

Mr. Editor, haven't you been bothered so much with the live controversy as to be out of all manner of patience with the patent-right chaps? Well, we just want to say a word or two on hives, and as we've no "right" to sell or give away, please tolerate us just a few minutes. Long idea hives had been lauded to the skies and their praise vociferated the wide world over, so we, too, must have 'em. Well we've got 'em, and *now* if we could only find the man who invented them, we'd be most terribly tempted to call him—well, we won't say what, but 'twould not be pretty, we can assure you. The simple truth, plainly told, is this: these great, long, ungained, ill-shaped monstrosities of a bee-hive are unmitigated humbugs, both theoretically and practically. Adair may tell us of the obvious advantages to be derived from using a hive ten feet long; that we may increase the fertility of the queen; Gallup may triumphantly point us to his 800 pounds of liquid from one hive in a single season. Novice can predict that these fearful "new ideas" will 'ere long, rule the (bee) world. But why won't Adair have the kindness to say that he loses more than 90 per cent of his bees in winter; Gallup the manliness to frankly state that he can get his 800 pounds from the same number of combs in smaller hives and with much greater certainty; and Novice the candor to admit that he hasn't used such hives at all. These rose-colored pictures of long, one story hives, are evanescent bubbles ready to explode upon practical experiment and investigation. They offer no possible advantage over smaller hives, while they are deficient in many prime requisites which small hives possess. And if any "new idea" advocate wishes to "go for us" because of our heresy in this particular, let him "pitch in."

And now in conclusion, we must confess to having been a trifle belligerent, perhaps, but will try henceforth, to be a steady sober

ECENTRIC.

For the American Bee Journal.

A Home-Made Bee Hive.

A correspondent of the Cincinnati *Gazette* gives such plain directions for making a bee hive that every boy on a farm with a bit of a taste for mechanics can readily make one for his own bees. He says: In the first place you want rabets, half an inch deep, at each end of the hive, to receive the ends of the frame; next you want your frames made true so that they will hang plumb in the hive. There should be one frame for every inch and a half of space in the width of your hive. Next prepare your bottom board and lay it level. Put your hive on the board so that the frames will run from front to rear; then elevate your hive about three inches, and your hive is ready for the bees. Make your frames just three-fourths of an inch shorter than the inside of your hive, and have them so that they will not touch at either end nor swing against each other. I have a center opening that is very convenient, and different from any that I have seen.

I wish it understood that when I raise the rear of the hive, I raise the bottom board with it. If your hive leans to one side, the bees will build across the frame. I have my bees in a yard, and each hive is covered with a cover made by nailing two boards together and resting it on the top of the hive. I make the top board of my hive in three pieces, by nailing two cleats on the top of them, and making two holes to run across the frames, each hole six inches long. This is to make room for the bees to pass into the surplus honey-boxes. When the boxes are on, the cover alluded to rests on the box.

G. LONG.

For the American Bee Journal.

A few Remarks.

I find different writers in our bee journals and standard books, published for our instruction, often come in conflict on questions of some interest and information to the bee keeping community.

There has been considerable written on the subject of the Italian and native bees in comparison with each other.

With regard to their peaceable and quiet disposition, I have read remarks by some giving preference to the Italians as altogether more peaceable than the native, and that they would hardly ever use the sting, if treated with gentleness. Some have given the hybrids the name of being the cross-est and most difficult to manage.

W. M. Kellogg, in your October number, tells us: "Many say that Italians are not so cross in brushing off the combs as hybrids and blacks, but we don't find it so. We have handled a good many stocks this season, of all three kinds; and when we come to the extracting, give us the hybrids and blacks in preference to the Italians, every time. * * and the worst stinging we have had this summer, has been by Italians."

I think that a little reflection will satisfy us that the three kinds will probably fly their different weapons when rudely assaulted; and that under quiet and gentle treatment we may succeed, with little trouble, with either of the three.

I confess I have never discovered any marked difference in the three varieties, in this particular.

Again, it has been claimed by some that the Italians will gather more honey than the black bees. There has been so much said in their favor, and they look so handsome, I think if a colony of equal strength of each kind was offered me for choice, I should take the Italian.

It may, probably, be favorable to make such a change as their education among our native bees will effect. The largest amount of box honey I ever secured as surplus from one hive, in one season, (200lb), was by hybrids. The largest amount I ever secured, except in that instance, was by a colony of natives (174lb). It was in different seasons, and in different fields—hardly admitting of any satisfactory or certain comparison.

From my experiments, thus far, I have no doubt that much more depends upon the character of the hive, than of the question which variety of bees are employed. The most important point to secure is the largest force of workers, through the honey season.

Take a hive in the early part of the season and divide it into three or four colonies, and little surplus must be expected. With all the workers operating in one hive, a handsome surplus may be secured.

My doctrine is,—Secure a large working force by removing all disposition to swarm from the abundant box room, given in intimate connection with and easy entrance from the breeding apartment, and secure from 100 to 200 pounds of box honey from each colony. Let others do better than can.

For the American Bee Journal.

Superior Fiddlesticks.

In the December No. of the JOURNAL, friend Ross pitches into me, and says: "are there not too many that have nothing to report but their failures, after trying to keep the Italian bees pure?" And, "will our learned friend, W. M. Kellogg, please state the condition those four insignificant black stocks were in at the time his Italian queens became fertile?"

I do not know what condition they were in at the time, for they were a neighbor's stocks, and I had nothing to do with them. But I know that they were medium strong stocks, and but one of them cast a swarm. But their condition just then hasn't much to do with it, for it was not only at that time that the Italian queens were mated with black drones, but *all the season through*, when they had no need for their drones.

At the time I wrote, but a few queens had been raised, but later a good many have been raised, and some quite late in the season, and fully three-fourths ($\frac{3}{4}$) of the Italian queens were mated with black drones, weeks after the blacks were done raising queens; when, according to friend Ross, they should be out of condition, but still we were "troubled with black drones." With one exception none of us were trying to keep the Italians pure, had no black drones of our own, but plenty of Italian drones. One person was raising queens, and of course wanted to keep them pure. Tried to buy the black stocks of the owner, or put in

Italian queens, but he'd have none of it. So we had to run our chances. We kept our Italians in good condition, saved all the drone brood we could get, and I cut out and gave to my friend several sheets of Italian drone brood, so that we had thousands of drones flying. Besides, I killed a great many black drones while transferring one of the four black stocks, and still we were troubled with black drones, to the extent of three-fourths ($\frac{3}{4}$) of our queens.

I think now as I did then, "Superior fiddlesticks."

"What kind of bees has K. got?"

The same kind as you have probably, at any rate they have got legs, wings, stingers, etc., and gather honey etc., when there is any to get. Any one who has noticed bees clustering in front of the hive during warm weather, has seen flies around them too: drawn there by the scent of the hive, trying to get in, and continually on the jump to keep out of the bee-guards way. Then it was the chickens walked up and introduced the flies down their throats, and I never noticed more than one or two that got stung.

Our bees are very quiet, generally, and friend Ross could step up and pick out the flies himself without being stung.

I think it would not be a good plan for any one to put a chicken inside of his hive if living near to friend Ross, for if he is as fond of chickens as he says, he'd "go for" the chicken if he had to take bees and all. Brother bee-keepers, keep an eye on your hen roosts.

New Bee Pasturage.

I have been keeping bees in a limited way for the past 27 years, but the number of my colonies never exceeded 40 or 50, until the past season. In the mean time, my experience has met with occasional drawbacks and losses, but I have made the business of producing honey a success, and therefore feel encouraged in my old days to expand it a little.

I have been using the Langstroth hive mostly, but I prefer the large Trellis hive of Mr. Simons, of Fairfield, Iowa; in which I find no difficulty in wintering on summer stands. My Langstroth hives I have to store away in a dark, dry cellar, to keep them safely through the winter.

In my backyard I have growing a few bunches of a perennial plant known here as the "pleurisy root." It is a pretty and fragrant blooming plant, upon which the bees cluster busily for more than a month, and do not forsake it until the bloom is entirely gone. What are they after? Honey, pollen, or both?

I consider it worthy of cultivation for bee pasturage. What do our experienced bee-men know about it? Will they answer through the JOURNAL. DANIEL RIDER.

Fairfield, Iowa.

No other branch of industry can be named in which there need be so little loss on the material employed, or which so completely derives its profits from the vast and exhaustless domains of nature, as bee culture.

For the American Bee Journal.
Upright Ventilation.

Bees have done better this year than they have for several years past. Two-thirds of them died in this county, last winter, on account of not giving them upright ventilation. The frost accumulated in the hive until the bees were frozen, in a solid mass. The first warm day they would thaw and fall down dead, and leave plenty of honey. Some old fogies came to me to know what was the matter with their bees. They died with plenty of honey. I replied, nothing but laziness. Had you done as I told you, you would have had all of your bees now! "Oh," said they, "they died with some disease. I know they did, for they had plenty of honey left. Did not your's die?" "No, not one. I fixed them, as I told you to do. Take off all the honey; then pack the top of the hive with corn cobs, just high enough so your cap will cover them; put 2 one inch holes in your hive, one on each side, cover well, and your bees will be all right next spring, on their summer stands."

We have quite a large bee firm here. It consists of some 200 persons. They all belong to the Methodist Church. Their church has a very tall slender steeple. On their church, about 20 feet from the top are 4 small holes; left for ventilating the steeple. Above those holes the cross timbers are so close together, that I can scarcely get my hand through. Above this is a large space 4 feet at the bottom, and running up to a sharp point. A large swarm of bees have been working all summer. How long they have been there I don't know; the members all, claim to be members of a new bee firm.

Council Bluffs, Iowa.

H. FAUL.

For the American Bee Journal.
My Method.

The philosophy of my method I believe to be this: The bees when hived in an empty hive, want brood-comb first; and being cramped for room, starts combs in little bits near together, along all the triangular guides which they join at the edges before they have extended them so far as to get them materially diverged from line. I have sometimes, (though seldom) had them wavy, and if the frames are not properly spaced, they will build to one side, and get irregular. The difficulty which causes this is having established their brood nest; the next thing is, to store, for which they need room.

Having filled the cells adjoining the brood, they lengthen the cells next a vacant space, before starting comb on the next frame, so that they have to set off a proper distance. Or having started rightly, in extending comb edgewise, they come to the lengthened cells, and diverge from line, to avoid crowding, and obtain room for full length cells next to lengthened ones. This tendency to lengthen cells, adjoining a vacant space, continues; and the further they go, the worse they get.

Of course as soon as they get well started they should have additional room; but here comes another difficulty, growing out of this same tendency to lengthen cells for storage. In building on the frames inserted between

those started, they are apt to come in contact with those lengthened on the adjoining frames, and hence have to make short cells to preserve space between combs, which gives irregular surface. This has to be remedied by so placing them between straight combs as that they will properly lengthen the short cells on the new comb; but by inserting the new frames as needed between broad combs or sealed cells, this difficulty is largely avoided.

I made the discovery accidentally by placing two very large swarms in one hive in a hurry, when they were coming fast, and the next day having some friends call, and wishing to show them what my big swarm had done, I opened them and found the state of things described above. The hive used was six and one-half deep, 14½ in width, taking 21 inch frames and they had as stated above, stacked combs close together the whole length of all the 10 frames.

This was a grand success under difficulties, which I had found so great that I had begun to think camb frames and modern bee-keeping a humbug. I acted on the suggestion and had no farther difficulty; observation and reflection have convinced me that the theory I have given you is correct. At all events the method succeeds.

H. HUDSON.

Douglass, Mich.

For the American Bee Journal.
Queen Raising.

I promised to give more facts on queen-raising, in my last letter. This is the main point in bee-keeping; if every bee-keeper sells full colonies or queens it would give them a better reputation. If you send for good stocks of course you want a young and profitable queen. If I pay the owner the price he asks for good colonies, has he a right to send it with a worn-out queen, that I have to try 8 or 10 days or a month to raise; when I have paid for a good hive. Such men should be published through the JOURNAL, so that strangers may know them.

After every stock had a good queen, they became strong and yielded over 5 per cent; I had from one good swarm, in 8 Langstroth hives. Sold 2 queens (\$5) and about 9 gallons of Extracted Honey, at 25 cents per lb. I had a swarm that was weak in the spring that did not give quite so much.

The Tulip Tree Again.

On page 223, October No. of the AMERICAN BEE JOURNAL, I notice an article from the pen of J. Ralston Wells, upon the value of the tulip as a honey producing tree. As he says there are many making inquiries how they may be obtained, I will take this method of informing the readers of the JOURNAL that I can furnish a few hundred of the young trees—1, 2, and 3 years old. The tulip tree will not grow from cuttings, but lives readily when transplanted, from 1 to 5 years old. Older than two years would be unhandy and difficult to ship long distances.

Alsike Clover in the South.

Having had several years' experience with this specie of clover, I trust some of my conclusions may be of value to a portion of your readers.

Alsike produces more honey than white clover and continues much longer in blossom. The honey is of a good quality, a little higher colored than that of the white clover and not quite so delicate in flavor. It branches like red clover, and the same stock will often have at the same time many ripe heads, and even to the embryo bud, so that when the crop is cut for seed, the straw makes a second quality of hay if well cured. Horses, cattle and sheep are fond of it for hay or grazing.

I sow about five pounds of seed to the acre, with the same quantity of timothy. It makes better hay than the red clover, though not so productive. It does best on moderately moist soil. If grown with timothy for seed, the latter should be cradled before the Alsike is cut. Sorrel and other small seeds should be carefully sifted out After Alsike is threshed out, but before it is ground out of the hull.

In my opinion every bee keeper should try Alsike clover for his bees. I say try, for I am not confident that it will succeed in sandy soil at the South. E. NEED.

For the American Bee Journal.

Whistling Down Swarms.

Mr. George T. Hammond, of North Bergen, N. Y., (a successful and progressive bee-keeper) tells me that he practices whistling down swarms, and has never failed in causing them to alight, since becoming acquainted with this method of arresting their flight. His attention was first called to whistling for them, in this way. A neighbor had a swarm that were flying over. Being asked how he stopped them, he replied "the boy whistled them down," but would or could not tell how he did it. Mr. Hammond says he did not take any further notice of it, till the subject was again called to his attention by reading in the proceedings of the Bee-Keeper's Convention, that a gentleman stated that he could control a swarm of bees on the wing by whistling to them, and by request gave a specimen whistle, which was pronounced by the reporter to be indescribable upon paper.

My informant, at the proper season, practised and hit upon a sound which seems to have the desired effect and can be tested by any person of ordinary whistling abilities. As I heard him repeat the sound I should describe it as not being very peculiar, but a brisk modulated repetition of whist-whist.

Now if this whistling theory is a success, how superior it is to all other known methods for stopping absconding swarms. What easy control it would give to the apiarian over his bees, during the swarming season. How easily "Novice" or P. G. could have stopped that swarm of Italians led off by "Giantess." This running through the house pell-mell kicking over the stool and scalding the cat, in your efforts to pull the looking glass from its hangings, mean-

while one of your largest swarms may be doing its level best for the woods—and then when you think you have your glass in position and the sun does not shine, or is disappearing behind a cloud, is not just the thing to preserve that mental equilibrium said to be so necessary in handling bees.

My object in writing this article is to broach the subject, and get reports from others who have tried the experiment; as I cannot confirm Mr. Hammond's success by my own experience, not having any confidence in my whistling abilities to imitate the call of the queen, yet think if I were again to go through the past season's labors in the apiary I should attempt some tall whistling when seeing swarms making for the woods, and I without means to hinder their progress. C. R. ISHAM.

For the American Bee Journal.

Dysentery Again.

Bidwell's paper, as printed in the November No., will create a general row among bee-keepers, and no doubt new ideas and profitable experiments will be discovered. The discovery of bees flying under glass will be of great importance for bee-keepers who are in a very windy situation, like myself. Last year every one wintered his bees so well out-doors and in cellars that no complaints about dysentery were heard off; but I fear very much if Bidwell's plan, when tested with bees having the dysentery, may yet prove a failure; because the space being so small they will smear each other so much that nearly all will be soiled. I find in time of dysentery that there is always a great loss of bees, partly through weakness and by the smearing of their wings in their first flight.

Last year my bees soiled the snow but very little, and the consumption of honey was very small. By the burning of my farm, and the lack of time in October and November to feed them. I was compelled to feed every week all through the winter; so every Saturday afternoon I examined frame after frame, as in mid-summer, to see what honey they had, to prevent starvation.

Sugar syrup in bulk they would not take, I must coax them in every manner. By care and continual feeding they came through in good condition, although they had to coil over the top of the frames once a week, and I got a good deal of stinging too. No man was ever bothered so much with his bees during winter. Had I given strained honey it might have been quite different. Novice mentions that dysentery is often attributed to the quality of the honey. That is my opinion and experience.

In Belgium the honey season is over with August; many bee-keepers instead of killing them put several stocks together, these new hives are sent to the province of Antwerp where one-half of the State is very barren, but a low brush is found from which the bees gather fall honey. Some years, in wet seasons they gather very little, and some years enough is stored to winter on. Now many bee-keepers, and myself among them, have never been able to winter a colony without dysentery. It is a common saying that the honey of this flower is too hot to winter them. I believe those bee-keepers do not know what they say; yet

dysentery is a fact too well known to be disputed. Ventilation, or warmth, have nothing to do with it, because they are set in their straw hives in the same rows with the other hives, and the ventilation and warmth is the same for all. This is a clear proof that "Novice" is right in saying that the nature of honey has much to do with it.

A Question, I should be glad to know—Does any bee-keeper's experience in warming his bee house, during a cold season in April, with his hives on the shelves, advise such treatment? Will any one give his experience on this matter in the BEE JOURNAL?

Will Gallup and Adair gives us a report of their apiaries with their 4 ft. hives?

Weuquoick, Wis. JOSEPH DUFFELER.

For the American Bee Journal.

Bees in Aroostook Co., Me.

We have had a very poor season for bees in this county, the past summer; and the causes are very obvious. Last winter there was but very little snow and in consequence the spring frosts pulled up and killed all the white clover which is usually abundant in this vicinity, and from which our "little pets" gather the most of their honey. Leaving them not much else to gather from except the blossoms, which are not very plenty in this section, and dandeloin. They were prevented from gathering honey from them by the excessive rains, which kept up a continual spatter all through the months of May and June, leaving nothing for them to gather until they got at a species of golden rod, from which they gathered a small amount. Very few colonies have gathered enough to winter on. Scarcely a hive has swarmed, and the hives on an average are lighter than they were last spring. Hundreds of colonies will swarm the coming winter if not fed.

This county has been, for the last ten years, the honey garden of Maine. But this year we are having a big share of "poor luck." If we keep our bees on "luck," this winter, I am convinced we shall lose most of them. It is so strange that those who keep bees do not inform themselves on bee culture, when they have a chance to take a paper like the AMERICAN BEE JOURNAL, that will repay them the subscription price every month, and scarce a volume since it was established but would pay a bee-keeper to lay by at five dollars each, for future reference.

Houlton, Maine. R. S. TORREY.

For the American Bee Journal.

Breeding Peaceful Hybrids.

After carefully studying the natural history of the bees for some time I have come to the conclusion that the disposition of the workers depends altogether on the drones, and that there can be a cross made between the Italians and blacks, which will produce a race of bees as gentle as the pure Italians.

I began bee-keeping with a few stands of Italians and hybrids; the latter being the progeny of Italian queens which had mated with black drones. These I found to be very cross, which is the reported experience

of all who have kept them. The Italians were, as represented, gentle.

Last year, some of the old Italian queens, whose worker progeny were hybrids, were superceded and the young queens that were raised from them mated with Italian drones. This spring I found that the progeny of these queens had wintered better; also that the queens began to lay earlier, and were more prolific, and consequently were the first to raise drones and become strong enough to divide. These hybrids, unlike the others, were as gentle as the Italians. Several of my young Italian queens which I raised this summer have mated with drones which are the progeny of these queens, and the workers from this cross are also gentle.

I have never owned any black bees, but observing my neighbors, I find that the pure blacks are always cross compared with the Italians, but the progeny of a black queen which has mated with an Italian drone is gentle.

Thus I conclude that the worker bees which are the progeny of an Italian queen, a hybrid queen, or a black queen which has mated with an Italian drone, are gentle. Those who are the progeny of an Italian queen, or a black queen which has mated with a black drone are cross. Those which are from an Italian queen and a hybrid drone are gentle.

I have not had a chance to make any observation concerning the disposition of bees that are from a hybrid queen which has mated with a hybrid drone, but if my conclusions that the fighting qualities of the workers depend on the drone are correct, they will be as gentle as those of an Italian queen which has mated with a hybrid drone.

My Experience.

MESSEURS. EDITORS:—I am not in the habit of writing anything for publication, but as I am deeply interested on the bee question, perhaps a word from me would not be amiss. I am now 64 years old; have been raising bees since 1849; but my love for the little insect, whose life is so suggestive of industry and wisdom, is unabated. Last winter I lost between \$300 and \$500 worth of bees. Since that time, the season has been better, and I have averaged \$25 to the hive. I have been raising the Italian bees for 4 or 5 years. Am well pleased with them. I see them very busy sometimes, when the black bee is idle. I have sold the Italian bees for \$30, when the black bees could have been bought for \$5. I have been using the Langstroth hive since 1856, and think it the best I have ever seen.

Your JOURNAL is invaluable. I have been a subscriber to it from its infancy up to the present time. Its visits are like the visits of an old friend—always welcome. I wish you success. JOHN C. DAUGHERTY.

Owingsville, Bath Co., Ky.

Always have the cheerful rays of the morning sun fall upon your hives; but contrive to throw a shade upon their front for a few hours in the middle of the day, when the weather is very hot. Such a shade will be grateful to your bees.—Nutt.

Honey Producing Plants.

We give a notation of honey-producing plants in the vicinity of Aurora, Marion Co., Oregon, for the year A. D., 1874;

FEBRUARY.

The willow was in bloom from Feb. 14 and continued to April 18.

The varionica from Feb. 16 to April 24.
 Chick-weed, from Feb. 16 to May 20.
 Hazel, from Feb. 26 to April 8.

MARCH.

Meadow-cress, March 16 to April 24.
 Cedar, from March 16 to April 8.
 Brush unknown, (No. 1) from March 20 to April 24.
 A. Bahn of Gilead, from March 20 to April 8.
 Salmon berries, from March 28 to May 4.
 Dandelion, from March 30 to July 12.

APRIL.

Peach, from April 1st to April 28.
 Wild currants, from April 1 to May 18.
 Oregon grapes, from April 4 to May 3.
 Gossberries, from April 4 to May 10.
 Plumbs, from April 1 to April 28.
 Cherries, from April 9 to May 14.
 Bear, from April 10 to May 6.
 Soft maple, from April 10 to May 20.
 Common currant, from April 11 to May 14.
 Apples, from April 16 to May 18.
 Prunes, from April 16 to May 3.
 Vine maple, from April 18 to May 24.
 Raspberries, from April 22 to June 3.
 Iris grass, from April 23 to June 6.
 White clover, from 25 to Oct 12.
 June berries, from April 25 to May 22.
 Sheep sorrel, from April 25 to Sept. 2.

MAY.

Oregon crab apple, May 3 to May 20.
 Blackberries, May 6 to July 20.
 Brush unknown (No. 2.) from May 5 to May 28.
 Barberry tree, from May 3 to July 10.
 Red clover, from May 12 to Sept. 30.
 Man-in-the-ground, from May 14 to July 25.
 Thimbleberries, from May 14 to June 30.
 White swale flowers, from May 14 to July 10.
 Wild and cultivated camomile, from May 14 to Aug. 18.
 Huckleberries, from May 10 to June 3.
 The mallow flower family, from May 10 to September 25.
 Laurel, from May 17 to June 20.
 Alsike clover, from May 18 to September 1st.
 Snowberries, from May 18 to July 16.
 Brush unknown (No. 3.) from May 18 to June 20.
 Thistle, from May 18 to Aug. 10.
 Roses, from May 20 to July 25.
 Umbelliferous family, from May 20 to August 10.
 Salalberries, from May 23 to July 29.
 Milk weed, May 28 to September 12.

JUNE.

Lobelia, from June 1 to July 30.
 Flowers in swamps (unknown), from June 1 to August 15.
 Common grape, from June 8 to July 10.
 Spirea, from June 8 to July 20.
 Heal-all, from June 15 to July 25.
 Indian arrow-wood, from June 15 to July 25.

A little bell shaped flower (name unknown), from June 15 to July 24.

Elder, from June 18 to July 26.

Cat mint, from June 18 till heavy frost.

King's tapers, from June 22 till heavy frost.

Weeds in bottoms (unknown) from June 28 to September 1.

Various kinds of the mint family, from June 25 till frosts.

JULY.

Blackroot, from July 2 to August 25.

Corn, from July 8 to Aug. 20.

A vine in bottom (unknown) from July 12 to September 1.

AUGUST.

Ripe fruits commence, such as apples, pears, plums, etc., which bees work on when first pierced by birds or other animals; some last to winter.

Spanish needle from August 10 till heavy frosts appear.

Farm products that produce honey are successfully raised here, such as rape, buck-wheat, etc.

SEPTEMBER.

A number of the above named flowers bloom again after the early fall rains and continue till the frosts kills them.

J. W. WILLS.

Wintering Bees in the South.

The great object of bee-keeping is the production of honey, and to promote this object successfully, is to provide suitable homes for the bees, and give them suitable care, both winter and summer. Man cannot change the season or the instinct of the bee, but he can provide suitable homes for them.

The necessary requisites for successful wintering are 1st. Plenty of good honey, not too much. 2d. Sufficient warmth, 3d. Pure air and dryness. Bees having a supply, and being provided with the above requisites, there need be no fear but they will winter successfully. They will generate their own warmth in the coldest weather. Should they remain on their summer stands they will get pure air, which is a great necessity to their prosperity. In the north it will be better to protect from the cold, by placing the hives against a tight board fence or a building. This will break off the bleak winds, and with a few boards to protect them from the sun, they will winter finely. Have a small upward ventilation, but guard against a current of air passing through the hive, and keep them dry.

Bees need but little care, comparatively speaking, to what they do in the North or West. They should have good honey and plenty of it; protect from the sun by giving them some cheap cover, which will prevent them from coming out every warm day; also it is a great saving in the consumption of honey. Bees need no mattresses to absorb the moisture arising from their breath. Where they can have a fly as they do in the South every few days, there is but little frost accumulates in the hive. The greatest destruction to the bees in winter is the dampness which accumulates in the hive, which occurs when a period of cold weather sets in for several days or weeks, without a warm day or two to give the bees a fly.—*Bee World.*

For the American Bee Journal.

Failures in Safely Wintering Bees— The Proposed Remedies.

There are about as many plans proposed for the proper wintering of bees as there are writers, and yet every winter shows the utter failure of nearly every plan. We have a great deal of theory, but very few facts. The few facts published are generally accounted for in the most unreasonable way. An old and much respected acquaintance once told me that a neighbor of his had lost all his bees. The reason was (he said) an old uncle had died in the family, and they forgot to tell the bees. The two circumstances did actually occur. His mistake was, supposing that one resulted from the other.

An old bee-keeper, and an intelligent one, lately asserted that uncapped honey was poisonous. His reason for saying so was that he had heard so, and once he became sick after eating uncapped honey. So with the failures in wintering bees. A few facts are observed, but they are supposed to be connected together in a very illogical manner. Thus, water is often found in the fall or winter in the hive, or the mats if used are partly saturated. Its presence is accounted for by supposing that the bees evaporate a large quantity, which afterwards condenses on the combs, and sometimes on the bees themselves, causes mould, disease and sometimes death. The mats are often shown, saturated, as an evidence, but my experience is that the moisture comes through leaky roofs. My blankets are covered with tarred paper, lying close upon them, yet the blankets are dry in damp weather, because the tarred paper sheds the rain.

Novice feeds a few swarms on sugar syrup, after extracting all the honey gathered in the fall, and they live through the winter. Many bee-keepers therefore conclude that all fall honey is unhealthy for the bees, and that they would have died, if they had not been supplied with sugar syrup. Straightway they adopt the infallible remedy of pumping out all fall honey and feeding up with artificial food. One or two winter's experience will kill that remedy.

Another bee-keeper says he does not want more than a pint or quart of bees to winter with. The difficulty here is to measure a pint of bees. It would be an interesting sight to see a man stuffing bees into a measure. How tight should he pack it, or rather how tight *would* he pack it. The trial would not last long and he would be as uncertain at last how many bees make a pint. I think he would find that a great many had *points* if they couldn't make a *pint*. The lookers on, if well protected would enjoy it.

Another bee-keeper surrounds each hive with a large box, and packs between with saw dust, straw, dry earth, chaff or other good non-conductors. Another puts his swarms in a dry cellar, moving them out and in on warm days to cleanse themselves as he imagines they must, and talks about their being swelled up with the enforced confinement of the feces within their bodies. Just imagine a dog swelled up to double size because he could not find a convenient door-step on which to make a deposit, or a man wailing about with an apparently sudden attack of dropsy, because our city council has not provided a public water-closet.

Others build special houses to winter their bees in. Still others put on their hives, blankets and mats with special provision for ventilation, in the face of the facts that the bees, when they can, will stop air-tight every crevice except their entrance hole. If another hole is left two or three inches in diameter perhaps they will not close it because it is too big a job, but if the owner will put a piece of wire gauze on it, they will plaster it all over and make it air-tight.

The blankets and mats appear to be good, because they are non-conductors and not because they ventilate the hive or absorb the moisture. The latest, and therefore most approved, plan, is to winter bees under a cold frame, or, as the phrase is, *under glass*. That will have a run for a winter or two. A short time ago one of my acquaintances made an experiment which appeared to be successful. He surrounded one of his hives, early in the spring, with fresh manure, thus making a hot-bed of it. His intention was that the extra heat should start the queen to laying and aid in hatching out the brood. In this he succeeded very well. With a view to public benefit, he wrote a circumstantial account of it to a certain person who being of a volatile, sanguine, harum-scarum disposition immediately procured several loads of manure and buried up his whole apiary of fifty hives more or less. He published, from time to time, how he was progressing with this great invention, but suddenly his proclamations ceased and nobody knows from him, how it resulted. They only know that as usual his bees did not winter well or as it is now fashionable to say they did not *spring* well.

In considering the subject of wintering bees a good plan is to examine the condition and progress of the life of a swarm in a state of nature, and to ascertain what instinct teaches them to do. Art can only slightly improve on nature but cannot entirely change it. Bees in nature are generally found in hollow trees. It is not probable that many accurate observations have been made, but the best knowledge we have, is, that they select a home in the hollow of a tree, which hollow has resulted generally from decay.

These hollows are from one foot to perhaps fifty feet in length and of different diameters. The walls are generally in a decaying condition, being spongy, and full of air cells, thus making a first rate non-conductor. Here they work from year to year, no honey being taken away by man, comb accumulating every year until the whole cavity is filled and if the seasons are good the honey also accumulates, so that when a bad season happens they will have probably the surplus of several years to tide them over. If the cavity is large they probably never swarm, their numbers will increase according to the laying capacity of the queen. These several conditions always ensure large swarms and plenty of food. In such hives where is the ventilation? If there should be a hole above, which would happen maybe once in fifty times, such strong swarms would live in spite of its ventilation, but they would stop it up if possible.

If there is any superfluous moisture it may be taken up by the decaying wood lining the cavity, but there is probably no moisture. In human life there is so little extra moisture, that it requires accurate experiments to find it.

In what case of animal life does the moisture emanating from their bodies, condense to such an extent as to dampen and mould their beds? Then why should a swarm of bees be so exceedingly productive of water. From my reading, from conversations with bee-keepers and from my own small experience, I think I can point out the principal causes of our want of success in wintering.

The extended use of frame hives makes it so easy to take away honey that they are often left with insufficient stores. It is so easy to divide or swarm artificially, that in the fall our swarms are often too weak in bees, to keep up sufficient animal heat for winter. The beauty of the Italian queens and the apparent prosperity indicated by the number of swarms, hinder us from doubling up, consequently we are very likely to go into winter with a large number of weak swarms with insufficient food, and come out in spring with one half or one tenth of the number of weaker swarms in starving condition.

At the Pittsburgh Convention, on the discussion of the question whether it would pay to carry bees to a warmer climate to winter, bringing them back in the spring to this neighborhood, several old bee-keepers seemed to think that such a process would be useless, because nature provides that in very cold weather bees become torpid, and in that condition consume almost no food, and that the difficulty of wintering is not directly from the extreme cold but from the lack of means of resisting the effects of the cold.

My conclusion from all the foregoing is, that, if swarms are strong in numbers of bees in the fall, and have plenty of honey, all the difficulties of wintering would vanish. Therefore bee-keepers must avoid extracting honey to an extreme point. If they multiply swarms in summer beyond propriety, they must reduce the number in the fall by doubling up or joining together.

It is much better to lose several queens in the fall, than to lose both bees and queens in the spring. If the swarms are strong in winter and have plenty of honey, all experience shows that the dangers from want of ventilation, extra moisture &c., are very small and very remote. Use as many blankets and other non-conductors as you please they are generally very useful, and strong swarms can stand a good deal of ventilation if your ideas run strongly in that direction.

Cincinnati. O.

H. W. S.

STANDARD FRAMES.—S. D. McLean, in the *Bee World*, says: "The size of a suspension frame I use in my own apiary is fourteen and one-quarter by nine and one-quarter inches, though not the size I prefer. Were I to commence anew I would make my frames fifteen by ten inches, exactly, outside measure, with three-fourths of an inch extension at each end of top bars to rest on the rabbets of the hive. I suggest that size to the advocates of a standard frame, as a compromise among the many now in use. The length would be about a medium between the Quinby and the Gallop frames—the longest and the shortest frames made—and the depth would be amply sufficient for brood combs, and not so deep as to be liable to swing together at the bottom or have the wavy combs in them,"

For the American Bee Journal.

Answer to Mrs. Spaid's.

If the copy books of the Chicago Honey were not burned, Mrs. Spaid's would see that her answer to my inquiry of what they were paying for fall honey, was simply, "We are paying fifteen cents,"—without any condition of its being good. And as to my saying it was *vice*, I made no such assertion. When shipped to them, it was candied. They had it in their possession for several weeks, and when it was turned over to Perrine, it was thin and watery. How the change come, I cannot say. Has anyone ever known candied honey to turn thin and watery? My advice to bee keepers, and what I intend to do in future, is to keep the fall honey for winter supply, or increase of bees, and sell only the summer honey.

WILLIAM W. BIRD.

Napoleon, O.

HONEY DEW.—A. H. R. Bryant, Kaufman, Texas, says: "Some two years since I was attracted, by the hum of bees, to a box elder that stood in my yard, and when I looked for the cause, I found not only the leaves of the tree covered with honey dew, but the limbs, and also the weeds and the grass underneath, liberally covered with the honey dew. On my first examination I did not find the aphids, and came to the conclusion that it was sure enough, honey dew from the atmosphere; but on a closer inspection, I found the young, tender twigs—which are very green—litterly covered with a very green aphid, (plant louse), hence the abundance of the so-called honey dew, that was litterly dripping from the tree to the weeds and grass below,"

TRAVELING APIARIES.—The *New York Tribune* says: "Some of our apiarians are talking of a wagon with frames for a large number of hives, that can be moved about from one location to another. The benefits claimed are to take advantage, first, of the maple and willow blooms; next come back to orchards and white clover; then off to the forest for the basswood and other flowers; then for the blossoms of the tulip tree, and finally back to the fields of buckwheat and flowers of Autumn. The plan has been pursued in a small way for some years."

In the ordinary glass honey boxes now in use, it requires about 35 cubic inches to hold a pound of honey. Larger boxes lose less space, and hence require a less number of cubic inches. Thus a box 4x5x6 inches contains 120 cubic inches, and, therefore, when well filled and sealed over, holds about 3½ pounds. A 5lb box requires about 33 inches to the pound, and a 10lb box about 30 cubic inches.

I get rid of fertile workers thus: Change places with a strong stock and let them remain a few days. Then open the hive, and if no eggs are found, I introduce a queen. I succeeded once in rearing a queen, having her fertilized, and remain in a stock with a fertile worker, and she did well. It was a stand of pure Italians, very quiet and peaceable.—W. H. Nicholson.

For the American Bee Journal.

Hives for the South.

MESSEURS. EDITORS:—Your correspondent "Edgefield," of South Carolina, wishes me to give a description of the hive I use and recommend for our climate. Now there are hardly two bee-keepers that entertain the same opinion in regard to the arrangement and construction of hives. What suits one does not suit another. While it is of the utmost importance to have our bees in a good hive, large yields of honey (other conditions being the same) are less dependent upon the sort of hive than upon right management of the bees.

While I believe it is impossible to construct a hive against which no objections can be urged, I think they can be made so that very little more need be desired. In making a hive for the South, an observance of the following principles and laws seem to be very essential:

1. Perfect adaptability of the hive to the instinct and habits of the bee.

2. Simplicity. All parts, including frames, must be so arranged as to admit of great ease in opening and closing. There should be no parts about it that cannot readily be gotten into, and examined when necessary. And all these arrangements must be made with special reference not to crush any bees, and to disturb them as little as possible.

3. Enlargement or contraction of the brood chamber at pleasure, so as to suit the size of the colony. There is much diversity of opinion in regard to what should be the size of the brood chamber. I find about 2,000 cubic inches to be a good size for a strong colony worked for box honey; if extracted, I prefer it at least 4,000 cubic inches.

4. Shallow frames, not deeper than the Langstroth. Small frames are desirable in the surplus department. These should be arranged immediately above or near the sides of the brood chamber. If boxes are preferred, place them the same. This is very important.

5. Good ventilation. In our climate we need the top of the hive to be kept well shaded and cool, particularly if we desire box honey. If this is neglected, the heat is often too great, and prevents the bees from working in boxes even in the midst of an abundant yield of honey. Shallow frames can be kept cooler than tall deep ones. Large roomy caps with ventilators attached are most excellent.

The hive I use is a modification of the Langstroth. The frames are $16\frac{1}{4} \times 8\frac{3}{4}$ in. in the clear; open at top, with the exception of each end which keeps them equally distant apart. They are made to hang true, and rest on the edge of a strip of metal. I use no nails, wires, etc., to keep them apart at the bottom. Allow a half inch space around the ends and bottom of frame. Make all hives with tight bottom boards. The body of hive is 16 inches wide in the clear, with a division board. By pressing this board back against the side of hive, ample room is gained so that frames can be removed with great ease. There is a ventilator on the side of hive near the bottom, next the division board. This produces an upward current of air between the side and

division board, and also around the honey-boxes, through the cap.

My honey boxes have small frames in them which are in direct contact with the brood chamber, with no honey board between. When a colony is to be worked for extracted honey, I prefer them in long, one-story hives with 20 or 30 frames of the above size. Entrance only at one end. Keep the frames covered with a "honey quilt" made out of gunny bagging. Hive is covered with a shallow cap with ventilators at both ends. With these hives the bees do not hang out in the hottest weather.

For the information of all concerned I will say that there are no patents on the above described hive. J. F. H. BROWN.
Augusta, Ga.

Voices from Among the Hives.

JOHN L. DAVIS, Delhi, Michigan, writes:—"We commenced this season with forty-seven hives of pure Italian bees, and have obtained 2,500 lbs. of comb, and 500 of machine honey, and sixty-six new swarms or nucleus. We sold seventy queens, and several swarms also. By the middle of September every hive, both large and small, was crowded with honey, except three or four that were hived about the 8th or 10th of September. While trying to obviate, or avoid, the cutting of comb in queen raising, we have discovered that we can, with a pointed instrument, remove the worker larvæ from the worker cells, and introduce them into incipient queen cells, and the bees will raise them into nice queens. This we call the Davis transportation process. It can be done in any queenless colony, and in very populous ones that do not swarm when they should, which is the case with black bees, frequently."

W. D. WRIGHT, Knowerville, N. Y., writes:—"The past season has been an excellent one for bees in this section, and honey is very plenty, and low in price. Basswood yielded more honey than for several seasons past. Bees swarmed abundantly in general. To have had such poor success for several seasons past in wintering bees on their summer stands, that I concluded to try some other way. I have built a repository similar to Novice's. Size 12x14 feet, walls 12 inches thick, filled with saw dust, material; cost about \$125.

If I fail to winter bees successfully in this, I will at least have a good building in which to extract and store surplus honey."

M. H. MILSTEN, Frohna, Mo., writes:—"I commenced in the spring with 21 stocks, most of them very weak; increased to 25 strong ones. From these I took almost 1,400 lbs. of extracted honey, besides running my farm. I had the pleasure of visiting some apiaries this fall, one of which was Dadant & Son's, of whom I purchased a small stock of bees with an imported queen."

THOMAS FROST, Gillespie, Ill., writes:—"The past season has been very dry till August. The rains then started white clover and other blooms so that bees filled their stands, and some of the stronger worked in boxes. The bees are all black in our neighborhood; the season was very poor till the fall blooms came on, then it was only an ordinary season."

L. C. AXTELL, Roseville, Ill., writes:—"Bees have done very poorly in this vicinity for the past three years. Nearly all the bees that have had no care have died off. I have been keeping bees for two years. Last year they had no honey harvest, I fed considerable. I think their increase paid me for their food, and the labor of taking care of them. This year no harvest but buckwheat, which yielded bountifully. From 24 colonies I got 23 swarms and 1500 lbs. extracted honey, which retails at 25 cents per lb. I do not know of a natural swarm that will live through the winter."

J. B. RAPP, Owsnsville, Ohio, writes:—"I am very much pleased with the AMERICAN BEE JOURNAL; you can count me as one of your life subscribers. I would not do without it if it cost twice or three times as much as it does. This is a poor honey section. Our main dependence is white clover, and the drouth usually cuts it short. I have thirty colonies, about half of them are Italians, and all but one are in movable comb hives. They have an abundance of honey, and although a part of them are not as strong in numbers as I would like, yet I think I can winter them safely. I carried twenty colonies that were much weaker and had but little honey through last winter and lost but one, and that starved. I bought a weak stock at a sale, this month for ten cents. A neighbor gave me two last evening; all were good swarms when put in hives. Laet spring I bought four good stocks for \$10

L. W. HARRINGTON, Clyde, Ohio, writes:—"The AMERICAN BEE JOURNAL is the best paper published. In it farmers can find information that they can rely upon, and not too much theory and wild-goose speculation; and bee-keepers that make a specialty of the business, can procure information that is practical. I have stored my bees in my grainery and barn, have given them ventilation above and below that they may know that they are not prisoners. This grainery is not very cold as it is double boarded, and I make this part dark."

ALBERT BULL, Bloomfield, Ont., writes:—"I feel thankful for past instructions from your valuable paper, hoping that I may receive more. I have done well this season with my bees. I have 48 swarms. I extracted 4,350 lbs. from 31 swarms, commencing July 29, and finishing August 18."

G. E. CORBIN, St. Johns, Mich., writes: "I observe on page 251, of November number of AMERICAN BEE JOURNAL, that L. F. asks: 'Why do bees *always* use the left hand hole for ventilation?' Being something of a yankee—which I suppose implies one with 'an inquisitive turn of mind'—I should like to reply to his question, by asking another: 'Why do shads *'always'* climb sign-posts, 'tail first?'"

B. FRANKLIN, Franklinton N. Y. :—"I lived in Iowa two years, I was in the bee business there, bought 9 hives, paid \$60; kept them 2 weeks, brimstoned them, sold the honey in Davenport, lost \$35.00, went to Wisconsin, came back here, started in the business and kept it up. Came out with 47 hives last spring, some very weak ones increased so that I have 86 now, and have taken 3000 lbs. of honey this season 2150 lbs. of it box honey in 2 lb boxes, the rest ex-

tracted. I have a very simple hive; my frames are 14½ by 10½ inside frame, use from 8 to 22 frames in a hive; they open like the leaves of a book, stood up on end. I have seen a great many different kinds of hives, but I have not seen one that I can open and change combs, or do anything I want to, as in this hive, for boxes. I put boxes on the back end of frame and on top, some on three sides and on top. I have 15 hives that I box on 3 sides, these I winter out-doors with chaff around and on top. I wintered some 50, which came out in splendid condition, comb all bright and nice. I see some are in for a standard frame 12x12. Mine is near that: I have no trouble to get straight combs without elevating the hive, either. I have a thin strip in the top bar sometimes they will build the comb over half way down, before they will touch the top bar. I have transferred quite a number of common hives and find this size frame is just right. I don't have any trouble to get the combs in all right."

M. C. H. PURYEAR, Franklin, Tenn., writes:—"I do not keep bees for profit, but as a luxury; have fourteen colonies, give the increase to an old friend who takes charge and manages them, who is engaged in bee-business as a support in old age. I give him my JOURNAL: he files it away and prizes it next to his Bible. I have no white family: all on the farm except myself, are negroes, most of whom belonged to me before the war. After supplying the family with honey, I distribute the surplus gratuitously among my neighbors. I have a substantial and permanent shelter over my bees, which protects them from the cold and rain and snow of winter. I never move them from their summer situation and have never lost a colony from exposure to the winter's cold.

HENRY FAULS, of Council Bluffs, Iowa, makes the following exhibit:—"He says 'a lady can take care of ten swarms, with less labor than is required to take care of an ordinary lot of house plants. Fauls's number of swarms last spring was nine; valued at \$10 per swarm, \$90. The increase was six swarms—total fifteen swarms. He sold eight swarms for \$80; two hundred and forty-one pounds of honey, at 35 cents per lb. \$84.35. He saved for his own use thirty pounds valued at \$10.50, making a total realized of \$174.85. He has seven swarms on hand valued at \$70, making \$244.85, and the original cost being \$90, leaves Mr. Fauls a net gain of \$154.85."

M. VOGLE, a pioneer at the head of Pine Lake, Mich., writes:—"THE AMERICAN BEE JOURNAL is a very welcome visitor at my house. May it prosper forever."

JOHN L. CRABB, Onawa, Iowa, writes: "I am highly pleased with the consolidation of the National with the AMERICAN BEE JOURNAL. I commenced last spring with eleven stands and increased to over thirty, and took several pounds of surplus honey, both extracted and box. It would make you laugh to see my honey extractor. It did not cost me anything, only a little time. I can make one in half a day, that will sling a barrel a day."

J. W. MCKINNEY, M. D., Camargo, Ill., writes:—"The present consolidated form of the 'JOURNAL,' is not to be excelled by any publication on aparian literature in America."

For the American Bee Journal,
For Lectures.

MR. NEWMAN: Dear Sir, According to your remarks and those of Mr. H. A. King, I see there is room for bids for those who are willing to accept a chance to lecture on apiculture. Put me down on the lowest seat, of that list, "for lectures." My time is precious and valuable and I have engagements now until Jan. 22nd, but I am always willing to do my part with common labor of that class called bee-keepers. I would say to those interested, enquire of Mr. H. A. King, New York; J. W. Winder, Cincinnati, O.; or Mrs. E. S. Tupper, Des Moines, Iowa, concerning my ability, as they are practical aparians. My terms are R. R. and hotel fare from Pittsburgh, Pa. It takes two days and costs \$5 to go to and from my place to Pittsburgh, but call Pittsburgh my starting point. I will go anywhere in the United States, and no other charges unless it requires more than three days from time of leaving Pittsburgh, until I return there; and for all time over that, I must charge \$5 per day. I don't ask anything in advance, but the payment of charges must be secured by deposit in a bank of sufficient amount for expenses to my credit, to be paid on presentation of receipted bills of R. R. and hotel. Best to organize in the morning, have a general talk in the afternoon, lecture in the evening and follow by queries. I will stay longer and give practical lessons, at \$5 per day. Notice should be given in time, if practical lessons are wanted.

Simpson's Store, Pa.

W. B. RUSH.

We have concluded to continue our offer of the beautiful Chromo, "JUST ONE," to all who will pay up at once for the year 1875, and also to all new subscribers for 1875.

One of our advertisers writes us that he gets more answers to his advertisement in the AMERICAN BEE JOURNAL than from all other papers put together.

We have received a report of the Michigan Bee-Keepers' Convention. It was received too late for this issue and will appear in the February number.

That excellent monthly *Purdy's Fruit Recorder* has been removed to Rochester, New York, where it will be published in future.

We do not give our Chromo when subscribers club with other publications, unless they add 25 cents to the amount of the club subscriptions, and say they want the Chromo.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

To Our Patrons and Friends.

At its last session, Congress passed a new law, making it obligatory on publishers to prepay postage on all the papers and publications sent out from their offices, to take effect on the 1st of January, 1875. Then, instead of individuals paying the postage on their papers at the office of receiving them, the publishers are required to pay the postage in bulk, and charge the same to subscribers, with the subscription price.

We have concluded not to ask the additional price of postage from our subscribers, and hope that they will so far appreciate their having no postage to pay in future, as to send us a new subscriber when renewing for next year.

We send all papers until a specific order is received for a discontinuance, but promptly stop it when notified.

If there should be one of our present subscribers who does not wish to take the BEE JOURNAL for 1875, he should notify us at once, so that we may not waste papers and pay postage too, on any one not desiring to "ride with us" another year.

We ask especial attention to this Notice. It will be quite a tax on us to pay postage on all our entire edition, and any assistance in the way of new subscribers will be duly appreciated and acknowledged.

Mr. H. A. King has disposed of his interest in the *Bee-Keepers' Magazine* to Mr. Cobb, to whom we extend our  for a welcome.

In this No. we issue the Title and Index for Vol. X. By cutting the stitch it can be taken out and placed at the beginning of Vol. X for binding, and reference. The extreme length of the Pittsburgh Meeting report crowded it out of the last number.

John K. McAllister & Co., are our duly authorized agents for the AMERICAN BEE JOURNAL, at Room 27, Tribune Building, Chicago, with whom any business may be transacted with our approval, and be promptly recognized by the manager of this paper.

 We ask our patrons to assist us by procuring new subscribers among their friends or neighbors, and thus increase the usefulness of the JOURNAL. By getting two new subscribers you can get all three for the year 1875 for \$5. This may be divided among the three, or you can get your own copy for \$1. Larger clubs would make your subscription still less. See club terms on page 28.

Honey Markets.

CHICAGO.—Choice white comb honey, 82@30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c.  lb.

ST. LOUIS.—Quotations from W. G. Smith, 419 North Main st.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00  gal. St. Domingo, and Mexican, 90@95  gal.

SAN FRANCISCO.—Quotations from Stearns and Smith, 423 Front st.

 Strained Southern Coast, at 7@10c; Comb, 12@20c; the latter figure for San Diego, in Harbison frames.

About one hundred and twenty-five tons of honey has been shipped East this season. Our market is firm at 7@10 cents for strained; with some fancy lots at 12@12½c. Comb 18@20c for San Diego. Gold quotations. We have had abundant rains, the grass is several inches high, with some flowers, and we have had but light frosts, bees are working, and with a good prospect of an abundant season. We shall ship fresh butter East next month. Surely this is a land flowing with milk and honey.

Our Premium Chromo—"Just One."

It is a beautiful design, and one of the finest and richest paintings that has come from the easel of that popular painter, B. S. Hays. The central figure is a beautiful child, (a little girl) who stands by a side-board loaded with fruits, (apples, peaches, and grapes), one foot is advanced forward, which brings the other on tip-toe—one hand is grasping the edge of the side-board, and the other reaching up for the basket of grapes; and two plump fingers are in the act of closing upon one large luscious berry. Her face is turned toward you, and wears a look of commingled mischief, anxiety and entreaty, and you can almost hear her say, "Just One." This picture is a complete story of the child's temptation, and her struggles to resist, through her awakening sense of right.

To every new subscriber as well as every old one who now pays for 1875, we will send post-paid, a copy of this beautiful Chromo.

Send on your new names and renewals at once and secure it.

Those who have paid for a portion of the year can secure the Chromo, upon sending the balance for the year 1875.

A Letter from the Rev. W. F. Clarke informs us that he cannot now take the lecture field as intimated in our last. His time being fully occupied by other cares.

Specimen Copies.

In order to assist our friends in procuring new subscribers, we will send specimen copies to those that they intend to call upon, if they will send us their names and addresses. It will take but a little time to get parties to subscribe when they see our paper. There are thousands of bee-keepers all over the country who take no bee journal and consequently are uninformed concerning scientific bee-keeping. These should all be solicited to take THE AMERICAN BEE JOURNAL, and the thousands who now read and prize the JOURNAL can easily reach them. Will they not do it? Every one who reads this is specially solicited to act as an agent, and present the claims of THE AMERICAN BEE JOURNAL. We feel assured that they will do it. A few hours time from each, devoted to the interests of THE JOURNAL will add thousands to our list.

To any person sending us a club of ten, with \$14, we will send a copy of THE AMERICAN BEE JOURNAL one year free, and also the Chromo. To any one sending us a club of twenty with \$25 we will send a copy of Worcester's Unabridged Dictionary in addition to a free copy of THE AMERICAN BEE JOURNAL and Chromo.

The *Bee-Keepers' Magazine* of last month said it contained the only report of the late meeting at Pittsburgh, Pa. A postal card from the publisher, states that it was an error to say "the only report." Our report last month was a fuller report of the proceedings than any other paper contained.

The offer of premium queens is now withdrawn, as we cannot supply Spring queens for that purpose.

Mr. J. J. H. Gregory of Marblehead, Mass., has his annual advertisement in our column. He was the original introducer of some of the best vegetables now found on every table. He comes this year with a new squash, and a number of tempting specialties, some of which are finely illustrated from engravings taken from photographs. The fact that so many of his varieties of seed are of his own growing, is a golden fact for farmers and gardeners.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Our New Club Rates.

We will send the AMERICAN BEE JOURNAL and the following periodicals for one year, for the prices named below:

THE AMERICAN BEE JOURNAL and	
Novice's Gleanings for.....	\$2.25
King's Bee-Keepers' Magazine.....	3.00
Moon's Bee World.....	3.25
All four Bee publications.....	5.00
Swine and Poultry Journal.....	2.50
The Chicago Weekly Tribune.....	3.20
The " Weekly Inter-Ocean.....	3.20
The " Weekly Journal.....	3.20
The " Weekly Post and Mail.....	3.20
The Western Rural.....	3.70
The Young Folks' Monthly.....	3.00
The Prairie Farmer.....	3.70
Purdy's Fruit Recorder.....	2.25

Newspaper Decisions.

1. Any person who takes a paper regularly from the post-office—whether directed to his name or another's, or whether he has subscribed or not—is responsible for the payment.

2. If any person orders his paper discontinued, he must pay all arrearages, or the publisher may continue to send it, until payment is made, and collect the whole amount—whether the paper is taken from the office or not.

3. The courts have decided that refusing to take newspapers and periodicals from the post-office, or removing and leaving them uncalled for, is *prima facie* evidence of intentional fraud.

It will be a source of gratification to us if all those in arrears for the AMERICAN BEE JOURNAL will settle the same as soon as possible. Our increasing circulation vastly increases our regular monthly expenses for paper and printing. "A word to the wise is sufficient."

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

Our subscribers in Europe, can now procure Postal Money Orders on Chicago. This plan of sending money is safe and economical.

Subscribers wishing to change their post-office address, should mention their *old* address, as well as the one to which they wish it changed.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

AMERICAN BEE JOURNAL,

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. XI. CEDAR RAPIDS, FEBRUARY, 1875. No. 2.

A Scientific Mare's Nest.

* * * * *

Prof. A. S. Packard Jr., has discovered a mare's nest in the realm of bee-keeping. He announces his discovery in an article headed "The Busy Bee" contributed to the Chicago *Advance* of Jan. 7th 1875. He says, "Notwithstanding the large number of bee-keepers with more or less leisure on their hands, and honey-bees by hundreds of thousands in the United States, and the many interesting questions constantly arising regarding their economy. *The bee has not yet found a biographer on this side of the Atlantic.* * * "He then goes on to say, it has been reserved for one of the busiest of men to study that busiest of insects, the bee. Sir John Lubbock, banker, M. P., Vice Chancellor of London University, entomologist, anthropologist, fox hunter, and what not,—he it is who has played Boswell to the honey-bee, and "noted the daily and hourly doings of the hero of the hive."

We are exceedingly glad that such a very busy man and one so shingled over with titles and honors, has had the inclination and found the time, to study the habits of the bee, and give the fruits of his investigations to the world. Nor can we have the slightest objection to Prof. Packard's trumpeting forth his praises in *The Advance*, or any other newspaper, whether secular or religious. But we can't permit him to write up his wonderful Englishman at the expense of truth, and at the expense of the reputations of "the large number of bee-keepers" on the American continent. What a discovery this is of the Professor's that "the bee has never found a biographer on this side of the Atlantic." Where has the learned Professor spent his days, that he has never heard of Langstroth, Quinby, Wagner, Kirkland, Gallup, King, Thomas, Root, Mrs. Tupper, and a host of others, who have played Boswell to the honey-bee, and noted "with a loving minuteness, the daily and hourly doings of the hero of the hive," giving the results of their observations to the public in the shape of books, pamphlets, periodicals, letters and scientific

papers well nigh innumerable? His prodigy of acuteness and industry, Sir John Lubbock, has discovered nothing with which all intelligent bee-keepers are not thoroughly acquainted, except those two startling things: *first*, that bees are unable to find honey at all hidden except by accident, and *secondly*, that when a bee happens to light upon honey in a rather by-place, or is carried to it by some scientist like Sir John, it has no means of imparting its knowledge of the store to other bees. Now having seen a pretty full report of a lecture by Sir John, embodying the substance of the pamphlet which has thrown Prof. Packard into such raptures, we find the first of these amazing discoveries if not indeed both of them contradicted by the great discoverer himself. Referring to the pertinacity with which bees pursue honey, he cites the fact that they will go for it even into "sweet shops," where multitudes of them perish. How does this happen, if instinct does not guide them to by-places where sweets may be found, and if one bee cannot, in some way, impart information to another? We can only say that Sir John's discoveries, as announced by the learned Professor in *The Advance*, are at variance with the experience of bee-hunters and bee-keepers on this side of the great Atlantic fish-pond. In hunting for bee-trees, dependence is put on the instinct and communicative power which Sir John denies to bees, while the robbing of isolated hives, and the gathering of honey in all sorts of out-of-the-way places, point to conclusions the very reverse of those arrived at by the scientific baronet.

Prof. Packard remarks, "It would seem that bees have enough intelligence to guide them in conducting the affairs of the hive." Well now, that's very astonishing, especially when you come to think that this was the identical end for which they were created. Its very like observing, with a note of exclamation, that birds, fishes, animals and insects generally, have intelligence enough to fill their respective spheres. Certainly the universe would have been very badly contrived, if this had not been the case.

C.

Seasonable Hints.

The impression prevails that the winter is the best time in which to move bees from place to place. In our opinion this is not correct. We prefer to move them at almost any other time. If it must be done at this season, a warm, instead of a cold time should be chosen, and at the end of the journey it is best to put them at once into a room or cellar quite warm and dark, unless the weather is so mild that if left out of doors the bees can fly.

A neighbor moved ten colonies in a very cold day last winter, putting them, when he reached home, into an out-door building. Many of the bees were lost and the remainder had dysentery, so that but two or three were saved out of all the ten colonies. Had they been put into a warm room until the agitation was over, the loss might have been avoided.

The principle is obvious. The bees when disturbed and alarmed, filled themselves with honey, the cluster was disarranged, and the bees scattered through the combs. In a warm room in the dark, the agitation would have subsided and the cluster become perfect again; but left exposed to the cold, the scattered bees being full of honey, all perish.

From March to November bees can usually be moved any distance with safety, under proper precautions; but between November and March, only those who are well informed as to the principles that govern the matter should attempt their transportation. We know bees are moved in winter, and moved safely but it is purely accidental. If they have honey enough and bees enough for safe wintering, the chances are largely against their being moved well. If one knows enough to take the honey from them first, and feed them again judiciously afterwards, it may be done; though then, all is greatly dependent on the weather. T.

British Bee-keepers' Association.

Below we give the Introduction and also the object of the First Exhibition of Bees and their Produce, Hives, &c. held by the British Bee-keepers' Association at the Crystal Palace, at Sydenham near London, last September. We commend them to the careful attention of all those who have anything to do with Fairs and Exhibitions in this country. We have not space for the whole Premium

List or numerous entries made, but these extracts give a good idea of its aims. We see that our friend, W. Carr, had a large and interesting collection, as follows.

305. CARR W.—Specimens of Ligurian Queens, Workers and Drones, Egyptian Workers and Drones,—Nest,—Brood comb and Bees of the Trigania or Exotic Bees from Honduras, Hornets, Wasps and Humble Bees with Nests,—combs, Royal cells and Wax scales of the Honey Bee; combs, showing the ravages of the Wax Moth with the male and female Moths.

Large Paper Cells showing the Bee's economy, Ten large Pen and Ink drawings of the Honey Bee, viz: The Internal Anatomy, The Bee's Stomach, The Queen's Ovaries, The Bee's Head, The Bee's Leg, The Bee's Sting, The Bee's Wing, The Bee's Antennae, The Bee's Abdomen, Showing the Wax Scales.

Hexagonal cells, Showing the Angles enlarged twenty times.

Super of Honey, 87 lbs.

Who will begin now to make a collection of equal value and interest for our Centennial Exhibition?

We need a change in all our Exhibitions and Fairs, and we are especially glad that at the last meeting at Pittsburgh, steps were taken to avoid premiums for bees, queens, &c. We hope and expect this to be the beginning of better days' as far as exciting an interest in the objects of the Society are concerned.

The following is the Introduction to the Premium List:

BEEs AND BEE-KEEPING.

From the earliest ages, *Honey*, the produce of the Bee, has been in all civilized countries an esteemed luxury of the human race; and Wax at great commercial value, as well as a useful adjunct for domestic use, sometimes to illuminate the halls of the noble and great, at others to brighten the humble furniture of the thrifty cottager.

The busy merchant, when wanting a symbol of industry for his house, could find no better sign than the "Bee-hive"—how common the axiom "a very hive of industry"—the poet and the moralist failed not to quote our little friend as an example to the young, and the beautiful rhyme of Dr. Watts, of "the little busy Bee," can never be forgotten as a memory of our early days, and in ages to come will be taught to our children's children

with the same loving wish of as good results as we hoped for us.

How then have we required our little friend? For shame, be it said, by *robbery arson, and murder*. For centuries the almost universal practice to obtain the sweets of the hive has been by destroying its inhabitants by fire and brimstone, and appropriating the whole of their gathered riches. With as much reason might the farmer slaughter his sheep to obtain their fleeces. Spare the laborers and they will work again; and after the toils of a busy summer, grudge not a portion of their gathered harvest to preserve the lives of those who have labored so hard.

The British Bee-keepers' Association was instituted in May last, for the purpose of advancing the cultivation of Bees, and particularly to bring to the notice of cottagers and others, more scientific, profitable, and humane methods of apiculture than has hitherto been generally practised. Our rural districts, from the fertile valleys to the mountain tops, wherever fruit, seeds, and flowers grow, offer pasturage to Bees. No rent to pay! No trespassers! Every farmer, every gardener, gladly welcoming the busy Bee! Darwin tells us that to Bees (of another species truly) we owe the very existence of red clover. Learned men remind us that the beauty of our fields and gardens, and the maturity of our fruits and seeds, are in a great measure attributable to Bees, who in their flights from plant to plant, unconsciously distribute the pollen by which the flowers are fertilized.

Thousands of tons of honey and wax are annually wasted in our native land, which might be profitably gathered by Bees, and the money expended to foreign countries for Bee produce, put into the pockets of our rural population. There is no reason why every man, and woman too, who has enough of garden room to stand a hive upon should not keep Bees. Any man who can make a rabbit-hutch can make a Bee-hive for use, as good as the best, and those who can afford to buy may gratify their taste or suit their pocket by selection from the many very good patterns now on view.

A glance at our Catalogue and Honey Show will prove to the enquirer that the profits of Bee-keeping are not to be despised. A stock of Bees may ordinarily be obtained for about £1—a little more or less according to the district, and instances will be found at this Show where the marketable value of the honey obtained this year, from a single hive, equals as much as six or eight times the original value of the stock, which is yet maintained to work again another year! Such

is the result of *good* management, which the Association would like to find general. Now a few words as to the danger of being stung. Bees are never aggressors without cause; treat them kindly, or let them alone and have no fear, for you will never be stung. Children soon find this out, and play about the hives as merrily as usual, gaining a lesson in industry and additional pleasure by watching the return of the laden workers.

JOHN HUNTER, *Hon. Sec.*

Notes AND Queries

Is there any demand for empty comb, and at what price ought we to sell it? I have about 500 empty combs, 12x16 inches in size, nice, clean and straight; and also a quantity of clean white comb of all sizes and shapes. Where can I sell, to whom, and at what price? W.

There is a good demand for such comb in frames, though the size you name is not a common one. We have paid \$1 each for such combs, perhaps no one else would give as much. Would advise you to advertise it, and get all you can for it, if you cannot use it yourself. As to the clean white comb in pieces, you can sell it to any dealer who is putting up honey for sale in jars. If you have much, it may pay you to advertise that also.

C. W. inquires if there has been any improvement within the past five years in making artificial comb; and says, "the one who perfects any thing in the shape of comb in which bees will work, will be the greatest benefactor of all bee men."

We agree with him so far as to fully appreciate the importance of artificial combs to bee-keepers. We know that Mr. Wagner was still at work perfecting dyes for the making of his combs at the time of his death, we are not informed as to his progress further than that. Mr. Quinby's artificial comb was a success so far, that the bees used it raising brood and storing honey. Why he has ceased using it we are not informed, or in what respect it failed to answer his expectations. We are sure the time is not far distant when we shall have combs made by men, that will be accepted as good by the bees. In the meantime we may, by proper management, stimulate the bees to build comb in good frames; and to do it when they would not be storing honey. Then if we cease to sell honey in the comb, we shall have a better supply than we have had in times past.

I wish to begin the bee business. I am offered ten colonies at \$10 each. Is that too much? and how am I to tell if they are good colonies? C. G. Missouri.

The price is not out of the way for good colonies of black bees, if they are in moveable comb hives. We would not advise you buy without examination, and if possible to defer until spring.

Early in spring they ought to weigh near 20 lbs. and have a cluster of bees that extend at least, between four combs. It is hard to give a novice directions so that he can tell exactly the value of the bees he buys, and we would advise you to have the counsel of some one that has experience, before purchasing, unless you know you can rely on the one of whom you buy, to give you only colonies he can warrant good.

Please tell us what colored honey Alsike, Lucerne, Catnip and other plants make.

JAMES MARKLE.

Alsike clover gives us a light colored honey of greater thickness than white clover, and of as good if not better flavor. We know little about the honey from Lucerne, and reports are so conflicting about its value as a honey plant, that we prefer to ask for "more light," before expressing our opinion. Golden-rod gives a very yellow honey; that from Aster is not so dark though of better flavor. Doubtless the color and flavor of honey from all plants, varies with locality and soil. All who know anything about Sorghum syrup, are aware that much depends on the soil where it is grown, and just so we think honey is changed by soil.

Please tell a beginner how to fasten moveable frames securely, when moving some distance.

H. LIVINGSTON.

In most cases it is only necessary, in moving bees, to drive a small nail into each and every frame and fasten them securely on the top. This is easily done, after smoking the bees so that they will not resent it. After doing this, put the cap on tight and fasten the entrance up, either with wire cloth, or a piece of wood, in such away as to give them air, while confining them. We have found no difficulty in moving bees prepared in this way, Jolting should be avoided as much as possible, and the less honey in the hives the safer they will go.

I am using Langstroth hives, but find great difficulty in getting bees to build in the upper chambers. What is the cause? Last spring I had 22 colonies, when the wet weather set in; when it closed, my apiary was reduced to 9 colonies. I took 400 lbs. of honey. It became crystallized early in the fall, notwithstanding I kept it in a dark place. I have let my bees remain out this

winter, have them wrapped in straw; they are keeping well, so far. I am very much interested in the JOURNAL.

Tenn. MRS. M. G. MARRISS.

Without knowing more about your hives, we cannot tell why the bees do not build in the upper chamber. Different causes may produce it. The openings into the super from the main hive may be too small, (we would always remove the honey board in such cases). There may have been too small a number of bees to enable them to have sufficient heat in the chamber. Below, the hive may have been so full of honey that the queen has been cramped for room and the bees are in consequence reduced in number. There is something wrong in a fair honey season if bees in a healthy, strong colony do not work in every part of the hive. If there are bees enough, they will work, if honey is being secreted, wherever they can find space.

Honey will granulate in all places and under all circumstances, it seems, contrary to all rule. Instead of that being a disadvantage, it is rather in your favor, since it proves that it is unadulterated. After it has granulated it will keep any length of time and can be restored to a liquid form by warming it, with very little trouble.

There is an increasing demand here for honey in the granulated state; many people preferring it so. You speak of honey as "crystalizing"; sugar syrup might crystalize, but honey granulates. There is a great difference between the two words or rather the states which the words represent.

LOCAL BEE-KEEPERS' SOCIETIES.—Some correspondents have written to us, enquiring how to organize local societies of bee-keepers. We answer, do it as simply as possible. Very little machinery is needed. A President, Secretary, Treasurer, and Committee, are all the officers required. A few rules, prescribing the membership fee, times of meeting, order of business, and so forth will be sufficient. In view of the privileges accorded by the North American Bee-keeper's Society, it is advisable to organize as auxiliary to the general body, and we hope that many such organizations will be found in various parts of the country during the present winter. C.

The Report of the "Michigan Bee-Men in Council" is so long that many other good articles are laid over for want of room. The Michigan Bee-keepers had an interesting meeting, and the Report will be read with interest.

Michigan Bee Men in Council.

KALAMAZOO, Dec. 16th, 1874.

The seventh annual session of the Michigan Bee-Keepers' Association convened in Corporation Hall, at two o'clock, p. m., President Balch in the chair. Notwithstanding the universal complaint of hard times, the attendance was unusually large, evincing a growing interest in this fascinating pursuit.

After the transaction of some preliminary business, the convention listened to an Opening Address by President A. C. Balch, welcoming the members to the hospitalities of the large-hearted and whole-souled people of this loveliest of villages—Kalamazoo.

The regular programme of the convention was then taken up. Secretary Burch read a paper from Charles Dadant, of Hamilton, Ill., on the best size of frames, in which the writer strongly favored a large frame as giving the greatest advantages to the apiarian. He also urged that American apiarians adopt a uniform-size standard frame, as being a long sought desideratum; in proof of which he cited the beneficial results that had followed such adoption in Italy. The paper elicited much discussion, the most important of which we give, as follows:

James Heddon—Large frames, the size of Quinby's, are, in my opinion, too large. I prefer a small, shallow frame, as it offers the most advantages, and gives the best results in amount of box honey. It has been almost universally recommended that a hive should not hold less than 2,000 cubic inches; yet a smaller size will give better proportionate results. It is better not to give the queen all the room that she will use, than go to the opposite extreme. Quality of bees, and not quantity is what we should aim to get.

Dr. A. L. Haskins—I use the American frame, 12 inches square, and think it about the right size. I like it better than Quinby's.

Prof. A. J. Cook—In this country of Yankee ingenuity and invention, it will be quite impossible to adopt a standard frame, as scarcely any two apiarians will agree on any one size, much less the whole fraternity. I have experienced much difficulty in handling the Quinby frame, in having the combs fall out, which is decidedly unpleasant. The bees do not fasten large combs as securely as smaller ones. They are inconvenient for queen-rearing, which is objectionable, as all bee-keepers wish to raise queens for their own use. I prefer the Gallup frame, as combs do not break out so easily, and are more convenient for rearing queens. They are also better for wintering, as the bees are in a compact cluster, just as they should be. Bees that cluster in an oblong shape, as they do in Langstroth's will get away from the outside of the cluster and die.

C. I. Balch—Would not a shallow frame obviate dampness better than a deeper one?

Prof. Cook—Such has not been my experience.

T. F. Bingham—Thought the subject an important one. Give a beginner a good hive, and good advice in the shape of a good text book, and if he has good judgment he is almost sure to succeed. If I used the Langstroth frame I should think a standard frame desirable. Small, shallow combs give more brood early in the season. Large combs ob-

struct the easy passage of the queen to various parts of the hive—shallow combs obviate this difficulty. Heat ascends sooner than it radiates; hence, in tall hives, it is lost. In wintering bees we should keep them near the bottom boards, and it will not get clogged up with dead bees. Early in the season the queen will lay in one or two large frames; in a series of smaller ones much more. Again, small, shallow frames are much easier to handle. There are but two methods of obtaining box honey successfully. Either use a tall, narrow frame, and side boxes, or a long, shallow one, and top boxes. Small frames are more convenient to manipulate in extracting. I prefer a cloth quilt, hemmed in beeswax, in place of a wooden honey board.

J. H. Everard—Large frames are objectionable; too heavy to handle. In visiting Mr. Bingham's apiary, had witnessed the best results with a long shallow frame, only six inches in depth.

C. I. Balch—Have always used a frame nine inches deep; would use one not to exceed seven inches, were I to commence again. Mr. Bingham once advocated a deeper frame.

T. F. Bingham—And would to-day, if obliged to winter out of doors. By the aid of a good bee-house they can be safely wintered in shallow combs.

Dr. Southard—Use only the regular Langstroth frame. Were I to change, would make them smaller, and more shallow.

Mr. Bryant—Have used ten Bingham frames to the hive, with good results. Have used sectional hives but do not like them. Bingham's gave the most box honey.

Prof. Cook—What is "box honey?"

Pres. Balch—Honey stored by the bees in small glass boxes.

Geo. Stray—I get more brood early from a shallow oblong frame than from a deeper, square frame, and consequently more honey. In wintering, have no mouldy combs. Leave hives on summer stands, pack well with straw keeping it dry, and bees will winter well.

Prof. Cook—I would like to hear from those who use deeper combs. I hope we shall not fall into the error that honey can be obtained only by the use of shallow frames.

Mr. Bryant—My twenty-five stocks in shallow, three-inch frames gave me over 2,600 pounds of box-honey.

H. E. Bidwell—I have used all sizes and shapes of frames; now I prefer a frame one inch deeper and one inch shorter than the Langstroth. It will give more honey, but is more trouble to winter successfully than deeper combs.

James Heddon—Years ago I took the tops off from box-hives, putting on a honey-board. In using all sizes and shapes I found that a hive 22 inches deep often gave just as much box honey as one only ten. I prefer the latter depth in movable comb hives, as we get a small hive in better shape, offering greater advantages in manipulation.

Mr. Helleney—Am using Langstroth hives; think them preferable; can get more honey from an extra set of combs on top, than from boxes.

James Heddon then favored the convention with an address on the subject of "The Art of Getting Honey into Money," the prominent points of which we give below:

Apiarians who raise extracted honey, are

now obliged to compete with cheap syrup and glucose in all the large cities. Exclusive honey dealers adulterate our honey with this stuff, thereby making one pound of honey sell seven or eight pounds of glucose. Had agitated this subject years ago, and now the dishonest practices of these dealers demand that we met the question squarely and firmly, or else we shall soon have no market for our honey—it will be utterly overstocked. If we put only a good article on the market, and continually keep it supplied, we can create a demand for our honey, by educating the people's taste for a prime article. Make honey a staple article. Honey dealers will buy honey, and *promise* to pay, and sometimes will do so, after selling it at double the price, besides selling eight or ten times as much glucose, worth seven or eight cents per pound. We ought to adopt the grange principle of combination, control our own products, and sell direct to the consumer. We must discriminate between the products of an apiary and a honey-house. Teach the people who eat honey, that the former produces honey—a pure article; the latter a conglomeration of honey, glucose and poor syrup.

C. I. Balch—Many people like to be humbugged, and will buy a spurious article in preference.

James Heddon—Honey dealers have created a demand for jar honey with a little comb in it, as much as to say, "Liquid honey is not good, so we'll put in just a little that is." This ought to be abandoned at once, as extracted honey is even better, because wax is not a wholesome article. I know from experience that, despite prejudice, the people who eat it, learn to prefer it.

C. I. Balch—Can honey that is candied in the comb be liquified?

James Heddon—Honey candies from cold. Put it in a warm place and it will liquify, though it takes time.

Pres. Balch—My bees will carry candied honey out of the hive in spring.

James Heddon—If you put a comb of such uncapped in the middle of the brood nest they will utilize it.

Prof. Cook—Honey is only a kind of sugar. The various kinds are quite readily told by the temperature it will grain. Nearly all syrups are adulterated. How then can we stop adulteration?

James Heddon—If you find a dealer keeping an adulterated article, publish him. Printer's ink works wonders, sometimes.

J. H. Everard—Create a home demand by keeping a good, pure article.

Mr. Bryan—Detailed his experience in mixing syrup and honey; thought it didn't pay.

James Hedden—Bee-keepers can raise the pure article cheaper than they can manufacture it.

T. F. Bingham—We might undoubtedly create a demand for honey, but it is easier to cater to a demand that already exists. Every man likes his own wife's coffee best. People who have long eaten comb honey prefer it.

After some further discussion, the Convention adjourned until evening.

At the evening session, among the papers read was the following by Prof. A. J. Cook, of the State Agricultural College:

FEEDING AND THE EXTRACTOR IN RELATION TO PROFITS IN APICULTURE.

Success in bee-keeping as in every other pursuit that looks to nature or natural phenomena for those prospective profits which make the heart glad, demand that we understand and take full cognizance of the science underlying those phenomena. To be sure ignorance *may* succeed, while full knowledge removes success from the realms of doubt.

Now, as a preface to this essay, let us recall some of those facts, which science has developed, which have a bearing on the subject matter in hand.

Science determines that, in the economy of the hive, the older worker bees gather the honey, the younger do the work of the hives, as comb-building, feeding young bees, etc., while the instincts and structural nature of the queen impel her to do the work of egg-laying alone. Moreover, science taught very early in the world's history, that the instinct of all these classes of the hive incited them to an industry which knows no abatement, save as the stern hand of necessity is laid upon them. Thus the gatherers work with unparelled assiduity, so long as there is honey to gather and room in which to store it. The in-door laborers build comb so long as room and the proper internal arrangements of the hive permit. While in the queen, a stronger instinct still causes her to labor untiringly in her work of egg-laying, yet leading her to pause, not simply from necessity but often from probabilities as well in that the queen ceases from egg-laying when the gatherers cease from storing. Can it be that parental solicitude for the welfare of her off-spring, makes her, even in the face of desire, to withhold from sending children to brave scarcity, want, mayhap starvation. What lessons has nature for those wise to read.

Such breadth of instinct, seeming to reason upon surrounding conditions, and what is more wondrous still, seeming to comport with structural peculiarities, is not alone peculiar to the queen bee. The male pigeon for example feeds the young, and with the hatching of the young fledglings, comes a peculiar development of the crop, which assists in the preparation of suitable nourishment. Here too, then, structural conformation, has relation to a peculiar instinct, which takes note of outside circumstances. Another example is found in the common high-holder, *Colaptes Auratus*, which usually lays six eggs. Yet if the eggs are taken from the nest, the bird will continue to lay often to the number of thirty, which number was actually taken from a nest at our college, by Prof. W. K. Kedzie, now of the Kansas Agricultural College. Here again then we notice that instinct varies with circumstances, and is attended by a structural change of the ovaries.

Hence we see, science teaches that to have honey stored, we must have, not only bees, but honey secreted by the flowers, and room in the hive to store the same. And again, to have bees to store, we must keep the queen laying eggs, which demands, not only room for the same in empty cells, but just as imperatively that storing is continued.

Now, let us see if these requisites are always at hand, without care and labor by the apiarist.

Suppose, as true of us at Lausung during the past season, we have an excessive yield of honey from the fruit blossoms, during May. The workers ever on the alert for such opportunities, will, in the two weeks of rich harvest, fill every cell in the hive with the precious nectar. What then? the queen, like Othello, finds her occupation gone, for if in the interim between fruit and white clover blossoms, the comb-builders do ply their calling, which in the general indolence of the hive, is not likely; still in the midst of idleness the queen will not even improve such opportunity. So with clover bloom, we have a depopulated colony all unprepared to make the most of this, the golden era of honey-gathering. Yet, even with the fewer bees, insures a repetition of the fruit season experience. With a good harvest of clover, such as the past season gave us, comes storing to repletion, and ruinous prosperity again confronts the apiarist. From white clover to basswood, comes a repetition of former experiences, only augmented, of course, so that the longed-for period of basswood bloom, finds the apiary with depleted colonies, all unprepared to reap the rich reward which a bounteous honey harvest presents. More than this, it never rains, but it pours, as the moth comes to make havoc with colonies too feeble to offer successful resistance. Now, if all these seasons of fruitfulness to the bee-keeper have been productive, as during the past summer, we go on from bad to worse, as we near the period of buckwheat, and golden-rod. And thus Autumn finds us with feeble colonies, small returns, and long faces, when nature has been most propitious.

After September we have no gathering, brood-rearing ceases, we approach winter with what few bees we have, old, torn and gray with labor, and ere spring, even these succumb, and what wonder if we say, "bee-keeping is played out." For in just such ways does it far too often become a source of vexation and discouragement.

Now is there no escape from these perils? With the science full in mind we see that if we can only keep the bees supplied with empty comb, enabling both worker bees and queen to meet their fullest capabilities, and more, can keep the worker bees constantly storing, so that the queen will be stimulated to her best efforts, even in the interims of honey secretion, we shall meet both the above difficulties, and shall welcome such seasons of infinite honey secretion as the past has been, with unalloyed pleasure. Now, thanks to Herr Hruschka, of Germany, we are enabled by the use of the honey-extractor, which his inventive genius gave us, to accomplish the former, and by feeding limited supplies during the periods of no gathering, using this same extracted honey, should it not find a remunerative market, we meet the second difficulty. Here, then, in use of the extractor, and by judicious feeding, the apiarist has power to leap one of the greatest obstacles in the way of success. And just here let me say that I fully believe that in this use we receive the greatest benefits of this indispensable machine. By its use, during the past summer, we have been made to rejoice in one of the best honey seasons I have ever known. Those who have not used it, have fallen far behind in the amount of profit received. Early during the past season

there was an astonishing yield of honey from the fruit blossoms, so that we experienced a peculiarity, new to me, of having our combs filled with this early honey.

Do you ask me then, when I would extract, and when feed?

I answer that I would extract whenever it was necessary to give the queen empty cells, never allowing all the cells to be filled with honey and brood. Whether I would use it at other times, would depend on the market for extracted honey. If I could find ready sale for such honey at 15 cents per pound, I should extract a good deal at other times, especially in the fall, as it is valuable to have empty combs in the spring as by their use we can most easily obtain non-swarming hives.

I would feed sparingly, obliging the bees to carry the honey into the hive from March till October, whenever the bees were gathering no honey. Do you urge the trouble and labor involved? Let me assure you it will prove the most remunerative, expended in your apiary.

Very likely some of you will desire to know where to obtain the best extractor, and how to feed in the most convenient manner.

So far as I know, there is no better extractor made than one sold by A. I. Root & Co., Medina, Ohio, for \$10, or made to fit his standard frame which is $11\frac{1}{4} \times 13\frac{3}{4}$ —\$9. Just the gearing, I think, can be procured for \$2, in which case, each of us can finish to suit himself.

As to feeding, if we have a close chamber above the brood chamber, all we need to feed is a common tin or wooden box, with a bottom of coarse cotton cloth. Setting the box over a hole the same size in the quilt or honey board, the bees will come up and sip the sweets as they ooze through.

Cloth bags nailed to the top bar of a frame which has a lobe through it and placed in the hive in lieu of one of the frames of the comb, as recommended by "Novice," will be cheap, convenient, and easily set aside when not needed.

EVENING SESSION.

The first topic, "Feeding,—How, When, and Why," was introduced by a paper from Prof. A. J. Cook, of the Agricultural College, favoring stimulative feeding, in times of scarcity, to promote breeding; also of the value of the extractor in times of great honey secretion. The subject was discussed as follows:

T. F. Bingham—Did the bees store from apple blossoms to exclude the queen?

Prof. Cook—They did.

T. F. Bingham—Did you have forage from earlier sources?

Prof. Cook—Yes.

T. F. Bingham—At that time of the year (last of May) the hive should be full of brood.

C. I. Balch—In times of scarcity of forage, uncapping the honey in the hive will promote breeding.

T. F. Bingham—You might just as well feed chips to induce brood rearing as honey. If bees are gathering pollen, as they usually are in warm weather, and have honey in the hive, the brood will be abundant. Feeding for this purpose is useless. Bees have little discretion—man should have it for them.

Prof. Cook—My bees would not breed when gathering pollen and no honey, and my queens were "yellow," too.

J. Tomlinson—I have had combs stored full of pollen, but got little brood.

Prof. Cook—Would Mr. Bingham ever feed stimulatingly?

T. F. Bingham—Never. Its requires lots of discretion, which our family don't possess. It may do for amusement, the same as boys play marbles.

J. H. Everard—Don't localities differ?

T. F. Bingham—I think bees will gather enough in any locality—usually too much for the benefit of the bees. Bees do not collect honey or pollen because they need it, but because it's their instinct—bees have no reason.

President Balch—Hives that have an abundance of pollen, do not work as well on flour in the spring as those that do not.

Mr. Walker—I tried every method last spring to get brood early, but failed until natural pollen came in, though they had eggs all the time.

Prof. Cook—I had some stocks with no pollen; stimulated, and got lots of brood. Commence the 1st of April, feed regularly, and you'll be surprised at the amount of brood. Though others claim that brood can be raised without pollen, I don't believe it.

C. I. Balch—Did you ever mix honey and pollen together and feed it?

Prof. Cook—I have never tried it.

H. E. Bidwell—Bees cannot brood without pollen; uncapping honey in the hive is a good method to promote breeding.

T. F. Bingham—If one has lots of leisure, it would be good exercise to take a carving knife and go around through the apiary and "carve" 200 stocks.

James Heddon—If your combs contain an abundance of pollen, feeding will pay well. Have tried every plan of feeding, and prefer to fill a Mason fruit jar, puncture the cover full of fine holes and invert it over the hole in the honey-board. It will not leak, and you can see at a glance just how fast the bees are taking the feed. Fed sugar syrup in this manner last fall, for winter stores; it is equally good for stimulative feeding. Bees in small hives will have lots of brood, when those in large hives will have less, as they fill up the brood combs with honey. Do not like Root's extractor—it's not strong enough.

Prof. Cook—What one would you use?

James Heddon—I make my own, after having tried several others.

T. F. Bingham—Extractors, to be durable, must be strong. In extracting, we are often compelled to do it in a hurry, as honey sometimes comes with a rush. Would use up a Novice machine in a half day's run. Use a revolving can machine—a Peabody machine, Bingham-ized. Can extract more in a day from black than from Italian bees.

C. I. Balch—Black bees run off the combs, making it easier to do a big day's work.

James Heddon—I can extract honey so solid, that a revolving can machine would not touch it. As Mr. Burch helped me extract some honey a short time since, I wish to ask him if he thinks any other machine would have done the work.

H. A. Burch—I have seen no other that does as good work.

A paper was then read by the secretary from James Bolin, West Lodi, Ohio, on the best manner of "Wintering Bees." H. E. Bidwell, of South Haven, Mich., read a paper on "Wintering in Cold-Frames."

J. Tomlinson—How many swarms do you put in each cold-frame?

H. E. Bidwell—Sixteen, two deep. Size of frame 6x12 feet, and three feet deep.

J. Tomlinson—Would not a conservatory do?

H. E. Bidwell—It might, but is not necessary. Besides it's too expensive.

J. Tomlinson—How far is the glass above the hives?

H. E. Bidwell—About six inches.

C. I. Balch—Do the bees cluster on the glass?

H. E. Bidwell—Not if the temperature is right. It should not be too cold, nor too warm—about 70 degrees is the best.

H. A. Burch—What is the slope of the glass?

H. E. Bidwell—Eight inches in six feet.

Prof. Cook—Would you confine the bees to the frames in spring and let them work on flour?

H. E. Bidwell—I would. They worked freely on it last spring. Would let them fly occasionally—once in four weeks is often enough—keeping the frames well covered in the intervals.

Dr. Southard—Am trying the experiment of packing hives in a box with straw, so as to guard against sudden changes of temperature. Each box holds 16 hives. Think this better than a cellar, as mine were uneasy when thus housed. Had them covered with quilts which I think injurious. The cellar was well ventilated—mercury 45 degrees.

A Member—Do not bees when flying in winter go back to the summer location when removed in the fall?

Dr. Southard—Mine do not.

C. I. Balch—As much stress is laid on keeping bees quiet in wintering, I would like to hear from Mr. Milner on this subject.

Mr. Milner—I have wintered stocks that had no honey in the fall, by feeding during the winter. The bees were kept in a house cellar, under the living room. When my bees are quiet in the cellar, I stir them up. There are many fine theories that are erroneous.

James Heddon—I think there is an endemic around the country. If the bees are right you may pound them—they will stand some abuse; but if diseased you must exercise judgment and work hard to save them. I think Mr. Bidwell's plan a good one, yet would prefer a house if that will insure success. Put the bees in carefully; do not let them know it. Carry bees out and in often in spring, if necessary.

C. I. Balch—There may be a bee disease.

Mr. Milner—I have handled my bees only moderately careful for the past four years, yet have succeeded well. They are certainly well stirred up in putting them in the cellar.

J. H. Everard—I have drawn bees over a rough road in cold weather, and they wintered well.

James Heddon—When I took my bees out last spring they were so dormant that I had to stir them up to induce them to fly at once. Wintered without loss, though I had lost nearly all in the previous winters.

A. C. Balch—Bees do not need upward ventilation at any season of the year, much less in winter.

Mr. Walker—My bees that had no upward ventilation died, others did not. They were

wintered in a special repository with a temperature of summer heat—too high. Bees clustered outside of the hives.

A. C. Balch—If the conditions are just right you can seal them up air-tight and they will live. I would prefer a tight barrel to a ventilated hive.

T. F. Bingham—I wish I had had 100 swarms "bottled up" last winter. To prevent mold have the comb "chock full" of honey.

A. C. Balch—Related Prof. Cook's experiment of wintering bees in a snow bank. One hive was sealed hermetically; it came out in good condition.

James Hedden—Can bees live without a change of air in a winter repository?

A. C. Balch—I think they can. In order to insure success, avoid all currents of air, especially in the hive. Have wintered for years in a house cellar, with no ventilation and no loss.

C. I. Balch—In explanation, I would state that the hives referred to are double walled, and will give some ventilation, even when closed so bees cannot get out.

J. H. Everard—Will Mr. Balch give the temperature of his cellar?

A. C. Balch—From 40 to 45 degrees—atmosphere perfectly dry.

George Stray—Will Mr. Hedden state his method of wintering?

James Hedden—My winter repository is 12x16 ft., with a foot wall filled with sawdust. Have shelves, so that each hive is separate. Put them in early, before cold weather. If the weather admits of a good fly, I carry them out, and re-house them before it gets cold again. By this means, losses in spring may be avoided.

Mr. Milner—The temperature of my cellar was 32 degrees—the success was excellent.

T. F. Bingham—Mr. Quinby and myself (showing the similarity of ideas of great men) tried artificial heat in the winter repository. Have had a hot time the past summer—just a little last winter. Without joking, I want a low temperature—32 deg.—to prevent breeding; and then a judicious use of Mrs. Winslow's soothing syrup will bring them out all right. If the bees are kept quiet, the hives and combs will remain dry.

James Hedden—My bees are more quiet with the mercury at 52 deg. than at 32.

Mr. Walker—The temperature in my cellar was so warm that one swarm built comb in an upper section which was occupied by the queen. Many of the bees left their hives and clustered on the ceiling.

A. C. Balch—Your bees were trying to swarm.

The "Question Drawer," a novel and interesting feature of the present session, was conducted by T. F. Bingham. The most important queries and answers we give as follows:

Are Italian bees superior to blacks?

They breed well, but think them no better. They are not good box honey workers. Are artificial queens as good as natural ones?

They are.

Are queens reared from the larvæ as good as from the eggs?

Think there is no difference.

Are small queens as good as large ones?

Just as good.

What is the expense of raising queens when bees are rearing an abundance of brood?

Merely nominal.

Can you get as much honey with increase as without?

Yes, and you have a swarm ahead.

Which will gather the most honey relatively, large or small hives?

Small hives, every time, if not too small.

Which are longest lived, Italian or black queens?

The black queen. Italians have to be constantly imported to keep up the stock. If Dadant could get a queen good for four years, he could stock the whole country with queens.

We would state that although the above answers are at direct variance with the generally received opinions of well informed apiarists, they are not so when taken from Mr. Bingham's standpoint.

The Convention then adjourned to meet at nine o'clock, a. m., to-morrow.

SECOND DAY—MORNING SESSION.

Kalamazoo, Dec. 17, 1874.

The convention was called to order at 9½ o'clock this morning, President Balch in the chair. The secretary read a paper from W. J. Davis, of Youngsville, Pa., upon "Queen Rearing." The best stock to breed from, and the conditions necessary to insure the most uniform and permanent success was considered at length. He urged beekeepers to use more care and exercise more judgment in rearing queens. The idea that the best queens could not be raised out of the swarming season, was strongly maintained.

J. Tomlinson—Can we not get good queens late in the season?

C. I. Balch—We can, according to my experience.

Prof. Cook—Good queens can be raised late in the season, but it requires more skill and experience.

James Heddon—I have procured a good many queens from W. J. Davis; have found no others equal to them; but do not agree with him in regard to the Darwinian theory of reproduction. Our best scientific men agree with Darwin.

Prof. Cook—Our best scientific men believe in evolution, not in Darwin. Evolution is—life comes from life—from the lowest to the highest. Darwin teaches natural selection,—that the fittest and best survive and the poorer and weaker perish.

Mr. Davis claims that the best time to rear queens is the swarming season; is natural because in accordance with nature. When bees supersede their queens, we have a natural process, yet it is often done out of season, usually in the fall.

A. C. Balch—Bees, in superseding a queen, commence from the egg, but when deprived of their queen use larvæ to supply the loss sooner, which accounts for the difference in quality.

Mr. Bryan—Prolificity is dependent on the age of the larvæ when the cell is started. One day old will make good queens, seven days very poor. Have never seen two queens in a hive at once.

Pres. Balch—There is yet room to learn.

C. I. Balch—Will Mr. Bingham favor us with his method of rearing queens.

T. F. Bingham—Man, of himself, can't raise queens, even with the help of science

—though that will aid us. New comb will make our success more certain. Cut new comb, containing eggs or larvae into strips three cells wide by ten long. Cut the cells off on one side near the septum of the comb, and insert in an opening made in a brood comb, with that side down in a vertical position; would use five or six such pieces to the hive. Cells built in this way can be cut out without destroying them. Old combs may be used by cutting the cells closer to the septum of the comb.

H. A. Knapp—What place in the brood comb would you insert these strips?

T. F. Bingham—I prefer the centre, though it's immaterial.

Prof. Cook—When bees supersede poor, short-lived queens our stock will grow worse; but one that has been prolific three or four years and then fails will surely produce better stock.

T. F. Bingham—Prof. Cook has struck the key note to success in this matter. The queen that lays well for four years, has a fine organism and good constitution, and will give us the finest queen progeny.

James Heddon—A queen that will live four years, and is prolific, will give us the best queen stock, if reared when she is in her prime—before she commences to decline. The offspring of young parents are weaklings, as well as those very old.

H. A. Knapp—Yes, and oftener.

C. I. Balch—I once reared queens from one of the bees were trying to supersede, for 50 stocks, and they were as good as any I ever saw.

J. Tomlinson—Was she a good layer at the time you reared the queens?

C. I. Balch—She had been very prolific—was moderately so at the time.

Mr. Bryan—There must be a natural cause for poor queens. What is it?

H. E. Bidwell—The eggs consist of many small ovals. When the eggs hatch, if to be used for queens, they should be fed as such from the start as they are more fully developed. Eggs from old queens are not as good as from those in the prime of life.

Prof. Cook—Why do cows that have proven to be extra good ones, command a higher price when quite old? Is it not because they will then perpetuate their desirable qualities, with more certainty, in their offspring?

T. F. Bingham—No, but simply because there is no uncertainty about their good qualities.

C. I. Balch—Would Mr. Bidwell breed from a very young queen in preference to an old one?

H. E. Bidwell—I would most assuredly.

Papers on the best method of obtaining box honey were read by the Secretary, from Seth Hoagland, of Mercer, Pa., G. M. Doolittle, of Borodino, N. Y., and J. P. Moore, of Binghamton, N. Y. Many valuable ideas were advanced, eliciting considerable discussion.

T. F. Bingham—Prefer boxes on top instead at the side of the hive, as bees will store pollen in the latter, spoiling the quality of the honey. Have no brood in top boxes if properly managed. If honey comes in fast when building comb, there is no trouble; if not, they must be watched, as the queen might go above.

Mr. Bryan—If you want to obtain the best results, keep the bees crowded—they will then store honey in boxes.

Henry King—I have used side boxes on the Eureka with good results. Was not troubled with pollen.

James Heddon—The fabulous tales we hear of side boxes are a myth. By elevating the back end of a hive we have all the supposed advantages of side boxes. To get honey stored above, keep the brood nest well filled with brood and stores. A low, flat hive gives more room on top—just what we want. Honey stored in frames don't sell equal to small glass boxes.

H. E. Bidwell—Put frame honey up in glass and it will sell at the highest market figures.

T. F. Bingham—Which plan gives the greatest quantity, boxes or frames?

H. E. Bidwell—I can get from thirty to fifty per cent. more in frames. Think the difference owing to increased facilities for rapid storing which they afford the bees. It sells just as well.

Mr. Bennett—I can get more honey in frames than in boxes, but must sell it to exclusive honey dealers, and they are regular cheats.

President Balch said the time for the election of officers had arrived. The convention proceeded to elect officers for the ensuing year with the following result:

President—Henry E. Bidwell, South Haven.

Vice-President—Arad C. Balch, Kalama-zoo.

Secretary—Herbert A. Burch, South Haven.

Treasurer—James Heddon, Dowagiac.

As the time allotted the morning session had not expired, an opportunity was presented for volunteer papers and addresses. The Secretary read interesting letters from R. M. Argo, Lowell, Ky., and James M. Marvin, St. Charles, Ill. T. F. Bingham read a paper on "Importing Bees" condemning in emphatic terms the promiscuous importation of Italian bees, and pointing out the danger of such a course. Julius Tomlinson read a paper on "Standard Frames," stating the impracticability of adopting a uniform size, and expressing the opinion that it never could be accomplished.

The convention then resolved itself into an "experience meeting" (to use a Methodist phrase) and many valuable ideas were brought out, the pith of which we give:

T. F. Bingham—Foul brood may be detected in various ways. Hives infected with it have a sickening nauseous smell.

The capping of the brood is concave instead of convex as in healthy stocks, and often has a slight opening as if punctured by a pin. It usually commences gradually, finally destroying the colony, and is very contagious. Procuring queens from infected apiaries will communicate the disease; hence the great danger of the importing business.

J. Tomlinson—Will the Secretary give us his experience with the "New Idea" hive?

H. A. Burch—It is very valuable—makes tip-top kindling wood. For a bee-hive it is worthless.

T. F. Bingham—Artificial swarming is the difference between the instinct of the bee and the will of man. Our success depends much upon our knowledge of the instinct of the bee and the honey resources of the locality. Perform the operation when clover begins to yield honey, so as to have the hive full of comb by basswood time, and you are

then ready to secure that harvest in glass boxes. Put on but few boxes at a time—no more than they can occupy.

James Heddon—The "New Idea" hive will give lots of bees, and some comb honey of poor quality. Will do very well for extracted honey, only it is twice as much work to get it.

C. I. Balch—How small will it do to make hives?

James Heddon—To give us a working force that will keep up animal magnetism,—the essence of life.

H. A. Burch—All who wish to manage bees with pleasure and the smallest amount of labor, should use Quinby's Bee Smoker. It is one of the most valuable implements about an apiary. You can get all the smoke ever needed, direct it just where desired and it is always ready for service.

J. H. Everard—Let bees out in the spring for a flight and then replace them. Sun catches them out and cold winds destroys them.

James Heddon—In accounting for the loss of bees let us be sure that they have not been wintered, often successfully, in previous years, under precisely similar conditions. By this rule, an epidemic is the only explanation, possible.

Mr. Bryan—We can domesticate bees, or rather educate them, so as to be perfectly docile; careful handling is indispensable.

James Heddon—Bees are naturally quiet and peaceable. They are made cross by education—improper handling.

T. F. Bingham—The best educator is a plug hat—they need no introduction to that, but will introduce themselves.

James Heddon—Extracted honey kept for several months is just as good as ever when ungrained.

Mr. Walker—Honey that is heated to the boiling point when first extracted will not grain.

The committee on resolutions—H. E. Bidwell and Dr. A. S. Haskins—reported the following, which were adopted without a dissenting voice:

Resolved That the Michigan Bee Keepers' Association tender to the kind citizens of Kalamazoo, our heartfelt thanks for the generous hospitality they have given us during this session of our association.

Resolved, That we return our hearty thanks to those at a distance who have furnished us valuable papers of great interest to our meeting.

Resolved, That this association return our sincere thanks to the reporters and press for their reports.

The convention was also unanimous in its condemnation of those engaged in adulterating honey, and all other dishonest practices.

The sessions were harmonious throughout and largely attended. It was, in the best sense of the term, a success, evincing a growing interest in this most fascinating pursuit, and marking a new era in the history of apiculture in this country.

Upon adjourning the convention decided to hold a spring session in Kalamazoo, on the first Wednesday of May, 1874.

HERBERT A. BURCH, Secretary.

There is a decided difference among bees as to industry in comb-building and honey-gathering, even where the location, weather and management are the same.

For the American Bee Journal. Can Bees Winter Without Pollen.

MR. EDITOR.—Several of my correspondents are complaining that they fear they will lose their bees during the present winter, from the fact they have no pollen. I will state a few facts and try to relieve their fears.

In Oct. 1868, Mr. Solomon Brown of Tama Co., Iowa, visited me and while examining my bees, 26 stands at that time; he noticed that they were not only nearly out of honey but were entirely destitute of pollen. This had been the poorest season I ever knew; the bees had not made one fourth enough to winter on. I was about to feed them for winter when Mr. Brown asked me if I thought they could winter without pollen. This question scared me so that I determined to double them to 13 stands, which I did and fed on A sugar syrup.

In the mean time I had written to an old bee-man of many years experience, D. Burbank, on the subject. His answer was that when I feed on sugar syrup I need have no fears for pollen. Now for the result. The thirteen stands *every one* of them came through the winter all right, and increased next season to fifty-two, and give me 560 lbs. of surplus and the season was only a tolerable one.

I think bees can winter very easily without pollen, especially if fed on sugar syrup, but I would by all means advise feeding on rye-meal as early in the spring as the weather will permit them to take it in.

Lowell, Ky.

R. M. ARGO.

For the American Bee Journal. Adulterated Honey.

I read in the report of the proceedings of the North American Society, that some honey dealers refuse to buy extracted honey because they can manufacture a "so called" better article, at less cost, in mixing a gallon of honey to seven gallons of sugar syrup.

I see also in the report of a committee appointed to study that matter, that the committee condemns such practice and menaces the adulterators of publishing their names. I doubt the efficiency of such a menace. The majority of the adulterators will assert that they do not sell manufactured honey. How can you prove their culpability, if you do not know the means of detecting the adulteration?

Such a means exists; it has been known and practised in France for centuries. It is infallible and in the reach of every one. Honey granulates, or as you term it in this country, it candies. Sugar syrup does not granulate, does not candy, if too thick it crystalizes.

But I see in the same report that bee-keepers want a means of preventing honey from candying. It is the same as to want to encourage the fraud; for if bee-keepers were deprived of this means of detecting false honey, the adulterators would become more daring and more numerous. What is needed therefore is not to find a means of preventing honey from candying, but to educate all the American consumers, which are accustomed to buy spurious honey and

which refuse the true article, because they don't know it.

It is consequently of the greatest importance that all the Bee Journals inform their readers that the best test for honey is the candying; that honey candies because it is formed of grape sugar, which granulates and does not crystalize; that on the other hand, sugar syrup is made from cane sugar, which does not candy but crystalizes. That if they find on the market, from December to June, a so called honey in liquid condition, they can, with absolute certainty, declare it a sophisticated honey, or at least a honey which, by boiling, or by pure mixture, has lost its character as true and pure article.

If you were in Paris offering for sale your best honey, you could not find a price, not even five cents per lb, if your honey was liquid; while a good, white granulated honey would sell readily at 15 cents. It is because the French people are accustomed to eat candied honey, and know that it is granulated.

Let every one of us write, in all the papers at large, these simple facts; and without waiting for the millenium, we will see all the amateurs of good honey ask for candied honey, for it is really better than liquid, better even than comb honey.

CH. DADANT.

For the American Bee Journal.
Bee Enemies.

My article in the September No., headed "Spring dwindling," does not seem to have drawn the attention I desired, but I deem the subject to be of such overwhelming importance that I dare to dwell on it once more, hoping that this time one of the many experienced bee-keepers, writers or observers may take up the subject and help me to awaken the interest of all bee-keepers to it.

The enemy in question is a fly, called the bee killer. There are three kinds, all looking very similar to each other viz: *Asilus Missouriensis*, about $1\frac{1}{2}$ in. long. *Asilus Cericeus*, about 1 in. long, and *Erax Bastardi*, about $\frac{3}{4}$ in. long. All these three species abound here (central Ill.) from June to the end of September, and there is no doubt in my mind that they are the main cause of the sluggishness of the hives, often shown from early June to the middle of August. My hives were quite lively in April and May, increased in honey and brood, so that I already dreamt of a large honey yield and a large increase in June and July. But alas, how were my hopes disappointed. In early June my hives became lazy, almost stopped flying, showed no increase in honey nor in numbers, and actual weighing proved that they lost honey. Of course I dropped at once all intentions to a further increase of stocks, and tried to study the cause. True, it was a dry season, but there were in June flowers enough for the bees to bring home some honey, but they hung before the fly-hole without attempting to fly. I thought of toads and watched them; of hornets, of all birds, said to be enemies, but none could have such a discouraging and decreasing effect on the bees, as I perceived on all of my stocks. I investigated the stocks inside, found them clean, combs well built, but

little honey and brood, and weak in numbers. None tried to build any queen cells. I almost gave up the search, when one morning while being busy in the apiary, I heard behind me a peculiar loud and short bee "hum." Turning around I saw a large long fly, hanging on a grass stem, have in its claws a bee and after turning the helpless victim so that the under side of the bee's thorax touched its proboscis, the latter as quick as lightning sunk into the thorax of the bee, at the same time the fly with its victim dropped to a lower place, between the grass, and after a few minutes dropped the sucked out, and of course dead bee, to look for a new victim. While I was observing the operations it struck me there might be more of these flies, and began to search, when I to my terror found that thousands were around in the field, all watching for the honey bee. The mystery of my bees dwindling down was at once explained. The bees I saw idle before the fly-hole were young ones. The old ones flying out, but not half of them returning from their honey and pollen excursions, of course the hive decreased in honey. Honey and pollen decreasing, the breeding was nearly stopped and a general discouragement lamed the hive. In July and August I killed a large number of the above named species but not enough to help me much. From the middle of August they seemed to disappear somewhat, and immediately the bees became lively, brought in more honey, began to breed again and enabled me to sling out from 40 hives, from Sep. 1st to 15th, 840 lbs. of fine honey.

The coming year I intend to apply all the time I can spare to hunting for this worst of the bee enemies. They are easily caught by a butterfly net. Just before sunset they settle mostly on top of a conspicuous weed, where they are easily seen and caught. I am very much astonished that none of our many writers on bees ever mentioned this enemy. The Missouri State Entomologist, C. N. Riley in his second annual report, gives a full description of all three species, I refer the reader to his article in that report page 121-124. What I would propose is, that all and every bee-keeper in the U. S. should from June to September be busy killing this fly. It is plain that this pest to the bees must increase, as the number of bees increases, but that a concerted action may thin down its numbers.

They are easily recognized by their long, slender conical abdomen, their transparent two wings, their long legs, thick thorax and their deep, drone-like short, loud hum while they fly. Their color is brownish and yellowish. Length of body from $\frac{3}{4}$ to $1\frac{1}{4}$ inch long. Wherever bees gather honey you can find this fly. I caught many a hundred on my buckwheat in the morning. On wild land in the afternoon. If it had not been for this blood-thirsty savage bee enemy, I verily believe that I would have gained 2000 lbs. more honey and at least 25 more new colonies than I actually did. I think it worth while for every bee-keeper to give this subject his full attention for 1875.

Sigel, Ill.

CH. SONNE.

We earnestly invite investigation on this point, being convinced that we cannot be too much on our guard against any enemy of the bee. We cut from Colman's Rural

World reports from Prof. Riley, describing what seems to be the same insect. Let all bee-keepers study these descriptions. T.

BEE ENEMY.

EDITORS RURAL WORLD: Please find enclosed an insect of the canibal species, subsisting on the flesh of the common honey bee. I have no name for it, neither can I tell from whence it came nor how long its visit will last. It appears to be confined to localities. I have not as yet seen any feeding on my bees, yet one mile from me they are committing a fearful devastation. Their mode of catching the bee is, by alighting on the back of the bee and carrying it to some prominence, and if left alone soon destroy it vitality. They are very swift on the wing, but easily caught, and less wary when feeding on a bee. Any information concerning its habits and general character will be thankfully received.

A. STURGILL.

Pickering, Mo.

Your letter was kept for some time in the *Rural World* office and was finally handed to me without the specimen. Yet I have little doubt from your description, that the insect which destroyed your bees, is a large two-winged fly, which I have called the Missouri Bee Killer (described in my second report as *Asilus Missouriensis*, but ascertained by subsequent comparison, by our dipterist, Baron Osten Sacken, to be the *Proctacanthus Milberti*, Macq.). These flies "capture the bee on the wing, pouncing upon it with lightning-like rapidity; then grasping it securely with his fore-legs, they alight upon some plant or even upon the ground, and rapidly suck out the inside of the bee, with the stout proboscis, leaving the empty shell when they get through. Mr. Thompson says that beneath some favorable perch that is near the apiary, hundreds of these bee shells may be found accumulated in a single day; while he has watched and found that a single fly on one of these perches destroyed no less than 141 bees in that period of time."—1st Report, p. 168.

There are several other species of these rapacious flies, which have the bad habit of killing bees, but the apiarian will care little about their specific differences. They should all be destroyed, "and though very strong and rapid flyers, they may be easily caught settled on any little prominence with a bee in their grasp; for they are so greedy of the bee's juices that they are at this time less wary, and even when disturbed will fly but a few yards away before settling again." A net, such as is used by entomologists, and as is described in my 5th Report, will be found useful in catching them, and there is no other way of preventing the mischief they do.

"The habits and preparatory stages of our *Asilus* flies are not very well known. They are all canibals in the fly state, sucking out the juices of their victims with the strong proboscis with which they are furnished, and by which they are capable of inflicting a sharp sting on the human hand. The larvae are footless, and live in the ground, such as are known in state are strangely enough, vegetable feeders."—2d Report, p. 123.

A box 6½ inches high, and 15 inches square, in the clear, will contain 20 lbs. of honey in the comb.

For the American Bee Journal.
Answer to H. W. S.

MESSRS. EDITORS:—Permit me to answer a few points as briefly as possible, in an article written by H. W. S., of Cincinnati, in the JOURNAL for January.

He says in the second paragraph, "That a few facts are observed, but they are supposed to be connected together in a very illogical manner." One of which is the collection of moisture in the mats and on the insides of the hives and the errors of attributing it to aqueous vapor emanating from the bees themselves, while "his experience is that the moisture comes through leaky roofs."

While this is no doubt the case when the roofs are defective, still there is no fact better established in apiculture—however "illogical" it may seem to some—than this one; that bees confined to the hive during cold weather consume a vast amount of oxygen from the atmosphere to keep up combustion, in order to maintain the requisite degree of heat, exhaling carbonic-acid gas and water in the form of vapor. In all animal life it is seen, that combustion is carried on more vigorously in cold than in warm temperatures. The temperature of the body undergoes no change in passing from the torrid to the frigid zone, the increased combustion compensating in a great measure the more rapid loss of animal heat in low temperature. The same power to adapt itself to different degrees of temperature no doubt exists though to a less degree in the honey-bee. If we expose a bee suddenly in the heat of summer to a temperature not lower than one in which it would fly briskly in the winter, it would soon perish; showing that the combustion then going on is not sufficient to resist as low a degree of temperature, as in the winter.

Now, the products of combustion whether from fuel in the grate, or that constantly taking place in animal life, is invariably the same; carbonic-acid and water, and the quantity produced—other things being equal—is always in proportion to the fuel consumed, and if egress is not given it in some way, the vapor will be condensed on the first cold surface with which it comes in contact.

He says "he covers his blankets with tarred paper which excludes the external moisture, and therefore his blankets are dry."

I suppose the tarred paper is laid loosely on the blankets with the tarred side up, allowing the air to pass between them, and evaporate the moisture.

Any one having any doubts on this subject, can easily demonstrate the fact, by inverting a tin box over the blanket the size of the hive, and securing it that no moisture can escape, and none enter from without; then examine it after the mercury has remained for a few days and nights several degrees below freezing, and he will be surprised at the quantity of moisture that has been condensed on the cold metal in the form of frost, which if it were allowed to accumulate during several weeks or months, he would have an approximate idea of the whole quantity thus thrown off and what the condition of the hive and bees would be if this had been retained.

The idea that moisture in any considerable quantity is generated by the bodies and respiratory organs of bees, seems to be ridiculed throughout the article, and he takes human physiology to prove his position, and says: "In human life there is so little extra moisture, that it requires accurate experiments to find it," while the fact is that it amounts to several pounds daily.

Put on gum boots without lining over woolen stockings; they will soon be found wet with perspiration.

The soldier finds the underside of his gum blanket that he has slept under during a cold night, lined with frost, from comparatively small portion of the aqueous vapor exhaled from the body during the night.

The question is asked, "In what case of animal life does the moisture emanating from their bodies, condense to such an extent as to dampen and mould their beds?" I would answer, whenever that moisture is confined to the bed. Try a rubber bed, with rubber coverings, at a temperature low enough to condense moisture; confine closely all the vapor generated by the body and exhaled from the lungs, and I imagine the bed in the morning will be found uncomfortably moist.

For this very reason we use the kind of clothing and bedding we do in cold weather; and try to apply the same principles in the management of our bees. One, while it is a non-conductor of the animal heat generated by the body, is sufficiently porous to convey the aqueous vapor to the external atmosphere. We have ventilators in our houses; our doors and windows, with our fire-places and their flues, constantly changing the atmosphere around us and carrying off the surplus moisture.

Each bee in the cluster is of itself a little chemical laboratory and furnace, with chimney attached, receiving its supplies of fuel from the atmosphere and the car-

bonaceous materials in its food, which, when combined in its system are consumed, generating heat, the carbonic-acid gas and water escaping as effete material or smoke.

Now, one great object in every bee-hive, should be to have some means by which this effete matter can be carried off. It is of no more use to them in the support of animal life, than the smoke that escapes from the chimney is fit for combustion; but on the contrary, the carbonic-acid is as surely fatal to animal life, when inhaled in large quantities, as water is to quench fire.

As we cannot very well use a single large chimney for this purpose we resort to a great number of small ones. We employ *capillary force*; that force which raises the oil in the wick, the sap in the plant and tree, and in this we have thousands of minute chimneys, as the medium, transmitting these gases to the external air, where it is diffused instead of being condensed within the hive, to be vaporised again and again as the temperature changes.

The writer further says; that, "In the face of the fact that bees will stop air-tight every crevice except their entrance," bee-keepers will persist in putting blankets and mats on their hives for the purpose of ventilation." That they will plaster up a thin piece of wire gauze, there is no doubt; but we do deny, that they in a state of nature, make or attempt to make their homes air-tight; a fact which further along in the article is practically admitted; where he says, speaking of hollow trees: "The walls are generally in a decaying condition, being spongy and porous, and full of air cells." Just so; not "air-tight" then, but just what is needed to absorb the moisture, and just what we try to imitate with our straw mats, quilts, boxes of charcoal and chaff, straw and shavings; in short, something that is "spongy and full of air-cells."

Thus far we can imitate nature and no farther. Here the parallel with the natural home ends.

With all our patent hives, with their air-chambers, and absorbents we cannot endow them with the vital force possessed by the living tree, with its millions of capillary tubes, terminating on its hollow surface, sucking up, as it were, every particle of surplus moisture, and carrying it to its remotest branches.

It is a fact, I believe, which has been generally admitted by bee-keepers, that bees, other things equal, as regards care and protection from severe changes of temperature, winter better in the old

fashioned log gums than any other kind of hive. I am unable to understand why this should be so; unless it is that the gum is a continuous cylinder, contracting and expanding with every change of temperature, charred as they usually are and exposing numerous fissures which expose the mouths of innumerable capillary vessels, so as to facilitate the absorption and escape of moisture.

I have frequently noticed that blankets or carpet, when tacked on hives just sufficiently large to cover them, they become damp; but when I have accidentally left them large enough to extend one-third or half-way down the hive on the outside they remain dry.

This can be accounted for on the same principle, that if we place a roll of candle wick in a vessel of water, extending only a short distance above the surface, the liquid will ascend in the wick and be slowly evaporated; but if the wick is drawn out some distance and allowed to hang down, this capillary force is greatly increased and will soon empty the vessel.

These are natural forces governed by natural laws which every day we see demonstrated, and which we need only to comprehend and apply to attain the objects in view; and before we are wedded to any particular theory it should be tried by the test and if that theory is not in conformity with those general laws it is sure to lead to false conclusions.

Washington, Ind. J. A. SCUDDER.

For The American Bee Journal.

Bee Notes From Kentucky.

MR. EDITOR:—After a long absence from the columns of the AMERICAN BEE JOURNAL I again appear; this time I presume to meet a great many new subscribers and novices, to whom I may be a stranger. We notice a great many new writers the present year, and but very few of the old veterans of a few years past. What has become of them. Where is Dr. Bohrer, Burbank, Gallup, and others whose articles used to adorn the columns of the JOURNAL? Have they become discouraged and lost interest in bees, in consequence of the great bee malady the few past winters? If so, this is wrong, for hog and fancy poultry breeders do not get discouraged to such an extent as to quit the business when their whole stock is cut off with *cholera*; nor would this be acting wise to do so.

I have never as yet encountered any sort of disease among my bees. But for the last three years, I have encountered bad seasons equal to a bee disease. The

season of '72 was but a poor one. That of '73, as bad as any I ever knew, and until May 1st. this season, we hardly had a day fit for bees to fly out, for the great rains. The rains ceased in the 1st week of May, when the great draught commenced that held out about 9 weeks with no rain of any consequence intervening. The honey season was but about thirty days, and when it commenced the bees were very weak and had to have time to recruit, during the honey yield. So weak were my bees when the long rain ceased, that I could have doubled up the thirty-five odd stands into ten strong ones. I had fed liberally during the rains—but it seems that the bees became tired, waiting so long for the rains to cease—and so a great many ventured out in the rain every day nearly and got lost.

I had such a number of queens engaged that I did not double up a single stand; keeping them all for nuclei. Now for the result. The thirty days from the day the rain ceased was the best honey season I ever knew. The 35 weak stands soon got strong and increased to 67 and gave me twelve hundred lbs. surplus, besides raising over a hundred queens. Besides this there was the best fall bloom I ever knew, in which I got about six or seven hundred lbs. more of surplus, besides every stand even the weakest is now very full of honey. I have two New Idea hives with about four or five times enough to winter on. So I think I can safely set the amount of surplus at 2000 lbs. as I was unable to attend to my bees part of the time owing to indisposition.

This is enough to encourage any one who is becoming discouraged by bad seasons in succession. Another encouragement was I found a ready market of 30 cents for comb and 25 for machine, right at home this season. This was doubtless owing to the great scarcity of bees, caused by the bee mortality the past few winters.

The above shows the importance of always getting bees strong before the honey harvest sets in. I had my bees stronger the 1st of April than they were the 1st of May. I found it easy to get them strong but how to keep them so during a continual rain, in the first part of the honey season, was the main trouble, especially when every day was a wet one. I could not keep them from flying out in the rain.

If any of your correspondents know how to keep bees from flying out in the rain in the midst of the honey harvest, especially when the rain is a continued one of a week or two—mine was about seven weeks—will they give it through

the JOURNAL. Had my bees been strong when the rains ceased I ought to have got two or three times as much as I did.

Lowell, Ky.

R. M. ARGO.

For the American Bee Journal.

Honey at the New York State Fair.

In notes on the Fair of 1874, held by New York State Agricultural Society at Rochester, we read that "the exhibition of honey was fine and never better." If the display of honey there made, was such as to draw the encomiums of the officers of the State Society, perhaps a detailed description, as seen by your correspondent, may not be uninteresting to the readers of the AMERICAN BEE JOURNAL.

The first premium for largest amount of box-honey produced by one colony, was awarded to Mr. M. H. Tennant, of Stranwix, whose figures stood at 180½ lbs.

The first premium for largest quantity of extracted honey, produced by 1 colony, was taken by Mr. J. H. Hadsell, of Breedsport, whose exact figures I do not recollect, but think they were something over 200. The main strife among competitors seemed to be mostly on box honey as to what style of box is best, all things taken into consideration, for marketing our surplus honey at the present time, is a question of dollars and cents with comb honey raisers. The variety in styles of packages attracted much attention and as there were competitors from different parts of the State, the display was not only attractive but practically instructive.

Mr. Tennant's sample was in old style of boxes and though of creditable appearance, not quite up to present requirements, the packages being too large to bring highest market prices—so with Mr. Griswold's sample—nice honey, but not in shape to call purchaser's attention. Mr. Bettsinger's of Marcellus Falls, was in narrow sectional boxes. I believe the same as advertised and sold by himself and Mr. Geo. T. Wheeler, of Mexico, N. Y., and largely in use in that section and known in New York as Syracuse style. As Mr. Bettsinger's were nicely cased, they showed to the best advantage and could but be very convenient for retailing purposes. Mr. Hadsell's sample hung in frames similar in size to Mr. Bettsinger's boxes, but not as tastily put up, yet well arranged to show all the merits in that way of getting surplus.

Mr. C. R. Isham's boxes were wood tops and bottoms of any desired size and of any kind of timber—some polished off in fancy style—some merely planed smooth

with glass sides and ends held to place by angular bright tin corner pieces pronged to pass through the wood and clinch, making as strong and nice box as could be desired by the most fastidious; and profitable to the seller, as they can be manufactured about as cheap as almost any style of glass box.

Part of Mr. Isham's lot was in small single comb flaked boxes 6½x2½ and weighing about 2½ lbs. gross, the ends showing the pure liquid honey in cells built against the glass, while the sides gave a view of the white-capped comb in all its natural beauty and purity.

Some empty boxes in which had been fastened pieces of white comb were quite a novelty to those not familiar with the workings of the honey-bee and drew forth many expressions of praise to the instinct of the industrious little insect.

The 1st premium was awarded to the honey in the glass boxes above mentioned and exhibited by Mr. C. R. Isham, of Peoria, Wyoming Co.

The committee found more difficulty in deciding to whom to give the 2nd premium, but finally agreed to give it to Mr. Bettsinger's sample; but as he declined the 2nd premium, they gave it to Mr. Peter Miller, of Fredonia, a well merited tribute to Chautauqua's veteran bee-keeper.

I will conclude by remarking that a spirit of good-feeling prevailed among the honey exhibitors, and though the premiums were liberal, they were not the only inducement that brought them there—but a desire to further the interests of bee-keeping, by presenting samples of honey put up in style to give satisfaction to both producer and consumer, eliciting their interest, as was evinced by numerous inquiries and demonstrating by practical example, what these industrious little workers will do, if care at the proper time is taken to give them plenty of room in which to store away their surplus gains.

"OBSERVER."

For the American Bee Journal.

Jefferson County Bee-Keepers' Association.

The Jefferson County Bee-Keepers' Association had since my last report organized, adopted a constitution and by-laws, and held several meetings. Every meeting was well attended and a great deal of interest taken by all who were present to promote the prosperity of the Association.

The following are the officers elected for the ensuing year: Christopher Grimm, President; William Wolf, Secre-

tary ; and Adam Fuerbringer, Treasurer. The election of a Vice-President was dispensed with. Fifteen members signed the constitution at the first meeting and a great many more have signed since.

Although the past season here could not be called a first rate one, the reports from the different members of this Association on increase of swarms and surplus honey are very good, and sum up as follows : Colonies in the spring, 1,285 ; increase 1,150 ; total 2,435, put into winter quarters.

Comb honey.....	28,467 lbs.
Extracted.....	15,032 "

Total.....	43,499 lbs.
------------	-------------

All of the above comb honey was sold for a price ranging from 18 to 30 cents per lb, and the extracted from 12 to 18 cents per lb, except 250 lbs. of comb, and 400 lbs. of extracted honey on my hands yet.

One of the main questions discussed in these meetings was as follows : How can bees be wintered without loss ? William Wolf, of the village of Jefferson, opened the discussion on this topic. I have wintered bees on their summer stands, in clamps, and lately in a house built for that purpose, I would not under any circumstances recommend in this northern country, to winter bees on their summer stands ; bees wintered out-doors would need just double the amount of honey as when wintered in clamps, cellars or repositories. And further I will state that I always lost one colony out of three when I wintered them out-doors on their summer stands. In regard to wintering bees in clamps I would state that they have done well, except one winter ; when in the spring the snow melted and water got into my clamp and drowned many bees. I would therefore advise bee-keepers who winter bees in clamps to select for that purpose a dry, high place where no water under any circumstances could get into it.

The last four winters I wintered my bees in a house built for that purpose, the first winter they wintered well ; 2nd, heavy loss ; 3rd, heavy loss ; 4th, some loss, but not so heavy as 2nd and 3rd winter. I account the cause for losing so many the 2nd winter to the smallness of my house, having put in the house 184 colonies of bees, they produced too much heat and before the weather was favorable in the spring so that bees could be taken out from the house, they left their hives, fell down on the floor and died, dead bees covering the floor from three to four inches deep. The third winter which was two years ago, when the ther-

mometer stood from 28 to 34 degrees below zero for one whole week, my house was too cold. The sawdust had settled on the sides and the naked boards were no protection for my bees and they froze to death.

The last winter I lay the cause to the weakness in numbers of bees in some of my colonies, at the time I put them in my repository. If our bees are in a good condition at the time we put them up for wintering, not kept too warm neither too cold, they will winter well, but if kept too warm it will induce them to commence breeding, they will get too dry and suffer from thirst, the young bees hatching while in the cellar, clamp or repository have no chance to fly and clean themselves, and on that account will get effected with disease. If kept too cold, the vaporation of the bees will freeze and the comb will get wet and mouldy.

C. Grimm stated, I have experienced very little difficulty in wintering bees. Since 1868, I kept bees in this country, have always wintered them in the cellar and had very good success.

In the summer of 1871, I built a new cellar at my farm for the purpose of wintering my bees there. The cellar is built on the side of a small hill, so that from one side where the door leads into it, it is level with the surface and I can walk in without climbing up cellar-steps. It is only protected on two sides, the other two sides had no protection, except one foot brick wall which was insufficient to keep the frost out, in this cellar I put my bees the next winter.

One cold morning when the temperature was 28 deg. below zero outside, I went into my cellar and found it only 10 above zero. I opened nearly all the hives which were on top, and was surprised in finding the bees, in every one I opened, inclosed in a lump of ice ; put a stove in my cellar at once and used artificial heat to thaw them up. From this time until the weather got warm I kept a fire every day to keep the frost out and to dry the hives.

On the 29th of March, 1872, I took my bees from the cellar and put them on their summer stands, and found among 77 colonies only two dead, although I disturbed my bees many times during winter.

In the winter of 1873, I did not use any artificial heat, I protected my cellar with sawdust to keep the frost out, and have succeeded in doing so. On the 26th of March, took them from the cellar and found after examination among 132 colonies, four dead, all the rest had wintered

well, but lost six colonies more in the spring, after I put them on their summer stands.

The last winter the weather was very mild and we had a great deal of rain in the months of February and March, so that water got into my cellar. I had it bailed out twice and sometimes three times a day, but one morning when I went to my cellar I found the hives standing next to the bottom, 3 and 4 inches in water, saw at once that it was an impossibility to keep the water out by bailing. I therefore employed some hands and ordered them to dig through on the lowest side under the wall of the cellar to let out the water, which came from the bottom of the cellar in a good stream; they succeeded after a day's hard work.

Although I had more or less water in my cellar for six weeks before I took my bees out, I found (March 18th) when I did take them out not a single colony dead among 134 I put in the cellar, and only two affected with disease. Every comb bright and clean, except those that had stood in the water. This convinces me, that bees in a dry cellar will towards spring suffer more from thirst, than bees will suffer on account of dampness in a damp cellar.

I agree with Mr. Wolf, that bees put up for wintering should be in a good condition, they should not be kept too warm, neither too cold; if kept too warm it would induce them to commence breeding, they would get dry and suffer from thirst, the young bees hatching in the cellar, repository or clamp, would not have a chance to fly out and clean themselves, and on that account would be effected with disease. If bees are kept too cold the evaporation of the bees would freeze the combs and get wet and mouldy, and if not sufficient ventilation is secured from the outside and plenty of fresh air admitted, it will create a bad smell and bees will get sick and die.

After further discussion on the same subject the opinion was general, that bees can be wintered in a cellar, repository or clamp without any or but very trifling loss; if, when put up for wintering they are in a good condition; (that is to have plenty of honey, to be strong in numbers, and have a young queen,) they are not to be kept too warm neither too cold; (temperature not below 35 nor above 45 deg. Fahrenheit,) they should not be kept in a too dry nor a too damp place; if kept too dry they will suffer from thirst, if kept in a damp place their combs will mould, create a bad smell, and bees will get effected with disease if plenty of fresh air is not admitted, or artificial heat used.

The meeting then adjourned until January 30th, 1875.

CHRISTOPHER GRIMM, President.
WILLIAM WOLF, Secretary.

For the American Bee Journal.

Why is it?

MR EDITOR:—Why is it that my bees always winter well on their summer stands, notwithstanding the mercury goes as low as 32 deg. below zero, as in the winter of 1872-3, and yet no sign of dysentery, when other bee-keepers who wintered otherwise, lost heavily while I lost none?

Why is it that bee-keepers object to fall honey for wintering, when we in this neighborhood, winter on honey that is gathered in September, and never have the dysentery among our bees?

Why is it that some box hives that I bought, wintered (without any upward ventilation at all, and was air tight) as well as my other hives that had on honey quilts and caps filled with chaff?

Why is it that I got 20 cents per lb. for my extracted honey in half bbls., from the oldest and most reliable wholesale grocery and commission house in St. Louis, and other bee-keepers are complaining of dishonest honey merchants?

Oskaloosa, Ill. D. M. LASWELL.

For the American Bee Journal.

Letter from Kansas.

EDITOR JOURNAL:—Three poor years for the bee-keeper in succession and two poor years for the farmer makes me feel as though there might be a better place for both professions, in fact after reading what bee-keepers are doing in other places we do not feel like owning that we keep bees at all. We did not keep them very well last summer; during about ten days in the latter part of June they seemed to be determined to fly away without much ceremony. If they would alight they would in many cases not give me time to get from the field to the house before they would be gone. That is one great objection to the Italians, they are bound to swarm just when you want them to stay in the hive and work. Mr. Hazen tells us to use a non-swarming hive, but we have no faith in it, for we have known them to swarm when the hive was not half full of comb, and last season we had one to swarm the second day after living, but they were put in a hive of empty comb and got away entirely unknown to me. I had weighed the

hive in the morning to see how much honey they would gather through the day, on weighing it again in the evening it was just 10 lbs. lighter. I then examined the hive and found there was a medium swarm and a queen.

I have said that the last three seasons were poor, and so they were as a general thing, but in some localities they done better than others; mine has paid but little over expenses in the years mentioned, last season I got 900 lbs. extracted honey, and this winter so far have lost about one-third of my bees.

N. CAMERON.

Iowa Bee-Keepers' Association.

On Wednesday Jan. 20th the annual meeting of the Central Iowa Bee-Keepers' Association was held in this city.

After transacting routine business the following resolutions were adopted:

Resolved, That this convention adjourn to Wednesday the 17th day of February next at the City Hall, in Cedar Rapids, and the committees are instructed to have their respective reports prepared—especially that relating to the success of Bee-Keepers in 1874.

Resolved, That the growing interest and value of the apiary, in the State, especially its central portions, invite not only a full attendance of our members, but also of others interested in this rapidly increasing source of wealth in Iowa—now standing only second to any State in the Union in this branch of material prosperity.

Resolved, That THE AMERICAN BEE JOURNAL of this city, and other city papers, daily and weekly, are requested to publish these resolutions, and that their exchanges interested in this subject be requested to copy.

J. M. MAY,
Secretary.

D. W. THAYER,
President.

For the American Bee Journal, Solid Frame.

On page 214, Vol. X, No. 9, of the AMERICAN BEE JOURNAL, in your reply to Mrs. G. W. Church, you say some beekeepers always allow a margin in this way to secure more care in taking out the first frame. When it is so left, care is necessary when honey is plenty to prevent the bees from filling the vacant space with comb."

Now, this care means a great deal of trouble and yet with hives that have no movable sides, this margin is positively necessary to save the life of the bees and perhaps the queen. To avoid all this trouble and yet to secure the advantages this margin offers I use what I call a solid frame. It is nothing more than a thin

and light partition of board made the size of the frame so as to move easily; this is put in the extra space or margin, and pushed up to the comb so as to allow a passage for the bees between. There is then no further trouble; when you want to open the hive you have only to push the solid frame back against the side of the hive and lift it out clear of the combs. You then have room to work freely, besides having no bees killed.

Austin, Texas.

B. H. IVES.

For the American Bee Journal, The Italian Test.

In a late number of the JOURNAL I asked if there was any fixed and certain test of Italian purity. I did this in part because some of our most prominent bee-keepers were maintaining that "a few black bees" among the Italians were "no mark of impurity." It seemed to me, that if black bees were to be found among the Italians, "even in Italy," as had been asserted by Mr. Dadant in a previous number of the JOURNAL, it would be of little use for us to hope to improve the grade of our hives by importations from that country.

But Mr. Dadant comes to our relief (?) in the November JOURNAL, by telling us that it was not *black* bees, but only "seeming black bees" that he saw in Italy. They were black, yet only in appearance, and that from the effects of their food and feces. This explanation may be satisfactory to Mr. D. but to my mind it seems "rather thin." If they were "seeming black" bees, as termed by Mr. D. how does he know that their color was caused by the matter within them? or how does he know they were not genuine blacks? May I not, with equal reason, say of any one and two banded hybrids, that they are only *seeming hybrids*; that one or two of their rings has been temporarily obscured by their food or feces, and that their rings will re-appear in their full luster as soon as the dark matter has passed from their bodies?

I don't believe that any three-banded Italian bee ever took anything into its stomach so dark as to render it in appearance like a black bee. On one occasion a year or two since I fed a few of my Italian stocks a mixture of very dark sorghum molasses. I could easily discern the dark matter through the wings, but the rings themselves were as readily distinguished as before the molasses had been taken into their sacs. I have also often seen Italians with their bodies greatly distended with very dark fecal matter, and yet they had no appearance in common with the black bee. The peculiar workings of the Italian and black bee are so different and distinct, that the merest tyro in bee-keeping can never be at a loss to distinguish one from the other.

I have no reason to doubt the statement of Mr. D. that he saw "a few black bees" among "the thousands of well marked" in Italy; yet I do question very seriously his judgment, that such bees were only "seeming black," and not black in blood. His own statement convinces me, that many of the bees he saw, were as much hybrids, as any we have in America. And I believe

that this fact accounts for the further fact, so many of the queens imported from that country are impure.

It is useless for Mr. Dadant to assert, or to guarantee even, that all the queens he or any body else imports, breed invariably "workers with their yellow rings." I know it is the general complaint with queen-raisers, that imported queens are very uncertain breeders.

I will close this already too tedious article by reiterating my judgment, that any queen that fails to breed workers *invariably with three yellow and distinct bands* can not be relied on as a *pure queen*. Whenever even one "seeming black," or "seeming" one or two-banded worker is found among her brood, she should be discarded as a breeder.
Charlestown, Ind. M. C. HESTER.

For the American Bee Journal.

"The 'Moon' Shone Bright."

Kind northern reader are you shivering in the cold? Are the dreary November days beginning to scatter down the round hard pellets of snow? Do even these messengers of the Ice King seem afraid of the cold? Yes, you look pinched up and your face is fairly blue. Why you are half frozen! Just get in by the fire, tumble in the fuel and let the blaze roar at old Winter, while you doze off and dream you are with me this warm sunshine day, away down in Georgia.

Leaving the Chattanooga & Atlanta R. R. at Kingston we take the pleasant little family railway leading over to Rome—a distance of 20 miles. The beautiful Etowah—"clear water,"—down whose banks we wind, sparkles under the sunlight, the bright foliage of the deciduous-leaved trees interspersed with somber evergreens, the warm breeze which fans us through the open window, and the drowsy quietness, all combine to render almost perfect the illusion that we are entering the long-sought Elysium.

But be sure, my friend, that your fire is kept up for if you should get chilly and rouse up so as to catch a good glimpse of those fields of cotton clad in their snowy whiteness, the spell would be broken and the stern old Ice King would again reign over you. Members of the "colored persuasion," of nearly all ages and both sexes are leisurely pulling the cotton from the opening balls, and the train pauses every now and then for a breath, and to afford us a better view of the dexterity of the pickers.

We have our minds made up that "while in Rome" we will "do as the Romans do" but on arriving at that pleasant little city at 2 p. m. we are somewhat surprised to see the Moon, bearing a face radiant with smiles, shining brightly down upon us, while the quiet inhabitants

seem to regard the occurrence as a common one.

We find the sanctum of the *Bee World* vacant, and wending our way to the apiary find its manager, our friend Moon, with sleeves above his elbows, in the midst of transferring. His cordial welcome places us at ease immediately. Then comes a ramble and a bee-talk among the 140 neatly painted hives which decorate the south-eastern slope from the house. We find a beautiful lot of Italians obtained from various sources and we are gratified at having an opportunity to compare the stock of so many of our prominent queen-raisers. Mr. Moon prefers frames 10 in. deep by 15 long—certainly a very good size for a standard frame. What surprises us most is the statement which our friend makes in answer to an inquiry concerning some colonies that appear weak. "Certainly they will winter here. It is no trouble in the world to winter bees in this climate." Then too it takes only about 12 or 14 lbs. of honey.

Why couldn't you sorry chaps, that put the quilts over your bees and tucked them up more than a month ago, have sent them down here and had 20 lbs. of honey gathered by each stock after Sept. 15th, let them frolic the whole winter, and then (if you didn't change your mind before spring) you could ship them back home after the March and April revels among the Southern flowers, to regale themselves among the linn forests and orchards of the North?—A winter resort in the South and a summer home in the North. How delightful—eternal spring and summer.

After the friendly bee-talk and the pleasant entertainment by our charming hostess—our friend's daughter-in-law,—we find ourselves the next day reluctantly leaving the beautiful little city which nestled among seven hills, like the ancient "Mistress of the world," gives promise that it will yet make its influence felt. We think it is the most beautiful little city we have visited in the "Sunny South." May the culture and evident progress of its inhabitants "rule the world!"
FRANK BENTON.

Nov. 19th, 1874.

I wintered on summer stands, losing two stocks out of 25. Sold one stock in the spring and one stock became queenless early in the spring, and again in July, and gave me no increase or surplus, so I count 21 working stocks. With those I have increased to 44, and took 2418 lbs. of nice comb honey. Average price of honey 27¼ cents. I have kept bees but four years, and my bees are mostly black.

Tully, N. Y.

J. E. LLOYD.

For the American Bee Journal.
On Wintering Bees.

MR. EDITOR:—As there is a great deal said in your Northern journals about wintering bees in cellars, caves, etc., which does not interest us in the sunny South, where we can winter them far better on their summer stands, perhaps it may not be amiss to give my way of wintering here. If you think it will be interesting to your readers you may insert it in your valuable journal.

You may think we need take no precaution here to winter our bees, where they are able to fly almost every sunny day during winter, but observation shows me that the mortality of bees here is as great in winter as in the far North, for we do not take pains here to prepare them that our Northern friends do. But if every one here would take a little trouble to cover the tops of the frames with a sheet of straw wrapping-paper and put a little cotton-seed on top to the amount of 1 or 2 inches thick, we should hear no more of bees dying in winter. The above is my practice, and of 200 stands put up in this way last winter, I lost but two, which I think died for want of honey. As I kept on swarming my bees last year until the 7th October. It is not strange that I should loose one per cent of them in wintering. In preparing for winter I even up all my colonies, by taking from the strong and giving to the weak, which I consider no robbery.

D. STAPLES.

Columbia, Mauray Co., Tenn.

For The American Bee Journal.
Remarks on Eccentric.

MR. EDITOR:—Who is Eccentric? How do you distinguish a man who is afraid to write over his full address from a coward, or if this name is too hard, I take it back and say "timid." I dislike to read articles under fictitious names, and were I editor of a Bee or Poultry Journal no such articles could enter into its pages. But men differ; it takes all sorts of people to make a world. I am not condemning at wholesale. But let us examine and see what good such articles do. In reading the JOURNAL my custom is to hop clear over such articles and first read our responsible names, and such as Eccentric's last. Yet, Eccentric's article was good, notwithstanding. Let us look for the bad.

He says: "The season just closed has been rather a dull one in our locality."

Now what good does this do the readers of the JOURNAL unless he told us where or in what latitude his locality was. Is it not mere idle scribble; do we care to know how the honey season was, unless we know the whereats and whereofs, at Black Hill or Florida? But enough of this.

He asks where are the old brilliant writers of the JOURNAL. They are all living, except Dr. Hamlin, of Tenn., whom we

miss very much indeed. The others did not disappear from the JOURNAL without cause, known to themselves only. I as well as Eccentric wish they would return, for I want to read their spicy articles again.

Next he pitches into the City Honey dealers; there now, friend, Eccentric, you are right, "give it to em;" they have no business to damage or destroy our business. We who have spent seven years of hard study in winter, and hot stinging practice in summer to learn Bee-ology, not for our own but for the benefit of coming generations; are we now after a hard toil among bees, in the heat of the day, to get nothing but a mere pittance for our honey or be cheated out of it altogether, by these City Honey dealers. No, this is too hard for us; we can't stand it. Something must be done and that quickly. We must either form a Grange, or unite with the Granges and have our own Honey houses. But I would say to Eccentric, if he does not already know it, that it is not all the City Honey dealers who will adulterate honey. Some of them are too honest and conscientious to do such a thing, as for instance C. F. Muth, of Cincinnati. I have not been in Muth's Honey store, but a friend of mine whose word I have entire confidence in, has assured me that he has been all through Muth's honey store and that he buys and sells nothing but the pure unadulterated article. This is the sort of a house to recommend itself. I sold my honey at home at fair prices. If I had any so send to a city, I would sell to no other than such a dealer as Muth.

He next pitches into New-Idea hives. True they were lauded to the skies, in such a way as even to induce Argo to try *em*. Last season was the first one that was fit to try a hive, and I gave four of them a fair trial, reported once or twice and said: "so far, they have given entire satisfaction." By the words "so far" I mean so far as I had tried them. But the winter trial was to come yet, and now Jan. 11th, so far, I am not satisfied with their wintering. Thus far we have never had a milder winter, and yet bees do not winter well in those long new-idea hives, at least mine do not. The bees all crowd to the front part, leaving about three-fourths of the hive, or nearly, unoccupied and unprotected. In all of Gallup's writing as to how his bees wintered in them he said "splendidly." So also said Adair; if I am not mistaken. Well how is it that Gallup's bees in the far and cold north could winter so splendidly in those long hives and mine here in a much milder climate, not winter at all? Will Gallup or Adair answer?

But for Italians in a good honey season I know of no better hive to get large amounts of surplus. I got the most surplus from one of these, and I believe the others give more in proportion. I am well pleased with them in summer so far as tried, but not so in winter, yet I would advise novices to wait until I try them further. I promise a faithful report, not like the man who would persuade himself that a thing was so, then report it as a fixed fact, when it was so only in his head.

Lowell, Ky.

R. M. ARGO.

For the American Bee Journal.

A Friend or Enemy?

The Illinois State Horticultural Society held its annual meeting in this city, from Dec. 8th to 11th inclusive. Prof. C. V. Riley, State Entomologist of Missouri, was present, and delivered a lecture on the grape phylloxera or gall louse, a leaf parasite very troublesome on some varieties of grapes, particularly the Clinton. He stated that the phylloxera was less troublesome on sandy than on clay soils. The reverse of that is true in this vicinity at least. During the session of the Society I took occasion to hand the secretary the following:

MR. PRESIDENT:—I would like to know whether this Association considers the honey bee a friend or enemy? A certain professor of entomology considers it an enemy, and has recommended poisoning it. I consider it a horticultural assistant. Would like an expression of opinion by this Society. Respectfully,

MRS. L. HARRISON.

The president read the communication to the Society, and immediately, H. J. Dunlap, of Champaign, moved that the bee be considered a friend, which was promptly seconded. Prof. Riley jumped to his feet and exclaimed "that means me, that's to draw me out," Mr. President, I hope that question won't be passed without discussion; I would like a chance to explain my position, and as the time is all occupied this afternoon I hope the question will be deferred until evening. At the request of the president, Mr. Dunlap withdrew his motion for the time; but at the evening session it was again brought before the house by Mr. Gaston, of Lacon, who said "Mr. President, I would like an expression of opinion on the bee question. I consider the bee a friend to horticulturists; nature's great hybridizer, beneficial in the cross fertilization of flowers, and in rendering fertile many sterile ones, a true tillerian, saving many cracked fruits

that would otherwise be wasted, and the great nation of Russia finding they can get more clover seed with the fertilizing of the blossoms by bees, are importing bumble bees to fertilize the red clover."

The speaker was loudly applauded; and Prof. Riley being called for, arose and said, "Mr. President, I think highly of the honey bee, very highly indeed; I am a friend of the bee, I think it does a great deal of good; but in some seasons, in times of great drouth, when bee forage is scarce, I think it does damage, indeed I am certain of this. I watched the bee very closely for several years, before I could tell whether it did any damage or not; but one season, a very dry one, I saw two acres of Herbemont grapes nearly ruined by them. I think it is only on exceptional seasons that it does any damage. I would not recommend poisoning them, but think persons living on a small plot of ground ought not to keep them, in sufficient numbers, to annoy their neighbors at times when bee forage is scarce. On the whole, I consider the bee more of a friend than an enemy."

The members of the Society, that I conversed with, seemed to think the professor had "come down," considerably from his first statement on the bee question; admitting as he did "that the damage bees did (if indeed, they did any) was so slight that it took several years of close observation to discover it." I think the damage is becoming microscopic.

Peoria, Ill.

MRS. L. HARRISON.

For the American Bee Journal.

Evaporating Honey.

Friend Ives, in Jan. number, speaks about evaporating honey by heat, in shallow pans in the oven, and in a kettle brought nearly up to boiling point. We tried the latter plan and made a grand success of it, for we succeeded in changing No. 1 honey into third-rate sorghum, without the least particle of a honey taste in it. We used it to make vinegar of. We now have in the cellar some large crocks of honey, very thick and clear, without a sign of souring or candying. Some of it was extracted after being capped over, and some the next day after it was gathered. We put it in large jars, cloth over the top, lay a board on it, and have no trouble in getting it evaporated without any more work. Therefore, friend Ives, if you want to keep the flavor of your honey *don't boil it*.

In my article in Jan. No., page 13, the name "Ross," should read "Roof."

Oncida, Ill.

W. M. KELLOGG.

A Dozen of the Same Ilk.

Yesterday about a dozen bee-keepers met at the house of Mr. Tennant, about seven miles north of Eureka. We spent the day in talking bees and topped off with a fine supper. While we were in "council assembled" in a large upper room, the wives of the sturdy bee-manipulators talked bonnets &c. &c., below.

Those present represented about 800 stocks of bees, and about 15000 lbs. honey, of which 7000 was comb and 8000 extracted.

Nearly all doubled their stocks during the season. Mr. Bardwell, of Omro, got 2200 lbs. extracted, and made no comb honey, he sold most of it at 20 cents per lb.

Mr. Editor, this was a model bee-keeper's convention, for we agreed at least on one thing, and that is, that 45 degrees is about the right temperature to keep bees in winter.

Our next meeting will be held July 1st. after which semi-annually. No initiation, no fees, no blow, but a good social time; we hope this may give others a hint.

Berlin, Wis. J. D. KRUSCHKE.

Voices from among the Hives.

C. McDERMOT, Malone, N. Y., writes:—"I wish some one would advertise cat-nip seed in the AMERICAN BEE JOURNAL. I would sow some if I could find the seed."

A. E. KITCHUM, New Garden, N. C., writes:—"In answer to your enquiry as to the number of bees kept in this State, I estimate 18,000, or about an average of five colonies to each keeper."

ROBERT T. JONES, Flat Rock, N. C., writes:—"I would recommend all who wish a hedge fence to plant the holly. It is an evergreen, and in a few years will make a good impenetrable fence, in good soil, from the seed. The seed should be sown before spring. It is difficult to transplant, unless taken up with great care."

J. M. TELLER, Chandlerville, Ill., writes:—"I have 35 stands of bees, and four are late swarms. Last summer out of 32 stands I had 2,200 lbs. of honey in the comb. Can any one beat that? My bees are nearly all Italians, never allowing more than one swarm from each stand, and sometimes none. The season will decide about that."

JOSEPH JONES, Pittsburgh, writes:—"This has been a poor season for Bees. Very few swarms and little honey. The spring was cold and backward. I commenced with nine in the spring, all weak. Increased to sixteen in fair condition for wintering. I winter in a double-walled house this winter. Will let you know how they come out in the spring."

H. GOODLANDER, Leesburg, Ind., writes:—"My bees are all right, so far no signs of dysentery, nor the famous "bee disease," (except stocks under experiment), while my neighbors' bees are badly affected with the dysentery, and I think fully one half, if not more, will die before spring. If Mr. J. W. Margrave will send me his P. O. address he can have the information asked for. Some one has sent me \$1.00 for seed but gave no name or address."

M. VOGLE, Boyne, Mich., writes:—"The December and January numbers of the *Resources of California* contains particulars about Mr. Harbison's apiaries in San Diego, his crops, sales &c., with the honoring testimony that our brother bee-keepers there are the best settlers of the country. The editor says: "We are informed that the bee-men alone have done more in the settlement of the country of San Diego this year than all other classes, and more than had been done in the past five years. I long for a chance to sell here to go there."

JOHN W. WILSON, California, writes:—"This seems to be the natural home for honey bees. They do extremely well in almost any kind of box, keg, barrel, or hive, for they are kept in all those things here. Of late there has been considerable improvement made by a few enterprising bee men in this lower country, in the mode of keeping and managing bees. We started in the spring with 120 stands, 50 of which were weak and in the old box hive, which we transferred to frame hives. The other 70 were in frames deeper than we wished to use and we had those to cut down; so we had rather a bad start. Our stock increased naturally to 300 stands. We have taken nine tons of extracted honey and one ton of comb. I took 302 lbs. of comb honey from one of our early swarms, and they, made $\frac{2}{3}$ of the combs themselves. Our bees are all doing well and gathering some honey now. If the season continues as it has set in, we will have swarming in February."

AARON BENEDICT, BENNINGTON, O., writes:—"The instinct of the bee is to void its excrement only on the wing, and will not do it any other way, as long as it can possibly contain it; hence the advantages of the box. The boards should not be less than a foot wide. Place the hive in the warm room near a window, and the bees will take wing readily and discharge their accumulated feces—keep bees well supplied with flower as soon as they will work on it. Wheat screenings is as good as anything. Many bees starve after they are nearly wintered; when a little food would save them. If honey is not at hand to feed, take Coffee A Sugar, add soft water sufficient to make a syrup about the consistency of thin honey, bring to a boil, and it is ready to feed. Take common glass tumblers, fill nearly full with syrup, tie a piece of cotton cloth over them, turn bottom upwards, place them immediately over the bees on the frames; or if common box hives, over holes in the top, place a box, to keep out the robbers. If bees have to be fed when it is too cold for them to fly out, and void their feces make a box of suitable size to cover the hives, make the box without bottom or top, for the upper side, tack on wire, screening or bobinet will answer: take the bees into a warm room, place the box over the feed on top, and let the bees have a chance to fly. There must be strips of cloth or paper spread over the frames, or the bees will smear the tops of the frames. After the bees have consumed their feed and had a good fly in box let the room gradually cool, and the bees will go down and cluster in the hive, they should then be set out on their regular stands. In the above manner I have saved many colonies that otherwise would have perished. Bees should not be fed with liquid food, unless they can fly out."

THOMAS G. NEWMAN,
Cedar Rapids, Iowa.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

The offer of premium queens is now withdrawn, as we cannot supply Spring queens for that purpose.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

Subscribers wishing to change their post-office address, should mention their old address, as well as the one to which they wish it changed.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

JOURNALS are forwarded until an explicit order is received by the publishers for the discontinuance, and until payment of all arrearages is made as required by law.

We do not give our Chrono when subscribers club with other publications, unless they add 25 cents to the amount of the club subscriptions, and say they want the Chrono.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

Honey Markets.

CHICAGO.—Choice white comb honey, 82@30e; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. $\frac{7}{8}$ lb.

ST. LOUIS.—Quotations from W. G. Smith, 419 North Main st.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 $\frac{7}{8}$ gal. St. Domingo, and Mexican, 90@95 $\frac{7}{8}$ gal.

SAN FRANCISCO.—Quotations from Stearns and Smith, 423 Front st.

We wrote for your January number, that the season was very forward and the bees were working on new feed. As we have had but two slight rains for fifty days, and none in thirty, once a very heavy frost, the prospect is not now as favorable for an early and abundant crop of honey. Prices unchanged from our last quotations.

☞ Strained Southern Coast, at 7@10c; Comb, 12@20c; the latter figure for San Diego, in Harbison frames.

Back Volumes.

Complete sets of back volumes are scarce. But few can be procured at any price. We have a set, consisting of the nine volumes (complete), which we offer for sale, either bound or unbound, for a reasonable sum. Many of the numbers we have paid fifty cents each, for to complete them.

We have several single volumes (complete) which we will send postpaid for \$2.00 each.

Several volumes, which lack only a single number of being complete, we will send postpaid for \$1.50 each.

Vol. 1, we can supply in cloth boards, postpaid, for \$1.25. Bound in paper covers, \$1.00 postage 10 cents. This volume is worth five times its price to any intelligent bee-keeper. It contains a full elucidation of scientific bee-keeping, including the best statement extant of the celebrated Dzierzon theory. These articles run through eight numbers, and are from the pen of the Baron of Berlepsch.

☞ Beginners in bee-culture, who desire to read up in the literature of bee-keeping, are earnestly advised to obtain these back volumes. Many of our best apiarists say they would not sell their back volumes of the AMERICAN BEE JOURNAL for ten times the sum they cost, if they could not replace them. They are exceedingly valuable alike to beginners and more advanced apiarists.

John K. McAllister & Co., are our duly authorized agents for the AMERICAN BEE JOURNAL, at Room 27, Tribune Building, Chicago, with whom any business may be transacted with our approval, and be promptly recognized by the manager of this paper.

Wintering Bees.

Sir Robert Peel was accustomed to say, "Ireland is my difficulty." In like manner, the bee-keeper in this climate, may say with truth, "winter is my difficulty."

We have found a remedy for most other difficulties, but it is not too much to say, that this one remains unconquered. The serious losses of the past two or three seasons, induce feelings of uncertainty and apprehension, now that another winter is upon us.

Until recently, the common custom was to winter bees on their summer stands. During a moderate season, this was found to answer very well, but long-continued severe weather, and especially the pervailance of bitterly cold winds, caused great mortality and heavy losses, even with doubled walled and so called frost-proof hives.

In-door wintering too, has been tried and found wanting. Sometimes it works well, and on the whole, it has been more successful than the other method. But there has been many failures. These have been variously explained. Lack of warmth, insufficient ventilation, too great warmth, close confinement, damp, impurity or thinness of honey, disturbances of the bees, extreme quietude, artificial feeding, and the want of it, are among the most prominent theories that have been put forward to account for the failure of in door wintering.

Mischief usually develops in the form

of dysentery, and the explanations above enumerated, relate to the cause of this trouble. In a state of confinement, the excrementitious matter is retained in the body of the bee. Its habit is to discharge its fœces when on the wing; If bees cannot fly, the fœces are undischarged, unless distension and discomfort compel them to befoul the hive. Under favorable conditions, in which but little honey is consumed, and the bees get into a state of semi-torpor, this retention of the fœces may continue a long period. Bees have been known to remain five months in winter quarters without a discharge, and yet came out vigorous and well. A warm day is chosen to release them from confinement, so that when set out doors they can at once enjoy a cleansing flight. It is not always possible however to secure the conditions necessary to enable stocks to endure a whole winter's imprisonment. If they are too warm they become active. Exercise creates appetite, appetite leads to a larger consumption of food, the digestive organs become over-crowded, and vent must be had. When once a hive becomes foul with excrementitious voidings, it is unwholesome, and things go on from bad to worse. If there is not proper escape for the moisture of the hive, or if the winter quarters are damp, mould is developed and the fatal dysentery sets in. As already stated, other causes lead to the same lamentable result.

To prevent the over accumulation of fœces, means have been adopted to give the bees a mid winter flight. The hive has been taken into a warm, well-lighted room, and opened, so that the inmates might sally forth, and relieve themselves. Or a box covered with wire-cloth has been fitted to the top of the hive, and the bees have been permitted to have a

little liberty in it, once or twice in the course of the winter. In some cases these expedients have been successful. But they are attended with considerable trouble, and with a large apiary, they are well nigh impracticable.

An intelligent bee-keeper has recently propounded the theory that the cause of all the trouble is want of water. He argues that bees are well known to be large consumers of water during the active season. They cannot manufacture honey or rear brood without it. All animals require more or less water, and cannot sustain life any length of time without it. In proportion to its size, the bee consumes more water than the horse or cow. Why then should the bee be expected to do without water all winter, any more than larger stock?

The theorist referred to contends that dysentery is caused by a feverish condition of the system, with a high state of local inflammation in the stomach and intestines, and an evil condition of the humors or juices of the system, accompanied by inflammatory action. In this corrupt condition, these humors have actually become a disease, occupying the whole system of the honey-bee, and being so diseased, the physical system of the bee attempts to expel the offensive matter, by sending it to the intestines, where it is thrown out in the form of dysentery, and death follows, as there is no supply of water to replenish these juices, which are as essential to life as the breath. Water would have prevented all this, by keeping up a supply of these juices, and maintaining an equilibrium throughout the system; but dry food cannot replenish the juices without the aid of water.

There is certainly an air of reasonableness about this theory. We do not know whether its author has experimented upon it so as to be able to sustain it by facts. But it is worthy of attention by bee-keepers generally. When bees are wintered out of doors, they have occasional opportunities for flight, and at such times, can obtain a supply of water, as it

is only when the sun has power enough to thaw ice and snow, that bees venture to fly in winter. It may also be the case, that in those well authenticated instances of in-door wintering which are on record, there was enough moisture generated in the hive to supply the bees with moisture and yet not render the hive damp and mouldy.

It seems to us that experiments are greatly needed just now in three directions, with regard to this matter of wintering.

1. To get, if possible, a hive for out-door wintering which shall be impervious to frost, and yet not so close as to keep the bees too warm. Keyes & Finn, of Clyde, Jasper County, Iowa, advertise in the AMERICAN BEE JOURNAL, that they have a hive which meets these conditions. It is double walled and has a chaff ventilator and feed box. They state that the past three winters have established the fact that their hive "*winters bees safely every time on their summer stands.*" Quite an array of testimony from bee-keepers of good standing sustains their advertisement. We have not tried the hive in question. In fact, our first knowledge of it was derived from an advertisement in the December number of the AMERICAN BEE JOURNAL.

2. The plan of giving bees one or two cleansing flights in winter is deserving of further trial. Though difficult of adoption with a considerable number of colonies, and as we have said, well nigh impracticable with large apiaries, bee-keepers who have only a few stocks might practice it to advantage.

3. The water theory should also be thoroughly experimented upon.

Serious as the winter difficulty confessedly is, it ought not to be regarded as insurmountable. Surely it can be overcome by patient investigation and persevering experiment. He who shall tell us how to winter our bees with unfailing success, will certainly deserve the well wishes of his fellow-bee-keepers, and of mankind at large, for it is here that, just now, we most of all need enlightenment.

Seasonable Hints.

The first of March is, in most places, too early a date to take bees permanently from a winter repository, or cellar, but if they have become uneasy and excited, it is well for them if on some warm day, the hives may be set out and opened, so that they can fly freely, and then be returned again to winter quarters. We do not advise this, however, when the bees are quiet. In that case they are just as well to be left undisturbed until there is a prospect of continued pleasant weather. In many localities bees flew so freely last fall until a late date, that they will bear a little longer confinement this spring, without injury.

No exact time or rule for weather can be given. Every bee-keeper must exercise judgment and common sense in this matter. We are always pleased, when we are able to set our bees out early in March. A few cold days, after they have once taken their cleansing flight, does not injure them, but much of the season's success depends on the care taken of them the first month after they are placed on their summer stands. Every opening in the hive should be closed except a small entrance—the bee quilt or mat placed snugly over the frames, plenty of food be provided near the cluster of bees, and the entrance shaded in some way from wind and the direct rays of the sun. One thing must be borne in mind now. We want a good, strong force of bees to gather our honey harvest, when ever it comes. To secure this, brood must be in progress six weeks at least before the time of the harvest, and plenty of it. If, then, we expect our honey harvest in May, we should in this month be using all efforts to foster brood rearing, and if this is done the colony will be full of bees at the time when they are profitable. This same advice applies to those further South, who expect their harvest a month or two earlier. Their feeding to stimulate brood rearing should begin six weeks at least, in advance of the main honey harvest. If bees are amply supplied with

sealed honey, it may be unnecessary to feed them, and yet we find that a little diluted honey or sugar syrup fed to them regularly stimulates them to rear brood faster. After the brood is well started, if you can give them a comb or two of sealed honey, it is well.

Put out rye meal for the bees just as soon as they are set out of doors. We often receive inquiries how to feed rye meal, in spite of all the directions that have been given how to do it. In reply to them we say here, that we feed the meal in some sheltered place and in shallow pans or boxes, using several of these boxes and putting only a quart or two at a time and spread it thin, dry not wet. The bees can best work it into pellets if given in this way. It is no use to feed it to them inside the hives.

A piece of honey comb put with it in the first place, is useful in attracting the bees to it; after they find it, they will take it strictly until natural pollen comes in the fields and trees. We know that in our locality this feeding of meal is very important,

We cannot too strongly impress upon beginners the importance of attending well to their stocks when they are first put on their summer stands. Every hour of care bestowed on them now will be repaid largely in the months to come.

T.

Answer to Mr. Dadant.

We are glad to give Mr. Dadant's article a place in the Journal, being willing that in the matter of imported bees, as in all else, both sides should have a fair hearing.

In regard to the assertion that Mrs. Tupper is "changeable" in this matter, we are willing our readers should decide whether a woman who has followed bee-keeping persistently for seventeen years, can hardly be called "fickle;" and leave it to them also to say, if after having spent over three thousand dollars in the one branch of importing, she is not very wise now to let others bear the expense of further risk in the matter, or at least until

those who have been to Italy and Lombardy decide if black bees are found there now, even if they have been "imported there from outside Italy!" Not having been there, we are not competent to talk on that point. We have names and letters from those who have received queens from Mr. Dadant direct, that can be given to any inquirer who wish, either privately or in the JOURNAL, asserting that queens direct from Mr. Dadant, said by him to be imported, produced black bees and hybrid ones. To our minds these letters prove nothing until we know the circumstances under which they were introduced, &c. Our readers may think differently. Now that Mr. Dadant has "said his say," we cry "enough," unless Mr. Bingham or Mr. King wish to be heard. While our columns are open for both sides on any subject of interest to bee-keepers, we have no room for prolonged controversy.

T.

Progress in Bee Culture.

We clip the following item from the Vinton, Iowa, *Eagle*.

Mr. William Hunt, an extensive farmer in this county, living three miles west of Center Point, has lately given special attention to bee culture. Mr. Hunt secured the services of A. W. Colburn, a practical apiarist, who has recently transferred about a hundred hives of the ordinary black bees from the old gum logs to Langstroth's improved two-story hives, in each of which are placed from sixteen to twenty-four frames. About half a ton of honey has already been secured, without the destruction of a single hive. A friend called at Mr. H.'s the other day, and witnessed the process of extracting the honey. With one of Murphy's improved extractors, the honey was removed from several sets of frames in a few moment's time, without injury to the combs, which were replaced in the hives. The hives have been averaging twenty pounds of honey daily. The large forest of basswood trees near by, gives the bees a fine chance to make a good report. If bee owners want to make the business pay, they had better take a look at Mr. Colburn's operations at Mr. Hunt's.

Mr. Hunt is very enthusiastic over the management of his bees. He calculates to clear over a thousand dollars on his bees this year, although the recent trans-

fer from one set of hives to another, did not enable them to make as good returns as they would have made had they been ready to go to work on the improved plan early this spring.

Co-Relation of Bees and Flowers.

The bees, Mr. Darwin says, have solved a difficult problem. They have made their cells of a proper shape to hold the greatest possible amount of honey with the least possible consumption of precious wax in their construction. No human workman is skillful enough to do what a crowd of bees can do, working in a dark hive—make cells of wax, of the true form.

The number of bumble bees in the country will depend upon the number of cats. How can that be? Because the number of bees is dependent upon the number of field mice, which eat the bees. Hence the more cats, the fewer mice, the more bees.

If the whole genus of bumble bees became extinct, or very rare, the heart's ease and red clover would become rare or would disappear. How is that? Because bees promote the growth of those flowers. The visits of bees are necessary to the fertilization of some kinds of clover, and almost indispensable to the fertilization of the heart's ease.

In a word—no bees, no seed; no seed, no increase of the flowers. The more visits from the bees, the more seed from the flower, the more flower from the seeds.

Nearly all our orchidaceous plants absolutely require the visits of insects to remove their pollen masses, and thus to fertilize them.

Twenty heads of unprotected Dutch clover yielded 2,900 seeds. The same number protected from bees, produced not one seed; one hundred heads of unprotected clover yielded 27,000, and the same number protected from bees, not a seed.

OBITUARY.—R. C. Otis, who is well known to the bee-keeping fraternity, died at Mount Pleasant, Iowa, August 31st, 1874, in the 61st year of his age.

M. M. BALDRIDGE.

Foreign Department.

CONDUCTED BY CH. DADANT.

For the American Bee Journal. The Birth, Mating and Laying of the Mother-Bee.

Generally, eight days and twelve hours are necessary from the sealing of the cell until the birth of the young queen.

According to F. Huber, eight days elapse from the moment when the cell is sealed over the larva until the time when the young queen leaves her cradle, but she ordinarily remains in the sealed cell for eight days and ten hours, provided the proper heat be furnished, for the royal larva spins its cocoon in a day and a half or thereabout, and is a pupa for seven days. I once noticed that a royal cell remained sealed for 8 days and 15 hours, and another for 8 days and 9 hours only. It is known that with an inferior heat the pupa might remain in the cell much longer than the usual time. I have introduced royal cells that had only been sealed for three days, in empty hives with a temperature of 19 to 23 deg. Centigrade (66 to 73 deg. Far.). The birth of the young queen was then retarded from 3 to 6 days, when returned to their colonies two days after. Many pupæ died on account of the low temperature. In experiences of this kind, when the thermometer is attentively watched to find the degree of heat in the brood chamber one can with certainty ascertain the time that it will take for the young queens to emerge from their cells. In the absence of a thermometer, all the observations that can be made on the duration of the pupa state, are valueless for scientific bee-culture.

We can divide the time that it takes for a queen to hatch in three parts, as follows:— From the time when the egg is laid. From the time when the larva leaves the egg. From the time when the larva is chosen as royal larva.

You should proceed with great care to calculate the time during which a queen lives in the brood state. No certain result can be arrived at, if we take a common brood comb and employ it for experiment, for in this case we do not know when each egg was laid that will be chosen for a royal larva. To ascertain exactly the time when the egg is laid I introduce an empty comb, clean, in a rich colony whose queen needed room to deposit her eggs.

After half an hour, I found this comb occupied with eggs. I removed it immediately although it contained but five or six eggs. If I had waited until it was entirely occupied with eggs I would not have known at what time the eggs had been laid. I did not give this comb to a newly made artificial swarm, for such a swarm is not quiet enough to insure that the egg will be properly cared for, on account of the excitement caused among them by their having been queenless for a short time. It often occurs in such swarms that the bees when hunting for larvæ, extract the eggs from the cells. In such a case the experiment would be without result. I preserved colonies that had been queenless for some time al-

ready, especially for this purpose. I removed all the unsealed brood from one of these hives and replaced it with that comb containing but a few eggs. Now these bees were obliged to raise a queen from eggs of which I knew exactly the time of laying. But here again one might mistake, if we did not use the thermometer in the brood chamber, and if we did not ascertain that the eggs are continually and properly hatched, for if they lack the proper heat, the period of development of the egg will be prolonged further than the normal time.

To know exactly the hour when the eggs were laid we can also form an artificial swarm with a laying queen. By giving this swarm clean empty combs, two hours afterwards, eggs will be found in the cells.

For the American Bee Journal.

Bees, Wasps and Grapes.

Some persons imagine that the bees injure fruits and especially grapes. They are greatly in error. It is useful to insist on the part taken by bees and hornets in the prejudice done to our vineyards. First let us consult the books. I do not find a single book on agriculture or horticulture, fruit or grape culture, that does not cite the wasp among noxious insects that should be fought incessantly and mercilessly; while not a single book mentions as such the industrious honey-bee, whose vindicator I now am.

The wasp pierces the fruits; to the grapes it leaves nothing but the skin and the seeds. The bee only profits by those spoils; for she usually goes from blossom to blossom, gathering honey in gardens and fields. If at times she is seen in orchards or vineyards, where she only goes after the wasps, it is only to gather the remains of the feast.

Curious experiments have been tried, it appears: Some sound fruits were placed simultaneously within the reach of both wasps and bees, the former have soon achieved their work of destruction, while the latter starved to death.

Therefore, bees do not eat grapes. So, it is with profound conviction that I say to those who wish if not to prohibit, at least to render impossible the establishment of hives in the neighborhood of large cities, under the fallacious pretext that they destroy grapes. Respect the bee, since she respects our fruits: let her live in peace near us, she never will be ungrateful. Is she not the mysterious instrument that helps and facilitates the phenomenon of the fertilization of flowers, and perhaps produces those innumerable and beautiful varieties by carrying pollen from the calyx of one into that of another? Is she not the living image of work, that gives us the perfumed honey and the wax that we use so diversely?

Respect the hives, leave them where the industrious genius of man placed them, for they are a source of wealth for the roof that shelters them, and for the country that nourishes them.—*Rucher du Sud Ouest.*

September, 1874.

Always feed your bees for two or three days after they have swarmed, be the weather fair or foul. They will repay your attention and your liberality with usury, before the season is over.

Correspondence.

For the American Bee Journal.

Odd Tidings.

The "Proposed Remedies," No. 1, pp. 18 and 19, 1875, are excellent, but will not prevent failures in safely wintering bees, while paying no attention to that most important factor,—quality of the honey!

"Novice" is right in saying, that the nature of honey has much to do with it. I experienced and witnessed this many times; but the best testimony is given by Baron von Ehrenfels, the too-long forgotten master in the kingdom of queens and bees, who will find his resurrection amongst the bee friends of this new world.

In his excellent, old treatise or bee-book, this man of 1,000 lives, in olden times, tells us about bee-dysentery as follows: "At Stollhof, in an apiary, next a pine forest, I wintered 300 stocks, weighing from 30 to 80 lbs. The winter was a hard one and therefore much honey was consumed for keeping up the warmth. In March and April, 1801, I found more than half of the colonies so very unpeopled, that often the queen was left with only 20 to 30 worker bees in a honey-store of 40 to 50 lbs. It crawled around, discouraged and alone, smeared by the droppings, the fly-holes coated by it, and the workers, swollen bodies, lay motionless scattered on the hive!

"I guessed quickly the cause, else I should have lost all stocks. In a hurry I ordered from my traveling apiary, near Vienna, flower-honey and buckwheat honey, strained pure and cold, that is got out of the combs without any crushing or melting, fed this in open troughs, often and plentifully before the stands. All the workers who could make efforts enough, went for this honey and, just now, dysentery ceased, brood and bees multiplied daily, and stocks, many weakened down to 100 workers, recovered!

"So, in forest regions, honey abundance turns out to be more dangerous than honey dearth. Miraculously, here also in other cases, I always saw the queen being the last to die. After all workers were dead, she alone was left living. Wherefrom this durability, this conservation? Never taking honey out of the cells, but ordinarily out from the mouth of the workers, even in this case she gets warm honey and probably fresh digested for her, insuring and saving her from being poisoned."

I say by this kind and quality of honey, most abundantly and extraordinarily produced from other organs, processes and sources than flowers, richly flowing, dropping like dew—honey dew—hurriedly gathered, stored and sealed, and so not enough, not twofold or twice digested, that is neither first by the proper organs of plants (the blossoms) nor finally and sufficiently in the stomach of the bees. And now you see, even a fly-spell under glass, muslin and the like would not help and save your pets from this bad occurrence. But your bees can be cured and saved from death by dysentery when this fatal disease is caused by the bad effects of the three kinds of honey,—

dew honey; unripe, (thin or unsealed); sour honey,—or artificial food.

But "prevention is better than cure," and therefore each bee-keeper ought to prepare to preserve and to feed in the right time and manner, this only one safe and normal, natural winter food,—full combs of (or extracted, swung out) blossom honey, (best from buckwheat) and ought to keep always a full reserve of such pure and healthy feed honey on hand for his own and other bees.

APIPHILUS.

For the American Bee Journal.

Down With the Importation of Bees.

In the last convention of the North American Bee-Keepers' Association, a few bee-keepers have fired at the importation of bees.

Mr. A. Benedict was first to begin the fire. He said that he supposed that there were hybrid bees in Italy. Upon reading this I wrote to our friend to know on what he had based his supposition. But in his answer, he could give nothing definite. He had seen some so-called imported queens, who were undoubtedly impure. But, for himself, all the imported queens he had received were pure, and gave him the best bees.

The second bee-keeper who spoke against importation was Mrs. Ellen Tupper. Mrs. Tupper has since denied, in the AMERICAN BEE JOURNAL, what Dr. Rush had reported of her sayings; so I have nothing to ask but the names of the many bee-keepers who with Mr. King, complained of having received impure imported Italian bees, with the names of the importers. I will here notice that in a few months Mrs. Tupper has greatly changed her mind as to imported bees. In France we have a saying: *Souvent femme varie*. (Often women vary) and Mrs. Tupper shows that she is not an exception.

It seems that Mr. King is endowed with the same qualification, for, two years ago he asked praises for the importation, that he opposes to-day. As I like well-defined positions, after reading the assertion that he has seen impure Italian bees in Italy, I wrote him, to know the name of the apiaries, where he found these impure colonies. He answered, the same as Mrs. Tupper, that the report of Dr. Rush contained many errors, corrected, in part, in the *Bee-Keepers' Magazine*. In this paper Mr. King corrects indeed, some of his sayings, but he maintains that he saw impure bees in Italy. I wrote a second time asking for the name of the apiarian. "Mr. King thinks best to mention no name." Best! for whom? For me, or for Mr. King? As it is not for me it is therefore for him. Yes! and as I know the why, I will disclose it to my friends. It was at the apiary of Major Hruska, that Mr. King saw, or said that he saw, impure bees. In narrating the fact Mr. King adds: that Mr. Hruska told him that these bees were brought to his apiary from other parts. Now, when Mr. King and Mr. Hruska were face to face, they were both in great embarrassment. Mr. Hruska could not understand Mr. King, and Mr. King could not understand Mr. Hruska. The one could only speak German and Italian, the other only English. Hruska, who is a rich man, worth about \$300,000, is apiarian by pleasure, and enjoys

his time in experimenting. He had received black bees to experiment on the pathogenesis, and these stocks, or their offspring, were those that Mr. King saw at his apiary. But why is it that Mr. King does not think best to mention the name of Hruska? Aye! there's the rub. A few months after his return from Italy, Mr. King received 18 stocks of bees from the same Maj. Hruska, and advertised them in his paper for \$30 apiece, as *unquestionably pure*.—See the *Bee-Keepers' Magazine and National Agriculturist*, of Dec., 1871, p. 92, 1st column. Thus the words, burning shame, and other flourishes, which seasoned the speech of Mr. H. A. King, against imported bees, fall on his own head.

Now I will pay to Mr. King \$200 for the name of a bee-keeper in Italy having hybrid bees in his apiary, unless they were imported there from outside of Italy. We will appoint the president, cashier, and secretary of the Central Society of Bee-Keepers of Italy, all three men of honor and reliable, to ascertain the fact. And if the assertion of Mr. King proves true I will pay all the charges of ascertaining the fact. If the assertion is proved untrue, Mr. King will pay the charges, but these charges only.

I know in advance that my offer will remain a *dead letter*, as did the offer of Mr. Furman about the fertilizing of queens in confinement; but it will end the accusation of impurity of bees in Italy.

Let me say that I know the motives of these attacks against the importation of bees and that I will disclose them in the *JOURNAL* if my opponents desire it.

Had not my name been mentioned by Mr. Bingham, in the Michigan Bee-Keepers' Convention, I would have let pass unnoticed what he said about imported bees. But he said, "if Dadant could get a queen good for four years, he could stock the whole country with queens." How does Mr. Bingham know if my imported queens are long or short lived? He has never received one from me; besides I dare him to name some bee-keepers complaining of having received short-lived queens from my importations. I suppose that before complaining to Mr. Bingham, these bee-keepers would have complained to me first, and I have as yet received but one complaint. The Italian bees are as long lived as the black, the only difference is that as soon as the Italian bee begins to show signs of profligence, she is replaced by her bees. While the black bees preserve their queens even until she becomes drone laying by old age, and that difference is to the advantage of the Italian bees and their owner. But Mr. Bingham has never had confidence in the Italian bees, and I remember having seen some articles by him against them, a few years ago. It is therefore little to be wondered at, if he was opposed to the importation of queens in a paper which condemned, in emphatic terms, the promiscuous importation of Italian bees. As I am the only regular importer of Italian bees, I suppose it is my importations that Mr. Bingham aimed at, and I want to answer, when the American bee-keepers were receiving queens from Germany, Tyrol, Switzerland and Italy, the term promiscuous was applicable. But I receive my queens from one of the best bee districts of Italy. The man who sends these bees is reliable and honest; he owns 300 stocks of bees and I pay 30 per cent.

more per queen than their value in Italy, to get only young and prolific queens, tested from chosen stocks. Is that what is commonly called promiscuousness?

Mr. Bingham adds: "In carrying queens from apiaries affected with foul brood, it will communicate the disease; hence the great danger of importing bees." Now if Mr. Bingham can point me to a bee-keeper able to read the Italian language I will send him the full collection of the Italian bee paper *L'Apicoltore*, and I will give Mr. Bingham ten stocks of bees if this man can find in the whole seven years, a sole complaint of foul brood by an Italian bee-keeper. Foul brood has never existed in Italy. If foul brood could be imported with queens, I should be the first victim, as every queen, as soon as received is introduced into a colony of our apiary till she is rested and has commenced to lay. But I am less fortunate than Mr. Bingham, I know the foul brood only by books and hearsay, for I have never seen that malady in our apiary, nor in our neighborhood.

I think that Mr. Hester will find in this article an ample answer to his article on the purity of the Italian bees in Italy. If he could come here in the beginning of April, I would visit with him sixty stocks of bees with imported mothers, and to show him that he was too hasty in judging imported bees from the bogus imported queens that he had received. Shallow or Tall Frames.

I have just been reading in the Feb. number of the *JOURNAL*, which came promptly as usual, the report of the Michigan Bee-Keepers' Association at Kalamazoo; and as a whole I regard the meeting as a very useful one; and the report contains many good things and useful suggestions. But then there are one or two things I notice that seem very strange. For instance, Mr. Bingham gives us some of the "tallest" special pleading in favor of shallow frames, that I ever read.

Now, Mr. Bingham is no doubt a successful bee-keeper; but his reasons (?) for the use of the shallow frame (except that of facility of handling) are, it seems to me, as shallow—begging his pardon—as the frames themselves. He says: "Small shallow combs give more brood early in the season. Heat ascends sooner than it radiates; hence in tall hives it is lost." I can't see how Prof. Cook could listen to such assertions as these. Now let us see what these reasons amount to.

1st. Heat or heated air ascends. True,—but wherefore lost? Can you tell us, Mr. B.?

Now, I am only an amateur and consequently not "set in my way" about any particular form of hive; but what little experience I have had goes to prove the opposite of the proposition, and in favor of the deep frame, and I think I can tell *why*. And, first, the air of a hive may be likened to strata lying horizontally upon one another, and numbered for convenience, say from 1 to 5 from bottom to top, and growing warm as you go from one to five. Secondly, bees cluster either outside or inside a hive

when left to themselves, in a compact mass and shaped like an egg; or to speak mathematically, an oblong spheroid. Thirdly, brood rearing in early spring, other things being equal, depends on the temperature inside the hive. Fourthly, the brood must be at that time of the year conform to the shape of the cluster. For example, we will take a frame say 10x15 inches; lay it down, *a la* Langstroth, and place your cluster of bees on it. Now, I claim that if the cluster preserves its normal shape the brood nest will be nearer the stratum of cold air at the bottom of the hive, than if the frame was turned longest end up and down; because the bees will cluster in the highest portion of the hive where the air is warmest. If a cluster of bees belonging to me stays up in the top of the hive where the air is warm, and a similar cluster belonging to Mr. Bingham spreads themselves out along the lower portion of the hive, I don't believe that even Mr. Bingham can get his bees to begin rearing brood any earlier than mine will, or get more brood in the same time.

I use a frame 12x12 and notice that my bees, now in cellar, all get as high up in the hives as they can.

I have no doubt that for facility of handling the shallow frame is best; but when you have said that, you had better stop. In the 12x12 frame I have struck, I think, between the extremes and can handle it easily enough.

R. J. COLBURN.

Chicago, Ill.

For the American Bee Journal. Some Items.

If perchance somebody had been peeping through the cracks of our tight board fence, about the last days of June, they might have seen that your humble servant was not in a very pleasing mood, but was a fine subject "For Blasted Hopes" (see Gleanings in Bee Culture.) And now we will try to tell you what had ruffled up our feathers. We couldn't make those golden yellow-jacket bees work in boxes. We determined in April, that we would build up a given number of our stocks, so that their hives should be running over with bees by the time fruit trees were in bloom. We did so, selecting Italians, blacks and hybrids, as our apiary contains about her equal number of three banded blacks and hybrids.

In May we had 33 swarms, so we built up 20 by removing brood from the rest, such as could spare any. By the time white clover bloomed our 20 swarms were ready for the boxes; so we put them on—and now mark the result: Hybrids and blacks entered them and commenced work immediately. But those golden beauties (as some one calls them) preferred to lay out of doors. A few bees would go into each box, and some of them started small pieces of comb, always building it upward and some built up and down at the same time, making miserable work. A black bee would have been ashamed to turn out such a job.

Some one may say, this is no fair test.

Well, for the last three years, our apiary has been stocked with the same kind of bees, and the great bulk of our honey has been stored by the hybrids and blacks, while all have received the same care and attention, and for box honey I will give more for a

black or Italian queen that has mated to make a first cross, than for a pure Italian.

And yet I do admire them and honestly believe that they will store considerable more honey than blacks, providing the extractor is used exclusively; but I must have bees that will store box honey, for you know that is my hobby.

Some one may say, your hive are not right or the boxes are not adjusted so that the bees can enter them without much trouble. Our frames are 12x12½; we use from 8 to 13 in a hive; we use glass 5x7 inches for ends and tops of box scant ¾ inch thick for bottom. We get pine lath dressed to 3-16 thick; we cut them to length, and put them on the edge in mitre box and saw down ¾ and split out the piece. After they are nailed on the bottom you have 3 slots 5½ inches long ¾ wide in each box. Our frames drop 3-16 or nearly ¼ below the top, and when we put on boxes, we lay on a strip 3-16 on top of frames, right through the center, and then put on the boxes, resting on the top of hive and strip. The bees can then get into the boxes from any point, without a guide post, and if any one has anything that is better, and will give better results in box honey, send it at once to our good old A. B. J. for we want all the best plans we can get.

SIZE OF HIVE FOR BOX HONEY.

After using 3 different sizes of hives, respectively 8, 10 and 13 frames, we have come to the conclusion that 10 frames suit us the best, for box-honey. This size will accommodate 6 boxes, about 40 pounds. We sometimes wonder why some writers to the JOURNAL recommend box room for a hundred and fifty pounds all put on the hive at one time. Experience teaches us that no ordinary hive will furnish bees enough to work in more than 6 or 8 boxes from 40 to 50 pounds, at any time. We will admit that possibly they might enter a dozen boxes and build more or less combs in all of them, at the same time, but we prefer to have on just as many boxes as they can fill. If the flowers are yielding honey 6 boxes will be filled before they send out a swarm, but if you had 12 boxes on, you would have more or less in all, but none filled; neither will it prevent swarming.

When we have new swarms in our 10 frame hive, if we have no combs to furnish them, at first we put two swarms in each new colony, about 3 or 4 days apart; and put on boxes when we put in the last one. The first swarm furnished just bees enough to carry on the labors of the main hive, and the last swarm will furnish bees for the 6 boxes, and all will have plenty of room. If honey is plenty you may expect two sets of boxes filled, and a rattling swarm the first of August. We had swarms last year that gave us 18 six pound boxes, and swarmed in August.

As I said before, the Italians have a fashion of building upwards, through the slats in the box, and guide combs must run the same way or your combs will be in all sorts of shapes. We always get dark or fall honey, broadside to the glass, for this reason it looks much better than crosswise.

Many articles in the JOURNAL, from various sources, affirm that black bees amount to nothing in comparison with Italians. This certainly has not been my experience, and sometimes I am almost led to ask, if they give them an equal chance with Italians.

BETTER THAN QUILTS.

May 1st, 1874, we had a visit from a brother bee-keeper, and went to examine our bees, to show how they were doing. He said "I never saw so much brood as you have in your hives, for the same number of live bees." This is the way we got it: A box on each hive 4 inches deep; some kind of woolen tacked on for a bottom, 3 inches of wheat bran packed down firmly, and quilt nicely tacked down on top; when we put on the cap or cover we raise the quilt and the bran is warm as toast. For the American Bee Journal.

Winter Passages—Machine for Cutting.

Those who are in the habit of making winter passages in the comb (as all should do who undertake out door wintering,) will at once see the utility of the implement I am about to describe.

I make a tin tube 3 inches long and $\frac{3}{4}$ of an inch in calibre, on one end I cut teeth similar to those of a rip saw, through the middle of the tube there is a slot in which to drive a tack to hold it in position while turning. I then make a wooden piston to fill the tube, insert this into the tube, drive your tack into the slot, and you are ready for work. To use it, you simply draw out the piston, turn until it locks itself; place it against the comb, turn it half round and push it gently through and the work is done. To prevent the bees from filling these passages in the summer, I take a thin pine shaving ($\frac{1}{4}$ of an inch wide) and place it in the cut, the bees will do the rest.

I have used this implement for three years past with much satisfaction, it is a decided improvement when compared with a knife used for the same purpose. "B."
Beaver, Penn.

For the American Bee Journal.

My First Year's Experience in Bee Culture.

I commenced in the spring of 1857 with two old box hives, in the last stage of decay from the moth, with all the care and attention I could give, increased my stocks to 20 in three years and sold not a pound of honey, the war closing out my stocks. I learned two important facts with box hives, that where the bee went, the miller would. Secondly, without some good work on bee-culture one had as well devote his time to other pursuits. But on investigation of the improved system, with the movable frame hives, I determined to make one more attempt at bee-keeping. So in the spring of 1873, I procured the two-story improved Langstroth hive. (I will add and make my own hives, what all bee-keepers should do) I bought of a friend, two box hives of black bees, paid \$3.00 each. May 8th had a fine swarm to issue, hived them in my new hive all right, eager to have my bees in my new hives the same evening I transferred the mother hive, did a good job for the first got one sting, but dark found me gathering up the young bees crawling in every direction. Now don't smile old bee-keepers, you can

imagine my feelings next day on examination to find young brood all dead, with my new hive full of good worker combs. I went immediately to my friend paid \$1.00 for a swarm, introduced them and they did well. So much my young bee-keepers, for not having the A. B. J. or L. L. Langstroth on the honey bee, both of which I have now, that would have instructed me to wait 15 days before making that transfer. I bought July 10th two more box hives, paid \$3.00 each, transferred them all right. I will not give in detail, my mode of transferring, you had better have your information beforehand. I bought of Dr. T. B. Hamlin, of Edgefield Junction, Tenn., August 3d, two full stocks of Italians in the transport box hive, paid \$12.00 each and at the same time three tested queens paid \$5.00 each, and with Dr. Hamlin's instruction on the mode of introducing queens. I destroyed 3 of my black queens, after six hours, removed honey-board placing my caged queens on the frames, over the greatest cluster of bees, in twelve hours, (had put four workers with each queen) on examination, found three of workers in two cages dead, the third all alive, and in twelve hours more, found the two queens and remaining worker all dead, and in the third found all alive, which I liberated in the usual manner, and I was in trouble again. Season far spent and my stocks getting low, I made known my loss to Dr. Hamlin and he agreeing to share half my loss, sent me two more tested queens for \$5.00. Now some twenty days had transpired. My two queens received, on examination found two fine plump black queens, killing them and after waiting six hours, I commenced by moving my frames from the center, leaving room to place my cage, end down between the frames, supported by a wire pin across the frames, being sure to bring the cage in contact with honey, so if necessary the queen can reach the honey if neglected by the bees; and in forty-eight hours I had my two queens safely housed and would advise this plan to the novice.

I should have added if weather is cool place your blanket quilts over the frames. Now this brings us up to September 1st. My first queen has her combs full of young Italians, crawling and quiet. Something I had never witnessed in native bees. I am prepared to state the Italians far exceed the black in gathering honey. I will add that the superiority and value of Italian bee has not been over estimated or half told. Now I have no stocks or queens for sale. They are the admiration of all who see them.

November the 1st, overhauled my seven stocks; found as I supposed sufficient stores to run them during the winter and fed some weak stocks some from those that had to spare. I then made some blanket quilts and straw mats. Such as C. F. Muth of Cincinnati, O., uses. My bees were out nearly every week through the winter, it being a very mild winter, my bees came through the winter safe, but we had the worst spring I ever saw in the South. Our fruit trees did our bees no good. I lost two stocks during February and March, and came near losing the third; had I not taken it in my family room and fed sugar syrup, and kept it there forty-eight hours they would have perished. My bees made no surplus honey in 1873, all I got was in transferring.

I have in my yard young peach trees planted eight feet apart, with a hive be-

tween each tree, and a covering made of five elab boards; that is all the protection I have had. I don't think it sufficient shade; my trees were small and headed back well and will be sufficient the coming season. My hives are arranged to face the southeast, on an elevated point. Our people are taking some interest in bee-culture. We plant nothing here for our bees, they depend on natural supply, which is good some years, in our bottom. We have the poplar, holly, and maple, and from these the gums give us the most of our honey.

I desire to plant something, did I know what was best adapted to our climate. Will buckwheat do with us, and what time should it be sown? will some one tell us through the JOURNAL.

For the American Bee Journal.

Notes on Bee-Keeping.

Bee-keeping in these parts is far behind the times; the general impression being that it is a business that does not pay. Ask a bee-keeper to subscribe for the BEE JOURNAL and learn to keep bees right, and he will tell you that he knows all about them, that is necessary. Rather than pay two dollars for the JOURNAL, whereby they might form some idea of what a patent hive should consist, they will allow themselves to be humbugged as some have been the past season by paying three times as much for a patent hive, that is a disgrace to the little workers and when their bees are in they look no more to them until the time arrives as they suppose to take the surplus, but to their dismay the moth trap has been successful in hatching moths enough to eat up both bees and honey; such is the result generally.

I use a plain simple constructed hive with loose bottom and honey boards with back opening, frames set in from front to rear, size of frame 11x13 inches, inside measurement, and not less than eight frames to the hive, (no patent.) I used last season two of these hives one upon the other, making a two-story hive with ten frames in each; and once in buckwheat time, I extracted from this one hive four gallons of nice honey, with from three to five hives. I have honey for the table the year round while my neighbors with more swarms in box hives get no surplus. I have the only extractor that there is in my neighborhood.

There is another subject that I wish to notice; one which I have been watching with interest and which interests a great many. The question is asked by S. S. Elliot, (page 205 September number AMERICAN BEE JOURNAL,) how to purify wax and prevent its becoming of a dark color. I have not seen any answer to that question yet, and I will give your readers my plan. Heretofore the plan has been to take it through a process of boiling; but I use no water in extracting wax. Last season in transferring a swarm from a box hive to moveable frame, I had, as is always the case, some, some surplus comb fit for nothing but to be melted into wax; and having left them in the sun through the day, I discovered the sun had melted them and I had an article of pure white wax from the darkest comb; and acting upon that principle I procured a

piece of sheet iron turned the edges up around, leaving one corner open for the wax to run out as it melted, placed it upon the stove elevating one side, and as it melted put in more being careful not to burn it; the result was I had a wax of beautiful yellow color.

In conclusion, I shall as ever press the claims of the AMERICAN BEE JOURNAL.

Adair, Ill. W. M. G. WILKINS.

For the American Bee Journal.

Posting Up the Accounts.

We should now look over our last year's experience, and take into consideration our success and failures; examine into and find out the causes of both, so as to profit in the future by our past experience, and avoid failures hereafter.

The amount of honey taken by me last season, was about half as much per stock as the season of 1873, being about 28 lbs per stock: my increase was from 9 to 23. Our honey crop from linden, here, was splendid, and caused bees to swarm to too great an extent, as it was so dry here that there was no honey to be gathered from that time until after the middle of September; that being the first time that we had any rain since the middle of January. We had several days in July and August with hot southwest winds that cooked vegetation to some extent. The thermometer raising as high as 114.

I had two stocks out of the 23 that were very strong. They stored honey all through the season. My medium stocks about held their own; light stocks decreased in weight. That makes it evident that in a poor season, strong stocks are necessary. I fed about 300 lbs of sugar this fall, as an experiment to see whether it would pay to feed to any great extent here, in the fall, or not.

For the American Bee Journal.

Proper Winter Temperature of the Bee House.

In the Report of the U. S. Patent Office 1859, Department Agriculture pp 90-91, is given some account of observations on the winter temperature of the bee hive, made by Prof. Newport. His experiments show that the temperature of the air in the bee hive and right in the cluster of bees may be as low as 30 degrees or two degrees below the freezing point. Upon one occasion the thermometer in the external atmosphere stood at seventeen degrees, the one in the bee hive stood at thirty degrees, but upon rousing the bees by tapping on the hive it rose in sixteen minutes to seventy, or fifty-three degrees above the external air. He states that the bees are torpid only at a moderate temperature, as it grows colder they generate heat by motion and quick breathing so as to considerably modify the temperature of the hive.

Although it is quite common for bee-keepers to winter their colonies in the cellar, I know of very few attempts to control the temperature and to keep a record of the winter temperature of bee houses and cel-

lars. A cellar that will keep fruit is considered good, yet the thermometer may work as low as 28 or 30 degrees and the fruit not be frozen. This appears to me to be quite too cold. My colonies are kept in a cellar, have ventilation above and below so that the air in the hive must be at very nearly the same temperature as that in the cellar. Now I have observed that the bees are more quiet when the mercury stands at forty-one degrees than when it is either several degrees above or below. From repeated observations made during last winter and this I can judge pretty well as to the temperature, by the sounds issuing from the hives. Upon allowing the mercury to sink to thirty-six degrees, the increased noise of buzzing told plainly that the bees were trying to keep up the temperature. I warmed up the cellar to forty degrees in four hours, and twelve hours after the bees had quieted down to their former condition. Of course it is easy enough to keep the temperature from falling below 40 or 41 degrees, but quite another matter to keep it from rising above that during warm spells of weather, at least it is so in Northern Kentucky; and just as soon as it becomes impossible to keep the temperature below 48 or 49 in the spring time, I move my bees out to their summer stands. As to the other conditions necessary to successful wintering, such as absence of light, moisture, and disturbance from the cellar, they are much better understood than the proper temperature; because their effects may perhaps be more easily traced back to their causes. But I would urge upon every bee-keeper, who houses his bees in winter, the necessity of keeping a record of the temperature of his depository, if not daily, at least at every marked variation of the weather. It may be, that in trying to comply with the conditions for successful wintering in the cellar, we have overlooked one of the most important.

January, 1874.

"A Friend or Enemy."

EDITORS AMERICAN BEE JOURNAL:—In reply to Mrs. L. Harrison's communication in your last issue, permit me, for the present, briefly to say that your correspondent not only fails to quote my language correctly, but that she misconstrues and falsifies my statements. My statement that the *Phylloxera* is more injurious in a clayey than a sandy soil, was made in reference to the root-inhabiting form; while Mrs. H., lacking a proper comprehension of the subject, evidently has reference only to the leaf-inhabiting form. In what I am quoted as saying about the honey bee in its relation to horticulture, my language has been so garbled, and my statements so perverted that no greater injustice could have been done me even by one filled with malice and bent on carrying a point by fair or foul means. I beg of your readers, therefore, in weighing my opinions and statements, to consider them as given over my own name rather than as presented by others. In speaking of the injury bees sometimes do to fruit I used no uncertain, but quite positive, language; and as no one has ever read anything from my pen that would warrant the charge of my being an enemy to the honey bee—however much others may have

misrepresented me—I fail to see where I have "come down," to use the elegant language of my censor.

In reference to the statement of Mr. Gaston that the great nation of Russia * * * are importing bumble bees to fertilize the red clover;" while there was scarcely any necessity of correcting it at the time it was made, I may as well state, since it is repeated, that New Zealand and Australia, where the bumble bee is not indigenous, are the countries that have been considering the question of importing the insect, in order that they may no longer be obliged to import all their red clover seed. Russia has no need of such action.

For the American Bee Journal.

Chips from Sweet Home.

It will be remembered by the readers of the AMERICAN BEE JOURNAL, that we were among those who lost heavily in bees. It is now Jan. 22nd and there is no sign of the disease. We think the disease was caused by confinement on poor honey. Last fall we fed two hives or rather put in some combs we had saved from those that had died, and as yet I see no difference. Our bees (100 hives) are in the west half of the cellar, a partition running through the centre, we filled the two opposite window holes with straw, we can raise the windows and have a current of air without admitting any light, but find the bees quieter with the least circulation. The only ventilation I give is an opening in the base of chimney which carries off the damp air. One morning I heard quite a roaring among the bees and upon examination I found the noise all proceeded from one hive, with my knife I raised the honey board a little and all was quiet. The thermometer has ranged from 40 to 45 deg.

B. Miller, of Lee Co., Ill., in answer to some questions from me on wintering bees, said: "I never lost but two hives in wintering. I winter in the cellar, never allow the thermometer to go below 35 deg., never disturb them, give plenty of ventilation both in the hive and in the cellar, leave the whole front of the hive open and push the honey board forward so as to leave a half inch crack at the back, extract 2 or 3 frames and put the empty combs in the centre, put in cellar the last of October and take out the last of March."

SELLING SLUNG HONEY.

We can make more money in selling slung honey at 15 cents than box honey at 25 cents. But there is the trouble to sell. Seeing that others were successful in selling it in small jars nicely labeled that "they went off like hot cakes," we were induced to put up over 500 lbs. in jelly jars, nicely labeled, and started out, passed through the town where "slung honey in jars went off like hot cakes," but the grocerymen told me it would not sell although they had them piled up right in view; and from a man they knew, I sold some of my jars and left most of it on commission, but they write me: "Have tried to sell your honey but can't. And now I have offered to exchange 332 lbs. for 100 grape vines, and return the jars. I sell a good deal of slung honey each year, nearly all in the county, and prefer it

to be candied, I sell some for money and a considerable for trade, *e. g.*, I paid \$4 and the balance in slung honey for a bureau, 100 lbs. for a 2 year old Durham heifer, 275 lbs. for carpenter work, some more to mason, some for corn. A neighbor told me that he was putting up a variety of Illinois fruit for some friends in Indiana. I suggested putting in some of our honey, he got 21 lbs., and brought a neighbor who got 6 lbs., he thought his friends might want a barrel of honey; my blacksmith's bill is paid in honey, &c., &c. My neighbors prefer the slung honey because it is cheaper and healthier, and no wax in it. Many persons cannot eat honey because it gives them colic. I have yet one of such to find who cannot eat slung honey when candied solid. Last fall neighbor M. told me he wanted some honey and would take more but his wife could not eat it, the last time she tasted it he went for the doctor. When he came for the honey he brought her along and she ate liberally of it and it had no bad effects.

We would advise all bee-keepers to make home sale of slung honey, and if city style will have comb honey make them pay for it.

An Address

DELIVERED BEFORE THE SOUTHWESTERN KENTUCKY BEE-KEEPERS' SOCIETY BY DR. N. P. ALLEN, THE PRESIDENT OF THE SOCIETY, ON DEC. 30, 1874.

The objects of this Association are to advance the science of bee culture, by associating in one body those who are interested in bee-keeping.

The importance of association when there are common objects to carry out will be readily conceded.

The value of consultation about matters in which all are interested, and especially where there is room for difference of opinion cannot be over-rated.

We have our Agricultural Societies and our Granges to look after the great foundational industries of the country; and conventions and meetings are held all over the land in order to carry out the ends for which they were organized.

No sensible individual undertakes to carry out solitary and alone the ends he is aiming to accomplish when there are others equally anxious to succeed in the same direction, with whom he can consult and cooperate. There is no class of men whose interests calls louder for consultation and association than bee-keepers.

When we take into consideration the fact that bee culture is both a science and an art; that but few in our land have any knowledge of the great discoveries or inventions that have been made; that the mass of bee owners are ignorant of even the simplest operations of the apiary. It behoves us to do all we can to dispel the cloud of ignorance which over-hangs them, and so far as we can to impart that knowledge by which they may prosecute bee-culture successfully.

I regard bee-keeping in this country in its infancy. I feel sure that the great foundational principles of success have been at-

tained with the movable frame hive, the honey extractor, and the Italian bees. There is nothing wanting but a thorough knowledge of bee culture and a determination to succeed. There are a large number of determined men in the northern States that are producing honey by the ton, they are realizing large profits from the labor of honey bee, many of them are growing rich, and why can we not as well as them, when our gardens, fields, and forests are strewn with flowees rich with honey?

Bee-keeping has taken a high stand among the productive industries of the world, and many are reaping a rich reward in its pursuit.

Honey as food for man was of sufficient importance to be recorded in the sacred Scriptures: "Sampson enjoyed a rich feast of honey taken from the carcass of a lion." John the Baptist while he was preparing the way for the coming Savior, dined upon locusts and wild honey.

It is absolutely certain if man is to have honey the bee must collect and store it for him, and it is none the less certain that the proposition of honey gathered and made available for human use is very small compared with what might be got if there were bees enough to gather it.

The question, will it pay? is the question that interests most persons, in the various pursuits of man. I answer that bee-keeping, like all other pursuits, has its successes and reverses, but I am fully satisfied that it is no more subject to failure and disappointment than any others.

I am aware that many who have bees fail to realize any profit from them, but that is no reason why they should not. If they were to give their farm stock no more attention and care than they give their bees they would prove even more worthless than their bees.

There is no good reason why our land should not flow with milk and honey. We could, if we would turn our attention to it, produce tons where we now produce pounds. It does not take long to learn to swarm bees artificially, and thereby insure increase of stocks, nor to Italianize our black bees and cultivate a superior race of bees that are more prolific and better honey gatherers. We can soon learn to extract the fluid honey and return the comb to be filled again, in fact all the operations of the apiary can be learned by any one who will give it their undivided attention, for there are no secrets in bee-keeping. But in order to accomplish this we must use exclusively the movable frame hive. We cannot succeed to but a limited extent with the box hive. Then I would earnestly advise all who are interested in bee-keeping, either for pleasure or for profit, to get the movable frame hive, and transfer your bees into it. Procure a honey extractor and thereby increase your honey to an unlimited extent. Take the publications on bee culture, I would recommend the AMERICAN BEE JOURNAL, *Moon's Bee World*, and *Gleanings in Bee Culture*, as invaluable to those seeking knowledge in the management of bees.

It is said that he who causes two blades of grass to grow where but one grew before, is a benefactor of his race; and it can be no less true that he who causes two pounds of honey to be made where but one was made before, is a benefactor, and a blessing to

mankind. Then let us strive to obtain a high stand in our favorite pursuit by storing our minds with that knowledge that will enable us to overcome all difficulties that we may have to encounter and to surmount every obstacle in the pathway of success.

For the American Bee Journal.

How to Save a Queenless Stock.

On a bright warm day in February, I examined a number of my hives, to see if they had sufficient stores and if the queen was laying. In some hives, I found more, and some, less, of sealed brood, all except one had eggs and larvae. One hive on examination proved to be queenless. There was plenty of bees and stores enough to last until the honey harvest. I gave them a card of comb from one of my strongest stocks with sealed brood, larvae and eggs in it. I closed the hive up and did not open it again until April 11th, as the weather was cool and not suitable to open the hive. I found that they had made three queen cells; the cells were open but no queen cells could be found in the hive. I gave them another card of brood, and on May 2nd, a beautiful day I saw the queen as she returned from her bridal tour with unmistakable evidence of her impregnation; and I gave them another card of brood in a few days. She began laying and soon filled the hive with bees. The queen was pure Italian and was impregnated by a pure drone, and that hive today is as valuable as any hive I have. I winter on summer stands altogether. If we would raise early queens, we should hardly fail to get them purely impregnated as the Italian drones are earlier than the black drones.

For the American Bee Journal.

Candied Honey—Empty Comb.

I was somewhat surprised in reading Dadant's article under the above caption in the Feb. No. of the JOURNAL. He says that to want a means of preventing honey from candying is the same as to encourage a fraud. Now my extracted honey had always candied until the present winter. None that I put up in one and two lb. glass cans has as yet candied and we have had as cold weather as we ever had for twenty-five or thirty years.

Last spring I read an article in the JOURNAL from C. Muth, on "how to prevent honey from candying. His directions were to let it set in a cold and dark room for a day or two after extracting, with no top on the vessel it was in and skim off carefully then cover. This was to give it time to work and send all the impurities to the top. I treated my honey in this way and no other, and if it is not pure, I ask Dadant to say in what has rendered it impure. It was fully sealed when extracted and very thick honey, but as it has not candied yet; it is according to Dadant impure. I never thought of honey being impure that did not candy or I would never wished to know how to prevent its doing so. Every one who has bought this honey pronounces it the very best.

I like candied honey myself better than I do that that does not candy, but we read in the JOURNAL that candied honey did not sell so well as the liquid; that it looks like a can of lard. Dadant's reasoning is good if he can explain why mine and Muth's honey in glass jars didn't candy. I did not, nor would not, mix a single ingredient with honey. Also it has been in as cold a place as the rest of the honey that candied every other winter.

It is plain that my honey this winter has not come up to Dadant's test of purity; I have given the simple and plain facts how it was treated and put up in the sealed cans. It now remains for Dadant to say why it is not pure, if he can.

EMPTY COMB.

I see in several Bee Journals and also by my correspondents an enquiry for empty comb. This is a move in the right direction, for very few know the real value of such combs. Hundreds of pounds of nice worker comb is yearly melted into wax, by those who would have gladly sold it for the price of bees-wax. But we had better watch and be careful from where it came or we may bring disease among our bees by means of it. I have never yet experienced the bee-disease, and would willingly give every stand of bees in my Apiary to prevent it. I believe that foul brood and dysentery are diseases among bees, but I very much doubt whether there are any other. I do not believe there is such a thing as Bee Cholera.

For the American Bee Journal.

Numbering Hives.

I have received much information from bee books, and as far as I am able, will do my share in giving information to promote the cause. There is one particular branch that ought to be known to all, especially those that remove their bees from their summer stands, and that is numbering. It is said by one standard writer that it is all a whim, but if he has ever read the Pilgrim's Progress, where he often stepped out of the straight and narrow path, he will take warning and not use unkind words, because others do not agree with him. I know whereof I speak for I have had two cases this spring. Last fall I had three Eureka hives, and left them on their summer stands; two were near together and one a rod off, so I removed it near the other two, and in February there was a warm day and they all had a fly, and the bees from many of them went back to their former home and if there had been another hive of bees there, they would have tried to go in, then it would be said they were robbing. At the same time I took some bees out of the cellar, and by mistake moved two hives three rods from their former stand, and on coming out many of them went back to their former stand, and had there been other hives there, they would have tried to go in, and a stranger would have said "your bees are robbing." Now let the unbelievers try the experiment place some hives on their former stands and misplace others and see which are robbing.

A. WILSON.

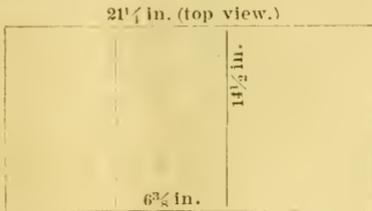

Is it a fact that first swarms issue in the forenoon, and second in the afternoon?

Getting Honey in Frames.

A PAPER READ BEFORE THE MICHIGAN BEE-KEEPERS' ASSOCIATION, DECEMBER 16TH AND 17TH, 1874.

I will here give a description of the small frame for surplus, as we use them here. First, the frame that holds the small frames we call a case. It is similar in construction to the clamp that holds the boxes but requires more accuracy in construction, more lumber, and some glass.

The Langstroth hive we use measures on the outside $21\frac{1}{2}$ inches in length by 16 inches in width, and I will give the dimensions to fit that size, as I think I can convey the idea more accurately in that way. The size can be varied, however, to fit any hive.

Take $\frac{3}{8}$ inch thick stuff by $6\frac{1}{4}$ wide, and cut two pieces (ends) $14\frac{1}{2}$ inches long, rabbit the upper inside corner $\frac{1}{4}$ inch only $\frac{1}{2}$ inch deep, to receive the ends of frames; cut two pieces (middle divisions) $14\frac{1}{2}$ inches long, $5\frac{1}{2}$ inches wide, $\frac{3}{8}$ inch plump thick; cut four pieces, (sides) $\frac{5}{8}$ inch stuff, 2 inches wide by $21\frac{1}{2}$ long. Now, nail the lower side piece on one end (with thin sixes) flush with the bottom, then put in a form, $6\frac{3}{4}$ inches wide and press the division against the form and nail, keeping the bottoms all flush; in the meantime put on the upper side piece, and place a movable strip of wood, gauged to $2\frac{1}{4}$ inches wide, between the side pieces while nailing, so as to leave the space for the glass always the same width. Then cut the glass with a gauge and it will always fit, press the glass down against the ends of the divisions and tack a light wooden stop against it, and your case is ready for the frames.

The top side-piece should be flush with the top of end-pieces, and the top of divisions should be $\frac{1}{2}$ inch lower and on a plane with the rabbit in end-pieces. The stuff should be cut with circular saw and gauge, as it is cheaper and more accurate. There is a space of $\frac{1}{4}$ inch between the honey board and top of small frames, and the same space between frames when tiered up.

The case is to contain 24 small frames. The end pieces of the frames are tight

fitting to each other and also to the case. To make the ends, get a plank planed at the mill on both sides, $1\frac{1}{2}$ inches thick, a little plump, so that when you put eight end-pieces side by side they will measure across them $14\frac{1}{2}$ inches, and that will leave $\frac{1}{4}$ inch side shake, for convenience in getting them out when filled; eight frames fill a space across the hive, (the frames run the same way as in the hive.) Now cut the plank into pieces 4 or 5 feet long, for convenience in handling, and set the gauge to a circular rip-saw $\frac{1}{4}$ inch from the saw, and rip the stuff off the edge of the plank $\frac{1}{4} \times 1\frac{1}{2}$ inches; then cut them $5\frac{1}{2}$ inches long and you have your small frame ends.

To make tops and bottoms have a plank planed $1\frac{1}{2}$ inches thick, and rip as before; cut the tops $6\frac{3}{4}$ inches long, and bottoms $5\frac{1}{2}$ long. The saw should be sharp and trued to cut smooth. Nail on the tops of frames in a form, so they will just slip in the case without touching; $\frac{1}{8}$ inch end shake is sufficient. Nail through the top into the end and through the end into the bottom. Leave projections on each end of top-bar alike and nail the tops and bottoms in the middle of ends, leaving space on each side alike. When the frames are all put in there is a space $\frac{1}{2}$ inch wide between the bottoms of every two frames and the same between the tops, making a splendid entrance for the bees, both before and after tiering up.

We think every working bee can make two or three trips per day more than she can in boxes, if the field is near, making one-third difference in the amount of surplus. Use $\frac{1}{2}$ -inch finishing nails, six to the frame, four in the top and two in the bottom. Stick a nice white piece of drone comb 2×3 inches in the the top of each frame, and when the honey yield commences take off the honey-board and put on a case of frames, and put a quilt on top of the case or, if the cover is high enough, the honey-board can be put on top of the case instead. The after management is about the same as with boxes, with these exceptions.

It will not be necessary to take away as much brood as with boxes, to prevent swarming, as the supers are better ventilated and the clusters are larger, being divided into but 3 apartments, while with boxes they are divided into twelve; and in the second place small frames can be tiered up sooner than boxes, as the entrance and ventilation to the upper tier is as good as it is to the lower tier.

If the yield of honey is good they can be tiered up as soon as the first case is filled with comb and honey, and before

they begin to seal much. The same plan should be adopted as with boxes to get the three rows started all together. If they work the strongest at one side or one end, reverse the case and get them to distribute their work, as it is so much easier to tier up a whole case than it is one or two rows. However, some bees will start one or two rows and leave the others severely alone. In that case, as soon as the one or two rows of frames are ready to tier up you will take the case off and set it up on end on a bench or chair, and take a thin table knife and run it from the bottom between the frames and the case, on all sides of the empty row, in order to loosen the propolis; then push the row all out together and put them in the tier up case and fill it out with new frames, then put it in the hive and put the partly filled case on top; then fold up some cloth and lay it down in the empty space, so the bees cannot occupy it, and if they have a good lot of food and the yield is good they will probably start the next case more even. We frequently get the three tier under before the first one is ready to come off.

These cases will weigh when filled from 50 to 55 lbs. each, after deducting the weight of the case. The frames sell with the honey and will weigh from one to two ounces each.

I see by the journals some advise taking out a frame as soon as it is finished and replacing by an empty one. It seems to me if they had ever made a ton of honey in that way they would think there should be some easier way to do it, as I can certainly tier up a dozen full cases while I could overhaul one set. That might be a good plan if the bees were allowed to swarm. There are one or two objections urged by beekeepers, when first looking them over. One is, it seems to them as if it was more work than with boxes; but our beekeepers here, after having a few years' experience in the make and use of them, say they think a man can run 100 stocks with frames with about the same labor that it takes to run 50 stocks with boxes. Another objection is, that as the bees cannot get in between the case and the frames, they say the moth worms will get in there, but having made a good deal of honey in that way, and having seen several tons in different seasons made in this county, I have yet to see the first worm in that place. Of course they are put on none but strong stocks. One wing of each queen is clipped and all swarms returned and managed the same as with box honey. As a result of all this, I advise all to get their supers

made in the winter. Make all small frames and boxes that will be needed, put in the glass, stick in the combs, get them all ready to set in the hive, and set away in a safe place till wanted. Make at least super capacity enough to hold 100 lbs. for each full stock in winter quarters. If you have twenty such stocks make ten new hives—and no more—and make it your business to see to it, that those bees shall fill those supers, and on no account draw more brood than is sufficient to build up ten stocks for the season. If you have the supers all ready it will be half the battle towards getting them filled, as I believe a great deal of box honey is lost by not having the supers ready in season. Get the supers on several days before the yield of surplus commences. If the stocks are strong in bees, (crowded) it will do no harm to have them on a week or more before they use them. Better not put them on at all than to put them on a week late, as it will probably be labor in vain. I suppose I should qualify the amount of super room to suit the location. If the location is such that there is little or no surplus from locust trees, white and alsike clover, raspberry, and the tulip tree, and there is an abundance of basswood, the whole crop, nearly coming from the latter source, and all delivered within a few days, my advice would be to use no surplus for comb honey, or if they were used they should be used over a two-story hive and the combs extracted from the upper story of the hive, as the time would be too short to make the wax comb necessary to hold the whole gathering, or daily yield, but if the yield of surplus commences, as with us, on locust, and runs down through the list, getting a slight sprinkling of basswood, and after a few days is followed with buckwheat, we think we can get nearly as many pounds of comb honey as we can extract from ten brood combs. My theory is that the young bees elaborate the wax as fast as needed and use but little more honey than they would to perfect the growth of their wings and other organs.

You will see that as soon as the bees are out of the small frames they are ready to ship. As the case is as cheap as any crate you would make to carry small frames and show the honey. The honey is made in the case, is waxed fast and will ship safely to any distance. We generally place a sheet of wrapping paper over the top of each case and fix them so they will not slip off from one another where they are piled three or four tiers high.

For the American Bee Journal.
 "Eccentric."

Didn't friend "Argo" go for us right lively, though, in the February number of the AMERICAN BEE JOURNAL? Notwithstanding his vigorous assault we "still live," and if nothing serious occurs to frustrate our intentions or mar the even tenor of our way we shall continue to retain the name of "Eccentric?" Are we timid or cowardly? Methinks friend "Argo" would hardly have said that had he known us personally. But we had a good, hearty laugh when we had concluded the perusal of "Argo's" article, to think that he should skip clear over "us little folks" and read us last of all. Yet we could not help thinking of a private letter in Mr. A.'s own handwriting, stating that he valued our writings and prized them very highly. Ah! friend A., did you but know that "Eccentric" has appeared in these pages often, (over his own name, too,) very often before, had often had right lively scuffles with "Novice," "Gallop" and the other "big boys" who used to box one another's ears so soundly in these columns, you would never have called us cowardly. Many thanks, however, for saying our "article was good."

We begin to receive reports again of the destroying work of that fell "bee disease," and the indications are that large numbers of our little pets will, ere the return of April showers and balmy spring, "go where the woodbine twineth." Are these things always to continue to baffle our endeavors and thwart our designs? Is *successful* apiculture to forever remain a thing of the past only, to tantalize us with the sweet remembrance of those halcyon days of the long ago? It may be so, but we are too hopeful yet to indulge the thought. Even now, through the dark and somber clouds which veil the horizon of our vision do we catch a glimpse of the happy, prosperous future that awaits us if we with patience but persevere yet a little while. Success, complete and triumphant, can but be the reward of patient waiting, thorough investigation and tireless industry. It may not be out of place to state, in connection with the foregoing, that we are anxiously awaiting the arrival of a copy of "Money in the Apiary," which we see is advertised in another column of the good, old AMERICAN BEE JOURNAL. We are assured by the author that it contains instructions for wintering which will, if put in practice, enable us to bid defiance to that "bee disease" which has produced such fatal results during the reign of old Boreas and Jack Frost. Knowing Mr. Burch has no patent

hive to sell, and that he has been a successful apiculturist, we have indulged the hope that his investigations may give us the key to success, and if this be the case we say "long may he wave."

We are glad to note that our bee conventions are making it lively for those dealers in a conglomeration of honey and glucose. We sincerely trust that they may persevere in the good work, until these dealers shall abandon "the ways that are dark and the tricks that are vain" and engage in some more legitimate occupation.

When we shall have attained complete success in wintering our "little pets," and shall have secured a sure and reliable market for our honey, (which we can do by having it stored in small glass boxes,) then may we hope to make apiculture a pursuit at once "sure, safe and highly remunerative." That this may be fully realized in the near future is the earnest wish of
 "ECCENTRIC."

For the American Bee Journal.

Swarmers and Non-Swarmers.

In the issue of the A. B. J. for February, I observe a communication from N. Cameron. He tells us he has no faith in the non-swarming hive, "for we have known them to swarm when the hive was not half full of comb." Mr. Quinby tells us he took four hives of bees full of comb and placed each upon another empty hive; they each neglected to occupy the added room and sent out a swarm. Probably any bee in the exercise of common sense would have done the same. Bees will issue from any hive from want of acceptable room, from excessive heat, from the presence of enemies, or from lack of food.

Indeed in the home apiary it would be less objectionable to have enough swarms to sustain the working forces for the field.

My experience has been, that with acceptable room for the whole colony the whole season, secured from excessive heat from the sun, or want of ventilation, they will not swarm. A few facts, resulting from the use of the non-swarmers hive.

1. An apiary in non-swarmers hives will secure four times the amount of surplus, from the same field that would be secured by an apiary of swarmer hives, in the same field.

2. An apiary in swarmer hives will consume from two to four times the amount of honey gathered from their field, that would be consumed by the apiary of non-swarmers.

3. The surplus honey gathered by the swarmers costs from two to four times as

much by the pound as that gathered by the non-swarmer.

4. The care and trouble of an apiary of swarmer, is four times that of an apiary of non-swarmer.

5. An apiary of non-swarmer, is more durable than swarmer, non-swarmer often remaining efficient, thirty years and more, and swarmer rarely enduring one fourth of that time.

6. Swarmer reach periods of destruction, and waste in from five to ten years of almost the whole apiary, while non-swarmer may be efficient for a whole generation.

7. Non-swarmer give from one-fourth to three-fourths of the product of the field in surplus; the swarmer gives but from one-thirtieth to one-fourth of the product.

I have here presented a few statements that I believe to be a fair comparison of the operation of bees in the two classes of hives, swarmer and non-swarmer. If any of my friends have doubts of the correctness of either of the statements made, and wish for my reasons for adopting these views, I can give my reasons, or some of the reasons that have led me to adopt them.

I am aware that longer seasons for gathering honey at the south, and the shorter winter season for consumption of gathered stores may effect this question. But how, or how much, I am poorly prepared to judge.

JASPER HAZEN.

Woodstock, Vt.

Report from the Pacific Slope.

I accidentally got hold of the November number of the AMERICAN BEE JOURNAL, and became quite interested in its perusal. Although I am but a novice in bee-keeping, yet I keep my eyes open, to see what others are doing in that line. I suppose that San Deigo county is as good a honey producing country as there is on the American continent, if not in the world, and that I am in the center of the best portion of the county. I notice in an article copied from the S. D. World, that the honey crop of this county for 1873, was 119,000 lbs., I know also, that the crop for 1874 was 475,000 lbs., an increase of 356,000 lbs. I know also that since that honey was produced, there has been a large importation of bees into the county from the northern part of this state. On the 15th day of March 1874, Mr. John Watson got the first load of bees here out of the 103 stands he started with from Sacramento. By the time he got them all here and straightened out

ready for work, they were reduced by being smothered, to 75 colonies. He sold six and a half tons of honey in comb from them, and has now 160 swarms. He sold his honey at 20 cts. per lb.

One month earlier than that, or in Feb. 1874, Dr. Marshall started with 53 swarms of Italian bees, (Mr. W's were the black.) He increased to 203, and sold over \$1200 worth of honey at from 14@16½ cts. per lb here at home, and probably has from one to one and a half tons of honey now in the tops of his Harbison hives, as he was unable to procure section boxes for them to store it in.

Last spring Messrs Trask & Thompson, started with 19 swarms which they had got from the woods. They sold over \$1,000 worth of honey, and a short time ago sold their apiary, numbering 110 colonies, and their bee-ranch for \$2,000 more, to a Mr. Hicks from Chicago.

Mr. Crannell living three miles from me had, last spring, 40 swarms of black bees. He sold six tons of strained honey and has now 150 swarms of black bees. At his place, at the mouth of the San Bernardo river he had one swarm of Italian bees. From that one hive he saved 24 colonies. How many got away he knows not, but several of his neighbors got swarms of Italian bees that were astray, and as there were no others nearer than 10 or 12 miles, they think they must have come from his.

C. Paine, at Paway, had last spring three swarms in King hives; from the three he got 24 swarms, total 27.

I had one in the same kind of hive, my one increased to nine, others have done equally well.

Now with the same ratio of increase of the honey product of 1874 over 1873, 1875 ought to produce 1,421,000 lbs; but the probabilities are that it will exceed that by nearly one million lbs. Why? Because large numbers of people who only had a few colonies last year and sold no honey, are gathering up all they can get from the woods and rocks, and are going to make it a business to produce honey for market.

Two planing mills have been kept constantly running for months at their utmost capacity, cutting out Harbison and Langstroth hive stuff; lumber for thousands of hives has been hauled out into the country without being cut, to be made up at home, and large quantities have been cut and shipped down from Sacramento and San Francisco.

Some of the statements made above may seem marvelous to your readers, but that they are all facts can be proven beyond cavil, by affidavits from all of the

above named persons, and numerous others here who are knowing to the facts.

From what I have seen of the workings of the different hives here, I prefer the Langstroth with some modifications which we put on here. For instance; We find that three section boxes do not give room enough for the bees to store honey in as fast as a strong swarm can gather it, so we put on six by deepening the lays and placing them two courses high.

Of honey producing flowers, we have the Manzanita (little apple) for the past month in full bloom, a sort of wild lilac just in bloom now, and a purple lilac also wild, just coming into blossom. By the time these are gone, the valleys will be covered with the blossoms of the Alfilar and burr clover, mixed with a small sort of fleur de luce on the plains, and willow and oak blossoms among the timber. We also have a kind of mountain sage very similar to the garden sage of your locality which comes on earlier than the white sage, and is almost if not equally as good as the white as a honey producer, after which comes the white sage, followed by the Sumac Fusica, and buckwheat, greasewood, with vast quantities of other flowers of which I do not know the names. Of course they work on the corn tops, fruit, pumpkin and melon blossoms. In fact there is an endless succession of flowers from Jan. 1st to Jan 1st again. Not one day in the year but that I could show you flowers if you were here.

W. J. WHITNEY.

Bernardo, San Diego Co., Cal.

For the American Bee Journal.

How I Built a Bee-House.

I selected a dry piece of ground where no water would stand, dug out a place 18x30, twenty inches deep, dug post-holes a foot deeper than the bottom of cellar, put in posts about six feet apart all around, reaching twenty inches above the top of the ground, and put sills on top of the posts; size of sill 6x16. I now had my foundation laid 18x30 feet. I put joist in 2x12 and 18 feet long, thus leaving a cellar underneath about forty inches deep. I now stud with 2x4 scantling, ten feet long, on the outside of the sill and inside also, nailing joist 1½x12 on top next to the top plate. I then sheet with inch lumber outside and inside, nailing at the same time 1x3 inch strips three feet long every two feet from floor to ceiling, from outside to inside stud, letting them project twenty inches into the room, forming supports for shelves all around the inside. Three rows of strips just make fair space

for hives, it being just eight feet between ceilings. I now put a blind floor in both sets of joists, fill between the lower joists with sawdust, then lay floor on top, fill the outside wall, which has sixteen inches of space with dry sawdust, also about fifteen inches on top. Roof it the same as any other building, and put in two windows and one door. I cut a board the size of the windows and put it in when I wish to darken or keep out frost, also double doors. I built a chimney in the end between the door and window, letting it come down into the room. It forms a ventilator, and I use a stove in the spring to warm up weak stocks, after the bees are moved out. I always keep several thicknesses of cotton over the chimney-hole, to keep in heat, and allow the damp to escape. I bank the cellar all around the building so that no frost gets in, and have an opening or hatchway two feet square through the lower floor to let the foul air or poisonous gas settle into the cellar.

I have wintered three years in this house and never had any losses in wintering. It is no trouble to winter in it when the thermometer goes 25° below zero and continues cold a long time. The inside temperature never varies more than one or two degrees, standing at about 40° or 42°. I frequently go in and can scarcely hear a sound from one hundred pure Italian swarms, they are so quiet.

I weigh every swarm when I put them in in the fall, and also when putting them out in the spring, and they consumed in the winter of 1872-3 six pounds and two ounces of honey per hive; in 1873-4 five pounds and three ounces of honey per hive, or about one pound per month. Thus far this year they have been doing well.

Now, a word about extractors. I see by your February number that some prefer the Peabody, or a revolving can machine, to one of the Root style. I have used a Peabody that cost me about \$20, counting express charges, &c., for years. Last season I got one of Root's machines and it ran so easy that the little boys in the village would come and help extract for amusement. One day a small boy extracted over two barrels of honey. I took out and put in the combs for him. I want no more revolving can machines. If the Root machine is not strong enough to suit you, put a steel wire inside the tin braces and put in a ½-inch steel rod or mandrel, as you call it, and you can sling out any honey that can be removed.

I am making and selling at cost extractors of the Root style, only I strengthen some weak places. I could use a Root

machine for years, but I find that some not accustomed to extracting require a stronger inside frame when extracting very heavy combs. In conclusion allow me to say that I will furnish bee-hives containing twelve frames of improved style, division-board, bee-feeder, (latest,) entrance blocks and everything complete, painted three coats, ready to put in your bees, for \$1.50 each. I will do this in order to encourage bee-keeping. There is no patent on it that you will be charged for and those who wish to do so can get one for a sample and make their own. I also will give any person one hive free who will get five new subscribers here in Canada for the AMERICAN BEE JOURNAL for 1875, they sending me the editor's certificate for the same, those already sent in not to count.

Kentucky Bee-Keepers' Meeting.

At a meeting of the bee-keepers of Southern Kentucky, at the residence of Dr. N. P. Allen, near Smith's Grove Station, Warren county, Dec. 30, 1874, Prof. C. M. Wheeler was called to the chair and R. A. Alexander appointed Secretary *pro tem*.

Prof. Wheeler stated that the object of the meeting was to organize a Bee-Keepers' Society for the promotion of bee culture.

The following persons gave their names as members of this society:

Rowlet's Station.—Robert S. Mumford.

Smith's Grove.—J. H. Wallace, H. W. Sanders, Dr. N. P. Allen, David Kirby, Wm. G. Allen, J. T. Allen, L. P. Smith, Mrs. M. J. Wolf, R. A. Alexander, Mrs. Kate E. Allen, Mrs. Amanda Allen, Mrs. Lizzie Alexander, J. C. Ellis, Charlie N. Allen, Mrs. Julia Wheeler, Mrs. Mollie Allen, Mrs. Mattie Sanders.

Caverna—Elmore Winn.

Bowling Green.—Eli Howel.

Glasgow Junction.—P. P. Colier, Prof. C. M. Wheeler, David Lock.

Edgefield, Tenn.—H. T. Arnold.

The society then proceeded to elect officers for the ensuing year, as follows: Dr. N. P. Allen, President; H. W. Sanders, Secretary; R. A. Alexander, Assistant Secretary; W. W. Wright, Treasurer. The following Vice Presidents were elected: L. P. Smith, Warren county; S. S. Dunall, Barron county; James Reed, Allen county; R. S. Mumford, Hart county; James Johnson, Todd county; Moses Gath, Butler county; J. H. Ritchey, Cumberland county; James Harlin, Monroe county; J.

F. Ray, Metcalfe county; Thos. Sydnor, Logan county; James Richards, Hardin county.

The President-elect on taking the chair thanked the Society for the honor conferred on him.

The following committees were then appointed:

Committee on constitution and by-laws—Prof. C. M. Wheeler, L. P. Smith, R. A. Alexander.

Committee on questions for discussion at evening session—R. S. Mumford, P. P. Colier, W. W. Wright.

While the committees were out the President delivered an able and appropriate address on bee-keeping.

The committee on constitution and by-laws presented their report which was accepted and the committee discharged.

The Secretary read the constitution and by-laws and on motion they were unanimously adopted.

On motion the wife of each member was declared entitled to membership.

The Society then adjourned, to meet at 1 o'clock p. m.

Afternoon Session.

A communication was received by the President from Mr. Frank Benton, Edgefield Junction, Tenn., on the advancement of bee-culture. The communication was read by the Secretary and on motion the thanks of the Society were tendered Mr. Benton with a request for its publication. Mr. Benton was on motion made an honorary member of the Society.

The President stated that he had received a communication from Mr. James H. Ritchey, of Burksville, Ky., regretting his inability to attend this meeting. Mr. Ritchey stated that his bees continued to gather honey rapidly up to October 10th.

The committee on questions for debate presented the following which were accepted:

1st. What are the advantages of the moveable frame hive over the old box hive?

2d. Is the Italian bee superior to the native or black bee?

3d. How can we manage bees so as to secure the greatest yield of honey?

4th. Is honey, taken before it is capped over by the bees, pure honey?

5th. Can bees be tamed by handling, or can they be educated so as to know their owner?

The first question was then taken up. Mr. Alexander said that the moveable frame hive possessed many advantages over the old box hive. First, we can ascertain at any time the exact condition of

our bees. If they are weak we can by exchanging a card of empty comb from the weak colony for a card of comb with capped brood in it from a strong colony strengthen them in winter. Or if queenless, we can furnish a queen, or give them eggs from which they can raise a queen. Second, if the moths are about to destroy our bees can remove every frame—comb, bees and all—from the hive and destroy the last moth; and if we find them short of stores we can feed them and give them a card of sealed honey from a rich hive, and thereby save our bees from death. We can also Italianize our bees and cultivate a much better bee for honey gathering. It gives us the advantages of the honey extractor, enabling us to extract the honey and return the comb to be filled again, and we can realize a much larger yield of surplus honey.

Mr. Mumford said the moveable frame hive also enabled us to clean our hives of all accumulations of wax and other matter, by removing the combs and bees into a clean hive, and we could make any repairs the hive might need. We could divide our bees and insure increase of stocks without danger of loss by swarms decamping, as was often the case with box hives; and that we could improve our bees in size, and in many respects make them more valuable.

The President said that during rich yields of honey the bees would store it in the brood nest, and by the use of the movable frame we could extract it and make our colonies much stronger in numbers; and that we could insert empty cards of comb in the center of broods, enlarging the brood nest and raising double the amount of bees that would be raised in the box hive. That with the frame hive we had as much control of our bees as we have of our domestic animals.

The second question was then taken up. Mr. Mumford said that the Italian bee was larger, hardier and more prolific than the black bee, and a much better honey gatherer. He had seen them gathering honey from the red clover and from the sapling clover, and that they would gather honey when the black bees were idle; would go farther for it, would defend themselves against the moth better, and that they were more pleasant to handle. He said he had a large gray bee that could gather honey from red clover.

The President said he had never seen the Italian bee gather honey from the red clover except when the blossom was short from the effects of drouth.

Mr. Smith asked what flowers the Italian bees gathered honey from that black bees did not?

Mr. Mumford—"From the red clover and various other flowers."

Mr. Smith—"I understood the gentleman to say he had a large black bee that gathered honey from red clover."

Mr. Mumford—"I said I had a large gray bee that gathered honey from red clover. It is an improved variety of the common bee, as large as the Italian."

Mr. Smith said he had never seen any bee but the bumble bee gathering honey from the red clover, unless he mistook the Italian for the bumble bee. [Laughter.]

Mr. Alexander said in his experience with the Italian bee they were much superior to the black bee as honey gatherers.

The President said that the Italian bee was acknowledged by the great mass of apiarians to be much superior to the black bee and in no respect inferior.

The third question was then taken up. The President said by feeding early and getting the bees strong by the time the honey harvest opened; then give them empty comb in top of hive and as fast as it is filled and before it is capped over throw it out with the extractor. By that management he had the past season taken from one hive 423½ pounds of honey.

The fourth question then came up for discussion. Mr. Mumford thought it was not perfect honey until capped over by the bees.

Prof. Wheeler asked if the fact that honey was taken before it was capped was not the cause of the difference in the flavor of honey.

Mr. W. G. Allen said he got some honey from the President of this Society last season that had been extracted before it was capped over. It was so thin he feared it would sour; he put it in his cellar and now it was candied so solid that he could slice it like butter, and richer, better honey he never saw.

The President said the difference in color and flavor of honey was on account of the different sources from which it was gathered; that honey taken before it is capped over by the bees is pure honey, but was not thick and rich like capped honey until all the moisture it contained was evaporated, which could be done by heating it or allowing the vessels containing it to remain open, so that moisture could escape.

The fifth question was then taken up. Mr. Arnold said he found his bees tamed by handling; that when he visited them often they seemed less spiteful.

The President said there was more in our getting used to the bees than in their getting used to us.

The Southern Kentucky Bee-Keepers' Society then adjourned, to meet at the residence of Mr. B. A. Alexander, near Smith's Grove, Warren county, on the third Wednesday in May.

W. H. SANDERS, Sec.

Notes AND Queries

I found one of my best swarms dead this morning; it was smothered or frozen. It was a box hive and contained about 75 lbs. of honey; the combs were like cakes of ice. The weather is very cold and I fear I shall loose more of them. The JOURNALS came to hand and I find them very interesting.

Denver, Ind.

AARON LEWIS.

It is strange that bee-keepers are so long in understanding that frozen honey is no better ice for bees to winter on, than frozen water would be. We have seen many colonies in just the state your bees were in—hives full of sealed honey with no space empty for the bees to cluster. The very first cold weather, all the bees that come in contact with the sealed honey die, and thus with every cold day the cluster is diminished until there are not bees enough to keep up any warmth. Even when protected, bees in this situation are not safe from freezing. We repeat what we have often said: "More bees die every winter in Iowa from too much honey, than from the want of it."

I have seen it stated that the Italian bees protect their combs from the moth much better than the common bees do; and that when there is no bee disease prevailing the Italian workers are much longer lived than black ones. Please inform me whether these two points in their favor are generally conceded by those who have tried them.

ALLEN WEATHERBY.

We are sure that no one who has kept both Italians and black bees, will dispute that the Italians protect their combs from the moth much better than the black bees do. We have never seen an Italian colony injured by the moth while it was in every tolerable condition, while we have seen many black ones ruined by worms. We doubt if Italian workers are any longer lived than black workers, we think they are quite as long, and do more work while they do live; and if left queenless by accident, an Italian stock will maintain itself longer than a black stock can in like circumstances.

Belleville, Canada. Do you think the tulip tree would grow as far north as this

place. Apples, pears, plums and all kinds of fruit grow very well, white clover is indigenous, basswood is the ordinary fruit wood, with maple and beech. Buckwheat is an abundant crop generally; wild raspberry and all small fruits grow well. The tulip tree is a new idea, to me, and I would like to try one to see if it can be made to grow. Is it more productive of honey than basswood? L. WALLBRIDGE.

We would like to see the tulip tree tried in your section of country, and are quite sure it will do well. Here they grow fast and, so far, are handy. It is not more productive of honey than the basswood, but the honey is of very different flavor, and we think it remains in bloom longer. If any reader in Canada has tried the tulip tree, let us hear a report as to growth, even if it has not yet bloomed with him.

I am a beginner, and started last spring with an Italian and a black swarm. I got from these one black swarm and nine good hybrid swarms, and I received from all, over 200 lbs. of honey, which sold mostly at 20 cents per lb. I have now about 30 good combs in Langstroth frames. We had a terrible drouth here, I succeeded very well in every operation except introducing queens. Late in the season I ordered two Italian queens from Mr. Dadant, put them in, following Mr. Hamlin's plan; both died. From eggs the bees raised a queen, but it is doubtful whether she got fertilized or not. Now instead of having two more Italian colonies I lost the queenless one. Now, I intend to move to another place where there are no shade trees at all, so I would like to know what to plant to have shade by the latter part of May. How will hops do? and how to arrange it, or if it is better to erect a shed? I shall have to manage from 8 to 12 hives. Also, which is the best way to protect combs not in use in winter, as well as in summer? GUSTAV ILISCH.

Hickman, Ky.

You are unfortunate in getting queens so late, but your experience will help you next season. Try some other way to introduce; there is no need of loosing queens when putting them in.

In regard to shade for your hives, another season, we would recommend sunflowers planted like a hedge, south and east of them, as more sure to afford shade the first year. Grapes or hops, if planted this year, will give them shade next. We do not recommend a shed; if your hives have deep caps it is not necessary to have any other protection, but we like shade for bee hives, and believe on the whole it is best.

Riverton, Iowa. We are having very severe weather here. Part of my bees are buried, and a part surrounded by straw. I am afraid I shall loose many, because my stocks were weak in the fall. On the last part of September and first part of October, when it was warm, my bees were busy, but I noticed hundreds of fall flowers in a

stupor. They could crawl but not fly. I can give no cause for it. I noticed it at mid-day, when the thermometer stood at 80, and on moonlight nights.

E. WELLINGTON.

What blossoms were the bees on? Can any bee-keeper account for this, or has any one noticed the same thing?

I think it would be interesting to many readers of the JOURNAL, and particularly so to me, if you will answer the following: Is Florida a good State for the honey bee?

If so, what localities are considered best?

At what season do bees swarm there?

What are its honey resources?

Can you give the address of one of its intelligent apiarians?

J. B. H.

Florida is a good State for bees. Reports from bee-keepers there, who are giving attention to the business, are very favorable.

Any location where man can live is good—none have been tried long enough to decide comparative merits.

Bees swarm from the middle of March to May.

Honey resources are wild flowers, tulip tree magnolia, various wild shrubs, orange blossoms, etc.

Mrs. Charlotte Atkinson, Live Oak, Fla.

I have my bees in good comfortable winter quarters, a good bee parlor partitioned off from the main cellar of the dwelling house where they are apparently enjoying themselves cherily, with the low humming song of the busy bee, wholly unconscious of the rigors of the elements outside, which are consigning millions of their less fortunate fellows to the cold embraces of eternal death.

P. MILLER.

We congratulate all who have their bees housed properly, this terrible winter. We shall hear of many losses when spring comes from those who are wintering on summer stands, without protection.

When can I transfer my four hives, now in common, rough boxes, into movable frame hives. I know that they have a goodly store of honey for the winter, and in this climate the bees go out for a little every day, excepting the few days in the year when it is very cold. At present we have still roses, sweet olives, scented violets, &c. in bloom in the open garden. I keep my hives under a large plum tree; they have no shed or other shelter. I know there are some worms in the hives, how can I get them out? When is the time to buy Italian queens? Should I need one for each hive? We are doing very well; but the water came and drowned all our little place and washed away the labor of years.

Hermitage Landing, La. L. LAWSON.

We have great sympathy with them who have seen the labors of years destroyed by floods or insects. We send you the JOURNAL, being sure that you will find in it

needful instruction. You have a good place to keep bees; they need no other shelter than the plum tree. You will find good methods given in the JOURNAL by which to transfer your bees into movable comb hives and after you do that, you can aid the bees to keep clear of worms. We think May or June would be your best time to put in Italian queens,—at the North almost any time from May to November will do. We hope to hear of your success.

Voices from among the Hives.

D. S. McCALLUM, Hornellsville, N. Y., writes:—"My bees have done very well this year. I had 60 swarms in the spring and some of them rather poor. I increased to 100 by natural swarming, and they made 5,100 lbs. of box honey, including that not capped. I put them into winter quarters in Nov., and they appear to be doing well."

B. F. H., Livingston, Ala., writes:—"There are plenty of bees in this section, but they are kept on the old plan—allowed to care for themselves; and if an annual "robbery" yields 15 to 20 lbs. of honey, the "robber" thinks he is doing well. My first task will be to try transferring to a movable frame hive. Shall undertake it with fear and trembling, and numerous stings, I guess."

J. W. DUNN, Corpus Christi, Texas, writes:—"Last March I got a hive of Italian bees from S. W. Cole; they were 13 days on the road; came out in good order, increased to five and lost one (run-away); the five I have are doing well, plenty of honey and brood. I shall not run my bees for honey, as there is a demand for all the bees I can raise at \$20 per hive. I use single-story Langstroth size."

F. C., Bethlehem, Iowa, writes:—"Bees have done well, when attended to; mine average 80 lbs. to the swarm, and an increase of $\frac{1}{2}$ during linn. I extracted 1,200 lbs. in 84 days from 20 stands, in hives containing 20 frames, one story, "a la Gallup." I am fully convinced the majority are upon their right track on wintering. Put your bees away early, or at least do not let their combs become frozen or damp. Keep them dry and cool. If your depository is dark, dry and frost proof and the bees put in proper shape with regard to ventilation, according to size of swarm, you need not fear bee diseases."

Mrs. M. E. CHANDLER, New London, Minn., writes:—"There are no Italian bees nearer than 3 miles of us, yet out of thirteen queens fertilized last summer, four produced hybrids; two of these swarms were very light colored two banded bees; the other two were a mixture of black and one banded hybrids. A friend of ours also had a swarm of hybrids, when there were no Italians nearer than 6 miles. Under these circumstances I think it would be well for Italian queen breeders to be careful how they warrant their queens, when there are black bees within five or six miles of them, that is, if black drones will go as far from home as the Italian drones."

B. H. IVES, Austin, Texas, writes:—"I beg to be excused for contradicting "Purchase" on page 203 vol. 10, No. 9, of A. B. J. He says "bees express no more love for their keepers than for a stranger," my experience is different. I left my bees in the country in May and went to town where I remained until Nov. When I left them I could stand near the hives and in front of them without fear of molestation, and could work with the bees without protection.

But when I returned I could not go near them, they would not let me stand near the hives, and it was several days before they became acquainted with me, but when they did, they allowed me the same privileges as before I left.

JOHN T. CONNLEY, Union, Ky., writes:—"The bee business is at a low ebb in Boone Co., Ky. We have never recovered from the disaster of 1869-70. In the spring of 1870 there was not left in this large county as many as 10 swarms of bees. Movable frames were never introduced until since that time, they are only used now by 3 or 4 persons. Italian bees are very scarce here. My bees paid me last season over 225 per cent. I use the Langstroth 21 frame hive; have never seen an extractor in use. "The old Log Gum" is common, and in use in every neighborhood about here yet. This has been a disastrous winter on bees in old Boone Co. They are all dead as far as heard from; lots of honey in the hives, combs sweet, clean and bright. My bees are Italians, all went into winter quarters strong in numbers and in good condition. I have lost two swarms; winter on summer stands. What kills the bees? Who can say?"

SALLIE DICK, Maple Grove, Mo., writes:—"We wanted to extract, and as we could not wait to send off for a machine, my husband made one. He ordered a galvanized iron can with shoulders for the running gear to rest on; and then procured some wire cloth, coarse mesh, to hold the frames in; put a stay in the bottom of can with iron or steel point in the end of wooden upright; on top of wooden upright was a small wooden wheel attached to a larger one by a leather band. We extracted 28 gallons of the nicest honey. I think made from golden-rod, by the color. I would not do without the extractor another year for anything. Our bees are put away in good order. We made our yard fence on the west, with boards fitting together, and by setting a row of posts in front shorter than the fence so that a roof is formed from the fence to them. Our hives are placed there, packed with straw and boarded all around. The entrance of hives are open on the east, one board left off at the bottom. But on cold days a board is placed along on the east to keep out cold winds. We have six stands in the cellar. It has been very cold here for the last three weeks; the ground is frozen hard. The mercury standing from 6 above to 15 below zero.

I wish John L. Crabb, of Onawa, Iowa, would give a description of his honey extractor through the JOURNAL. A man can give so much better description of such things than I can. He says in the last JOURNAL that he can make one in half a day that will extract a barrel a day. He says it would make us laugh to see his extractor. Why not indulge us in a good laugh?"

American Bee Journal.

THOMAS G. NEWMAN,
 Cedar Rapids, Iowa.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

MELLOT CLOVER, for sale at 30 cts. per lb. Larger quantities at low prices by Italian Bee Co. Des Moines, Iowa.

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

Subscribers wishing to change their post-office address, should mention their old address, as well as the one to which they wish it changed.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

JOURNALS are forwarded until an explicit order is received by the publisher for their discontinuance, and until payment of all arrearages is made as required by law.

We do not give our Chromo when subscribers club with other publications, unless they add 25 cents to the amount of the club subscriptions, and say they want the Chromo.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

"MONEY IN THE APIARY."—Such is the title of a practical little work just issued. All who wish to make the most money out of their bees should send 25 cents for a copy to Herbert A. Burch, South Haven, Mich. See advertisement in another column.

I use an article that never fails to subdue bees while I work among them. One ounce is enough for ten years issue. Those who wish to know anything about it should write me. I will trade for Italian bees.

W. N. CRAVEN.

Poplar Bluff, Butler Co., Mo.

TO WHOM IT MAY CONCERN.—Mrs. Tupper has received at different times through this office, in the years of 1873-4 imported bees and queens from Italy, to the care of the United States Express Co., at New York, and they have come through in apparent good order.

W. H. QUICK,

Div. Supt.

We have received a sample of friend Muth's one and two pound green glass square Honey Jars. They are very nicely made, and have a "hive" and "Pure Honey" moulded in the glass, besides being labeled. The cork and tin foil are of the best quality, and the cap is also stamped "Warranted Best Quality." They are very nice, and our readers will do well to get them for retailing and creating home markets for their honey.

THE AMERICAN NEWSPAPER DIRECTORY is an epitome of newspaper history. It is also regarded as an official register of circulations. This feature, requires the closest scrutiny to prevent it from leading to abuses. The plan, adopted by the publishers of the DIRECTORY, to secure correct and trustworthy reports, is rigid in its requirements and adhered to with impartiality. Successful publishers who have something to gain by a comparison, are generally prompt, not only to send reports in conformity but give Messrs. George P. Rowell & Co. such information as enables them to weed out unsubstantiated statements of pretenders in journalism. The popularity of the book, and the general confidence in its accuracy and good faith are attested by the immense body of advertisements it receives.

Back Volumes.

Complete sets of back volumes are scarce. But few can be procured at any price. We have a set, consisting of the nine volumes (complete), which we offer for sale, either bound or unbound, for a reasonable sum. Many of the numbers we have paid fifty cents each for, to complete them.

We have several single volumes (complete) which we will send postpaid for \$2.00 each.

Several volumes, which lack only a single number of being complete, we will send postpaid for \$1.50 each.

Vol. 1, we can supply in cloth boards, postpaid, for \$1.25. Bound in paper covers, \$1.00 postage 10 cents. This volume is worth five times its price to any intelligent bee-keeper. It contains a full elucidation of scientific bee-keeping, including the best statement extant of the celebrated Dzierzon theory. These articles run through eight numbers, and are from the pen of the Baron of Berlepsch.

Beginners in bee-culture, who desire to read up in the literature of bee-keeping, are earnestly advised to obtain these back volumes. Many of our best apiarists say they would not sell their back volumes of the AMERICAN BEE JOURNAL for ten times the sum they cost, if they could not replace them. They are exceedingly valuable alike to beginners and more advanced apiarists.

Our Club offer made on page 24 of the January number concerning the clubs of ten and twenty is withdrawn.

Italian Bees & Queens!

AMERICAN BEE JOURNAL,

DEVOTED EXCLUSIVELY TO BEE CULTURE.

Vol. XI.

CEDAR RAPIDS, APRIL, 1875.

No. 4.

American Bee Journal,

W. F. CLARKE,
MRS. E. S. TUPPER, } EDITORS.

Seasonable Hints.

The eggs of a queen are developed by heat, just as are the eggs of a fowl. Bee keepers are apt to forget this, in the spring, and do not economize the heat of the hive. We have seen hives out of doors in this month of changeable weather—with all the holes or top open, and the entrance as large as it ought to be in summer. Bees need no ventilation now. Every crevice should be closed and the quilts kept on the frames, that none of the heat generated by the cluster escape. If there are but few bees in the hive, we always remove all comb except as much as the bees can cover. For instance if the bees can only protect the brood, deposited in two combs, take out all the others. As the circle of brood grows larger and the weather warmer, add one comb at a time until the hive is full. In this way we succeed much better than we did when we left the hives full of comb. We have always fed colonies that needed it inside the hive, on top of the frames or in one side—and have no experience in feeding all together in the open air; but Mr. Dale, one of our most successful Iowa bee-keepers, tells us, that he has practiced feeding outside the hives with good results. We inquired if he did not in that way feed his neighbor's bees, with his own, and he gave us his method of preventing this, as follows:

“I put the sugar syrup into my shallow feeders, near the hive, quite late in the afternoon, after all is quiet about the hives. At that time my neighbor's bees are at

home and will not be attracted by the food. To make my own bees find it—I go to the hives, with a dipper of the syrup and a spoon and throw a little into the entrance of the hive. The bees rush out, as bee-keepers know they will do, in such cases, go to the troughs and work busily until all is taken up. I give them no more then they can carry in; if any remains over, I take it away.”

Mr. Dale says it is fun to see how busily they work at it, and how much good it seems to do them. We shall try this method in our own apiary as soon as spring comes. We need not say that it should not be tried when there is any chill in the air, and would also advise that the syrup should be quite warm when put in the troughs. Weak colonies will be the better for feeding inside the hive, in addition to this.

Be on your guard against robbery. Prevention of this is easier than cure. See that every hive has a queen—have all entrances closed, and there is little danger. If you see that robbers are attacking a hive, take it at once to the cellar until all bees are in the hives, then take it out and examine it. If it is queenless, give it a frame of brood from another hive, if you have no queen for it; but if it is only weak, protect it, and it will take care of itself. T.

Experiments with Honey.

A correspondent of the *Scientific American* has been experimenting to prevent honey candying, and states his experience as follows: During the past autumn, I have experimented as follows: I put up six 1 lb cans of beautiful linden honey, being careful to make it into one homogeneous mass by stirring. It was thrown from the combs by an extractor on July 20, and put into cans on Aug. 1. The cans were placed respectively as follows:—one in a dark, dry

cellar, one each under shades of red, yellow, green and blue glass, and the sixth can in full light. On Nov. 8, the honey in the cellar candied to a white. Nov. 22 to Dec. 10, honey under colored shades candied, first in the red, next in the yellow, green and blue; while the honey in full light remained transparent until January, when it soon candied after exposure to intensely cold weather. From my experience an equal temperature would preserve certain kinds of honey, while other kinds would candy under almost any circumstances.

I think that candied honey, instead of being looked upon with disfavor, should be recognized as evidently pure. I hope, however, that the above experiments will lead others to follow up the light theory with beneficial results.

HONEY LOCUST FOR HEDGING.

In reply to a question respecting the honey locust for hedging the *Western Rural* says:

The honey locust, *Gleditsia triacanthus*, is a tall, handsome tree with a spreading top. So far as hardiness is concerned the honey locust is entirely so, far north of the line of hardiness for the Osage Orange. It is not a hedge plant, if by this you mean a plant that may easily be kept within the bounds of an ordinary hedge, but as forming a barrier to stock, it is cited by practical Western horticulturists, among others Mr. A. R. Whitney, of Lee Co., as being among the very best. It is not liable to disease or insect depredations to any considerable extent.

It would take five or six years from the time of transplanting into the hedge-row to make a barrier against cattle, and unless good care was given it, longer.

Plant the seed by all means in seed beds as is practiced with Osage Orange and transplant at one year old, cutting the plant back to a height of six inches when dug for putting into the hedge-row.

Before the Legislature.

The Michigan Bee-Keepers' Association is before the Legislature of Michigan, with the following memorial:

To the Honorable, the Legislature of the State of Michigan: The Michigan Bee-Keepers' Association would respectfully represent that they have been organized and in successful operation for the past 7 years, and its proceedings have been published throughout the States and Europe with great credit to the organization and the State of Michigan, and that it has in view the building up, out of comparatively nothing, one of the greatest industries of the State, thereby effecting the perfect crossing and fertilization of our vegetables, grains and fruits, preventing their deterioration and greatly increasing their certainty and productiveness, collecting only the surplus pollen which would fall to the ground

and the excessive nectar which otherwise would evaporate into the air, storing it in frames and boxes for use as food, ultimately saving millions of dollars worth of waste product. Your memorialists, therefore ask an appropriation of one thousand dollars to enable them to make an exhibition of Michigan flowers and honey at the Centennial Exposition at Philadelphia in 1876, believing such exhibition would redound to the credit and honor of the State. Said honey to be furnished gratuitously by the members of the Association and finally sold and the proceeds used for printing our annual discussions for gratuitous distribution.

H. E. BIDWELL, Pres't.

HERBERT A. BURCH, Sec'y.
South Haven, Mich., Jan. 20, 1875.

A CHINESE BEE.—The Apicultural section of the Entomological Society at its annual meeting in Paris, August, 1874, made many interesting statements. M. Durand Saint-Armand, a government officer in Cochin China, states that that country possesses a bee twice the size of ours, which consequently ought to have a proboscis long enough to extract the honey from red clover, which is known to be very abundant. This bee is found in great numbers all along the coast, in a wild state, in hollow trees, and the natives hunt them for their wax. The extensive forests of this country are leased for the product of wax, which is to be sold to the Chinese. M. Durand Saint-Armand has acquired a certain knowledge of bee culture so to be able, if possible, to domesticate the bee and send them to France. Would it not be well for our bee keepers on the Pacific to investigate this? It has a promising look.—*Country Gentleman*.

One of the last Acts of the late Congress was to double the rates of postage on books, pamphlets and general merchandise. The following from the new law will be interesting to publishers:

That section 8 of the Act approved June 23d, 1874, making appropriations for the service of the Post Office Department for the year ending June 30th, 1875, and for other purposes. "Be and the same is hereby amended as follows: Insert the word "ounce" in lieu of the words "two ounces." Approved March 2d, 1875.

The second semi-annual session of the Michigan Bee-Keeper's Association will be held in Kalamazoo, Mich. May 6th 1875. We earnestly request a full attendance of the members of the association, as matters of vital importance to all engaged in apistical pursuits, will be presented for their consideration. We also extend a cordial invitation to all persons, interested in bee-culture to be present. Remember the time and place—Kalamazoo, May 6th, 1875.

HERBERT A. BURCH Sec'y.
apl2m South Haven, Mich.

AND Notes and Queries

Are queens wings clipped to prevent them swarming? or to prevent them leaving hives at other times. If queens do not leave at other times, cannot you give some other method that will accomplish this result?

Would you advise attempting to increase from two strong pure Italian stocks to six this season, the object being to increase with honey enough to winter on. Would it be safe to increase further?

CLAS. E. SELKIRK.

Some queens wings are clipped to prevent swarming, but more are marked, we think, to be sure of their being the same one bought. It does not prevent their leaving the hive. They do not seem to realize that they cannot fly and are more liable to be lost if clipped, than if they can manage themselves naturally. We do not clip a queen for any purpose.

We are sure you will find no trouble in increasing from two good colonies to six. To do it surely, however, you would have to feed liberally in the spring and perhaps again during dry weather in August.

Will you tell us if there is any danger of bringing "foul brood" to our aparies, by purchasing queens from Europe as Mr. Bingham and others assert.

T.

There may be danger, if the queen is brought from some parts of Europe, but we think foul brood has never existed in Italy. We have never seen a case of this disease in all our experience. All the queens we have received from Europe have been healthy, if alive.

I sent my last letter for publication in the JOURNAL. I think where persons impose on us and take a high price for hybrid queens, they should be exposed, that others may not loose money in the same way.

G. H. WILLIAMS.

There are two sides, to this question. This JOURNAL has not taken upon itself to pass judgment upon others; believing that its columns may be better filled. If we give place to complaints, we must in justice to the other side give explanation, and the door once opened to complaints and excuses, however just, much valuable matter would necessarily be excluded to make room for them.

There is still another reason. The law gives us no right to publish facts even, if their tendency is, to injure the business of another. If a suit for libel be brought against us—it would not be sufficient for us to prove that what we had published was

the truth. In law "the greater the truth, the greater the libel." If we have ourselves been injured by any one, we have redress in a suit for damages. By no law, human or divine, have we been made a judge of the business, even of those who advertize with us. We admit nothing to our columns, known to partake of the nature of a humbug. Though we may not believe all that our advertizers say about their patents—hives or other articles—we learned long ago that all do not think alike on these matters. Others may value what we do not think valuable. We try to give rules and records of experience, and let all judge for themselves. Every one has a right as well as a desire, in bee-keeping, as in other matters, to "prove all things, hold fast that which is good."

Please describe Melliot clover. Is it good for anything but bees?

JOHN H. GUENTHER.

Melliot is good for nothing but honey, unless it may pay to plough it under for mulching. It is the "sweet clover" found in many flower gardens; grows three feet high or more, branching out at the bottom, and remains in bloom nearly all summer.

Is it best to give bees flight before moving them ten miles. They are yet in the cave.

NEWSOM BROS.

It is alwas best to give them a flight before moving them any distance, after taking them from any winter repository.

Having a friend going to Europe I intend to send for some bees. Can you tell me how many Mr. Dadant brought home alive on his second trip to Europe?

J. C. B.

Mr. Dadant did not go to Italy the second time as he advertized and expected to do. We are not informed, why he changed his plans. We sent him an empty comb to take with him by his request, and until July, thought he had gone. No doubt unforeseen occurrences prevented. Last season he imported queens direct but did not go himself.

What is the best way to Spring weak colonies? Is wild rice a good honey plant? What time does it blossom, and how long does it stay in bloom?

A. ASPINWALL.

You will find this question partially answered in Seasonable Hints. Be sure your weak colony has a good queen, keep the hive closed, leave no more comb than the few bees can cover—and feed them regularly, all the syrup they will use. We have seen a pint of bees in March with a good queen and two combs changed to a large colony having twelve combs well filled with brood by last of May. Will some one who knows—tell us about wild rice?

Is sugar syrup as good as honey to feed bees; and if so, what grade of sugar is best.?
ELLA.

We prefer sugar to honey, even at the same price. I have always used Coffee A., but Mr. Dale informs us, that a good grade of New Orleans sugar goes farther, and he prefers it, having fed it in quantities with best results.

Voice from among the Hives.

JOHN H. GUENTHER, Theresa, Wis., writes:—"Finding my bees uneasy I gave them water and by this means soon resorted the hives to their quiet condition."

A. SALISBURY, whose directions for wintering bees were given last fall in the JOURNAL, writes:—"Out of near 200 swarms of bees I shall not loose one this winter. 56 are on their summer stands, the balance indoors."

B. Y. THORNTON, Knightstown, Ind., writes:—"I have received "Money in the Apiary," advertised in the A. B. JOURNAL, and must say it is the poorest thing (the nearest nothing at all) that I ever saw or heard of on bee-culture, or any other subject. Two whole pages devoted to managing an apiary for profit in that miserable little 2x3 pamphlet, the balance all taken from the A. B. JOURNAL. They are certainly all cheek to ask 25 cents for such a miserable little advertisement."

JOHN J. WILLIAMS, Bachmanton, Ohio, writes:—"I wish to ask a question. My bees commenced dying last fall, in the warm spell after severe cold for several weeks. I found many in the bottom of the hive and in the cells dead, but puffed up almost as large as a queen. If I squeeze them they will pop, and the perfume is almost unbearable. On the 22d, of Feb. it was a bright day and the bees had a fly and the snow looked like as though it had red paint thrown on it. This is the first fly for 9 weeks. I winter on the summer stands. In the hives that died there were no brood but plenty of honey. I use Davidson's Patent American Hive, made of pine wood. I don't know if diet has anything to do with it. I hope some one will be able to give me some light on it."

J. P. MOORE, Binghamton, N. Y., writes:—"Bees are wintering finely here, though the winter has been severe. I am using saw-dust pillows this winter, over my bees, and like them much. They are made of heavy old wollen carpet with 2 inches of sawdust for in-doors, and 4 inches for out-doors; use very coarse hemlock sawdust, from a log saw, thoroughly kiln dried. I raise up the pillow at any time and put my hand over the cluster, and find it warm and dry; my out-doors hives are packed with about 6 inches of buckwheat chaff, underneath and on all sides. Some stocks have died in the neighborhood, that were left out in some hives, without any preparation for winter. I think they might have been saved if a portion of their honey had been taken away and a quilt, a straw mat, or a sawdust pillow had been put over them, and the cap filled with straw."

J. D. M., Richland, Wisconsin writes:—"I have 60 swarms in the cellar, some in the American hive. I built a house here about 20 years ago and got my bees from a tree close to the house and saved them when they swarmed."

GEO. PERRY, Peru, Ill., writes:—"I have nine swarms in the cellar, put in the 2nd of Jan. and thus far they seem to be doing well; three of them got uneasy and I gave them a little water; they have quieted down. I am in hopes to set the little prisoners free in a few days."

MILLER WILSON, Meredith, Pa., writes:—"My repository worked like a charm this winter. See page 20, Jan. 1874. Potatoes would not have frozen had they been in it. But fully one half of the potatoes is frozen in this country."

Although the weather has been dry I have heard of no bees dying in this vicinity yet."

J. W. MCKINNEY, Camago, Ill., writes:—"The same thing spoken of by C. Wellington, in March number of "A. B. J." was noticed by me last Sept. The bees were on the bloom of the Spanishneedle. The under part of their body was usually daubed with a resinous, sticky, aromatic exudation from the bloom. The bees appeared to be stupefied as if badly intoxicated."

I noticed some in the same condition about the month of the hives, daubed with this Spanishneedle gummy pollen."

H. E. CURRY, Cincinnati, O., writes:—"I have examined our hives and find them all in good order; some of them have brood in three sheets, they got natural pollen one day, but we have had cold weather since and I am afraid it will be killed. I never had our bees work on flour, as they did this year; they were as crazy after it as they are at robbing in August. We winter out of doors with mats on, and on examination we did not find the slightest trace of mould. The thermometer stood 12 degrees below one day but I need not tell you we have had a very severe winter."

CHAS. SONNE, Sigel, Ill., writes:—"The winter here in Central Illinois was probably as hard as almost anywhere. I wintered on summer stands, 42 hives. 19 of these were in hives which had straw packing on top, on the back and in front. The sides are double inch boards with thick wool paper in between. Of these 8 died, although they had plenty of honey and plenty of bees. The other 23 were in hives which had straw packing as above, but had also straw packing of 4 inches on both sides. Of these none died. Query: Does this show that warm packing saves bees?"

MOSES BAILEY, Winterset, Iowa, writes:—"Last May I had 12 colonies of bees with queens and 2 without. I increased them to 74 colonies, took 1000 lbs. of honey (ext.) and most of them had sufficient stores left to winter well, but on account of several queens mismatching, &c., (brood hybrids.) I reduced the number down to 42 colonies by sale and uniting colonies, the 42 were set in my cellar Dec. 16th, 1874, and a chance one shows a slight indication of dysentery for a few weeks past. Some colonies appeared thirsty and I gave water two or three times. Some took it eagerly. Shall set them out in 3 or 4 weeks if the weather warms up sufficient to do so."

Correspondence.

For the American Bee Journal. A Word of Cheer for the Workers.

AN ADDRESS BY FRANK BENTON, OF
EDGEFIELD JUNCTION, TENN., BE-
FORE THE SOUTHERN KEN-
TUCKY BEE-KEEPERS'
ASSOCIATION, DEC.
31st, 1874.

It is gratifying to know that, in a time when the country is suffering from a great financial depression, a body of her intelligent citizens will gather to unite in the discussion and dissemination of knowledge concerning a branch of economy, which, with proper attention would add no inconsiderable amount to the wealth of the country. The eight millions of dollars annually produced in the United States through the agency of that industrious insect, the honey bee, is almost a clear gain to the country since their labor saves what would otherwise go to waste, a fact which has been frequently expressed by the sentence: "They work for nothing and board themselves." When we consider that the country could, to say the least, support three times as many bees as are now within her limits, (and that too without decreasing the average yield per hive,) and thus place the annual return from this branch of rural economy at twenty-four millions of dollars, we see the importance of such assemblages as this for the promulgation of all practical knowledge of the habits and best method of managing these sweet creatures, and the "Goddess of Liberty" may well afford to smile at the *honeyed* words dropped by her hardy sons of toil.

There have been three steps in Apiculture which, when compared with the rest of its progress might be termed mighty strides toward perfection: The introduction of the movable-comb hive was the first of these. It is well recognized among progressive beekeepers that this step has completely revolutionized the keeping of bees. By the use of movable-comb hives the bee-keeper can ascertain at once the exact condition of the interior of every hive and is thus enabled to remedy all accidents which happen in each little community, (for accidents do happen to bees as well as to human beings); he can secure larger yields of honey and in a more saleable form, while rapidly increasing the number of his colonies in a new and safer manner than by the old method; in short, he can regulate the labor of his bees as certainly as he can those of any other domestic animals.

The second stride in apian pursuits was the introduction of the beautiful golden-banded Italian bees. Though discovered among the Alps mountains early in the present century they were not brought to this country until 1860, and this date marks the commencement of an important period in the history of bee-culture in the United States, an era of progress. The peaceful disposition of the Italians, their great industry, causing them to accumulate a surplus of honey while common bees are gathering none, their complete defense of their

combs against the ravages of the wax-moth larva, their disposition to adhere evenly and quietly to the combs when handled, the prolificness of the queens, and their great beauty,—all these are qualities which commend themselves to us, while we cannot find that they are inferior in any respect to the common race of bees. Their introduction has aided in the practical solution of many disputed points in the natural history of the bee. How easy, now, to determine the average length of life of the worker-bee. Just place a purely fertilized Italian queen in place of a common queen in a populous colony. At the expiration of three weeks the last black workers will have hatched, and the yellow-banded Italians will begin to gnaw their way out from their prison-like cells. In a few more weeks none but the gentle race of Italy can be found in the hive. Each little laborer has but a few weeks to live and labor, and then, having literally worn herself out tugging in her loads of bread and nectar-food she bequeaths her accumulated wealth to the support of the generations that come after her and which are to perpetuate the little community through the dreary period intervening between the harvests. Surely here is an example of patience and persevering industry that should not be unheeded by the fretful, the irresolute, and the idle!

Last, but not less justly entitled to rank as one of the mighty strides of modern Apiculture came in 1867, the honey extractor or mellipult as it has been styled,—the result of the inventive genius of Major Von Hruscha of Austria. This machine is simply a tin cylinder in which to revolve the combs and throw the honey from the cells. It is so simple that the inventive American wonders why it was not thought of sooner. By its use two or three times as much pure honey can be obtained from each hive; and many seasons when no surplus can be obtained in boxes a good yield can be secured with the extractor; besides, colonies can be assisted greatly in keeping up their numbers by having the brood combs emptied of honey frequently. Who can say after all this progress that there will not yet be such additional advancement made as will place apiculture in the front rank among rural specialties?

Thanking you most heartily for your kind attention, I close by expressing the hope that, in this—your first meeting you will not, as true Kentuckians forget the motto of your beautiful State: "United, we stand; divided, we fall."

For the American Bee Journal. Criticism.

In the *Prairie Farmer* of the 13th, Prof. C. V. Riley takes up the cudgel ostensibly, in defence of Dr. Le Baron, State Entomologist of Illinois, because I had briefly criticised the fact of Dr. Le Baron's copyrighting his Fourth Annual Report. My criticism was in the form of an enquiry; and if Dr. Le Baron considered himself aggrieved, he is doubtless abundantly able to defend himself. But the latter part of Prof. Riley's communication, shows the animus which prompted it. It was to say a word for Prof. C. V. Riley, and to vent his spite against me, for giving a plain and correct statement of facts, albeit said facts were not especial

ly flattering to him; forgetful of the fact that in a Republican form of government it is one of our inalienable rights to discuss every question affecting our welfare."

Now for Prof. Riley's investigations in the department of entomological research, in so far as they have been beneficial to horticulture or agriculture, or to any of the human family, in any of the pursuits of life; he has my thanks and my gratitude. For his language and logic in his communication he has my contempt. He says, "she puts language into my mouth which I was never guilty of, (i. e., misquoted him) and otherwise falsifies my statements." How otherwise could I falsify his statements? And again, "I ask the readers of the *Prairie Farmer*, who are also readers of the *AMERICAN BEE JOURNAL*, to consider what I have said on that subject over my own name rather than the garbled account in question."

Where "over" or under his own name, has Prof. Riley given an account of what he said on that subject, (the relation of the honey bee to horticulture) at the last meeting of the Illinois State Horticultural Society? What he may have said at any other time, or place, in the *New York Tribune* or elsewhere, "over his own name," is no proof of what he said, or did not say at Peoria. If Prof. Riley has said at a Methodist class meeting that "milk is good for babes," is that proof that he has not said at any other time or place that "oysters and champagne are fine." Thus much for his logic. Now for the truthfulness of his language. That he did express himself substantially as quoted I affirm; and for the correctness of my assertion refer to Mr. Dunlap, or to Mr. Gaston, who took part in the discussion, to Dr. Hull, and especially to Mr. O. L. Barler, who I believe reported the proceedings of the Society; and finally to any member of the Society who was present. And furthermore, that as far as his remarks were pertinent to the question under consideration, (whether the honey bee was the friend or enemy of horticulture) I believe my report was a verbatim one.

Now this very polite and courteous professor says that I gave a "garbled account, misconstrue and falsify," now I shall not say that his statements are as far removed from the truth as he is from being a gentleman, and leave the public to judge the distance; but think if this polished and urbane professor can stand such language and such logic, I, being a woman, certainly can. If I were a man, I should simply say C. V. Riley is a——; gentle reader, you know how it is yourself. Mrs. L. HARRISON, Peoria, Ill.

For the American Bee Journal.

Three Hundred Years Ago.

My object in writing now is to give some extracts from a book on bees published nearly 300 years ago, and through it I will endeavor to show that with all our boasted knowledge of the bee we know but little more than was known at that time. The only difference is that but few knew anything of the habits of the bee, to-day many know it. The book is entitled "A Theatre of Political Flying Insects," wherein the nature, worth, work, wonder and right-ordering of the bee is discovered and des-

cribed together with Scriptural and moral meditations added. Written and published by Samuel Purchas, M. A., in the year of our Lord, 1600. The moral meditations I would like to give the advice, would be of benefit to our more modern bee-keepers and there would be less backbiting, ill-feeling and desire to over-reach each other. S. Purchas speaks of consulting writings on the bee written many years before. His book is dedicated to Lord Robert, Earl of Warwick. I shall only give extracts that relate to the bee so that you can form an idea of his bee knowledge and compare it with yours.

In regard to queens, he says: If the queen bee should fall from a swarm through weakness her attendants will remain with her and starve with her rather than forsake her. The queen bee is a very amiable creature, of a bright color and more transparent than other bees, she is somewhat yellow about the belly and on her legs inclining to a golden color, and the color intimates the princely nature and royal blood (could this be the Italian?). If a queen bee miscarry in the hive, or by flying forth for recreation or impregnation, or otherwise stirreth not forth, come in some mischance, all her attendants are in mourning and confusion.

The queen is a royal creature, therefore she works not, it is beneath her dignity to drudge and toil. Though she has a sting yet rather an ensign of power than an instrument of revenge, for she never useth it. There is a magnetical attractive force in the queen bee, so that what the loadstone is to iron so is she to the rest of the bees—where she is, so will they be.

In regard to drones, he says: Bees when they are weary of the drones and have no further use for them, and fearing future want by their gormandising, show their dislike by molesting them. If this will not cause them to depart, set upon them and slay them. Drones labor not, but to the eye are goodly creatures, fairer and larger than worker bees, make great noise and are vain glorious. Observe them as often as you will and you will never find them carefully endeavoring their present or future good. *Nil dignum tants sonitu.*

As to workers, he says: Worker bees are laborious in their youth and yet are not idle in their old age. Even if she findeth not honey in one flower goeth she to another. They feed on honey, which over liberally eaten produceth cholera. No wonder they are furious and choleric creatures. If confined closely they will gnaw away the impediment, though they have ease and air.

The field wherein bees feed is not a whit less from their feeding, but that oxen and sheep may grow fat. Bees can with facility dart out their stings, but have no power to withdraw them, except from a dead body, which she taketh no hurt, but in a live body she looseth both sting and life. It is a fabulous conceit that a bee when she looseth her sting becomes a drone, for it is not so, she dies. Bees though they be engaged in a furious strife with other insects wreck their spite by biting, and only when transposed with rage will they use their sting, only to their own ruin and destruction. She may trouble awhile with her buzzing but can do no further hurt. Bees smelling a field of cole-seed though three miles away will fly directly thither and be not tempted with other blossoms on the way.

As to the habits and creation of bees, he says: Many have troubled themselves as to the several kinds of working bees, whereas of working bees in this part of the world there is but one sort, and all bees agree, if not in size and color, yet certainly in operations, so that our bees and bees in Spain, and other parts of the world make all their combs with hexagonal like forms. Bees in frost are torpid, and the little worm from the egg after a short life of a week, stirs not and feeds not but lie dead and entombed in the cell it was bred, yet in a few days it will revive and appear a far more noble creature than it was before. The first life of a bee is scarcely worthy to be called life.—*Vita est non vitalis*. She is in a narrow cell without power, neither can she hear, but awaiteth to be fed.

The grub or worm in its first state of life is a rude creature, but when it is shut up to become transmuted then it is for a time a formless lump, without any beauty, but wait a few days and it will come forth in all its beauty. The young bees as soon as they have passed their second birth are winged and strengthened to fly and presently do fall to work and imitate the elder bees.

In swarming, he says: If a swarm come forth they await with impatience for the queen, go with her, encircle and protect her and where she goeth, so will they go. If a swarm be checked and stunted with bad weather after it is hived, or late in the year, the bees will be desperate and gather nothing to purpose, for they are out of hope to get enough for their winter store. Some hives will live two or three years and cast not a swarm, or if they do very late then 10 to 1 they miscarry and die, both the old stock and the swarm too. Now the best way to preserve such a stock is timely to drive it into an empty hive, and the bees being many will provide for themselves, if not they may be fed sufficiently against winter, and swarm seasonably another year. When bees are most angry in their swarming, or fighting, cast a little sand or water among them and they are presently quiet. Bees when they go forth in a swarm will sometimes be provided of a habitation beforehand. A hollow tree or an old hive, they will at once purge it of dead bees, rotten combs and stinking substances, for bees are neat, sweet and cleanly creatures, abhorring stinking places.

Let a swarm be hived ever so carefully and the hive prepared and shadowed from the sun, yet if the queen be wanting, there is nothing but discontent and confusion till she be found. Bees that are new driven or go forth in a swarm, even if they be few, will labor more diligently than other hives that are well provided for. The bee master on all occasions of want will feed his bees but never the drones. Let a swarm remain at the place where it was hived for a few days and then remove it to a new standing, yet for 2 or 3 days if they fly a brood will repair with their labors to the first place. Bees in violent frosts if they have not a few rays of sunshine become diseased from their inability to discharge their foulness, except in the hive. Bees will not continue well without a leader therefore if a union of swarms or castings be made the bees will then dethrone all queens but one.

Many, observing bees flying into their hives suppose them best furnished when they see them go home laden on their thighs,

and think the others idle, whereas the others are best laden being well freighted with honey. Plundering bees will spoil and rob their neighbors, but if they find sentinels before the posts to question and oppose them, and if numerous will through treachery work their destruction.

Bees extract but little honey in July but if a honey dew falls they in a short space are largely replenished with sweets. Bees, as many other creatures, have wit enough to find out remedies for the cure of their maladies. If they be near the sea, delightfully gather from flowers in salt marshes, if they be remote from the sea they drink water from sinks and saw-pits and extract the nitous saltiness therefrom.

Bees when they are contented give forth a delightful hum but if acting illegally give forth an uncertain noise like an instrument out of tune. Bees when they have filled themselves with water cannot gather honey till they have vomited it up. Bees live like soldiers, in camp and have always night and day their scouts and sentinels to keep watch lest their enemies surprise them. Bee masters tell us that the hives that make the most noise are the best ones, and they are also over-diligent to kill all the drones (as they will not only pester but prejudice the hive) and will also feed the bees but never the drones.

A bee sting enters easily and when the bee has flown away the sting works itself deeper, diffusing thereby the venom more strongly. The combs of bees are perpendicular from top to bottom of the hive and so they are long, yet have breadth likewise.

Some cells are filled with bee bread, some with honey, some with brood and others are empty. Mice are hurtful to bees and so are moths but not at all times alike. In the swarms when the bees are lusty and keep constant guard, no hurt will come to them, but when weak, or cold weather beunumbs them, they can without hazard rob, plunder and destroy them. The enemies of the church are compared to bees. "Fear not their rage they are bees not lions, they buzz and make great noise, they cannot do what they would but work their own destruction."

The forgoing are but a few extracts from his book. In his preface he advises all cottagers to meet and form societies for discussions on the bee. He would be glad to give them instructions on the bee, as they can be made of great profit.

Mr. Purchas travelled a great deal as he speaks of bees in Spain were he saw and compared them. A Book Worm.

For the American Bee Journal.

Wintering Bees in Glass Observatory Hives.

As many Bee-Keepers fail in keeping their bees alive in glass hives over the winter I send you an account of my Improved Glass Observatory revolving bar-frame Hive; the four sides and top of which are composed of layers of glass, and I have kept bees in them for a great number of years all through the winter, and never lost a stock of bees in one of them yet.

My Observatory Hives are kept in an open latticed arbor and are always exposed, winter and summer, to the light and cold, and

are the warmest hives in winter of any kind of hive I have tried, either made of wood or straw. The thermometer in the hives (observations of which have been taken for a number of years, three times each day all the year round) indicate a mean temperature of about 4 degrees in December and January, and $4\frac{1}{2}$ degrees in February, higher than the mean temperature inside my other woods or straw hives.

The bees do the best in these glass hives in winter and summer of any hive I have ever tried, and I have never lost a stock in any of them yet, and fewer bees die during the winter than in any of my other hives. The great success of these glass hives is caused by being made with several layers of glass, with a space of confined air between each, as confined air is the best non-conductor of heat of anything we know; and the reason I adopted this plan was that I noticed the bees (in some hives with a glass side my father got made in 1806) always went the farthest from the glass side in winter.

In 1844 a gentleman went to Russia, and when he returned he told me, that it was so cold there in winter, that in their cotton factories they put double windows, otherwise they could not spin their cotton yarn. I said to myself this is what my hives want, and I tried them with two glasses, which was a great improvement, but I afterwards increased them to four, as I then got three spaces of confined air instead of one, and the result has been most satisfactory.

A great many bee-keepers have tried in this country to keep bees over winter in uncomb hives made of thick wood, and also of glass and they have been placed in green-houses and all other situations where the temperature is kept uniform, but I have not heard of a single stock that did not die before spring, or so many of the bees died that they did no good afterwards.

It seems to be essential for bees to cluster together to survive the winter, and in the uncomb-hive they cannot, as both sides of the combs are exposed to an outer surface.

In November I remove the glass cover of my Observatory hives, and tie one or two folds of blanket over the top of the hive, and never have any dampness in the hives, the outside combs being as free from mould as the centre ones. I leave the blankets on during spring, but in February I put the glass covers on the blankets and make all tight and warm to encourage breeding, and to further stimulate the bees and queen I give each hive about half a pound of sugar syrup each week, taken down through just the number of holes under the bottle, so that the half pound just lasts them a week.

WILLIAM CARR.

Newton Heath Apiary, near Manchester, England, Feb. 12th, 1875.

For the American Bee Journal.

Eccentric.

The March number of the "old reliable" is at hand in good season once more, reminding us of the "long ago" when it used to put in an appearance with the advent of each month so regularly that we could have retold it without one of "Josh Billings' Almanax." We trust that it may continue to come with equal promptness and regular-

ity, as long as bee culture shall engage the attention of the American people.

We notice several items in our article this month that are not as we intended to have them; but as they are of minor importance it may not be worth while to correct them, especially as we might endanger our *nom de plume* by the attempt. However, we shall endeavor to prevent any errors creeping in the manuscript hereafter.

The article on "Wintering Bees" by our talented editor, while good in many respects, is, it seems to us, a little partial. In speaking of the various means devised to avoid the bad effects of cold and confinement, he does not even allude to flying bees under glass, or in other words, Mr. Bidwell's "hot-bed method." Why? Is it because that proof is lacking as regards its utility? Or is it—well, something else? We are aware that this method has not been entirely successful as practiced by many; still, we think it more than likely the result of non-compliance with the requisite conditions. Mr. Bidwell's reputation for truth and veracity are, we think, above question.

The recent action of our bee conventions seems to puzzle our friend Dadant. We were surprised at what was said at Pittsburgh by several parties in regard to this question. Though those statements have been considerably modified, it still leaves an impression of the doubtful propriety of continuing these importations. The main point in the whole matter is simply this: if Italian bees possess qualities which make them desirable, and these qualities are only fully developed in their native climate, why, we must continue to import. The idea advanced by Mr. Bingham, that we endanger the health of our own apiaries by procuring these queens is, we must think, a little too far fetched, since Mr. Dadant first tests them in his own apiary. On the whole, the moderate price at which Mr. D. now sells imported queens, and the obvious advantage of having stock in its original purity is, we think, an ample inducement to patronize Mr. Dadant. At any rate we shall do so the coming season.

There is one topic which, though of vital importance to those engaged in bee-culture, has received but very little attention as yet, and that is, what are we to do with our honey in the near future? Though our bees have died by the wholesale during the past few winters, and drought has curtailed the secretion of nectar, honey is a drug in most markets, even now. When honey by the thousand tons shall be put on our markets from California, as it seems inevitably to be done, and that at no distant day, it will be no easy task to convert our honey into money. Of course, the demand will increase with the supply; still it seems to us that honey must "come down" in price until it reaches the "bottom." After all, it may be preferable to sell at a lower figure, provided we can do so at a ready cash sale.

At this date (March 6th,—we give it to please friend Argo) reports are coming in "thick and fast" of the great loss of bees. Since many were left out on their summer stands we cannot conceive of other than disastrous results in view of the fearful protracted cold and bitter winds of the present winter. With the mercury ranging from 20 to 40 deg. below zero and almost continual high winds, it would be surprising

indeed if bees could winter out unprotected. Well, bee-keepers like all other people must live and learn, we suppose, even if it be at the expense of a dear bought experience; at least, so thinks
ECCENTRIC.

For the American Bee Journal.
Adulterators of Honey.

In the JOURNAL, Page 35, No. 2, I see Mr. Dadant comes out to defend the adulterers of honey and makes some grave mistakes, but I do not believe him to do so intentionally, yet such mistakes bring serious injury. If I was in the business of selling bogus honey I should not ask any better defense for my trade than this one. He also condemns the members of the N. A. Society for wanting a means to prevent honey from crystalizing, granulating or candying. There are two motives behind this, if I knew which one then I should reply very plainly. He asks "how can you prove their culpability if you don't know the means of detecting the adulteration. I will let in the light from the "Old Keystone" from the hill top that it may be seen a far off, presently. Will some one tell us, was the honey that C. Dadant & Son took through Quincy, Ill., not long since, all candied if not, *it was spurious?* He asks that the Journals informs their readers that the best test is candying. That means then, that we cannot sell our honey until cold weather, so that it may candy, to prove its purity. That idea is absurd, but he admits it may be liquid from June to December, but from December to June they can with absolute certainty declare it sophisticated honey or that which has been boiled and lost its flavor.

I would inform the gentleman that we are Americans and not Frenchmen and do not need go to France for candied honey nor immortality; proud America can eat her virgin honey and boast of her morality. Please do not go to circulating such errors in our papers.

Now Bee-Keepers look out, for if such a test is adopted we would not get as much good honey as we do at the present time, mixed with glucose, we do get some now but would not find any soon.

I will note Mr. Dadant's scientific points which are not sustained and pass on to give the subject a true scientific ventilation and leave all your readers to decide if the points are well taken. His statements are: Honey granulates; sugar syrup does not granulate but crystalizes. Honey candies because it is — sugar, which granulates and does not crystalize. Sugar syrup which is made from cane sugar does not granulate but crystalizes.

We reply pointedly, that these statements above named may have exception, but in their relation as they exist in commerce are false.

HONEY.—A liquid prepared by *apis mellifica*. Honey exists already in the plant or flower of the same, and it is certain that the nectaries of flowers contains a saccharine matter, which is extracted by the insects. The character and flavor of the honey, are very much affected by the nature of the plants which predominate in the vicinity of the hive; still, it probably undergoes a change in the organs of the bee; as the saccharine matter of the nectaries, so far as

it has been possible to examine it, wants some of the characteristics of honey.

The finest honey is that which is extracted from new comb and if from a hive that has not swarmed it is called *virgin honey*.

In a primary state, (and as it always exists in a healthy colony) honey is fluid; but, in being kept, it is apt to form a crystalline deposit, and ultimately converted into a soft granular mass. Its color is white, but sometimes of a brown, or redish tinge. It has a peculiar agreeable odor, depending somewhat on the flowers from which it was collected, and a very sweet taste, a feeble aromatic taste followed by a prickly or sense of acrimony in the fancies. Its specific gravity greatly varies in the early part of the season but in December (in the colony) its specific gravity is about 1.333, (Duncan). Cold water dissolves it readily. Alcohol with less facility. It contains *crystalizable* sugar analogous to grape sugar, and according to Mr. SANBORN, two other kinds of sugar, one of which is changed by acids: the other is not. The first of these two sugars are not always present, as it is behind, that in time is changed by acids in granular sugar. It is found abundantly in honey taken from the comb. The second is found to be similar to the uncrystalizable sugar produced by the re-action of acids on cane sugar being identical with it in composition, and incapable of crystalizing and very sensitive to alkalies. But it is distinguished by the *impossibility* of converting it into *granular sugar*, and having twice the rotatory power of uncrystalizable sugar. Crystalizable sugar may be obtained by treating candied honey with a small quantity of alcohol, which when expressed takes along with it the other ingredients, leaving the crystals nearly untouched. Same results may be obtained with carbonate of lime.

SUGAR.—*Saccharum abum*, refined sugar, sugar cane, contains about 10 per cent of sugar, of which there exists from 3 to 4 per cent of uncrystalizable sugar, and from 6 to 7 per cent of crystalizable. The juice from sugar cane averages about 50 per cent and is at once treated with time to neutralize or separate the gluten and album. But it is useless to treat of sugar any more than to give the tests for the detection of it in honey, and will pass it to the tests.

Its specific gravity is 1.6. dissolves in $\frac{1}{2}$ its weight of cold water. An aqueous solution of sugar when in a warm place, has the property of corroding iron partly immersed in it, and the solution itself, become impregnated with protoxide of iron and of a deep brown-red color, a similar effect is produced on lead, but zinc and copper are but slightly acted on. Sugar is nearly insoluble in alcohol, but will in four times its weight of boiling alcohol, sp. gr. 83.

Cane sugar may be distinguished from grape sugar or honey by Trouer's test. If a solution of sulphate of copper and potassa be mixed with cane sugar, in excess, a deep-blue liquid is obtained, on being heated, lets fall after a time, a little red powder. A solution of grape sugar (or glucose) similarly tested, yields, when heated a copious green precipitate, which readily changes to scarlet, eventually to dark-red. Chemically pure muriatic acid, or sulphuric acid chars cane sugar. Cane sugar is often (erush sugar) adulterated with starch and may be detected by adding a solution of ulide of Potash or tincture of iodine to a solution of honey or

sugar, which turns the composition of sugar in C. 12, H. 11, O. 11.

GLUCOSE.—Glucose or grape sugar may be obtained in various ways, but is principally from grapes by the French and is found in commerce in the liquid and solid state. The liquid has a taste very similar to that of honey which has been candied and the solid or grape sugar has the appearance and taste of candied honey, and in very cold weather is difficult of detection, except the sugar be more dry, and of a taste more like that of fruits, but if the honey be principally from fruits in September and then candied, the distinction is scarcely noticeable. Like honey, or cane sugar it is susceptible of being crystallized or granulated. Honey contains one part in four of glucose, cane sugar (as obtained from the juice) three parts in ten. Glucose may be obtained from honey by placing crystallized honey on a porous tile, dissolving what remains on the surface with cold alcohol and crystallizing. It is obtained from concentrated syrup, and is in the form of crystalline grains, but crystallized from alcoholic solution it has the shape of square tables or cubes.

It is less sweet than cane sugar or honey. It is also less soluble in water and much more soluble in alcohol, its sp. gr: 1.386.

Strong mineral acids hardly act on grape sugar, but destroy cane sugar with facility. On the other hand alkalis destroy grape sugar and form compounds with cane sugar. See cane sugar in this article for further tests for glucose.

The composition of glucose is C. 12, H. 12, O. 12.

Therefore, any intelligent reader will soon see that Mr. Dadant's test is not at all to be depended upon, even if the honey be candied.

DR. W. B. RUSH.

Simpson's Store, Pa.

North-Eastern B. K. Association.

The fifth annual meeting of this Association was held at the Butterfield House, Utica, N. Y., Feb. 3d and 4th, 1875, President Quinby in the chair.

The minutes of the last annual convention were read by Secretary Nellis, and approved.

The chair was then filled by Vice-President Alexander, of Camden. Mr. Quinby having temporarily retired.

A report was received and approved from the treasurer, Capt. Hetherington. Some time was then devoted to the enrollment of members.

A brief opening address was delivered by President Quinby. The speaker alluded to the prospects for the present meeting. He suggested in particular the education of the people to do away with the popular and foolish fear of being stung by the insects. The president spoke of the newly-found method of adulterating honey, and suggested that each honey producer place a distinctive mark upon his product which would bear assurance of its genuineness.

The election of officers was next in the order of business, and an informal ballot was taken for president. A unanimous vote was given to Mr. Quinby.

He declined to again hold the office, however, and upon motion, the election of officers was deferred and the correspondence of the Association was read.

The first essay presented to the convention was written by Prof. A. J. Cook, of Lansing Agricultural College, Michigan. It was read by Secy. Nellis, as follows:

INSECT RESPIRATION AND BEE-CULTURE.

It is a curious fact, often wondered at, that no two human faces, nay more, no two blades of grass are exactly alike. Nor is it less wonderful that each class of the various branches of the animal kingdom, has its own peculiar methods of developing structure which implies peculiar organs, with special arrangement and adaption. Hence in the articulate branch, we find that the insect class, including the myriapods (thousand-legged worms); arachnids (spiders), and the higher six-legged insects possess a peculiar breathing apparatus. They, unlike those higher animals, whose physiology is more familiar to us, do not have a common mouth for the reception of both food and air, nor yet specialized lungs, where air and blood come in near contact, that the latter may be purified. But in this class there are always more than one, often several breathing mouths, which are always situated along the sides of the body. These breathing mouths are plainly visible in the so-called tomato worm, the larva of the tomato moth, which openings looking like perforations along the sides of the insect, must be familiar to you all, though you may never have known their function.

The breathing mouths may be seen by close examination along the sides of the larvae of bees, and even in the mature bee, the larger spiracles under the wings upon the side of the thorax, may be discovered by a little care in scraping off the hairs. As in the human nose there are hairs, to intercept the dust particles, so too these insect spiracles are not without even a more complicated arrangement, consisting of a sort of double valve to effect the same end. These spiracles or breathing mouths connect with two long tubes, running either side of the body, which in rapid flying insects, as our bees, often expand into very large vesicles, whose supposed function is to permit a decrease in the specific gravity of the insect which is effected by filling these vesicles with air.

These lateral tubes branch into an indefinite number of lesser tubes which ramify to every part of the insect. These tubes or trachee, as they are technically called, are composed of a spiral thread, and as microscope preparations are very beautiful, looking as if a gold thread had been wound closely around different sized wires, after which the wires were withdrawn. The number of these tubes is marvelous, and I am sure that I show my classes in entomology, no microscope specimen which interests them more than a preparation of these trachee which I took from a bee. The specimen not larger than a 3ct. silver piece, with a power of two hundred diameters, shows innumerable tubes, seeming to form a most intricate network. These minute air tubes extend to every part from the tip of the antennae to the very periphery of the legs and wings. Thus these air tubes, which are analogous with the lungs of our higher animals instead of being localized, or confined to a special part, extend everywhere, hence the blood in insects needs not to convey the oxygen of the air to the various tissues as in higher animals, for the oxygen is

everywhere ready to be taken up by the blood, which as is generally believed does not circulate in special tubes, but penetrates everywhere among the organs, passing through the Interstices, and everywhere bathing this labyrinth of tracheae or air tubes. Even the veins of the wings contain each its tracheae around which the nutritive fluid passes freely. It is a demonstrated fact that among higher animals, it is the function of the red globules of the blood to convey the oxygen, as we also know that it is the iron contained in the hematine of these same globules which gives the blood its characteristic color. Thus we understand why in insects, when the oxygen needs no transportation, there is an almost entire absence of globules in the blood, as also why their blood is white or yellow instead of red.

It was stated above that this tracheal arrangement of insects was analogous to the lungs of higher animals. Yet there is a marked difference, which it is well to point out. The lungs are localized organs, doing their special work for the whole body, and are doubtless none the larger for that purpose, hence could we get at them, and even lacerate them without harm to the body, still I think all physicians and physiologists would hold that even a limited slicing off of these organs would injure health. I suppose that all physicians would hold that even slight phthisis would affect the general health, and that our State boards of health would labor most diligently to remove any condition in nature or domestic life, which had the faintest tendency to obstruct the free action of these important organs.

But with insects the ease is far different. Each organ, or wing, or leg, has its special tracheae, whose only function is to minister to said organ. Now if the organ is an effete appendage, its removal carrying with it the air tubes does no harm. Nay more, is a benefit, as the slight nourishment which it, even if inactive, appropriated, is saved to minister to useful organs. Who would say that the amputation of a leg or arm, would entail perpetual ill-health, because forsooth the blood vessels, whose function it is to carry the blood, were removed? We all know that the vessels served the member removed alone, and the member gone, the vessels are no longer needed. So too with the insect member—it gone, the air tubes, could they remain, would be in the condition of Othello.

That this reasoning is correct is shown in the life history of the common ants (formicide), and the white ants (termitida) which bite off their queen's wings after the mating is over. This is done to protect against the roving proclivities of her royal highness. Are we quick to learn, if a similar need does not beget a like operation in our own management?

The history of these ants also shows that there is little danger from hereditary tendencies, as we never see virgin queen ants void of wings. Else we might pause in alarm since Mrs. Tupper and her followers have failed to convince the general public that fertilization in confinement is practicable.

Hence, we see that a thorough understanding of the anatomy and physiology of the respiratory apparatus of insects will preclude Gen. Adair's nervousness as regards clipping queen's wings, from becoming contagious.

I do not wish to be understood as committing myself in favor of indiscriminate clipping, for I readily concede that arguments can be advanced on the plea of beauty, and danger of losing valuable queens in time of swarming. Yet I do hold that the queen receives no physical injury, as proved both by science and experience, and that it is a valuable auxiliary to those apiarists who are wise to understand its dangers and advantages.

Insects, in common with many animals much higher in the scale of animal life, possess that strange power to hibernate during cold weather, at which time they seem to be

on the "dead line," just between life and death. In this condition the vital processes are held in almost entire suspense. No food is taken, the blood moves very feebly, and little oxygen is required. The condition is something like profound sleep. As there is no exertion or exhaustion, and the breaking down of tissues almost cease, while no doubt there is a slow but continuous recuperation of strength and energy. Now, this being the case, it seems highly probable, and, almost certain, that in the intervals of productive exertion the more protracted the hibernation, the better the condition of the animal.

Now does it not hold to reason that if we secure the best conditions for wintering, those which will ensure persistent hibernation, as indicated by the most perfect quiet, our bees will need scarce any air, and hence no ventilation either upper or lower. Reason proclaims this as a fact. My experience sustains it. I have had colonies surrounded by snow the winter through, with hives sealed with propolis above, and the entrance below frozen solid with ice, and in this condition from November till April, come out in spring as bright and beautiful as if only restful sleep had visited them, with scarce any dead bees, and hardly any consumption of honey. Hence I believe we may conclude from our study of respiration among insects, first, that the destruction of tracheae will of itself produce no harm; that the only harm will come through the loss of the organ. And, second, that if bees are in condition to winter best, the respiratory action is at the extreme minimum, and hence we need take no pains to arrange for ventilation.

Conclusion from second inference.

This being granted, what more important problem awaits solution than a method of wintering, which insures the most perfect hibernation. How can we arrange to keep our bees always at the proper temperature?

Then followed an essay written by H. A. Burch, of South Haven, Mich., concerning

FACTS AND FANCIES OF APICULTURE.— LETTER TO THE NORTH-EASTERN BEE- KEEPERS' ASSOCIATION.

Gentlemen:—By request of your worthy secretary I will present you, though in a necessarily hurried manner, a few thoughts on the subject of apiculture.

While recognizing the importance of the work which bee-keepers' conventions are aiming to accomplish, and appreciating the great good they have already accomplished, and being anxious that their field of usefulness may be greatly extended, it seems to us that a consideration of this subject is one which might result in good to us all. In reviewing the history of apiculture in America for the past decade, we find much to encourage us in our endeavors to establish our pursuit upon a permanent, scientific basis. While this is the case, we cannot deny that there is also very much that is to be regretted, much that mars the otherwise fair history of bee-culture. He who has attentively read our various bee journals cannot have failed to note the spirit of much of their contents as being prejudicial to our interests. How many of us have, with a sort of boyish impetuosity, urged people to engage in bee-culture. To the man broken down in health; the man whose pocket book was empty; he who had failed in other callings; those who were dissatisfied with the slow but sure accumulations of agriculture or mechanical trades; to all these have we pointed out apiculture, as the one sure pathway that leads to wealth and

happiness. In doing this, we have ignored the fact that all men are specially suited to some particular calling; that to make this occupation of bee-keeping successful, he who engages in it must, by nature, be adapted to its requirements, in some measure at least; that it requires money, brains and muscle to conquer obstacles and achieve success, as in other pursuits.

We have too often portrayed a path all strewn with roses without thorns; all sunshine and no storm; a pursuit that embodies the very essence of earthly happiness with none of its alloy. As if this were not enough, we have descended from the airy realms of imagination to life's every day level, and with all the fascination of a romance, portrayed the achievements of a Grimm, a Harbison and a Hetherington, in "honey gathering rapidly," forgetting that where one man has been thus successful, a thousand have failed.

Gentlemen, this is no overdrawn picture. Thousands of persons in this country will tell you that it is only too true. How many men who were urged into the keeping of bees a few years ago, and who have lost all during the past two or three winters when bee life "took wings and flew away," we know not. We do know that the number has been by far too many, and that it has been to our injury, bringing our fair calling into disrepute in many sections. We have been made to realize this most forcibly in receiving numerous letters from parties stating that they engaged in bee-culture by our own and the advice of others, given in bee journals, and had lost all.

While pleading guilty to some extent, in this respect, we have resolved to avoid this error in future, and make amends as best we may, by detailing that which may contribute to the success of those already engaged in apicultural pursuits. A few suggestions and we are done.

Let us *cease to urge* people to keep bees. How many men who are eminent in their callings or professions were urged to choose as they did? The men succeed who engage in any business from a *love of that business*, possessing talents which qualified them for it. These are the men whose names adorn the annals of every science known to man; the men who have led the advance in every department of the progress and improvement of our modern times; the men whose genius has given an irresistible impetus to our advancing civilization. Rather let us turn our attention to those things which tend to establish our pursuit upon a permanent basis; and when we shall have learned how to avoid failure and win success ourselves, it will be ample time to teach those who do not know how to succeed. Until bee-culture is rendered more certain and less precarious, let us cease to relate fabulous tales, which excite the curiosity and superstition of outsiders that must so often end only in chagrin and disappointment.

In behalf of the Michigan Bee-Keepers' Association which we in part represent, we send greeting and best wishes for your continued prosperity, trusting that your future sessions may be mutually present and profitable.

Fraternally,

HERBERT A. BURCH.

L. C. Root approved the position, claiming that there should be a careful

training and education in the direct care of bees before profit can be assured, and that those who attempt it without the study, may expect to fail.

A letter was read from W. W. Cary, of Mass., taking position that there has been much injury done to the bee-culturist by breeding queens not in accordance with natural laws, because degeneration is the result. A good queen mother should be of good size, large to the chest, trunk somewhat tapered, movements strong and even and by no means of a nervous temperament. A nervous queen is usually short-lived and should not be used as a queen mother.

Mr. Nellis and Mr. Tennant approved the growing of strong queens and of crossing the stock continually.

A letter was read from Dr. W. B. Rush of Penn., stating that he was engaged in a new method for wintering his bees. Capt. Hetherington remarked that it was apparent that Dr. Rush was an investigator, and moved that the secretary be instructed to request him to give the results of his experiments at the next convention. The motion was carried.

Upon motion Prof. A. J. Cook, H. A. Burch, W. W. Cary and W. B. Rush were made honorary members of the Association.

The convention then listened with interest to an address by S. Alexander, of Camden.

IMPORTANCE AND BEST METHOD OF EDUCATING MEN TO THE BEE BUSINESS, TO PREVENT LOSS IN POOR SEASONS.

The eccentric Thoreaux demonstrated by experience, that man may healthily subsist on a very small amount of expense. But the requirements of our modern taste and time, does not regard abstemiousness as virtue, nor denial of the good things of life as conducive to the truest enjoyment.

Honey has, in all ages, been regarded as the sweet, the nectar of the gods, the synonym of luxury and enjoyment, the highest ideal, "a land flowing with milk and honey," assuming with our savans, that honey is not made, but gathered, and consequently if not gathered, lost, it becomes a question, whether with knowledge adequate to its collection, man is justified in rejecting (which neglecting is) to secure such a valuable article of sustenance, perhaps the most condensed and healthy nutriment in existence. We think we may as well acknowledge that man is mainly, if not exclusively, controlled by self-interest. The nearest approach to unselfishness I know of is this Society, teaching and inducing others to enter the field as competitors). That being the case, we think to discuss this question of how best to educate our neighbors can best be done by our own success? If we satisfy them that every ten acres is sufficient for one hive, that every hundred acres, admitting that all kept, would give sufficient range for ten hives,

which properly managed and honey extracted, (which for surplus is the most rational method yet devised) would give an average of at least 1,000 lbs.

Besides, every enlightened cultivator knows that fertilizing of all fruits and grains is thereby secured to a much greater extent. When satisfied of these facts, what is the best course for those wishing to engage in the business? I would advise to associate themselves as partners or otherwise, with those who by experience and study had so far mastered the science as to be competent instructors—in one word learn the trade—reach in this way the knowledge which has cost years of study to attain; for it is my humble opinion, and I have kept bees more or less of the time for the last 40 years, that there is no business or occupation that man ever prosecuted or engaged in, that the scientific or right way is so different from the old way as bee-keeping. Having raised it above all chance or luck, except the occurrence of unfavorable seasons, the truly enlightened apiarian will have his stocks in a situation to make available every advantage which may arise. Strong at the proper time, less in numbers when bees can do nothing but eat, recognizing them as active, never being entirely dormant, keeping them in a comfortable and suitable temperature, health and condition; with this knowledge, with this care, I think the very worst seasons will afford as much for the credit side of the ledger, as most other occupations under like discordant circumstances, for I believe that there is no occupation where the same amount of capital, will be subject to less drawbacks.

I would not like to guarantee that ten per cent. of those who engage in apiculture will succeed. No power on earth can make them painstaking, persevering, intelligent and determined. The few will prosper, the rest will fail and scatter the seeds of disease and destruction among their neighbors, and then say bee-keeping is a humbug. I have tried it. A few will persevere, will read, will write, will meet together for the purpose of mutual instruction, and their success and satisfaction at having enhanced the means of enjoyment, secured a pecuniary compensation and opened a wide field for industry and enterprise.

Though the most advanced in the science of apiculture, like the disciples of other science, never expect to reach perfection, yet already much has been attained; and the agitation of thought is the beginning of wisdom, in this as in every other attainable acquisition. Mind, the great motor, will devise methods, recognizing law, not chance, as the true principle, from affects deducing causes, acting in harmony with our industrious pets, making their instincts available for our advantage, and while benefitting ourselves, make the world and its sentient creatures better and happier from our having lived.

Upon motion of Mr. Nellis, Messrs. L. C. Root, J. E. Hetherington and C. C. VanDeusen, were constituted a committee to open a question drawer. It was moved that a committee be appointed to examine the minutes of the North American Bee-Keepers' Society in order to see whether there was anything of which this society should take cognizance. Messrs. J. H.

Nellis and N. N. Betsinger were appointed the committee.

The election of officers was then effected with the following result:

President, J. E. Hetherington, Cherry Valley; Vice Presidents, G. B. Seeley, Syracuse, S. Alexander, Camden, I. L. Scofield, Chenango Bridge, N. C. Fisk, Abbotsford, Prov. Quebec, Canada, G. G. Dains, Antwerp, G. H. Byrns, Pratt's Hollow; Secretary, J. H. Nellis, Canajoharie; Treasurer, L. C. Root, Mohawk.

A discussion ensued concerning stings, and assurance was given that with determination and intelligent action and precaution, the danger of stings may be overcome and fear removed.

The Association adjourned until half-past eight o'clock the morning. In the evening an informal meeting was held at the Butterfield House, which was greatly enjoyed by those present.

SECOND DAY.

The second day's meetings began at nine o'clock, Thursday morning, the newly chosen president, Capt. Hetherington, in the chair.

J. H. Nellis, reviewing the proceedings of the North American Bee-Keepers' Society, noted the fact that preparations are being made for a honey display at the Centennial; that the Society adopted strong resolutions denouncing the trade in adulterated honey; that a standing committee was appointed to arrange a system of premiums for Italian queens and full colonies for the next meeting of the Society; that the next place of meeting will be Toledo, Ohio, and the time, the first Wednesday in December, 1875; also that a receipt was read which it was claimed, will prevent syrup or honey from souring or granulating. The receipt is, flavoring extract of lemon, 1 teaspoonful to 1 gallon of syrup or honey.

Mr. Van Deusen moved that the President and Secretary act as a committee on behalf of this Association to do what is necessary toward a representation of the Association and the productions of its industry at the Centennial. The motion was carried.

Considerable doubt was expressed as to the feasibility of the plan and the ability to judge of the merits of bees and queens by their appearance, in order to give premiums or diplomas.

Mr. Root thought the flavoring extract of lemon should be classed among honey adulterations and denounced. Educate the people to know that the granulation of honey is a good sign of its purity.

This seemed to be the general opinion of the Association.

A paper on "Hives" was read by R. Bacon, Esq., of Verona, as follows. We quote the concluding portion :

I do not propose to discuss the merits of this or that hive, such a course would only result in a buzz about my ears, without, as I think, leading to any good results. It is with hives very much as with mowing machines, the farmer often viewing and reviewing the different machines is puzzled to determine which is the best, yet, no doubt, some are preferable to others. So it is with hives, We see in market tall hives, short hives, narrow hives, wide hives, two story hives, one story hives, bar hives and box hives, and many other hives, and men ready to show you the good qualities of one hive over the other, and, when you have gone the rounds, if you have had no practical experience in bee culture or have no judgment of your own, you may be led to believe the poorest hive the best. I would advise the beginner in bee-keeping to use discretion in this matter and take the middle ground. He should choose hives containing frames of convenient size, and safe to handle, for general use. They should not be complicated or costly; they should be capable of construction by any man who is handy with tools. The bee-keeper who does not depend on his bees for support may lay out money for costly and fanciful hives; but the majority of bee-keepers want a cheap, practical hive. I have had rough, cheap hives, and elegant, costly hives, and I have found in every case, all things being equal, bees have done full as well in my rough hives as in the more costly ones. The wants of bees are few, and they are not partial to fancy hives, and all variations from their wants are to benefit or gratify the taste of man. Give the bees a proper-shaped hive, and sufficient amount of room in the hive, and good care, and they will give ample returns. Now, there has been much said and written on what constitutes a proper size and shaped hive. Some contend a hive should be large. Others say twelve inches square is the proper dimensions for a standard hive. Now, my experience with large hives has been anything but satisfactory; they neither gave new swarms nor a large amount of surplus honey. Of course I speak of working these hives for box honey. I think an extractor would show better results, but my experience in the other extreme of hive has been no better. A hive twelve inches square is too small for bees in any place. The swarms from such hives will be small and generally inferior compared with swarms from larger hives. There is but little room for surplus bees, and therefore not a very large amount of honey can be expected, and with the best of care in two or three years, the bees will be gone. Between these two extremes, I believe is found the correct medium. A hive sixteen inches long, twelve inches wide and twelve inches deep, and frames to fit, and have it so constructed that side boxes or extractor can be used, if the season requires it, comes nearer to what I think is the hive for general use. The frames are of convenient size, and safe to handle for either extracting or other uses. The size of the hive is simple for the wants of the bees, either in summer or winter, and I think we will hear of less mortality among the bees wintered in this hive than in our shallow ones, and I think for surplus honey will be satisfactory. Of course I am speaking of raising bees in the North. If we were in the Southern States, no doubt a different hive would be required. I believe it is often the case that localities cause very much contention about the style of hive and the management of bees, and were we to consider from each other's standpoint, and reason accordingly, it would save us many jangles in bee culture.

Mr. Alexander asked whether a frame 12 inches deep and 16 inches long, would sustain the comb.

Mr. Bacon—My frames fit a 16 inch hive and are not more than 14 inches long and less than a foot deep. These held

the comb perfectly and had no difficulty in breaking down. I have two reasons for this size. You will get more surplus honey from this depth of hive and the bees winter in them better.

Mr. Hetherington—Combs can be held in the long frames by putting the thorns of the red haw through the frame and into the comb.

Mr. Seely—Do not the bees try to eat out the thorns,

Mr. Hetherington—Yes, but only a trifle. A soft wood pin they will eat at, but one of these thorns with a glossy surface they will trouble very little. The thorns should be put in when the bees are gathering honey in abundance.

Mr. Betsinger—Thorns are good in large frames, but in small frames they are a nuisance. A frame ought to be the size of the brood chamber. This is rarely over nine inches in width. In the large frames the best honey is placed around the brood chamber and this honey is lost to the bee-keepers. I believe that for box honey the frame should be only the size of the brood chamber. For extracting, a larger frame could be used to an advantage.

Mr. Alexander—The insertion of the thorns requires time and trouble. What I wish to gain is a frame which will hold the comb without them. Mr. Bacon says his size will do this. Mrs. Tupper recommends twelve inches square. If it can be lengthened to 14 or 15 inches it will be a great advantage. It seems to me that a shallow hive like Mr. Betsinger's is inconvenient and not good for wintering.

A. L. Fish—Has there ever been a bead placed on the inner side of the frame to hold the comb steady. Would this be practical?

Mr. Root said experiments had been made in that direction, but they had not been found practical.

Mr. Nellis wished to know how many frames could be spread laterally to the best advantage in extracting.

L. C. Root—I would not have more than twenty-four frames in any hive. The queen is apt to move to one side, and the bees on the other side thinking they have no queen will proceed to rear one. I believe that the two-story arrangement, getting the frames into as near a spherical position as possible, is natural and best. If I have twenty-four frames I would have twelve above and twelve below.

A. L. Fish—A queen will work in the warmest part of the hive. I find that in a sixteen-frame hive, when a new swarm is put in, it is a good plan to put in a center board, confining the swarm at first to eight frames. If they afterward require

more room the center board may be removed.

Edward J. Wickson, of the Utica *Herald*, addressed the convention upon the commercial aspects of the industry. In closing, Mr. Wickson made the following reference to a subject of great importance, both to honey producers and consumers. He said:

Doubtless one of the most vital questions connected with the marketing of honey is called forth by the effort, which is now being made by unprincipled men, to sell the people that which is not honey. The article which they falsely offer as honey is very inferior, and one who is acquainted with the genuine article would not be misled by it, even if it had a honey label on the exterior and a comb inside. But the very ignorance of the people generally of what good honey is, affords an opportunity for the introduction of this spurious article. It is in the hands of shrewd, unscrupulous men, and they spare no effort in pushing it forward, because there is great profit involved in it. As it now appears, the people will become educated in bad honey much faster than in the genuine delicious product of the bee. This will be fatal not only because it will supplant the legitimate demand for the real article, but because of its inferiority it will lead them to look with aversion upon the very name. A land flowing with milk and glucose would not have led the Israelites through the wilderness nor will a copious dosing with glucose lead modern people to esteem very highly the historic sweets of Canaan. The whole matter is exceedingly unfortunate not to say criminal, and bee-keepers should prepare to meet and battle against its advance at every point. It seems to me no stronger showing could be made than by securing an accurate exhibition of the fraud, such as a skillful chemist might make by ascertaining the exact difference between the genuine product of the bee and this substance which can be artificially produced from a number of worthless sources. So long as the article they offer is not positively harmful, I can not see that there is any opportunity to meet it with a prohibitory law, but if there is any virtue in efforts to inform people of the imposition practiced upon them: if there is any effect in a square, generous exposure of these gentlemen, let them have it at the hand of this association which is formed in the interest of the legitimate production and in the promotion of a growing agricultural industry.

I think this convention owes it to the industry to take immediate steps to meet the advance of this specious fraud. First, we should know more about what it is and in what respect the artificial differs from the genuine. It has come upon us suddenly. It seems to me that we could act more wisely after gaining fuller information. I would suggest, Mr. President, that first this convention adopt some expression of a general nature denouncing the attempt to defraud and calling upon people to beware of being imposed upon. Then I would suggest that a committee of your leading bee-keepers be appointed to study the question during the coming year, to gain all possible information concerning its exact quality of material, and who is engaged in spreading it over the country. In order that next year, after listening to a full report of the committee, we may be prepared to act intelligently and effectively against the imposition in such way as the wisdom of the convention may indicate.

Upon motion of Mr. Nellis, the association heartily approved the action taken by the North American Bee-keepers' Society concerning the introduction of spurious honey. After much discussion and upon motion of Mr. Alexander, the following gentleman were appointed to present the fact of adulteration to the Legis-

lature, and ask that an act be passed requiring a label, "pure honey," to be placed upon all packages of the genuine article, and making it a misdemeanor to affix the name to a spurious article. The committee are as follows: J. E. Hetherington, J. H. Nellis, G. G. Dains, M. Quinby, E. J. Wickson.

A short discussion concerning wintering bees ensued. Mr. Root would winter bees in a place where they would be as free as possible from out-door influences. The temperature should be as little below 50 degrees as possible. There should be perfect quiet.

A. L. Fish—I built a bee house with an air chamber in the walls twelve inches wide. Overhead the space was packed with fine saw-dust and shavings. To overcome this I covered the floor with gravel and cement. I am not troubled with moisture as much as formerly, but still there is too much. I think some absorbent can be placed above to absorb this moisture as it rises. I think of trying a coating of loose straw. I can control temperature until June, if necessary; but how to get rid of the excess of moisture which comes from the exhalations of the bees has been a puzzle.

Mr. Bacon—I have used cut straw for this purpose with excellent results. It is contained in a box with a cloth bottom, and this rests over the frames in which the bees are.

Mr. Betsinger described a way he had devised of giving his bees a fly under glass. He built a bee house, in which each two hives sit in a little stall by themselves with a little space in front of each hive. The exterior of each stall is a little window, and about three times during the winter he admits the sunlight, and the bees take a fly in the stall. He intends next season to encase all his hives in the stalls. The cost of the house is a dollar a hive.

Mr. Bacon told of a hot-bed which he made in which to fly his bees. He had tried it once with one hive. The bees had a fly. They were left in the hot-bed all day and over night. Altogether, after having this long time in the air, there were found but three table-spoonfuls of dead bees. Mr. Bacon believes the hot-bed good for giving a hive which might have the dysentery a chance to fly and recover. He does not believe that it can be recommended as yet for general use.

AFTERNOON SESSION.

One of the most interesting exercises of the convention was the "question drawer," which was expounded by Mr. Van Deusen, with the aid of Capt. Hether-

ington and Mr. L. C. Root. These questions and replies are of such practical value to the bee-keeper that we print this part of the proceedings verbatim. Much discussion was intermingled, but nothing of importance was elicited aside from the answers as given here.

Question. Is there any profit in buckwheat honey? Answer. Yes.

Q. Can brood be reared successfully in March and April? A. It is best to have no brood started until the weather is sufficiently warm and settled to enable them to start a full brood. The presence of a sufficient amount of pollen must be assured.

Q. What effect has the shape and size of the hive on freezing or on the amount of honey stored? A. Very little provided they have plenty of accessible room and the proper temperature is maintained in the hive.

Q. The best mode of caring for bees after they are set out in spring and before the honey harvest? A. Feed and keep warm.

Q. Will bees store enough more honey in boxes with communications from box to box to pay the extra trouble, than to have the boxes separate? A. Yes, in small boxes, but not in large.

Q. How many swarms should be kept in one yard? A. This depends upon the quantity of honey-producing plants; from 50 to 100 swarms.

Q. What is the best size of the brood department? A. Let it vary according to the quantity of bees.

Q. About what amount of honey is sold in New York city, yearly? A.—About 400,000 lbs.

Q. What is the most suitable package to put extracted honey in for market? A. This depends upon the market in which it is to be sold. In some cases it sells best in bulk or by the pound net weight; in other cases in glass jars.

Q. What is the proper thickness for a single comb in a box? A. 2 to 2½ inches.

Q. How near to the ground ought hives to be placed during the summer. A. 4 or 5 inches.

Q. Will using the extractor on comb containing eggs or larvæ produce any injury; if so, at what time most? A.—There is no injury unless larvæ are thrown from the cells by too rapid motion.

Q. Is it advisable to undertake to Italianize your apiary when you are surrounded by black bees? A. It certainly is, if in a locality that produces much white honey.

Q. How long from the time the eggs

are deposited in worker's cells before it cannot be changed to a queen cell? A.—Would not use it older than the third day after hatching.

Q. If a queen's wing is clipped about half off by a trusty, experienced hand, is there any injury; if any, what, and in what way? A. There is no injury.

Q. Making an examination of my stocks in January, I found some stocks from which the honey was leaking. What is the reason? A. This condition is found only in hives that have been so exposed to the cold as to crack the combs with frost—or in hives that are so poorly ventilated as to retain the moisture and sour the honey.

A long paper was read by Rev. S. P. Lander, of Clinton, to refute the popular belief that bees do injury to fruit. Mr. Lander has raised grapes and kept bees, and after years of observation, he is sure a bee never attacks a sound fruit. Bees do not bite into fruits or blossoms to get the juices. If they did the hive would be enriched with honey of the honeysuckle, and some other similar plants from which full drops of honey might be gained if the bee could bite into it. Mr. Lander took issue with several newspapers in which were statements that bees destroy grapes, pointing out many inaccuracies in the statement, and throwing a strong suspicion of falsity upon them. The speaker alluded to Prof. Riley's recommendation that milk-weed be planted to rid buckwheat fields of bees. Mr. Lander thought if any man was fool enough to cumber up his land with milk-weeds, for the sake of killing his neighbor's bees, the bees could stand it if he could. The idea that bees destroy the buckwheat crop, Mr. Lander has considered and watched the growth of the grain and the behavior of the bee, and is convinced there is no truth in it.

After some general discussion, the convention adjourned to meet in Rome, N. Y., next winter, at the call of the executive committee. This year's meetings have been a great success, and have been enjoyed by all present.

All of the discussion of the evening meeting and much that occurred during the regular sessions, has not been reported.

The following table will be of interest to all bee keepers. The information was collected by Secretary Nellis. The whole seasons' operations, and a summary of the methods employed by each bee-keeper, are thus condensed into a line of type, and the records will reward a careful study and comparison.

SUCCESS IN WINTERING.

SUCCESS OF THE SEASON'S OPERATIONS.

NAMES.	No. of Stocks.		Condition in spring	Where Wintered.		No. of Stocks.		In fall.	Kind of Hive.	Amt. honey produced.		Amount of Wax.	Extra Queens Reared.	Principal sources from which the honey was gathered.	Average value of the honey season.	Amt. of sugar fed in fall.

+Degrees, Parenthetical.

J. H. NEELIS, Secretary.

Comparative Merits of the Italian, Black, and Hybrid Bee.

I see in the AMERICAN BEE JOURNAL during the past year, many articles written on the superiority of the Italian bee for honey-gathering.

Bee-keepers' meetings throughout the country still continue to discuss this subject. In nearly all these writings and discussions, a large majority unite in claiming superiority as honey-gatherers for the Italian bee.

Having kept bees for the last ten years, more as a source of pleasure and pastime than for profit, I have been an impartial but not indifferent observer of the habits, disposition, and honey-gathering ability of the Italian, black, and hybrid bee.

As a result of my observation I would submit the following short statement.

During the ten years I have kept bees, I have had some of each of the above named varieties; a larger portion however has always been pure Italian.

The Italian bee is superior to the Black in the following particulars, viz:

1st. In gentleness of disposition. 2nd. In graceful form, size, and color. 3d. In adhering to the combs when being handled. 4th. In storing honey close around and in the common center or brood nest. 5th. In gathering up and using wax, lying about the apiary. 6th. In defending their hive against the encroachments of moth.

The Black bee is superior to the Italian in the following particulars viz: 1st. In ability to withstand a greater degree of cold during winter. 2nd. In being less liable to abandon their hive in the spring on account of weakness of numbers. 3d. In maintaining their strength during an abundant honey-gathering. This is undoubtedly owing to the queen promptly depositing eggs in the cells as fast as the young bees emerge. 4th. In building new combs either in boxes or frames for surplus honey. 5th. strong texture of wings thereby enabling this member to last as long as the life of the bee. 6th. In rearing broods two or three weeks later in the fall; thus enabling them the better to get through the winter.

As the Hybrid partakes more or less of the Italian or the Black, so will the characteristics of the one or the other as above enumerated be manifest.

Hybrids that I regard as the best in my apiary, are descended from Black mothers; and were obtained in this way: A Black queen was fertilized by an Italian drone. From the eggs of this queen were reared Hybrid queens and where these young queens became fertilized by Italian drones,

I have Hybrid colonies the most satisfactory.

Therefore if we wish to secure in a colony, gentleness, beauty of form, size, color, etc., and good defenders against moth; ability to withstand cold, maintain their strength during bountiful honey-gathering, and build combs for surplus honey, secure these Hybrids. I obtained more than three times as much box honey from these, as I did from any of my pure Italians last season.

To obtain a large yield of surplus honey from the Italians, the extractor *must* be used.

They *will not* build combs readily in boxes or frames, for the reception of surplus, but instead will deposit the honey, when the flow is abundant, in the brood combs and forstall the queen.

My Hybrids above described will build combs as readily as the Blacks, and give nearly as much box honey as the extractor will from the Italians.

My advise would be to any one wishing to secure *extracted* honey only, to keep pure Italians; because they are the most agreeable to handle, and this has to be done very often during the season in using the extractor.

If you want to obtain large amounts of surplus honey partly in boxes and partly extracted, keep the *Hybrids*. (Second generation from a Black mother is best.)

If you want to secure box honey only, (a less quantity than you can obtain from the Hybrids,) and do not want to handle your bees often, and do not mind being frequently and unceremoniously stung when in the apiary, keep the Black bees.

Camargo, Ill. J. W. MCKINLEY.

Improved Breeding--Queen Raising, etc.

May it not be an important fact in the improved breeding of bees that more particular attention should be paid to the *proper manner of raising queens*; and this brings up a question upon which I with many others would gladly be enlightened.

Has any of our numerous queen breeders observed any difference between queens raised from an old queen, say three or four years, and those raised from one in her first year. In looking over the various volumes of our old *Journal*, I see but little that has a direct bearing on the point. Among poultry breeders it is now pretty generally conceded, that the largest and most healthy chickens are the product not of the pullet, but of the older hens. Such is contended also to be the case in

stock-raising, and even in the propagation of the different varieties of fruit, in fact many other and similar cases might be cited. Should this be an *established fact*, why should it be otherwise in queen raising?

It was my intention to have opened this question last season, with the hope of learning the views of careful and observing queen breeders. It was again brought to my mind by the re-perusal of a valuable article from the pen of the respected Langstroth, in Vol. 1, Page 92, AMERICAN BEE JOURNAL, (1861), as bearing directly on the question at issue. I will merely cite two instances which came under my observation in the season of 1873. I had a queen in her fourth year (the largest I have ever seen with one exception) which was so prolific, and her progeny so industrious, that although she was a hybrid I concluded to breed from her. Not being satisfied with the drones in my own stocks, I took my nuclei to the apiary of a friend about two miles distant (Mr. J. E. Moore,) he having drones from an imported queen, there I bred a number of queens, crossing with Mr. M's drones, and in every instance they proved both prolific and easily handled, some of them even excelling the queen mother in point of prolificness and the markings of their worker progeny. This queen was a descendent of a queen I obtained of Mr. S. B. Parsons in 1861, (which fact called to mind the penning of this article, Mr. Langstroth having spoken of his Parson's queens) and while herself was quite dark her worker progeny were so well marked that they were pronounced by many bee keepers as pure, and some of her daughters were a beautiful orange color. As she had a curious history I may again refer to her.

Again, the same season (1873) I bred from a pure Italian queen the marking of whose bees I was much pleased with, (she being in her third year,) using the same precaution as to drones I had before observed, and with nearly similar results, the progeny of her queens were fully as industrious as these before spoken of, but no more easily handled, neither were her queens any more prolific than were those of the hybrid mother. The same season I bred from young Italian queens (in their first year) as I have in seasons before but I must say not with like satisfactory results.

The old and familiar adage may here be brought to mind "that two swallows never make a spring," therefore, the two favorable instances of breeding from old queens (I am not at all partial to four years but would say at least in the second or third year,) will not establish the truth of

the theory of breeding only from old queens, but I ask in all candor, is it not enough by comparison of results to raise at least a doubt and open this question, if so, one object of my writing this article will at least have been attained, another, and the main object in view is to obtain the opinions or rather *the experience* of practical queen raisers on the subject. Can we not get the views of our Editors, Quinby, Alley, Dadant, Grimm, or indeed many others whose experience would be of great importance in the premises.

No one, I presume, will deny the assertion that to become a successful bee-keeper, to any considerable extent, one should be able to raise at least the queens he uses in his own apiary, if for no other reason than to have them just at the time they are wanted. If so, how shall he breed them? If there is any thing of advantage in the position we have taken it should be known. If it is only an idea, and a mistaken one at that, the sooner it is properly met and controverted the better for all concerned. But as I have already encroached too much upon space which might be more profitably occupied by others, I will close this already too extended communication. "R."

Beaver, Penn., Feb'y 24, 1875.

NOTE.—Since writing the above I have received Mr. Herbert A. Burch's "money in the apiary" in which I perceive he assumes the same position I have taken on the queen raising question.

For the American Bee Journal.

Wintering Bees.

I noticed in the JOURNAL an inquiry from C. D. Hubbard for Mr. Bidwell's *new method of wintering bees*. Now I do not know what method Mr. Bidwell has, but after three years trial of my present method I am full satisfied it is just what I want. I have kept from thirty to forty stands of bees and have not lost a swarm from freezing, in the manner I am about to mention, and I have talked with others, and all have met with the same result. The beauty of it is, that it is the least trouble of any method I have ever tried, and affords the greatest safety to bees in wintering. It avoids the lugging up and down cellar and the moulding of the comb. It avoids the packing in straw and like material, in the various methods resorted to, to keep them from freezing, my present method will leave them on their summer stands all winter with perfect safety. This is done by a peculiar construction of the hives.

The hive is constructed with double

walls and an air chamber between, filled with straw, and the top and sides so constructed as to allow all moisture arising from the bees to escape, and at the same time keep the cold out. This keeps the bees warm and dry, and consequently lively and vigorous, to resist the inroads of insects in spring. The manner of its construction readily meets the approval of one's reason. But it will also convince by the best of all reasoning, *actual experience*. This hive has not been brought before the public as fast as it ought, owing to the poverty of the inventor not being able to properly advertise it. But if any of the readers of the BEE JOURNAL wants further information concerning it, they can obtain it by addressing Keyes & Finn, Clyde, Jasper Co. Iowa.

Marseilles, Ill. A. F. WALBRIDGE.

For the American Bee Journal.

Stray Thoughts.

At our convention, I failed to get up the interest on some points that I wished. The question of wintering was somewhat discussed, but we failed to agree half as well on that point as did that "Dozen of the same ilk" of Berlin, Wis. They agreed at least, that 45 degrees is about the right temperature to keep bees in winter. That agrees with my views already expressed. Many look at the surface of things only, and get the habit of deciding without due consideration. We do not get all the facts, which in time I hope we shall be enabled to. I wrote an essay on the subject, but did not get it ready for the press before cold weather. There had not been a winter since 1871 suited to throw more light on the subject than the present, either for or against my theory. In this section, not a day through Jan. and part of Dec. was warm enough for bees to fly. Much of the time below zero. From Feb. 7th to the 15th, there was but one morning above zero. Feb. 7th, 16 dg. below; 8th, 8 dg. below; 9th 8 dg. below; 10th, 12 dg. below; 11th a few degrees above; 12th 6 dg. below in morning and at sundown 14 dg; 13th 32 dg. below; 14th 16 dg. below; 15th 4 dg. below. Bees have withstood weather as cold as this in the open air without harm, when there have been warm days, either immediately before or after. But how they will withstand such a pull of two months, and the coldest at the least, we have yet to see.

One man from Saratoga Co., has just written me that his bees show signs of dysentery now, 15th of Feb. If bees are lost in any section, I hope we shall get the

temperature to which they have been exposed.

Another point in which we failed to get up the interest which I thought the importance of the subject demands is the fear of stings. I have worked some time for this without much progress. A few have got rid of the fear, and made beekeepers. I cannot advise any one to keep bees that can think of nothing but stings, whenever he goes near them. Education on this subject should begin early. Teach children facts only, and perhaps the most disagreeable of these might be judiciously withheld, while the child is being trained in the methods of avoiding stings. I think I have helped some in this matter, in the smoker given to the public, even though my suggestions may not be fully carried out in regard to careful handling. Many persons are governed mostly by a desire to make money, and consequently are apt to attribute the same motive to the suggestion of others, hence my efforts to get people acquainted with bees are probably often thought to arise from a desire to sell my wares. I wish more persons having experience, would work in this field.

Could not bee-keeping be taught as a branch of practical education in some institutions, thus giving children a chance to receive the right kind of instruction. Perhaps Michigan would be central.

Standard frames is another point occupying considerable thought just now. I fear we shall never agree, because we have different interests. We have all heard of the old farmer who went to mill with wheat in one end of the bag, and a stone in the other, to balance when it was thrown across the horses back. He had done it, and his father had before him, and the method was sufficiently proved. Let us all look at it. See how it is proved.

I will speak of size of frames: Mr. A. wants shallow frames. "He gets more honey, he has' tried it." Mr. B. wants small ones for extracting. Mr. C. wants deep frames, "Bees winter better. They have such in Russia." Mr. D. likes them about square, say 12 inches. Many more want light frames because they are lighter to handle, &c., &c. Now it is not likely we shall all want frames square because D. does, for we probably have not the same reasons for it that he has. I am making surplus boxes 5x6 inches square. I can put six of them inside of one large frame, I don't want the frame any less. This and other advantages, counterbalanced the inconvenience of handling large frames. When one has a smaller frame and to him there are no counterbalancing advantages in a larger one, it seems to me to be very

silly to change. We need not expect one pound more of honey in one than the other, providing we avoid extremes, and give our bees comb enough, and the same protection. Have we not lost time enough in discussing this question and gained nothing. Let each one use what is most convenient in his circumstances. The convenience of manipulating any sized frame can be studied to advantage, and much gained by experience. This together with training bees and men into quiet, wintering, and many other things which we do not yet half understand, may be discovered with advantage.

St. Johnsville, N. Y. M. QUINBY.

For the American Bee Journal.

Wintering Bees.

I have tried different plans for wintering bees for the last seven years, and I think that some winters require different treatment for successful results. This winter I commenced early in the fall, by feeding and doubling up till they were both strong in colony and stores, keeping them on their summer stands, with no upward ventilation and but little below. If any of the fraternity have had good or bad results in that way, I would like to hear from them. It is not convenient with many of limited means to prepare a suitable repository for wintering, and must rely on other ways of management. Please inform me in regard to a suit commenced several years since by Olis & Langstroth against H. A. King, for infringement on the Langstroth bee hive. Has the case ever been settled by the parties, and how? I have not learned of the result. Let us hear; long live the combined Bee Journals.

Mendota, Ill.

Sundry Items.

In my article page 61, last number of JOURNAL there is a typographical error that destroys the sense of the passage. In second paragraph sixth line, for *then cover*, read "then can."

I had better be a little more careful how I attack the masked Ku Klux, for some of them may be my old friends as 'Eccentric' appears to be. See page 64. This reminds me what happened one day many years ago when I was a boy ten years old. I went up stairs to dress in a hurry, and while in the act of putting on my vest I noticed a white sheet crawling through the door of the next room toward me; in a sudden fright and seeing nothing within reach for defence, I suddenly doubled my vest and gave it a blow with all my strength. The object suddenly rolled over, and out emerged the negro servant, rubbing his eyes and face, smarting from

the blow I had given. Since then I could never stand masked objects.

I am sorry to hear reports of the bee disease again. I had hoped that from our close observations and experiments, during the past few years, we had got sight of a *remedy*, or at least a preventive. But it now appears that our observation will go on with experiments a few years longer.

My bees to this day are all O. K. not a single stand *lost*. No disease of any sort. All healthy—only one weak stand and I fear that my bungling work with it last night, has destroyed it. Ah! I know your readers want to know what that bungling work was. So I will tell it for the warning of others, *to let bees alone at night*.

A few days ago I had put these bees in a nucleus with five frames, so as to nurse them until they got stronger, as they had a fine queen that I wished to save. Last night it began to turn cold and I had forgotten to take them in before dark; so went out with a candle to take them in but the wind would not allow the carrying of the candle. So I thought I would risk it in the dark, but I had hardly picked up the nucleus and proceeded three steps before *down went all in a mass*, breaking every comb out of the frames. I then got a light and got the bees back, but found the queen almost dead. Today, it being freezing, it is not prudent to open to see if I am minis a fine queen, for my attempt to carry bees in the dark. The cause of this stand getting so weak was, water leaking through top of hive before I was aware of it.

I would here say to all who don't know how I winter, that I use nothing but the quilts, and in some cases I stuff the caps with straw. I leave off the honey boards from many stands all winter. Thanks to J. Butler, of Jackson, Mich., for his grand honey board, I made several of them yesterday, after reading his article on page 57. I made my boxes just the size of honey board $\frac{1}{4}$ thick by 3 in. wide, light pine and tacked a piece of woolen blanket on the bottom, and after filling with bran, tack any sort of cloth on the top; but for winter use I think I would prefer wheat or clover chaff, or very dry saw dust. I think the frames would be much less trouble than the quilts. We need not put anything else besides these frames on; the quilts are not always enough covering for the bees. I have tried the manure hot-bed around hives, but saw no benefit from it. I think these box quilts will prove very serviceable. I forgot to say that I keep a high close board fence on the north and west end of my

apiary, that effectually brakes the force the wind.

I would here ask friend Dadant if Edward Uhle of Switzerland, is in Italy—if so then Uhle's queen according to him are pure Italians. I have never received a queen from Uhle that was not a hybrid. Nesbit, Winder, and a few others got Hybrids of Uhle. I have had but two imported queens to suit me in every respect, I can rear better ones, but still I am in favor of importing, and would not do anything to discourage it. Friend Dadant may have imported good ones. There is rascality somewhere but I rather think it is all with the European bee-keepers, sending us hybrids when they could have sent pure Italians. Can it be that they are ignorant of the test of purity. I always take the three yellow band as the most acceptable test of purity.

Lowell, Ky.

R. M. ARGO.

Adulteration of Honey.

Seeing a good deal of discussion in the Bee Journals on the adulteration of honey, and being quite extensively engaged in raising honey for market, both box and extracted, I thought perhaps a few words to the many readers of the BEE JOURNAL who are engaged in the Apian business, might not amiss.

In the first place, if bee-keepers who are engaged in raising honey for market will take a little more pains to create a home market, instead of shipping all they raise to Chicago and other cities, to honey dealers, to have it adulterated and make five or six pounds out of one of honey or even more than that, and then for these honey men to ship it back where it was raised and sell it at double the price paid for it, looks like making a good deal from the honey raisers. Let every one who raises honey next summer see that every grocery is well supplied with good box and extracted honey, and there will be no trouble in selling all the honey at home. If the grocers will not buy it, ask the liberty to place it in their store, which no one will object to; allow them a commission on all sales from 10 to 15 per cent and there will be no chance for it to be fixed up with glucose, starch, and slippery-elm bark &c. Congress should make a law governing the adulteration of all articles for family use, placing a heavy fine or imprisonment or both for adulterating anything. There is no country on the face of the globe where adulteration business is carried on as it is in the United States. All kinds of spices, baking powder and other things too numerous to mention are shamefully "fixed up."

I put into winter quarters 165 good stocks of Italians, all right; but the hardest time is to come. I hope to come out all right; it looks as if the parties who write for the BEE JOURNAL were ashamed to have their place of business known. Let every one give their address in full, so that we may know where they live.

Seasonable Hints.

In this month, it is often best, if rapid increase is desired, to divide colonies. If the bees have been encouraged in brood rearing by feeding, and the heat of the hive economized, the bees are strong now—whether the season be late or early. We do not find bees, managed as we advise, dependent on early seasons.

We would advise all whose colonies are strong, and who desire to increase numbers as fast as possible, to commence in this month making new colonies. We would not do it in such a way as to weaken any hive materially. A comb of brood may be taken from one, a comb containing stores from another, and bees from a third. If a queen can be provided for every newly made colony, or a queen cell nearly ready to hatch and empty comb is at hand, the increase may be very rapid and with no danger of failure.

Those who wish to start nucleus hives, can do it best in this month, in this latitude.

There are various ways of doing this. The best one is this: Take a good Italian queen from the hive to which she belongs and put her in some other hive, from which the queen has been removed; with the usual precautions.

The hive left queenless will at once build queen cells, and at this season of the year, a number may be expected. Leave the hive undisturbed until about the eighth

day, then have in readiness several small hives each made to contain three or four frames, the same size as your large hives. Open your hive, ascertain how queen cells they are, and divide its contents among these small hives—putting in each a comb, containing at least one cell—more if you choose. Divide the brood combs and store combs among the small hives and if necessary supply one or more from other hives. Then take the old hive entirely away and set the small hives containing the frames of it close together where the old one stood, the entrance facing *the opposite way*. The bees disturbed by the unfamiliar appearance of things, will find the small hives, and as each has a cell and brood, they will soon settle to work. Care must be taken before night to see that each *small* hive has enough. If one has more than its share, change its place with that of a weaker one. You will then have two, three or four small hives in the place of one, and can keep them all the season rearing queens, or unite them again into one colony after they have served their purpose. There are other ways of starting a nucleus, which we will give hereafter.

Those who use surplus boxes will do well to put them on all strong colonies in this month; though in most localities, bees do better in them before June.

A strong colony of bees has been known to build one hundred square inches of comb in twenty-four hours; at that rate over sixty sheets of comb a foot square could be constructed in three months. The editor of the *Annals of Bee Culture* has had a report of a swarm that built nine sheets of comb ten by thirteen inches in ten days.

Office of the Iowa Board of Centennial Managers.

This is to certify that Mrs. Ellen Tupper of Des Moines Polk Co., being an expert in such articles as are enumerated in Group No. 34 of our Classification of Iowa Products, is duly appointed to act as Group Secretary in charge of her speciality, viz :

The Bee-Keeping Industry of the State, subject to such instructions as our Board may from time to time give in a written form.

Signed this 16th day of April 1875, and attested by the Seal of our Corporation.

ALEX. SHAW, S. H. MALLORY.
Sec'y. President.

I, C. B. Carpenter, Governor of Iowa, hereby indorse the foregoing appointment, this 16th day of April 1875.

C. C. CARPENTER.

Centennial Exposition.

COMMENCING APRIL 19, AND ENDING OCT. 19, 1876.

The undersigned having been appointed, by the Iowa Board of Centennial Managers, Secretary of Group No. 34, accepts the appointment with the hope that every bee-keeper in the State will aid her in the work, by preparing for the exhibition any hives, extracts, bees, queens, or anything pertaining to the industry within reach. Also specimens of all honey-producing plants and seeds thereof which may be found in any portion of the State of Iowa, for exhibition at the coming celebration of One Hundredth Anniversary of the Nation, to be held at Philadelphia, Pa., 1876, I have the honor to request your co-operation in completing this Group, by the preparation and contribution of articles properly belonging within the scope thereof.

Any aid or information will be cheerfully furnished on application. As the Secretary of this Group is also a member of the committee appointed by the National Bee-Keepers Association, applications from any part of the country will be in order.

All articles shipped to my care will be properly labeled and transmitted to the Exposition, under the care and direction of the State Board of Centennial Managers. Such articles as the individual exhibitor may desire can be shipped direct to the care of the Director General of the Exposition, Philadelphia, Pa., under such rules as the Director General may prescribe. All persons who desire to be exhibitors will be supplied with blank applications for space upon applying

to the undersigned. Applications must be made to the Director General of the exposition. For the purpose of keeping a record of Iowa applications, they will be signed in duplicate, one of which will be forwarded to the Director General, Philadelphia, and one to the Secretary of Iowa State Board of Centennial Managers, Des Moines, Iowa.

Trusting that State and local pride will induce you to give us your hearty co-operation I shall expect, without further solicitation, to secure from you, on or before the 1st day of December, 1875, a specimen of such articles as above enumerated, all of which will be duly acknowledged, and ordinary care exercised; but the loss of property by the accidents of transportation, by fire, or by the dispensations of Providence, will in no wise subject the undersigned to damages.

Respectfully,

ELLEN S. TUPPER.

Sec'y. Group 34.

Des Moines, Iowa.

From the *Practical Farmer*.

Uses of Wool in the Apiary.

For the last four years we have used *wool* quite largely for various purposes in our apiary. We use nothing else for stopping up our queen cages, rolling it for this purpose into a tight wad. The bees cannot gnaw it away, and seldom propolise it. We shut up all our nuclei, when first formed, with wool. It can be crowded into place in a moment, admits air, and is easily removed. If we wish for any purpose to shut up a hive, we use wool. In the working season, we keep one "pocket full of wool," and know nothing of the vexations we experienced when using wire-cloth. Occasionally a few bees are caught in the fibres of the wool, but they are for the most part very shy of it, and are quite indisposed to commit *felo de se*, by hanging themselves in its meshes. Robbers will very quickly retreat from a hive well woolled. If we use the words *to wool* and *unwool* a hive or nucleus, instead of to shut up or open the entrance, our readers will understand what we mean.

L. L. LANGSTROTH.

PERSONAL.—This heading, over my signature, may remind some, of my personals in the AMERICAN BEE JOURNAL in 1872. With no intention of reviving past animosities, I desire to say that soon after these personals appeared, I regretted some things in them. For the first time in my life, instead of a statement of facts with what seemed to me the necessary conclusions from them, I used bitter epithets and invectives. Coming from a man of my age and profession this was the less excusable. Perhaps

I never lost so good an opportunity of showing the best way of conducting such controversies as we deem necessary in defence of our rights.

About two years ago I personally expressed to Mr. H. A. King, my regret for the invidious comparisons in which I had indulged, and my intention of withdrawing them as publicly as they were made. Able again to use my pen, I am glad to carry out this intention. If my example has encouraged the acrimoniousness with which questions have been discussed, and controversies carried on among American Bee Keepers, I hope this personal may contribute somewhat to soften such needless asperities.

April 23rd, 1875. L. L. LANGSTROTH.

Voices from Among the Hives.

H. GOODLANDER, Leesburg, Ind., writes: "Bees can be wintered just as safely, and more easily than any other stock. The material from which a hive is made, has a great influence on the health of the bee."

ELIAS HERSHEY, Leaman Place, Pa., writes: "I wintered 27 stands out of doors, without protection, except blankets on top of frames, and they all came out strong, and are ready for work as soon as the blossoms come."

R. R. MURPHY, Fulton, Ill., writes: "About March 20th, some one sent me a registered letter, but the Post Office was burglarized on the 25th. The safe blown open, and the building fired. Nothing was saved. This is the reason why I have not been able to answer that letter."

JOHN DIVEKEY, Aurora, Ill., writes: "I put my bees—43 swarms—in a basement on the 15th of Nov. They came out all strong and healthy about the middle of March without loss. They had no flight for 4 months. They were carrying natural Pollen on the 4th of April. The winter here was very severe, but the opening of Spring is exceedingly favorable. Long may your valuable Bee Journal live and prosper."

DR. N. P. ALLEN, Smith's Grove, Ky., writes: "I have succeeded in wintering my bees in Langstroth hive on summer stands without losing a single stock. My bees are in fine condition and have been gathering from the fruit blossoms for the last week. I had eleven in top story, one week ago. I have four new idea hives. I like them very much. I see by the Journal that they are not so regarded by some, but my experience is that we can raise more bees by inserting empty comb in the center of brood-nest. Can enlarge the brood-nest to double the size, it is ordinary, and that they will come out in the spring with more bees than the Langstroth hive, and with more honey. I hope to be able to make a good report of this season's operations."

H. M. NOBLE, Mount Pleasant, Iowa, writes: "My bees have wintered better than for the past three winters. I had 20 swarms last fall. I put 5 of the poorest in a cave and one died. I put 15 in the cellar, and as some of them got the dysentery I made a box 3½ ft long and put a window sash in one end, and one on the top, leaving one of the sash that I could open so that I

could put my arms in and take off the quilt or honey board. I took some of the frames out and set them on the out side of the hive and cleaned out the dead bees, &c. The most of my bees came through the winter healthy. I got a queen one year ago last July; said to be from an imported mother. I think she is a regular Egyptian from what I have read about them. They have the grit; they work well, breed well, and sting like a demon."

JAS. B. WILSON, Des Moines, Iowa writes: "The winter that has just passed, has been a very hard one in Iowa. I had 4 colonies of bees to go into winter quarters last fall. My bees have been on their summer stands for the past 4 winters, and I have not lost any by disease or freezing, during that time. During the winter, any day that the sun shined or was a little warmer than other days, they would fly out as in summer.

I have not had to feed them this winter or spring, as they laid up enough feed in the lower combs for their own use during the whole winter. I have used the "Finn Porus Wall Hive," ever since I commenced keeping bees. I am not afraid to recommend it to apiarists, as the only one that their bees can be safe in, during the summer or winter. Each colony is so strong in the spring and summer that moths or robbers dare not venture near them."

WM. H. S. GROUT, Poland Center, N. Y., writes:—"The following is what I have done the past season with five, 32 (Kidder) frame Gallup hives and Italian bees:

No.	May 30,	June 11,	June 21,	June 27,	July 3,	July 9,	July 18,	July 25,	Aug. 4,	Total per Hive.
1	7½	3½	20¼	31½	35¼	53	52¾	73	27¼	304
2	7½	3½	12¼	25¼	37	36½	34	60	24½	242
3	6½	4½	18¼	32¼	43¼	44	31	90	27	296¼
4	0	2	16	23¼	19¼	48	38	85	18	229¼
5	6	4	19	44¼	45¼	43½	35	60	13	270½
T.	27	17½	85¼	150	180	225	190	348	110	1,342
	Spring Honey.		Raspberry and Clover.				Basswood.			

Average yield per hive, 268 2-5 lbs.

I think the Gallup hive is just the thing to work bees in, for extracted honey. It is more convenient than two-story hives, and I think will yield better. When you get all the light honey, you have swarms that will gather enough fall honey to winter on, and strong enough to winter on their summer stands. At least that is my experience. Mine having gathered enough for winter for the past three years. The supply is principally from smart-weed. The long hives are not humbug, practically, if my experience amounts to anything; and I believe that I can get more honey from them than I can from the same number of combs in small hives. If 'Eccentric' will try them in a good season he may think better of them, and conclude that they are not such a humbug after all. He should remember that strong swarms gather the honey, and stand a better chance to winter than if they were divided up."

ED. WELLINGTON, Rivertown, Iowa, writes:—"Our long and severe winter is now past. The bee-keeper now knows how many of his stocks of bees has been consumed by it. I came out better with mine than I expected, and as good as the

most of my neighbors. I lost two very light stocks that only had a pint of bees or less; the loss of which I lay to not having upward ventilation—and another lately. We had a fine warm spell. The bees flew finely, then came a severe cold snap, which lasted a week, when it again turned warm. I found one of my weak stocks had clustered in empty comb, away from their supplies, and had passed in their cheeks, and were dead. Making a total of 4 out of 23. Those that I had down 5 feet in the ground covered over with boards and straw, froze as bad as those that I had on top of the ground surrounded with straw. I know of 19 stocks that were wintered out doors, ten with tight honey boards on, and nine with quilts. The result was, that all with the quilts on were alive, and nine out of the ten that had on tight honey boards were dead. The other was a very strong stock in the fall, now it is very weak and troubled by robbers. My bees are now working finely on rye flour."

ARCHIBALD SMITH, Roswell, Cobb Co., Georgia, writes:—"I wrote you a few notes of experience. I *survived* the summer with two hives, large size, single story, movable frames, about a quart of bees in each, but little honey or comb, and had to take out much comb infested by moth. So little honey was made, that I had to feed; and looked into the hives the first week in January, when I found but from 4 to 6 lbs. honey in each. (The winter here has been mild enough to afford the bees a flight every week or two). About the 15th of June, I put a little sugar syrup into each hive, and soon finding great activity among the bees, I examined them and found that the bees from the larger hive were *robbing* the others; but the *peculiarity* was, that there was *no fighting* only great activity, but as there were no flowers, I looked closely until I found they were passing from hive to hive. I have continued to feed; but leave only one hive open at a time. The question here arises, and I want your readers to investigate; does not this account for much loss, in the spring, of swarms just put out of winter quarters, before there are flowers enough to supply the large demands of breeding? And does it not also account for the great increase of some hives?"

JOHN HUGH McDOWELL, Red Fork, Ark. writes: "Bees do well here, never die in winter from cold. I have had five natural swarms this spring from one hive, other hives all sent out more or less swarms. I would like to have a partner who understands bee culture, would *give* him a half interest. I use Adair's and Novice's hives."

ALFRED CHAPMAN, New Cumberland, W. Va., writes: "It has been exceedingly cold, but my bees have wintered very well on their summer stands. I have a shed roof over them and packed straw all around them, but in front. But they consumed much more honey than those in a cellar or house."

In the spring of 1871, we bought a farm remote from neighbors a mile or nearly so and on it was a swarm of bees which the owner did not care to remove, never having received any benefit from them, and in a year or so they were given to us. They were in an old decayed box hive, they

swarmed the first season in my absence, a neighbor hived them in another old box hive, and in the following spring they were all dead.

We put our new swarms into an old fashioned hive, just to make trial and see if they would live and thrive. It was in June, I think. If they lived through the winter, we intended to get a moveable frame hive. Heard of Kidden, of Burlington, last spring all were lively in both hives, and I sent for a patent hive, but they swarmed before it came to hand and I was obliged to put them in an improved, but still a box hive. I had not *learned* that I *must not* hive them on the stand. After they seemed quiet, I went out to see, and the hive was empty. Fortunately, they had gone home, instead of to the woods, as our swarm did the previous year. Now what shall we novices do next. My right hand was large enough for two, from four stings though gloved, bee-veiled, &c., for the little hive was full, and the weather hot. We studied and mustered courage to raise the hive and set another under it, and they accepted it and went to work in it. They built combs and it seemed to me as though were two separate families or swarms. The first year I had one ten pound box of honey, last year probably between forty and fifty lbs. of very nice honey. One box still remains in the chamber of one hive. They are in the open field protected partially by boards and pine boughs. MARY R. SANDERSON.

We send you the January JOURNAL and think you will find [it just what you need. We print your letter without your leave, because we like to show [others interested how one more went to work. You are on the right track and we hope will not loose your bees. We know if you read the JOURNAL you will learn how to manage them so as not to dread their sting, but on the contrary, will enjoy working with them.

Your bees that "went home" did not do so because "you hived them on the stand," but they lost their queen and therefore returned to their old hive. Putting another hive under the old one, was the best thing you could do under the circumstances.

☞ We have a lot of Adair's Annals of Bee Culture for 1870 slightly damaged, on hand—which we will sell for 10 cents each, Postage 4 cents.

☞ The Southern Ky., Bee-Keepers' Association will meet at the residence of R. A. Alexander, on Monday the 19th of May next, and all persons interested in the culture of the honey-bee are invited to be present. We hope some of our Northern Brethren who are posted in Scientific Bee-Culture will attend or send us communications, bee-hives, honey-boxes, &c., for exhibition. They will be cared for and put upon exhibition by the President.

Secretary. President.

Correspondence.

Our Plan of Wintering.

As many of our Bee Keeping friends in different parts of our country are in many cases, yearly being made sorrowful through the sad inroads made upon their pets—the beautiful Italians—and we, having been *blessed* by a course of management, which has not only given us our number of colonies in full, in the beginning of spring, in good shape, but has carried them safely through the *severe* trial put upon them, by our cold and backward springs, of which so many have cause to remember, and hoping to benefit some one or more of our suffering friends, we submit our plan of procedure, to-wit:

In the first place, our bees are wintered in the cellar, under the main part of the house, over which there is a fire but very few times during winter. Cellar 18x22, in clay; bee room, 9x12, partitioned off in one corner, between joists over-head we have stuffed with straw, held in place by a few lath tacked on, the partitioned side is also studded and packed with straw in same manner, while one side and end are stone wall, over all the portion stuffed with straw, we have tacked a covering of building paper, shelves arranged around the sides and one end, none coming *nearer* than *two* feet of cellar-bottom, we thus, you will see, have provided an absorbant, by which all dampness is absorbed. As a consequence, our rooms are as dry as a flint. Here let us say, were we going to arrange *an other room* in the cellar, for bees, would manage to have as *little* of the *stone-wall* in it as possible, for we notice, is there an uneasy colony, or one the least inclined to be diseased, or one weaker than the average in Spring 'tis sure to be, or have come from the stone-wall side, and whenever we were compelled to have a portion of it, would arrange to not let our hives come nearer than 12 to 18 inches. So much for cellars.

About 10th to 15th of Sept., or immediately after buckwheat season closes, which winds up the honey season with us. (During the flow of fall honey, should you not be sure your bees would store enough for their winter's use, do not put off supplying them with a safe amount, either honey or syrup, later than above date as the earlier they get their stores, the sooner will they cap themselves and as a consequence the better will they winter.) We carefully examine each stock and esit-

mate their stores and if any are short, immediately feed them on Coffee A. sugar syrup made 20 pounds to the gallon of water, until they have from 20 to 30 lbs. stores each, according to strength of colony. They are then left to themselves, to be as quiet as may be. As the cool nights of last Sept. and Oct. come on, we contract the entrance to keep them warm. Early in Oct., choosing a day in which the bees are flying lively, we open a hive and set frames in an empty one previously provided for the purpose, then proceed to tack a quilt (made of sheeting lined with a thin layer of batting, quilts made for summer use,) on each of the two sides of the hive, doubling over and to the inside, at top of hive, sufficient of the quilt to let it just reach bottom on back side, and elevated enough on front to allow the bees free use of entrance, use three 8 oz. tacks at top and one at bottom, driving only half way in, so they may be easily removed in taking off quilts. Your hive is now ready for the bees, which return, and when returning examine and see if they have as many as two empty combs in center of hive, if not supply them, placing a frame of honey or syrup between them. If they have unsealed stores, see that they are placed nearest the bees and the sealed removed toward end of hive, by this means the unsealed stores are first used up and you will have no soured stores to give your bees that fatal disease in spring, known as dysentery. Spread combs a little in center of hive, about where clustering is, and if necessary so to do, remove 1 to 3 frames, by a half inch strip across the top of frame and place on quilt, and your bees are ready to let alone, until time of setting away. You will see upon replacing bees in hive, after lining, that the frames do not go to place as easily as before, but by placing one end in position you can easily bring other to place, when you will find your frames are as firmly held to place as though made close fitting. By this process of lining, we not only do away with that great objection to frame hives for winter use, the dead air space around frames, chilling bees and combs, but we enclose our bees in a nice warm nest, surrounded with material which absorbs all dampness and keeps them as dry as can be. The first cold snap in Nov., we prepare to set them in winter quarters by setting them off bottom board, and cleaning that of all litter, and placing a frame, made of inch stuff, in square, on bottom board, then place, have back resting on the frame, take up bottom brood and gently carry them to their place in cellar, setting brood and hive on shelf, close door, and above all let them alone,

only occasionally looking in at door to see that the rats or any thing else have disturbed quilts. Our cellar has no ventilation, except what it gets when members of the family go into it for vegetables, mercurcy usually ranges from 40° to 45°, perhaps for a short time, dropping once or twice in winter to 35 degrees. Well Mr. Editor we have "spun our say," out to a greater length than any idea of at start.

We trust you will pardon us if we have tried your patience, but having once been beginners ourselves we realize how necessary are the details to assist in understanding, after all, success depends more on attending to the details and giving your attention closely, than in a mere attention to general principles alone.

Believing as we do, that there is more of a science in successfully "springing" an apiary than in wintering same, we will, if you so desire, give you an item on our course of spring treatment.

For the American Bee Journal.
Marketing Honey.

I find the best method of marketing my honey, both comb and extracted is to sell direct to the consumer or retail dealer, and not send to honey dealers for them to adulterate. Last year I put a half barrel of extracted and about 50 lbs of comb-honey into my spring wagon, and went among the consumers and sold to them at 12½ to 15 cts. per lb. for extracted and 25 cts. for comb honey, and in a short time I sold all my extracted honey, and could have sold as much more in about a week, as the people found out that it was genuine honey and not glucose, sugar syrup, &c., with a little honey added, as is most of the so-called honey sent out by the city honey dealers, and besides the spurious honey is so high in price that it is beyond the reach of many people that would like honey.

If the producer would take a little time and trouble to furnish the consumer with the genuine honey at a moderate price, and thus get a market established, he will be surprised at the amount he could sell and not be swindled out of his money by honey dealers. Parties that only got a few pounds of me last year, are beginning to speak for 50 to 150 lbs of ext honey, and the prospect is that I cannot half supply the demand, another year, without an extraordinary yield of honey, and I will have 80 colonies (if I do not lose any) to commence the season with. By the producer selling his own honey at a reason-

able price to the consumer, he will drive out all of the doctored honey, as the retail grocers will not handle it. One of our grocery men got some from Chicago, put up last year, and it soured on his hands. He says, no more Chicago honey for him, as he thinks the only honey in it was what little some small pieces of comb contained that was put in and pressed against the glass.

I sold of my own raising last year ext. honey 1700 lbs. comb honey 300 pounds, and comb honey I bought from a man six miles from me, 1000 pounds.

Fulton, Ill. R. R. MURPHY.

For the American Bee Journal.
Tall and Shallow Frames.

As Mr. R. J. Colburn takes exception to the shallow frame, in the March number, page 55, I would like to give some of my experience with tall and shallow frames. Mr. Colburn seems to reason a good deal from theory; but I find in practice, they pay but little attention to keeping brood in an exact circle, but have a wonderful adaptability to circumstances, and will place their brood where they can care for it and keep it warm the easiest. If stocks come out all strong, and keep so through the spring, they will probably breed up well enough in most any kind of hive, but if they get reduced down to a mere handful, as many did the last two seasons, that is what tests the shape of the frame for breeding up. The frames generally used here, takes a comb about 8 inches deep by 17 inches long, and we think that we don't want a comb that will breed up better in the spring; I have used the same frame stood on end, that is 17 inches deep, and found that when I got a stock reduced in those early in the season, I was completely swamped, no amount of cuddling would induce them to breed bees of any consequence, till hot weather and warm nights, they would have a little brood in the top end of two or three combs, and the only way they could spread their brood was to carry it downward, and they could not do that, as they were not numerous enough to carry the heat down. The same amount of brood and bees, started in the middle of the shallow frame, would increase to quite a nice colony, by the time the tall one would begin to do anything. In the long shallow frame, they will spread the brood each way, along the tops of two or three frames, and they have the heat with them, and will raise a great many more bees than they will in the tall one. With strong stocks, or in warm weather, the

tall comb will breed as many bees as the other probably.

I have never used a comb 12 by 12, but have used one 8 inches deep by 12, and found when bees were reduced in spring in that, comb 8 by 17 inches was far superior, from the fact, that bees will spread their brood along the top of a long comb, in weather, when they cannot be induced to spread it latterly across space into another comb. I am now using a comb 10 by 12 inches, and don't think it breeds up as well with weak stocks as the shallow frame, but can't tell why, unless it is because we leave out the lower cold strata entirely, leaving the hive so much warmer. My experience with pure Italians for box honey, corroborates Mr. Butler's exactly, on page 56. Can't our present bee, be improved by judicious selections in breeding?

J. P. MOORE.

Binghamton, N. Y.

For the American Bee Journal.

Missouri Bee Killer, &c.

On page 36, Feb. No. present Vol., Mr. Sonne's article calls for observers to help him to awaken an interest of all beekeepers to the importance of it. I have been acquainted with those insects for four or five years here in this section of Southwest Missouri, but never knew them in Central Indiana or the Alleghany Mountains. In Northern West Virginia, where I have formerly lived, I have seen them destroying many of my bees, and other insects and sometimes each other in the same manner. They are very stupid and dull in cool or rainy weather, and appear to be much more numerous in dry weather and when the sun shines very hot. This country seems to be a natural home for them and there are many of them here, and I think they are on the increase. How much they may interfere with our apiary in the future I cannot tell. I know they kill many of my bees but I cannot see that my colonies are weakened by them. My bees are kept at a good breeding stage all summer.

Mr. Sonne speaks of there being plenty of flowers, and that his bees would not bring honey in, now we have many times past had plenty of flowers for honey; but no honey, because the weather was not such that the flowers would secrete honey. As yet, the cold winds and rains early in spring, when peach and early bloom comes are more of a drawback to me than the Missouri bee-killer.

My bees are in prime order on summer stands.

E. LISTON.

Virgil City, Cedar Co., Mo.

For the American Bee Journal.

Honey Granulating.

In the February number, on page 36, Mr. Charles Dadant says: "That if they (the readers) on the market, from December to June, a so-called honey in liquid condition, they can, with absolute certainty, declare it a sophisticated honey, or at least a honey which, by boiling, or by pure mixture, has lost its character as a true and pure article."

That may be the case, where he lives or in any cold country, and cold may be the cause of honey granulating there, but it is not the case here. I am justified in thinking, that honey from certain flowers has a greater tendency to candy, than that from others, and possibly if both are extracted or strained together, it will all granulate within a short time. I bought in June last, one hundred stands of bees, and commenced to extract on the 27th of July. The honey of that extracting was gathered from white sage, sumac and other mountain flowers. After three or four weeks I extracted again. A great deal of that was gathered from a blue flower, which we here call flea weed, (it smells somewhat like vinegar, but rather strong and disagreeable), which came into bloom after the first extracting. Both lots were treated alike, sealed up in five gallon tin cans, placed out doors in the warm sunshine and stood there for several weeks. I use a great deal of honey myself, have for months, had a can of the first extracting open, only covered with a piece of thin paper to exclude flies, and it is now as liquid as when extracted, only thicker on account of lower temperature. Another can of the same lot, soddered up air-tight, was on examination a short time ago like the one mentioned, and a sample of the same in a two ounce bottle simply corked shows no signs whatever of granulating.

On the other hand, every drop of the second extracting became within two months as solid as lard. Cold could not have done it, for it was in the latter part of summer or beginning of fall, and it is even in winter seldom cold enough here, where I live, in the mouth of a cannon, to find in the morning a sheet of ice one sixteenth of an inch thick. I am therefore inclined to think, that the honey from certain flowers, and particularly from this flea weed, will granulate, while that from others may under certain circumstances do so, and that a mixture of both will granulate within a certain time, dependent on the proportion of the two kinds of honey.

I will only add, that I have five year's

experience in bee keeping, and that what I have stated in regard to last year holds good for the former four.

As people here prefer liquid honey to granulated, I had to melt all my honey of the last extracting.

On page 28, February number, you say: "There is an increasing demand there for honey." Please inform us, who will buy and at what price and in what size and kind of packages. We have always had trouble with our honey candying after it was shipped, and have had to take a considerably lower price on that account. Should be glad to find a market for the candied honey, which, as you say must be the pure article, although our liquid honey also is pure, even if remaining liquid for years.

WM. MUTH-RASMUSSEN.

Los Angeles, Cal., Feb. 22, '75.

For the American Bee Journal.

To Double the Capacity of Hives.

As the matter published in the January No. was designed simply as an explanation of a method, which I accidentally hit upon several years ago, of getting bees to build straight combs; I try to say, in addition, that the method consists in crowding the hive with bees, to double its capacity, (according to ordinary ideas), by means of a division board or, what is better, whenever possible, uniting swarms.

I fill the hive so full that in hot weather some bees will hang out the first night. I prefer the latter way of doing this, for several reasons: I secure not only straight, but mainly *worker* combs; avoid large increase of stocks; am apt to get a big lot of box honey; and avoid the great amount of labor and fussing, (mentioned in explanation published), which may be properly characterized as an application of the old laborious method to the new, necessitated by want of bees enough to properly apply the latter. I had observed that when I filled a hive by doubling, there was little trouble from drone comb in comparison with what there was, when I had to put in empty frames between others as guides, also I thought an increased tendency to build worker comb in boxes, and also a liability of the queen to lay drone comb in the boxes, both of which I attributed to the treatment mentioned, considering them as objections; the former, to be remedied by using only store or drone comb for guides in boxes, the latter, as the result of a want of drone comb below. But on reflection, I am inclined to think it may impart at least, be

owing to my exceedingly shallow frames, they being but little over $5\frac{1}{2}$ inches deep.

I had observed thus far, but had not thought, of this crowding, to get them to build worker combs exclusively, until I saw friend Dean's method of securing all worker combs, published in August No. of *Gleanings*, when it immediately occurred to me that his and my measures each corroborated the other. Novice saw the point, for in publishing, "How to secure straight combs everytime," he comments: "The principal is essentially the one friend Dean works on." *Gleanings*, Vol. 2, page 160. So it seems "the same stone kills both birds."

Douglass, Mich.

H. HUDSON.

Size of Hives.

As to the size and shape of hives, I think we should be governed by the climate we live in. All must use their judgment in the matter. As for me, I like deep frames.

My 16 stands of bees are all right, on their summer stands, though one only had three cards last fall, and was very weak. Now it is as lively as any of them, having bees enough to cover one comb 12x13.

I can open any of my hives, without fear of stings without the aid of smoke or anything else. As no stranger could do this, I argue that my bees know me. Recently I gave my bees some flour, and stood in their course, about 10 rods off, they lit on me, and then went to the flour. I tried the same with a neighbor's bees, but they took no notice of me. If bees do not know their master, why this difference?

Wooster, Ohio.

D. H. OGDEN.

For the American Bee Journal.

The Hive I Use.

Having experimented with boxes for comb honey for many years, I conclude the one I now use is the best that has come under my observation.

And if you think it of any value to the bee fraternity, you may give it an insertion in the JOURNAL.

I take thin lumber $\frac{1}{2}$ or $\frac{3}{8}$ inch thick, cut out two pieces four inches wide, $12\frac{1}{2}$ long, than cut out nine slats $13\frac{1}{2}$ long, and $\frac{7}{8}$ wide, then nail the slats on one edge of each of the two sides, leaving a space between the slats of $\frac{1}{2}$ inch. Then draw lines with a square from each slat across the two sides, and then nail on nine other slats opposite to the first. In putting on the last nine slats use an awl and

shoemaker's pegs, so that they can be taken off easily with the hand. Close the ends with slats $\frac{1}{2}$ inch square with spaces as in top and bottom, put on with pegs also.

The vacancies should correspond with those of the frames. Boxes can be put on top of each other. One filled with honey and bees should be raised up, and the empty one slipped under and left until the bees work in the lower comb.

The advantages are: the conveniences of taking out the honey, and the perfect view of the whole inside without the use of glass. I had two boxes filled the last season 16 lbs. each, would have had more, but had only two swarms to start with, and that in the latter part of May.

W. W. MOORE.

Gillett's Grove, Clay Co., Iowa.

Reply to Dadant.

Dadant, in the March No. of the A. B. J., says: In the last convention of the N. B. K. A., a few bee-keepers have fired at the importation of bees. He says, A. Benedict was the first to begin the fire, and says, he (A. B.) said that he supposed that there were hybrid bees in Italy. Upon reading this, I wrote to him (me) to know on what he had based his supposition. But in his answer he could give nothing definite. He had seen so called imported queens, that were undoubtedly impure; and then says, but for himself (meaning me) all the imported queens he had received were pure. Now if D., will read my letter again, he will see that I did not write him that all the imported queens I received were pure, but far from it. If I am any judge, I have received queens, imported ones, that produced one and two banded workers; and I have received queens that would produce queens, that if mated with black drones would produce a majority of three banded workers; and I have received queens, if there progeny mated with black drones they would produce a majority of black bees. Now, friend D., why is this? If one is pure, so is the other.

If I am not much mistaken, our friend D. in an article written a few years back, for one of the Bee Journals, claimed that there was a great difference in the color of the bees in different districts in Italy. He claimed that the dark ones were claimed to be the best bees; the light colored not so good. I sent friend Dadant some money a year or so ago, requesting him to procure me a queen that produced as light bees as could be found in Italy; but he failed to go, and sent back the

money. The best and lightest colored bees I ever saw, were produced from one of six queens purchased of S. B. Parsons, Flushing, Long Island, several years ago. Parsons had imported a full colony from Italy; this colony was carried over the mountains on mens' shoulders. Undoubtedly this colony was selected for its bright color. The above queen produced workers almost white; the drones were of a dark red color; to stand a few paces from the hive and look at the bees, they appear almost white. And the drones look as if they were entirely black, but on close inspection, they were very glossy and redish in color.

These bees looked very singular, basking in the sunlight, in front of the hive, the bees so light and the drones so dark, they were readily distinguished, the one from the other. I have never seen but the one queen that produced exactly such bees.

Now, my opinion is, that just such bees can be found in Italy. I am not down on importing bees. But I am in favor of a careful and judicious selection of the queen.

I hope friend Dadant will attend our convention, and if we say anything that is not right, he can there correct it, and tell us all about Italian bees.

AARON BENEDICT.

Bennington, Ohio.

For the American Bee Journal.

How to Make Hives.

For the benefit of those who do not know how to make bee hives, and who would rather make them than to buy, I will try to give directions as plain as I can.

In the first place get your lumber dressed on both sides to exactly $\frac{3}{4}$ of an inch. Use lumber just 12 inches wide for the hive, the frames should run from front to rear; the front and back boards are 12x16 with a rabbet $\frac{3}{8}$ x $\frac{1}{2}$ across the ends, and $\frac{3}{8}$ x $\frac{1}{2}$ across the top edge for the frames, the side boards are 12x15 $\frac{1}{2}$, nail on a $\frac{3}{8}$ board for bottom and clamp, and one with a $\frac{1}{2}$ clamp [on top] for cover. Have an extra wide cover to shade the hive in hot weather, make a stand four inches high, with the front board slanting to form an alighting board or "down step."

The frames are 11x14, top and end bars are 7-16 inches thick, bottom $\frac{1}{4}$, top bar is 15 $\frac{1}{2}$ long, ends 10 $\frac{1}{2}$, bottom 14 inches long.

For comb honey place a case six inches deep flat upon the hive, except that the end bars are only five inches long, of course the cover or honey board must be removed and placed upon the super.

Don't think of using extra rabbetts or bevels or quilts; its all nonsense, I think, except in Spring. Quilts or straw mats are then an advantage. For extracted honey use the $\frac{3}{4}$ bottom in upper hive, or not, as you prefer. I prefer the board between sections. For comb honey, don't think of using boxes or a honey board below your comb, I and others have seen the folly of it in cold weather. Section frames for surplus are good, but they are more bother than the common surplus, so I think it better to discard them and never more think of them.

The above described hive can be made for \$2.00, or cut ready to mail for \$1.50 or less by the dozen. R. S. BECKTELL.

New Buffalo, Mich.

A Closing Word With Mrs. L. Harrison.

As an offensively personal article published by Mrs. L. Harrison, some time ago, in the *Prairie Farmer*, appears word for word, in the April number of the AMERICAN BEE JOURNAL, as a communication to the JOURNAL, I ask you, in single justice, to make room for a portion of my reply as published in the *Prairie Farmer*, as follows :

The ill-natured epithets and redundancy of adjectives in your last week's issue, over the above named title, do not constitute argument. As to my logic, let me say to my profound logician-critic that to "put language into my mouth which I was never guilty of" is as she rightly interprets, to misquote me; to "otherwise" falsify "my statement," is to do so in her own language, without quotation marks. Further that "on that subject," (relation of honey bee to horticulture) is quite a different thing from "on that subject at the last meeting of the Illinois State Horticultural Society"—this last being her language, not mine. * * * I care not to waste your space in a war of words with Mrs. L. Harrison, and will simply say to her in conclusion that *were* she "a man," my pen would not be so guarded. As for her contempt, judging from both the matter and manner of her recent communications, I feel more honored by it than I should by her esteem.

The transactions of the Illinois State Horticultural Society, for 1874, which contains a report of the discussion which gave rise to this unpleasant controversy, are just published. I saw no proofs of this report which, with few exceptions, is as correct a statement of my remarks, as could well be made in so condensed a form; and those of your readers who can refer to it will judge for themselves whether Mrs. Harrison's communication in your February number was warranted or not.

In conclusion let me say to Mrs. H. that she is mistaken in supposing that I have any "spite" to vent against her or any one else. But when unjustly assailed

and misrepresented, I am apt to defend myself, even against a lady—however much I may regret the occasion.

St. Louis, Mo.

C. V. RILEY.

Foul Brood.

Having had some experience with this disease for the past five years, it occurred to me that my experiments might be of some value to others; I had noticed for several years, a few cells of foul brood, here and there in the combs, and had been in the habit of cutting them out, but was not aware at the time that it was foul brood, but now recognize it as the genuine disease in a mild form.

In the fall of 1870, the bees filled up the combs late in the season with watery honey, mostly from fireweed. Cold weather came on suddenly, and the bees were unable to cap it over. The result was, that most of the swarm had the dysentery, and were lost during the winter. Some may say that if they had been properly housed, they would have come out all right. This, I am inclined to doubt, as one of my neighbors lost fifty swarms in a house constructed for the purpose, when they had always done well before. In the spring the uncapped honey soured, and the pollen fermented as though yeast had been put into it. The combs were used the next season to increase the size of the hives, and became the seat of the disease, which was spread by changing combs, through all the swarms. The remedies resorted to this season, were to take away the combs most affected and replace with empty combs from the hives when the bees had died the winter previous. I learned in the operation, that while the first brood hatched in combs which had contained sound honey or fermented pollen was badly diseased; brood in combs that had been filled with capped honey was but slightly affected until the third set of eggs was hatched. All the honey was extracted from these combs before they were put into the hives. From two swarms which were badly diseased, the combs were all taken away, and the bees put into new hives, and treated as new swarms. One swarm was fed with honey extracted from the diseased combs, and at the end of four weeks, was found to be the worst diseased swarm in the apiary. There was not live brood enough to be worth saving, and the combs were again taken away, and the bees put into a clean hive as before, together with the bees that had hatched from the old combs. They were fed with sugar and water, to give them a start, and in the fall were examined and found free from any signs of disease. The other swarm from which the combs were taken, showed no signs of infection. The old combs with a few bees to take care of the healthy brood were left in the old hive. The badly diseased combs were destroyed as soon as the brood was hatched. Combs that were clean were left for the bees to store honey in. This swarm though not strong, stored a little over one hundred pounds of extracted honey. The bees were kept without a queen, and allowed to wear themselves out gathering honey, and as soon as they were so weak that there was danger of their being robbed, the combs were all taken away, honey extracted, and

combs destroyed. The few bees left were given to swarms, undergoing treatment, or destroyed as circumstances dictated.

The old swarms treated as new, this year, and the succeeding years, have come out free from infection with the one exception spoken of above. Unfortunately for my experiments both these swarms were lost the winter following, and I was left with none but the old stocks that had more or less foul brood in them. The next spring I kept the disease in check until swarming time, by vaporizing the combs with hyposulphite of soda. Then removed the combs and treated the same as the year before, with the exception of trying to clean the cells as Dr. Abbee recommends, with an atomizer. It did not work to suit me, and I afterwards used a small bulb syringe which did the work easier. I found it a long and tedious job, to open and clean the cells filled with putrid matter. It appeared to be effectual in all cases, except when there was a deposit of old pollen in the cells, which the bees would not clean out, and the brood raised on top of it would be infected. The most difficult work of all, was to clean out the cells where the larva had died and dried up in the cell, without being capped over. This dried up larva is the coffee colored deposit found on the bottom board. The bees will clean them out after it is vaporized, but the disease does not appear to be entirely eradicated from them. The bees seldom uncap a cell filled with putrid matter. They make a small opening to see what the trouble is, and leave it in disgust. The amount of work attending the cleansing of the combs, and the uncertainty of the result, brought me to believe that there was no economy in trying to save them. That it was better to keep the bees in the best of these old combs, without a queen, and get all the honey you could from them, and destroy all the combs in the fall. Since then I limited my operations to this idea. As soon as the brood was all hatched, the honey was extracted, the best or cleanest combs were vaporized with hyposulphite of soda, the hive washed with the same, making all as clean as possible. Whenever honey is extracted, the combs are vaporized and put back into the same hive until the honey season is over, or the bees are worn out. The combs not used, are melted into wax as soon as possible to make sure that no bees get to them. Too much care cannot be taken to prevent the spread of this disease. I should not handle healthy swarms after opening an infected one, or use any of the tools for that purpose. I am satisfied from feeding one swarm with the honey extracted from diseased combs, that it is almost sure to carry the infection with it. If I wished to experiment further with it, I should try soaking the combs in a solution of chloride of lime, and afterward clean with an extractor as suggested by Dr. Abbee. We ought to be thankful to Dr. Preuss for his microscopic examinations and Dr. Abbee for remedies. I treated my hives to a bath of burning sulphur by making a fire on the ground with a few chips, placing hives over the fire one on top of the other, without any top or bottom board, the heat passing through the hives like a chimney. After they were well heated up, a handful of sulphur was thrown in and a cap or board put on the top to keep the fumes of sulphur in. I then cleaned up the hives, gave them two good coats of paint inside

and out, and count them as good as new. All frames and honey boards that were worth saving, were baked in a stove oven, and put in order for use, confident that they are free from anything that will start the disease. I introduced the disease the second time, into my apiary with a swarm bought in the spring of 1873, and I am fully satisfied that in this case it was caused from fermented pollen, as these combs were the first affected and the only ones for some time. Had there been any disease in the hive the year previous, it could hardly have escaped my notice when the combs were transferred to frames.

By this treatment, I have as many healthy swarms at the close of the season, as I had diseased ones in the spring, beside the honey which the bees hatched from the diseased combs gather, which is largely in excess of what I had expected.

I have sometimes got a few boxes of honey from the old swarms treated as new, but am satisfied if the hive is well stored with honey, and the bees in good condition for winter.

One great problem to solve is, is there any danger to other apiaries in this way of managing the swarms?

My opinion is that after the honey has been extracted the second time, and the combs have had a second vaporizing, that the honey if taken to a healthy swarm would not carry the infection with it. I should be afraid to use the old combs for brood combs without further treatment, as the old pollen might still retain the seeds of the disease.

I have noticed that the swarms kept without a queen, cap a large portion of the honey with an oval cap like that over drone brood. This has been so universal that I suspect something wrong with the queen in any hive when I find honey so capped.

East Saginaw, Michigan.

Getting Honey in Boxes.

Paper read at the seventh annual session of the Michigan Bee-Keepers' Association, Dec. 16th and 17th, 1874.

At your request, I will give a brief description of our way of making box-honey. Not, however, with the idea of instructing your association, or of influencing any one, who has had more experience. We haven't got it perfect yet by any means.

THE HIVE.

I haven't had experience enough with the side-box hive, to be able to recommend it for general use. If bees will swarm from them, as readily as from top-box hives, then we have our labor in vain, in making more expensive hives, and in putting on a greater number of boxes. Bees swarmed immoderately last season in this section, from all kinds of hives.

I can safely recommend the Langstroth hives for box-honey, as I have had experience in their use, and they are successfully used, and are the leading hive in this section. It is ten inches deep, with ten frames.

THE MANAGEMENT.

As we have but little basswood, we are obliged to manage our bees, so as to have honey stored in boxes, from white and alsike clover, tulp, &c., in the early part of the season, (otherwise, we should have no

white honey to sell, and the business would be unprofitable). To do this, we design to get our combs well stocked with brood, and our hives filled with bees, by the time that clover begins to yield honey. Then we keep all old stocks strong, put on the boxes, a full set of 12 at once, and when they get so crowded with bees, both the hive and boxes, that we think there is danger of their swarming, we take away a card or two of cutting brood and adhering bees, and replace with an empty comb, or an empty frame. The brood and bees drawn, form nuclei. With some stocks, the drawing will have to be repeated after a few days, while others don't seem to start work in the boxes until we put in an empty frame, and set them to making wax in the hive.

Those stocks that are building comb in the hive, will need to have their combs looked over, about once a week while the yield of honey lost, in order to cut out the drone comb, before the brood is fed in it, so as to have it nice and white for the bees. It requires the exercise of some judgment, in drawing brood, as it is better not to draw any and let them swarm out, than to draw too soon, or too much. The amount of brood taken depends so much on the yield of honey, the condition of the hive, and the quantity and age of the brood on hand, that no special rules can be given, and each must learn from experience in his locality.

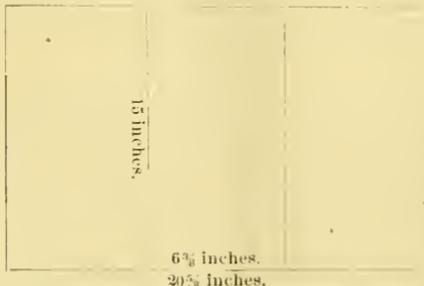

KEEP STOCKS STRONG.

Each old stock is kept strong, and the extractor is not used on any stock that is storing honey in boxes. If they are well shaded by large trees, and situated so as to have a free circulation of air around the hives, by raising these up a foot or so from the ground, and a little brood taken away from time to time, as they can spare it, they will trouble but little about swarming in seasons when the yield of honey is good.

THE BOX ARRANGEMENT.

We do away with the honey board entirely, in order to bring the boxes nearer to the brood, and to give more free access to them, than we could do through the honey board; we like the two-comb box best, 6 3/8 inches long by 3 3/4 inches, comb space 5 inches high. We put twelve such boxes on a hive that measures 21 1/4 inches in length by 16 wide (outside measure), by using a rack or clamp in this form.

TOP VIEW.

Take stuff 3/8 inch thick, 3 3/4 inches wide, cut four pieces 15 inches long, and two pieces 20 3/8 inches long, nail through the long pieces, into the ends of the short pieces, with finishing sixes, leaving the spaces 6 3/8 inches plump, so the boxes will slip in easy, four boxes in each row; then take hoop iron, cut four pieces 15 inches long, and

punch four holes in each, large enough for a latn nail, turn the rack over, and nail a piece of hoop iron on the bottom edge of each cross-piece, so as to support the boxes. The top of the hive should be planed down, until the bottom of the boxes come down within 3-16 of an inch of the frame. This rack will hold 9 three-comb boxes, or 18 one-comb boxes, or 12 two-comb. We prefer the latter, with three slits in the bottom of each box. The slits are 1/2 inch wide by 4 3/4 inches long, one in the middle and one within 1/2 inch of either side, leaving an inch of sound wood at each end for strength. There should be 1/8 of an inch side shake, to each row of boxes, for convenience in getting them out.

TIERING UP.

When the bees get the first tier of boxes full, and begin to seal up, and get it sealed up half way down or so, we raise them up and put a set of empty boxes under them, with slits in the top to correspond and guide combs in place. When the first set of boxes are nearly full, is the most critical time with us, as they are then crowded for room, and get the swarming fever in consequence. If the whole set are not ready at once, we would raise one row, or even one or two boxes if no more are ready; can give room by tiering up instead of drawing brood; use a rim to make the cover six inches deeper for each tier.

RISKS OF SWARMING.

In keeping all stocks very strong, we of course take some risks of swarming. One wing of each queen is clipped, so that there is no climbing of large trees, or going to the woods about it. We have found the following plan the most successful to quell the swarming fever after they attempt to swarm: Have saw-dust, or tan-bark around the hives, or else keep the grass cut very close, so as to find the queen readily when a swarm rushes out; pick up the queen and put her in a wire cage, and wad a piece of paper in the mouth of the cage to confine her till the swarm returns, then cover the old hive with a sheet or large cloth, to prevent the bees from entering it, and place an empty hive or box in front of it, in such a manner as to catch the swarm when it returns; lay the queen and cage down at the mouth of this hive, and when the bees begin to enter, liberate the queen, and they will go in more readily; when they have entered, remove the swarm to a new locality, a rod or two distant, in the shade if convenient; having swarmed they will adhere to the new location. Now remove the old hive a few feet to one side, and place a nucleus with an unhatched queen cell, or an empty nucleus hive, on the old stand; take off the boxes from the old hive, take out the brood combs, and brush off every bee remaining in the hive, into the nucleus. If the hive containing the new swarm, is the same size of the old one, we would put brood combs (as fast as we clear them of bees, of queen cells, and drone brood) directly into the swarm, and let them occupy it. The boxes should be cleared of bees also, and put on the swarm, and tiered up if any are ready. Now we have the bees sorted. We have a new swarm on a new stand, that is, we have all the bees that are favorable to the old queen with her, and have given them all the worker brood, and all the boxes, and we have got rid of all the bees that were raising queens. When we have

served them thus, we have found, that they generally resume work in the boxes, and make no further trouble about swarming for the season. In view of the condition of the honey markets, it looks as though box-honey would be superseded by small frames, as the exclusive honey dealers cut out a great deal of comb-honey, and put it up in jars with extracted honey. I believe small frames are well liked by consumers everywhere, but are not well liked by large grocers, where they deliver all goods to the consumer in wagons.

J. P. MOORE.

◆◆◆◆◆

For the American Bee Journal,
Patent Hives and Venders.

In reading the articles of some of your correspondents, one would almost be led to believe that patent rights on bee hives are and have been all humbugs and those owning or selling them the biggest swindlers outside the pale of law. Now let us carefully examine this subject and see if this business is wrong and deserving the condemnation of all honest apiarists. Is it anything against a worthy patent right, that some one has been made the dupe of sharpers and bought a useless article, perhaps, what purported to be a patented bee hive, when if they had subscribed for and read any one of our BEE JOURNALS, they would for half the money, been intelligently posted and proof against all humbugs in the shape of worthless bee hives.

Query: Does it detract from the merits of the old AMERICAN BEE JOURNAL, because its issues were copyrighted?

Are patent laws considered in all civilized countries so necessary to foster and encourage invention, but blots upon the Statute Books, which ought to be wiped out? Can any considerate person demur at their justness and hesitate to acknowledge their protecting influence in fostering improvement whether it be an intricate piece of mechanism, an agricultural implement or a movable comb frame bee-hive. Is Langstroth's work on the Hive and Honey-Bee of less value because it recommends a bee hive invented by its author, and explains the advantages of the movable comb frame? Do we think any the less of the teachings of this eminent apiarist because he presumed to obtain a patent upon the hive he had spent the best years of his life in devising to meet the wants of the apiary, and which added millions of pounds to the honey surplus of the country besides giving a new impetus to bee-keeping? Is not as quoted by Mrs. Tupper in her Essay for Agricultural Report "The laborer worthy of his hire." Have not patent hive men in bringing their hives to the notice of the public furnished advertisements for our journals, promoted bee-culture and helped to create an interest in this much neglected pursuit? Do not the articles written by the elderly gentleman, Mr. Jasper Hazen, though somewhat devoted to his pet theory "overstocking" infuse new life into bee-keeping and well repay an earnest perusal? Have not Mr. Hazen and Mr. Abbey demonstrated what may be done in the way of obtaining surplus honey from side storing hives, by piling boxes either at the side or ends of the frames?

Have not the frame of the American bee-hive introduced by Mr. H. A. King, become a standard with some apiarists, as has the varied forms of the Langstroth frame, and who would dispense with their use for ten times what their rights cost them. What Mr. Harbison has done to develop the culture in California, as demonstrated by his shipments of tons of honey from the Golden State is in beautiful contrast with the tableaux presented in the moving of his first swarms across the plains before the track of the iron horse had spanned the continent. Yet this same Harbison is, or was a patent right bee-hive man.

What is true in the above mentioned cases is the same with numerous other patented hives, each possessing more or less merit as skillfully handled by the operator having it in charge. In most cases a practical apiarist could take any of the movable comb frame hives now in use and be successful with them, whereas a tryo might fail with the best hive extant. Do we not see the hive invented and used by New York's venerable bee-keeper condemned by an Ohio "Novice" and yet read of a correspondent to his "gleanings" going through a yard of 60 Quinby hives in an almost incredibly short space of time for such an operation? And that New York's great honey raiser, Capt. Hetherington, of Cherry Valley, had gone to some thousands of dollar expense in changing his hives to this same (by Novice) condemned style. Who among your many readers would hesitate to purchase the right to make and use the perfect bee-hive (not yet invented.)

At present the hive best adapted to the attaining of surplus and successful wintering depends more upon the skill of the operator and not in the make of any particular style, though some may possess great advantages over others. In consideration of all these facts is it not more advisable to encourage improvement, trusting to our judgments to distinguish what is and what is not best for us to use and not frown upon or discard a worthy article, because the inventor has been to the expense of getting it patented.

Does it detract anything from the merit of a well made and painted hive, because you can get a non-patented simplicity for one dollar which in the estimation of many, would be dear at most any price. Does it look reasonable that one who has made a small fortune out of patented bee implements, prompted by a remorseful conscience should at this late day conclude that selling rights is wrong and advise bee-keepers "to invest no money in territory for patents of any kind." Yet in the same issue of his Magazine advertise for twenty-five cents to send directions for making the "International" which said directions sum up thus. "An ingenious mechanic might make a hive nearly correct from these directions; but we advise all to remit for a sample hive which we will send from the nearest factory." Probably a second attack of the above nature will lead to the publishing of these directions free but never include the sending of a sample hive. No one who has sent seventy-five cents for a much advertised bee-feeder and in return received a tin cup, worth about 15 or 20 cents, and which could be hired made at most any tinsmith's for 9 or 10 dollars per hundred will not be at all surprised at this change of conscience. Has this the look of a strictly con-

scientious move, or does it rather savor of a change in policy to create a larger demand for advertised wares perhaps at the expense of those who are selling patented articles. Another loudly proclaims that his wares are not patented, but when you think you could manufacture the metal corners cheaper than to send to Ohio for them and write for particulars, you receive in reply to your inquiries, that the corners are not patented, but the machine which stamps them out is, and costs in the neighborhood of \$2.50; that you can manufacture for your own use, but not to sell. Generosity unparalleled: you can have the privilege of paying \$2.50 for a patented machine to manufacture perhaps \$20 worth of tins for your own use and then hold up, or find yourself brought before Uncle Sam's bar of justice, to answer for infringement of the patent laws. Oh, consistency thou art a jewel?" While exhibiting honey at the N. Y. State Fair, last fall, I had an opportunity to converse with many bee-keepers, and found representatives for most kinds of hives in general use, not one of whom complained of ever having been swindled in buying a patent bee-hive. My observation is that improved bee-keeping and patent hives have gone together and that we are pretty certain to find the old gum in use where the brimstone theory is still in vogue. I would in no way apologize for a hive or queen swindler, but do not believe in condemning the genuine because there is sometimes a counterfeit. We have this consolation that the Patent Laws do not compel us to use a patented article, consequently it does not suit us, all we have to do is to let it alone.

The present demands the united action of those interested in promoting the interest of bee-culture as a broad field for occupation remains unoccupied, and those who are devoting time and money to the furtherance of this neglected industry are entitled to our encouragement, that they may succeed in devising means to secure more of the tons of liquid sweet which annually go to waste for want of gatherers. This secretion of honey which only takes place when atmospheric conditions are favorable, often vanishes with the disappearance of the morning dew and without plenty of laborers cannot be saved. The field is broad and open to all. There need be no clashing of weapons, for as a rule he who vends a hive will endeavor to introduce the best, as he has a reputation at stake and if he makes a mistake it will be an error of head rather than of heart.

C. R. ISHAM.

Peoria, Wyoming Co., N. Y.

Enemies of the Bee.

I notice in the February JOURNAL an article on "Bee Enemies," giving a description of the *Asilus* family, and an account of their operations as bee-killers. Now we have an insect here called the mosquito hawk, that is very destructive to bees, and resembling the insect described in the article referred to, but is much larger, measuring two and a half inches and more in length. It is no doubt of the same family, but being no entomologist, I cannot say. This "hawk" makes its appearance usually about the middle of June, and comes in numbers varying with the locust of Egypt, or grasshoppers of Kansas. For the first month or so, they are

seen only at evening, near sun down, but as the season arrives, they operate to some extent the whole day; always turning out, however, in great numbers, in the evening. They seem to be always on the wing, except when devouring their prey. The air is filled with them, darting hither and thither swiftly, like bees swarming, and almost as dense.

They take the bees while on the wing and when settled on the hive, by pouncing on them, just as a chicken hawk does upon his prey, and then light upon a perch, high up in a tree, if one is convenient.

In what way they operate on the bee in devouring it, or what part they eat, I have never been able to discover, from the fact that my apiary is in the midst of tall native oaks, to the limbs of which these cannibals resort to regale themselves on their captives. They all disappear about the first of September. From their great numbers and the length of time they operate, say three months, they must destroy millions of bees.

How to destroy these "Jayhawkers" or prevent their ravages, is what puzzles me. To knock down a few hundred with a bush, as you may easily do as they whiz past, does not seem to lessen the number. As McBeth said of the English: "The cry is, still they come." Let us hear from some of your *bug* men, on this mammoth asilus of the South. Last year was a very poor year for honey until September, when the bees commenced on the smart weed, and for five weeks they worked on it, gathering abundant winter supplies of the richest and most delicious honey. I never dreamed of that weed producing honey or being good for anything else before. It grows here in great profusion, and is certainly the most valuable honey-producing plant we have in this region.

J. APPLEWHITE.

For the American Bee Journal.

How I Succeeded.

I promised in the July No. to report my success during the summer, with the High Pressure Hive worked on the different plans proposed, viz: Hazens' Adair vs. Gallup, &c.

Well, after breeding up largely in the spring as I was able, it being a very late one, I arranged swarm No. 1, to work on Hazens' plan, and got 32 5 lb. boxes imperfectly filled, about 125 lbs., divided the swarm in September, and with an extractor took 60 lbs. that was not needed for winter.

Swarm No. 2, I worked on Adair's long one-story, extended it to four feet eight inches, eight inches more than I got occupied, worked exclusively with the extractor, got a trifle over two hundred pounds, divided in September made two very large swarms.

Swarm No. 3, worked two stories, full size, with forty frames. It seemed too large, and was not occupied to advantage. I worked with the extractor, got 148 lbs. divided in September.

Swarm No. 4, I divided as soon as bred up, worked them in the single high pressure hive, two story each; got 305 lbs. from the two.

Swarm No. 5 and 6, I worked full size, lower story, with twenty frames each, with long boxes and little frames, in supers. No. 5 gave a good yield of honey. No. 6 after

running some time in the summer with a poor queen, they superseded her or rather I did; but they hardly more than got into condition for winter. The six figured up to 1,200 lbs. and a trifle over, and four swarms of increase.

I would say that I had the benefit of about sixty empty cards. My whole apiary of 35 swarms, in the spring, gave me 2,400 lbs., and 32 increase, and are now, March 11th, in close confinement, numbering over 90. The thermometer ranging from 38 to 45 degrees above zero, all seem to be doing well. I am inclined to the belief that a long one-story hive will allow more increase than any other form of hive; but as to surplus honey, I choose to experiment farther before I decide.

A. H. HART.

Appleton, Wisconsin.

Wax Melting.

It is a great saving to have a good place to collect all scraps of wax, until melting time. I make an article that costs only three or four dollars, that makes a good receptacle. It is made in this way:

Get a piece of tin, zinc or galvanized iron, about 3½ feet long, and 3 feet wide, form it into the shape of a sap trough, put ends in of the same material, and in the bottom an inch hole. Then get 4 panes of glass and make a frame for them like a window sash, and put it over the trough-shaped tin, making it tight so that the bees cannot get in. It is then ready for use. Set it in a sunny place, and put in the comb, and in a short time it will melt and run out at the hole in the bottom. Set one end up about six inches higher than the other.

I put my bees out of the cellar on March 26th. They were in good order. Four were very weak and I expected to loose them. I also lost four others out of 153 swarms. All the bees that were wintered out of doors in this vicinity are dead, so far as I can hear.

Campton, Illinois.

R. MILLER.

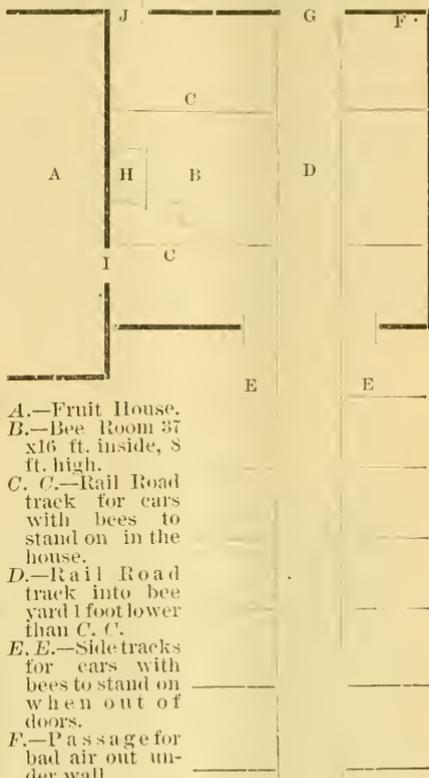

For the American Bee Journal.

Report of my Apiary.

One year ago I had 122 colonies of Italian Bees, in a second story room, 16x19 feet inside, double walls one foot thick, filled with saw-dust; temperature ranged from 39 degrees to 60 degrees. I had on May 1st, 86 colonies, 36 having gone up. I took 70 of the best colonies left, and united them, so as to make 44 colonies. On the 12th of May, moved them (the 44) on spring wagons (2 loads) 17 miles to a large poplar (*Liriodendron tulipiferus*) grove, where they gathered 5308 lbs. of honey, taken out with extractor. On June 20th, we took 36 of the 44 colonies to a linden (*Tilia americana*) grove, where they gathered 3259 lbs. of honey, also taken out with extractor. In all, 8567 lbs. of honey. The 16 colonies left at home, we made into 51 nuclei. August 7th, brought the 44 colonies home, built up the nuclei into strong colonies, fed them 1468 lbs. of A. coffee sugar made into syrup, 1 lb. of water to 2 lbs. of sugar, boiled, put nothing else in it. We took the combs all from 8 colonies, fed them syrup, and had 80 combs built by them, 9¼ x16½ inches. Fed one colony 94½ lbs. of syrup, they built 10 full combs; we then ex-

tracted 44¼ lbs. of syrup from the 10 combs, so that the 10 combs cost us \$4.00, with sugar at 12 cts. per lb. We have sold 4562 lbs. of honey for \$1,015.90—\$110.00 for cans, being an average of 19.8 cents per pound.

We have built a room 37x16 feet, 8 feet high inside; wall one foot thick, filled with saw-dust, on the following plan:

A.—Fruit House.

B.—Bee Room 37 x16 ft. inside, 8 ft. high.

C. C.—Rail Road track for bees with bees to stand on in the house.

D.—Rail Road track into bee yard 1 foot lower than C. C.

E, E.—Side tracks for bees to stand on when out of doors.

F.—Passage for bad air out under wall.

G.—Ventilator for air above the ceiling to come into room at the floor.

H.—Ventilator in ceiling for air to pass out.

I.—Small door into bee room.

J.—Door to give free ventilation at any time when necessary.

I have cars built so that 20 colonies stand on each car, 10 on one side and 10 on the other; fronting 10 east and 10 west, set 1½ inches apart, packed between with buckwheat chaff. When a day comes that the thermometer shows 45 degrees in the shade, we run the cars out of the house to let the bees have a play. We have had them out twice this winter. We have 100 colonies on 5 cars and 13 on another. Can run them all out in twenty minutes. Will let them stand on the cars until about the 12th of May, then move them to poplar grove. The chaff is to keep them warm in the spring, after they are run out of the house permanently, until moved away.

We have the yard in front of the bee-house covered with gravel, so that when a bee gets down on the ground it can get up on a pebble to start on the wing again easily. The yard is south of the house, and is dry and warm.

We will have a stone trough 3x5 feet with bottom covered with pebbles, and a water vessel so arranged that the water in the trough will stand just high enough for the bees to alight on the pebbles and sip the water. Also a zinc pan 3x7 feet, 1½ inches deep, with lath 1x¼ inch, standing on edge, every 3 inches across the bottom of the pan, so that when there is flour one half inch deep in the pan, the bees can get up on the lath to fake wing. The trough and pan will be on a car that can be run into the beehouse when the weather is unsuitable, out of doors.

We extracted the honey from the combs four times during the season. Four persons can take the combs out of the hives, extract the honey and put it in barrels, at the rate of 1500 lbs. per day, and put the combs in the hive again easily. Our extractor is one of our own make, and will take 4 combs at a time. The can is stationary. Next year we expect to have the machine arranged so that the honey will run into the barrel as extracted, which will enable us to take out 2,000 lbs. per day. Our hive is the Langstroth Double Story, 30 combs.

For the American Bee Journal.

Bee Items.

I notice in the March No. of the JOURNAL an article on numbering hives. I agree with Mr. Wilson, and think it very necessary that every hive should be numbered, and its stand numbered to correspond, especially if the bees are wintered in doors. I once concluded to change the location of my nucleus hives by setting them out in spring directly on their new stands. They had been in the cellar about four weeks and I thought would not remember their old location. But I soon found out different. The bees, in returning to their hives, all went back to their old stands, and I was compelled to set their hives back again on the old stands. Now if there had been other hives sitting on these nucleus stands, I would surely have lost all my nucleus swarm, as the bees would all have went into the hives that were sitting on their stands, and I should not have noticed it; but as there were none there I noticed the bees flying about hunting for their hives, and I moved them in time to save them.

I raised an Italian Queen in a nucleus, and as soon as she became fertile and laying, I attempted to introduce her to a queenless stock in the farther end of the Apiary. I caged her and waited the usual time, then examined them but they would not accept her. I kept her caged eight or nine days, feeding her every day myself, but they would not receive her. So I concluded to open the cage and let her out on the comb and see what they would do, but instead of that, she took wing and was out of sight in a twinkling. I stood still waiting for her to return to the comb, but she did not come. I gave her up for lost, but thought I would look in her nucleus where she was hatched, and sure enough, I found her imprisoned by the bees, they having sealed queen cells would not receive her. It has been said that it makes no difference in sitting bees out in spring if we do set them on one

another's stands. But I can't believe it. They will recollect their old stands a long time, and it causes a disturbance among them by having strange bees trying to get into their hives. Besides a great many are killed in entering the wrong hives, as they are taken for robbers. I have the entrance blocks to my hives numbered and a corresponding number on each stand. I carrying my bees out of the cellar, I notice the number on the entrance block and set the hive on its own stand. It is no more trouble or work to set them out right, than it is to set them wrong. "Have a place for everything, and keep everything in its place," I think should be applied to bees as well as any thing else.

J. M. BROOKS.

Columbus, Indiana.

New System of Bee-Culture.

"Coe's Apiary" is a Bee-House and Bee-Hives combined. The house is used as a permanent receptacle, or summer and winter stand, for the hives; and is so constructed, that the room containing the hives, is protected on all sides by a series of dead-air spaces. And, being warmed and ventilated by the heat generated by the bees, the air inside may, by the proper adjustment of the ventilating flues, be kept of an even temperature—higher or lower as desired—quite independent of the atmosphere outside.

It is not claimed specially for this system, that it will produce fabulous amounts of honey from individual hives, unnaturally pushed for that purpose. But it is claimed, that it reduces to a practical, well defined method, all our present knowledge in bee-culture; by means of which, an average annual product may be depended upon with as much certainty as in any other branch of industry.

Among the many excellences of this system the chief one perhaps, is, that it possesses in great perfection, all the conditions necessary to wintering bees without loss, with the smallest consumption of honey—combining the desirable features of a summer stand and special winter repository, without the expense, labor, and trouble of either. It is also specially adapted to the necessities of bees during the changeable, windy weather of early spring, when they require a higher and even temperature to facilitate breeding, and when the hives must be frequently opened.

As in winter the temperature of the room may be kept above that of the outside atmosphere, so in summer it may be kept below; thus protecting the bees from severe extremes, both of heat and cold.

Another valuable feature of this system is, that it overcomes entirely that greatest of all objections to bee-culture—the fear of being stung.

The bees adhere more closely to the combs, and are less disturbed, than when a hive is opened in the bright sun-light, and any that do leave the combs fly directly to the window, and not into the face of the operator. Veil and gloves are dispensed with, and visitors may stand by and witness all the manipulations of a hive without the least fear of being stung. For all the operations to be performed in an Apiary; such as, feeding, transferring, making artificial swarms, extracting, placing and removing surplus boxes, introducing queens, queen-

breeding, equalizing, &c., this system affords conveniences and facilities so far superior to the out-door system, that it is difficult even to make a comparison.

This mode of bee-culture also commends itself for general use, on account of its cheapness.

The house and fifty hives will cost about one-third less than the same number of good out-door hives. And while the house and hives will last a life-time, the out-door hives must be re-placed by new ones every four or five years.

Also by this system, bee-culture which has been very appropriately termed "the poetry of labor," is brought quite within the sphere of woman's work.

How untiring industry, tender sensibilities, and acute perception, eminently fit her, not only for the duties of this delightful employment, but also for the discovery of means for its more perfect development.

J. S. COE.

Montclair, New Jersey.

For the American Bee Journal,
Austin Texas.

I want to describe Austin, Texas, as plainly and concisely as possible, and try to induce some bee-keepers to come and settle among us. Bee-keepers don't know what to expect of Texas, and therefore are afraid to come here.

I don't know how well other places in Texas are adapted to bee-keeping, but I do know that Austin is a first-rate place. I will give you a record of my apiary for 1874.

I began with 30 colonies in the spring, these increased to 64, of which I sold 10 in about the middle of the honey season; this left 54, from these I took after September first, about 3,000 lbs. and could have taken more, had I began sooner. Altogether though the year I took about 4,000 lbs., besides raising a few queens. All this was done under disadvantages, I being sick every few days for two months in the honey season, and couldn't procure any help. Besides this, I was not in the best location, and we had a drouth of three months when the bees did not gather any more than enough for their own use.

This drouth was unusual; the usual length being only about two months duration.

Bees begin to gather honey about the 8th of February, though they don't store much of it.

If you have empty combs to use, you can begin to extract about the middle of March.

By the last of March, the Italians begin to swarm, though the Blacks seldom swarm before the 10th of April. After the swarming is over, the bees begin to store honey in earnest, and continue to store with little interruption until the middle or last of July, when the drouth sets in, and continues generally six weeks or two months, this is the first honey season.

About the 19th of September, the fall rains set vegetation growing again as in spring, but we gather a larger harvest than we did in the spring and in a shorter time. In many sections, this harvest is almost ruined by the bitter honey gathered from a plant that covers the poor land. This harvest lasts until the frost stops it, about the first or middle of November.

Friends, if any of you are going to move, come to Austin, we have a healthful climate, beautiful country and warm winters.

Don't undertake to bring your bees with you, sell them and pocket the money, come here and buy Black bees and Italianize them. You can buy bees from 50 cents to \$5.00, the price depends upon the locality. Hives will cost from \$2.50 to \$6.00 each.

Come, there is plenty of room.

B. H. IVES.

For the American Bee Journal,
Longevity of Bees.

In the February number of the JOURNAL, Mr. Weatherly enquires about the comparative longevity of the Black and Italian bees. Perhaps the following from my memorandum book, may interest him:

July 13th, 1872.—Selected two medium swarms, one black and one Italian; placed them at considerable distance from my other hives, changed their queens, confined them in cages, and placed them immediately among their new subjects. At this time the combs were well filled with eggs.

July 15th.—Set them both at liberty.

July 19th.—Found both queens laying freely.

Aug. 5th.—Three weeks from the time they commenced laying in their new hives, I found a few young bees leaving their cells.

Aug. 10th.—A very few young bees appeared at the front of each hive, and after flying a short time returned.

Aug. 19th.—A considerable number of young bees appear in front of both hives and seem to be at work, but do not bring in any bee-bread.

Aug. 21st.—The young bees in both hives are very busy, and occasionally one comes home with his legs loaded. After this time they are busy and numerous.

Sixty-one days after, I changed the queens. I examined them very carefully and found but three or four bees belonging to the old stock in each hive, which shows that these bees lived less than forty days after leaving their cells, the first five of which were spent within the hive; and they did not appear to be really at work until about the tenth day. —II.

Will Co., Illinois.

Introducing Queens.

Have your hive made tight, and of thick lumber, to receive the frames of any of your other hives. Have two doors in place of sash or frames, so that you can make the hive any size you wish. When you get your queen, go to some of your strongest hives and get two frames with hatching brood, place them in the center of the hive, with the two doors close to them, which makes a hive of two frames; then put the queen with the bees that come with her in with the two frames of hatching brood, and keep them shut up for two or three days in the parlor or queen house, or any warm place; keep up the warmth by placing bottles of hot water in the empty space on each side. After three days, add a frame of bees, etc., by putting them for 12 hours, on the side, in place of the bottles, and then shake them in front and let them go in; then add the

frames to the other two, and continue till the hive is full. Place them on the third day, on the stand they are to occupy, and allow them to fly, by opening a small hole. Release the queen at once, and there is no danger of her being killed.

We had large quantities of honey dew this year again, and bees have paid well, where they have had attention, and I think Western North Carolina is destined to be one of the greatest honey-producing countries in the world. It is well adapted to the culture of all the fruits and grapes that will grow in the climate of this temperature.

Stock raising is wonderful; it is very healthy, pure air and water, and water power to run almost all the machinery in the United States, if it was applied.

ROBERT T. JONES,

Flat Rock, N. C.

For The American Bee Journal.

Granulated Honey.

In an article in the February No. I think Mr. Dadant in his article on adulterated honey does the bee-keepers of this country a great injustice. I was astonished on reading that article. I had supposed he was better informed on that subject. He says: "It is consequently of the greatest importance that all BEE JOURNALS inform their readers that the best test for honey is the candying; that honey candies because it is formed of grape sugar, which granulates and does not crystallize. That on the other hand sugar syrup is made from cane sugar which does not candy but crystallizes. That if they find on the market from December to June, a so-called honey in liquid condition, they can with absolute certainty declare it a sophisticated honey, or at least a honey which by boiling, or by pure mixture, has lost its character as true and pure article." If Mr. D. had stopped when he said that candying was a good test that the article was not sophisticated, it would have been well enough, but when he asserts that all pure honey granulates before December with an absolute certainty he not only states what is not the fact, but he injures the business of all bee-keepers that wish to put a pure and first class article of extracted honey on the market. Honey will not granulate except through a process of deterioration while the flavor is not injured as much as by boiling, yet it is injured so that it is readily detected in tasting a sample of each. I have had honey two years old, and no more signs of granulation than the day it was extracted. If Mr. Dadant would drop in now at the Patron's Corporation store in Lawrence, he could see some of my honey that was extracted and bottled last June under four linden blossoms, that is as clear as when put up. The fact is, if honey is properly evaporated, it will not granulate for a long time, if at all. The thinnest honey granulates the first, and the best honey is honey that is not granulated, the next best is the granulated and the granulated brought back to the liquid state by heating, is still a little inferior. This of course has reference to honey from a given plant. But if care is taken in heating, the difference is scarcely perceptible. It must be held in water and the vessel that contains the honey must not come in contact with the bottom or sides of

the vessel that holds the water, and the water must be heated very slowly and must not be brought to the boiling point at all and only enough to dissolve the honey. If Kellogg had done that way he could have evaporated his honey without making sorghum of it and without very much injuring its flavor, and if the water is not heated more than 150 degrees, we doubt if it would be possible to detect any injury to the flavor of the honey. But the best way to evaporate honey is in vats or pans made of galvanized iron or tin and the honey put in about 2 inches deep, in this way in the summer time it will evaporate itself without artificial heat, and you will have from the thinnest honey taken out the same day that it is gathered.

Just as thick honey as you choose, you can prepare in that way that will, in many instances keep for years without any show of granulating. Sometimes honey is very thick when gathered. I will say here, that the honey that I had over two years without granulation, was put up as fast as extracted. It was gathered principally from the poly-gonum and buckwheat. What we want in the disposition of our honey, is honest dealers. Another way is for bee-keepers to put their own honey on the market, under their own name. Many are doing that way now, and there is no reason why it could not be more universally practiced.

Lawrence, Kan.

N. CAMERON.

For the American Bee Journal.

My Report.

I have started an apiary, and will show some bee-keepers here, how to keep bees. I think that I can keep more bees than has ever been kept by any one man here yet. Some claim that I cannot run my number higher than 40 or 50 colonies, if I do my best, but I don't believe a word of it. Quite a number in this county have started the bee business, and have a bright looking apiary, of 30 colonies, more or less, but when spring would come, they would have perhaps 10 colonies left to build up again through the summer. This is the way they have done for three or four years, they let their bees go down and then say that there is no money in them. We remarked that they gather honey, and we can get money for that. Yes, but they will die through the winter, they say; but I say there is a reason for your bees all dying. I have handled bees all my lifetime, more or less, and for the three last years I have done but little else.

Bees are wintering very well here, so far. I have 11 of my colonies put up a new way for wintering. I went to the saw-mill and got some slabs, cut short; $3\frac{1}{2}$ feet is about the right length to split up for stakes, and to cover with. I drove 4 stakes around the hive and about a foot from it, leaving the stake about as high as the hive with the cap on; then stuffed straw all around the hive, clear to the top, my bees all stand with the front to the southeast, then covered the hives, straw and all, with the slabs. In one of these hives I have three nuclei, each one having a queen. They were all O. K. when last I saw them.

A word for the Italians; they are the only bees for me. I wouldn't give one good Italian colony for five of the best black bees

I ever saw. The Italians are not so cross as the blacks, and it does not take as much to keep them. You can give the Italians some advice and they will take it, but little advice the black bees will take. They would sooner give you a sting.

D. H. OGDEN.

Wooster, Ohio.

For the American Bee Journal.

How I Wintered.

I have not seen anything for a long time from Mr. Gallup. Perhaps the abuse he has received has disgusted him with the bee-keepers. Myself as well as others have been buying the New Idea hive, and am satisfied that in a good location for honey it will give large results. Those who have failed to obtain large surplus have either a bad location or else they do not manage it properly, and if Mr. G. does not furnish the brains to run them, they should not blame him. I made a Gallup hive last spring, four feet long, found it larger than necessary for this place as honey is rather scarce here in town, but it gave me twice as much surplus as any other. Last fall I prepared them to winter on their summer stand according to Mr. G. direction, but I confess I did not have full faith in their wintering well. After we had had two months of the coldest weather known in this climate, I went to the hive to see if there was any of them alive but got no audible sound from them, and concluded they were all dead, gave them no further notice until March 10th, when the thermometer rose to 40 deg. the first time in months, I concluded to open the hive and know the result. Imagine my surprise to find them in the best possible condition; combs bright and clean, not more than half a pint of dead bees, very little of the stores consumed, and four frames containing brood. I could not help giving one good "hurrah for Gallup and the New Idea Hive."

I do not presume to give advice to any one, but for myself I shall winter my bees on their summer stands, in the above named hive, hereafter. I put ten swarms in a frost proof cellar, but none of them wintered so well as the one left out. B. L. TAYLOR.
Minneapolis, Minn.

For the American Bee Journal.

"Bee Lines" from Texas.

"Candied honey, a test of purity and excellence." That's the key-note, Mr. Editor. Sound it so loud, Bro. Dadant, that all bee-keepers and adulterators too, shall hear it, and let the latter tremble. We were really glad to see both of you take that stand. For I have long since considered granulated honey the best of all honey. I have been greatly surprised at apiarists making the inquiry how they might prevent their honey from candying, in order to change it back to a liquid state. But my greatest astonishment has been, that honey dealers should reject candied honey as unsaleable. But it is very evident that the dealers wished to get the honey at as low figures as possible, that they might make the larger profits out of it. I hope that all bee-keepers will fall into line and make "candied honey" a test of excel-

lence, and head off those honey adulterators.

I will say to Charles Some, of Sigel, Illinois, that we are troubled very much with the "Asilus fly." We have at least a half dozen that prey upon our bees, a large brown and 1 1/4 inch long (Promachus), and another 1 inch long, reddish brown with green head. (Dasyptozau), and still another 3/4 inches, very much resembling a bumble bee in color. They prey on other insects, and even on each other. I have seen them capture the Dragon fly, much larger than themselves.

The largest sized Dragon fly (Musquito Hawk), is one of our greatest bee enemies. They hover over our apiaries by the hundreds, and take the unwary bee on the wing, continuing their flight while they devour their victims bodily, or else alighting on some limb near by and take their meals more leisurely. I have written several articles on enemies of the bee, particularly of the "Asilus fly," and I am a little surprised that Mr. Some has not read them.

Our winter is pretty severe for Texas, but our bees are wintering well.

Kaufman, Texas. A. H. R. BRYANT.

For the American Bee Journal.

How we Wintered.

The plan of wintering bees, by which we have succeeded in saving every stock, on natural stores, all coming out in splendid condition, no signs of dysentery or bee disease, and with but very few dead bees under the frames, is as follows:

First, remove the cap and boxes, cover the frames with a piece of cotton sheeting, putting a tack in each corner to keep it in place. Then place the hives in a shed, boarded tight to keep out all storms, in rows about three inches apart; then pack straw between and around and on top of the frames, so they will be covered three inches with wheat straw; then lay plank on top, to keep the straw in place or you can put another tier of hives, on them. We prefer wheat straw for several reason: In extreme cold weather, there would a steam or vapor come out of the straw, like a person's breath; in mild weather it could not be seen. That vapor is what killed the bees, *we think*. Our bees had the same chance to get at cider, bug poison, honey dew, &c., as others in our vicinity, and why did they not die. *It was the manner of wintering, we think.*

Several years ago we tried covering half of the hive with straw and the other half empty boxes turned as for storing honey, all covered with cap, with two ventilating holes open in it. In the half of hive covered with straw the combs were wet, and mouldy, and the bees dead; whilst the other half was all right, combs dry, and bees alive, dry and nice. Can it be possible there was different kinds of honey in that half of the hive? No,

it was the difference in the manner of wintering. If the cap had been removed so the air could dry out the straw, we think that half would have been all right. The honey boxes on the other half were the common square boxes, made of white wood. When they got wet, they warped and sprung apart so the moisture escaped into the cap out through the ventilating holes and kept the bees dry.

The only source of danger we can see in our plan of wintering, is the mice. Yet we have had no such difficulty, the past two winters, and this one so far. We shake out all the chaff, so as to leave nothing in the straw to entice the mice or rats to nest in it. BARKER & DICER.

Marshall, Mich.

Historical Notes on Bee-Culture in Auvergne, (France.)

This interesting historical sketch has been translated for Adair's Annals of Bee-Culture, but as Mr. Adair seems to have abandoned the publication of that book we take the liberty to translate it again for the A. B. J. [TRANSLATOR.]

Among agricultural industries, bee-culture is generally the most neglected branch. It is only the exceptions among our husbandmen who possess a few bee hives. Mysteriously hidden under the shade of the bushy hedges that enclose the small village gardens, they are almost abandoned to their own chance. In the spring, the proprietor deprives his swarms of the fruit of their yearly labor, and then, until the ensuing year, they remain there, forgotten, and almost unprotected. It has not always been so.

Among the Romans, bee-culture was regarded as an important source of income. One of the most essential requirements to obtain the rent of a farm, was to give proof of one's apiarian knowledge. Domestic economy then required a large quantity of honey, not only for the making of confectionery, cakes, artificial wines, but also for the celebration of sacrifices offered to the rural divinities that watched over the gardens, the orchards and the harvests. For such a consumption, the Italian production of honey was not sufficient, and it is not too rash to advance that, among the reasons which induced the Romans to invade Gaul, the quality of the honey that the forests of that country furnished, can be taken into account.

The French have had for bees and their products the same relish as the Romans. The *Satie Law* contains a whole chapter of regulations on hives and their inhabitants.

The possession of bees was highly prized and each one planned to increase the num-

ber of his colonies. Several means were indicated.

Our country being then much more covered with timber than at the present day contained in its forests a large number of wild swarms, lodged in the trunks of old trees. The lords and monks maintained particular servants called *apiculteurs* whose office was carefully to collect those colonies. We could not discover what their process was. The study of the habits of the bee could have pointed out a large number of ways of the utmost simplicity. In South America, for instance, the bee-hunters know very well that a bee detained as prisoner for a few moments will fly to its nest in a straight line without deviating. It is only necessary to catch a few bees, to sprinkle them with dust from the stamens of plants so that the eye can follow them better, and to liberate them one after another, allowing them to start from different points: at the point of intersection of the lines followed by the liberated captives they are sure to find the swarm and the spoils that they covet.

In the month of April when the willows are in bloom, and in the month of May, when the white hawthorn disappears, the *apiculteurs* ascending along the brooks, and around the springs, succeeded easily in discovering them, by following the bees that came to water *en foule* and returned back to their hive after having visited the pine and the odoriferous grasses. Then they carefully studied the character of the swarms before removing them, so as to reject the lazy races of bees, for according to the erroneous belief of those people, they would have dishonored the good bees by their bad example.

Several lords, high justices, had alone the right of removing the honey bees from the forests. This right was called, in the feudal language, right of *abeillage*.

In relation to the fugitive swarms, according to the custom in Auvergne, which was consecrated by old usages, he who found them on his estate was compelled to declare them within a week to the lord under whose jurisdiction they had been found. By so doing, he acquired one half of said swarms, the other half belonging to the lord as waifs. In default of this statement, not only the finder was to restore the swarm, but he was condemned to a fine of sixty *sols*, and if he had found the swarm on the land of another, he was moreover condemned to an arbitrary fine. We possess one curious example of the execution of this prescription. *Claude Roux*, of *Pignoles*, parish of *Sistrières*, under the jurisdiction of the justices of *La Chaise Dieu*, had discovered a swarm of bees. He had neglected to declare it, and he refuses to pay the right of waifs, to his lord. By a verdict rendered on the 3d of August 1493 by the bailiff, *Claude Roux* was condemned to the fine and the restitution of the swarm.

As the first bees were found in the midst of the forests, it seemed at first natural to preserve them in their primitive habitations. They were, therefore, lodged in the trunks of trees; later they were put in baskets, of a conical shape, made of rye straw sowed up with splints of briars or of hazel. Afterwards, hives were manufactured by nailing four boards together closed with a wooden or stone cover. Sometimes also, but rarely, the bees were placed in the very walls of farm dwellings, by preparing cavities which

run through the wall and were closed on each side by disks. Fugitive swarms seem to prefer these lodgings to any others.

In winter these different hives were covered with straw mats. In the XVII century the straw hives with their straw mats cost four or five *sols* each.

The apiaries decreased at an epoch which it would be difficult to determine. Let us say, however, that the extreme cold winters of the seventeenth and eighteenth centuries must have destroyed many, as did the past winter. Besides, the collectors of taxes, contributed greatly to this decrease by their habit of taking the hives, when they could find nothing else in the houses of the poor peasants.

Notes AND Queries

"Will you give us your opinion through the JOURNAL, whether Mr. Dadant or Mr. King is right in the matter of there being black bees in Italy."

AN OLD SUBSCRIBER.

We do not see any disagreement upon this point, between Mr. King and Mr. Dadant. The only point discussed seems to be, what they were carried to Italy for. Mr. King merely says he saw them there, and Mr. Dadant does not deny it. He only says Mr. Hruska had received black bees to experiment on the pathenogenesis, and these stocks or their offspring, were those Mr. King saw. He also offers a reward for the name of any one who has hybrid bees, *unless they were imported there, from outside of Italy.*

It is conceded that black bees and hybrids are there, and are raised there; "black bees and their offspring."

Therefore the point to be discussed seems to be "For what were they brought there."

We do not care about this point. If any of our readers do, we doubt not Mr. Dadant or Mr. King will answer letters willingly.

Are bees likely to remember robbing six months after committing very successful depredations upon each other. How can we prevent their robbing in the spring, before the flowers begin to yield their honey? We have wintered them on their summer stands, in movable frame hives and so far successfully—as a recent examination, made while giving them a "fly" in the house has proven.

MRS. L. B. BAKER.

Laansing, Mich.

We do not think the bees will remember—there will be very few bees left in the colonies, that were there last summer.

Close all the openings to every hive—before they fly this spring, except space for one or two bees at a time to enter.

If they are in proper condition, and each

hive has a fertile queen there will be little danger that they will not defend themselves. Notice our seasonable hints.

I wish you would answer the following questions in the JOURNAL:

1st. Can quilts be used on hives with only $\frac{1}{4}$ to $\frac{3}{4}$ inches space between frame and honey-board? Can same quilts be used on hives when from $\frac{1}{2}$ to $\frac{1}{4}$ inches difference in width or length?

2d. Which is best for quilts, cotton or woolen cloth and how do you make them.

3d. Has C. Muth a patent on his straw mats, and how are they made. I have used mats for year's, made with straw in wooden frames, that leaves a space of about $\frac{3}{4}$ inches between mat and honey-frames for bees to cluster in, which they always do. Don't you think that is an injury to the bees when they are put on late in the fall?

JAS. E. FEHR.

1st. We would remove the honey-board entirely and let the quilt take its place, until very warm weather; then you can put the honey-board on again if you wish. The size of the quilt is not particular— $\frac{1}{2}$ or $\frac{1}{4}$ incl: is of little consequence.

2d. We have used both woolen and cotton, and do not see that one is better than the other. If we were making out of new cloth should use cotton, because it is cheapest. Two thicknesses of cloth with cotton batting between them, made the size of the top of hive you wish to use it on, is all that is necessary—quilt it or not, just as you please.

We never heard that Muth claims a patent on his mats. We do not like any quilt or mat that does not lie directly on the frames. We prefer the bees should cluster in the comb.

What is the matter, when bees plant themselves on all sixes at the entrance of the hive, and with hind legs spread out and tail stuck up, they make a noise like a distant spinning wheel, and there seems to be a crack on top of the tails? I thought at first they were robbers, but I watched them, and some of them did it, when loaded with pollen.

MRS. M. B. CHADDOCK.

We think that in this case the bees were not perfectly familiar with their locations, and were a little in doubt if it was safe to enter. Or it may be they discovered bees about. It seems to be a movement of fear and caution.

How is Rye prepared to feed bees? How many frames would you put in a hive. Would you put bees in a hot bed?

W. M. MOORE.

We feed Rye to bees ground, but not bolted. Put it in a shady place near the hives. It is no use to put it on top of the frame. We would put nine 12x12 frames in a common hive; for extra large, non-swarming hives, twice as many. Let older bee-keepers than yourself try the hot bed.

Books for Bee-Keepers may be obtained at this office.

Not one letter in ten thousand is lost by mail if rightly directed.

Single copies of the AMERICAN BEE JOURNAL are worth 20 cents each.

Upon the wrapper of every copy of the JOURNAL will be found the date at which subscriptions expire.

MELLOTT CLOVER, for sale at 30 cts. per lb. Larger quantities at low prices by Italian Bee Co. Des Moines, Iowa. tf

Any numbers that fail to reach subscribers by fault of mail, we are at all times ready to send, on application, free of charge.

Subscribers wishing to change their post-office address, should mention their *old* address, as well as the one to which they wish it changed.

Persons writing to this office should either write their Name, Post-office, County and State plainly, or else cut off the label from the wrapper of their paper and enclose it.

JOURNALS are forwarded until an explicit order is received by the publisher for their discontinuance, and until payment of all arrearages is made as required by law.

Those of our readers interested in Leghorn Fowls, should send for circular of White Leghorns as bred by J. F. Ferris, Stamford, Conn. he takes special pride in this variety and his birds cannot be excelled.

When a subscriber sends money in payment for the AMERICAN BEE JOURNAL, he should state to what time he thinks it pays, so that we can compare it with our books, and thus prevent mistakes.

Honey Markets.

CHICAGO.—Choice white comb honey, 82@30c; fair to good, 24@28c. Extracted, choice white, 14@16c; fair to good, 10@12c; strained, 8@10c.

CINCINNATI.—Quotations from Chas. F. Muth, 976 Central Ave.

Comb honey, 15@35c, according to the condition of the honey and the size of the box or frame. Extracted choice white clover honey, 16c. $\frac{1}{2}$ lb.

ST. LOUIS.—Quotations from W. G. Smith, 419 North Main st.

NEW YORK.—Quotations from E. A. Walker, 135 Oakland st., Greenport, L. I.

White honey in small glass boxes, 25c; dark 15@20c. Strained honey, 8@12c. Cuban honey, \$1.00 $\frac{1}{2}$ gal. St. Domingo, and Mexican, 90@95 $\frac{1}{2}$ gal.

SAN FRANCISCO.—Quotations from Stearns and Smith, 423 Front st.

☞ Strained Southern Coast, at 7@10c; Comb, 12@20c; the latter figure for San Diego, in Harbison frames.

☞ As the old stock of honey is about exhausted, all grades command better prices. Comb, 18@22; Strained, 8@11; bee's wax, 27½ cents, dull. Our new honey commences to come in, in June.

STEARNS & SMITH.

A subscriber from Oskaloosa, Iowa, sent us 50 cents recently for subscription, but signed no name. Will he please write again and give us the name.

☞ To ADVERTISERS.—Advertisements must reach this office by the 20th of the month, to insure insertion in the next issue of the AMERICAN BEE JOURNAL.

☞ A. C. Attwood, Vanneck, Ontario, is our authorized agent in Canada. He will be glad to take the names of 500 good beekeepers in Canada, for the old reliable AMERICAN BEE JOURNAL.

☞ Parties desiring either Langstroth's or Quinby's Works on Bee-Keeping can get them at this office; but, as the late Congress has seen fit to double the rate of Postage formerly paid—those ordering should enclose twenty cents each for postage.

BEE-KEEPERS' SUPPLIES.—We can supply Bees, Bee-Hives, Extractors, Honey, Jars, Labels, Straw mats, Blankets, &c., &c. at manufacturers' prices. When you want anything in the line of Bee-Keepers' Supplies, write to the office of the AMERICAN BEE JOURNAL, at Cedar Rapids, Iowa.

THOS. G. NEWMAN.

☞ The Italian Bee Co. will pre pay all express charges on queens ordered from them without extra expense to their customers. They do this because they cannot send by mail, as the Des Moines postmaster forbids it. Address, Italian Bee Co, Des Moines, Iowa.

No. 6.

How to Transfer Bees.

A subscriber writes us to know how to change bees without loss, from the round, log, square gum or common hive to movable frame hives.

As this is a timely question, we give an answer at length.

The best time to do this is about the season of swarming, which season varies with the latitude and climate. In the Northern States, June is the month of swarms; in the Middle and Southern States they come with early and abundant bloom.

About the time when swarms are expected naturally, take the hive which you wish to transfer, and blowing a little smoke into the entrance, remove it a rod or more from its stand, leaving an empty box or hive in its place, into which the bees that are out in the fields may gather. Invert the hive which you have moved, and put over it an empty box or hive, as near the same size and shape as possible, and stop all holes or cracks between the two with grass or weeds that may be at hand, leaving no hole large enough for a bee to escape. Then with sticks keep up a sharp drumming on the bottom hive, at which the bees, alarmed, will fill their sacs with honey and mount up into the upper hive. In from twenty to thirty minutes, most of the bees with their queen will be in the empty box on top. The beginner need not fear driving too many; let all go that will. Then carefully set the box containing the bees in a shady place, and take the old hive back to the place where it stood. While you have been driving, many bees will have come back to their home, and finding it gone, will be roaming in and out of the empty hive in distress. These will at once rush

into the old hives when it returns, and gladly adhere to it; then remove it to a location some yards off, when, as it contains many hatching bees and eggs, the bees will at once rear a new queen to replace the one just driven out, and in a short time be as prosperous as ever. Now place your new movable comb hive, with its entrances all open, on the old stand, and spread a sheet before it; on this sheet empty the bees you have driven into the box, and they will at once take a line of march for the entrance of the new hive; if they gather there, brush a few in with a wing or twig, and they will call the others, who will enter in a body and accept the new hives as their home.

You have now a nice swarm in your new hive, which will work as well as any natural swarm and quickly stock their hive. You have besides your old hive, in which the bees are rapidly hatching, and in three weeks they will have a young queen and a goodly number of bees, *but no brood* in the combs. Therefore in three weeks repeat the process of driving out the bees; and after this is done, split open the old hive, or carefully take off the side, and fasten all straight nice pieces of the comb into the frames of a movable comb hive;—a little melted resin will help hold them in place, or they may be kept in place with thorns. Comb need not be rejected because it is old or black, as, if it is straight and free from mould, it is quite as good to rear bees in, or to store honey for their use—indeed, it is proved that old comb is better than new for these purposes. No drone-comb should be put in the frames. This may be known by the larger size of its cells.

Arrange the frames containing comb in the hive, set it in its place, and empty the bees on a sheet in front, as before

described. They will soon securely fasten the combs, and work on all the better for this necessary disturbance. To the novice it may seem incredible that bees should be thus driven from hive to hive and directed as you please, but it is now done every day through the summer, by hundreds of bee-keepers, who find not only that it may be done without loss but to great profit.

The Attic as a Bee House.

EDITORS AMERICAN BEE JOURNAL:—Having lately been informed by an acquaintance that some of the bee keepers "down east" sometimes set apart a closet or small room in the barn or other buildings, and place therein a swarm of bees without giving it any further attention, and when new swarms come out they form new colonies in different parts of the room; that when honey is wanted it may be cut off—if there be any surplus—and used as comb honey. As I am about to build a barn, please inform me whether such practice is prevalent and profitable; how large the room should be, and how finished, &c. S.

Madison, Wis.

We have seen the attempt made repeatedly to keep bees in a closet, in the attic, on the lower floor of a house and in a room made for the purpose in a barn. But never have known the attempt successful more than one year. It is not true that as swarms come out, they form new colonies in different parts of the room; they go outside when swarming, and if put back into the room, the queen of one of the colonies would be destroyed, if the bees remained there. We have seen four strong colonies of bees put into such a room in June, probably all queens but one were soon destroyed, for the bees all worked together, and there being many of them, comb was built and honey stored very rapidly. The owner was delighted to exhibit to visitors how easily he could open the inner door and take honey whenever he wanted it. By fall, however, the old bees having died off, the colony was not so large, and the next spring only one queen being there with her progeny, the increase was not as large as in an ordinary hive, because there was not as much economy of heat in such a space. The result that year was, that only honey enough was stored to winter the colony,

and the next year it became queenless and died out. In other cases, we have known the bees to keep on for several years in such a room giving fair surplus but no increase.

This is a very expensive way of obtaining honey, as figures will show. Suppose a man to obtain from his bee palace an average of one hundred pounds a year for ten years, which would be doing better than they were ever known to do in such a situation, this would be worth at a fair average price for honey, 20 cts. per lb., or \$200.00.

Suppose the same swarm put into a good hive, and allowed to swarm every year, which bees may safely do, the increase in ten years would make his number five hundred and twelve colonies, which at \$5.00, an average price for bees in this country, would be worth \$2560.00. In this calculation no allowance is made for the honey which would be taken in the meantime from all these bees.

Seasonable Hints.

If bees have been taken care of as we have suggested they are now, in spite of a spring more cold and unfavorable than we have ever known, in good condition. By this we mean that their hives are full of brood and young bees, and they are in just the state to make the most of the abundant bee pasturage which is sure to come, during June and July.

There are two classes of bee keepers—the one class desires to increase their number of hives as fast as prudent, the other wishes to receive the greatest profit from the bees they now have, and cares little about increase.

For these classes different ways of management are necessary.

If increase is the object, it can be secured better far by division than by allowing natural swarms to issue. Those who have empty comb, can do it much more rapidly and safely than those who have none.

Suppose you have ten colonies strong in brood—on Monday you take a comb of brood each from nine of them, place the combs in order in an empty hive and move your tenth hive a yard or more directly back of where it first stood, and place the one just filled in the exact spot you take number ten from. You put empty combs in the places of the

ones taken from the nine hives: you can repeat this operation every other day as long as you have empty combs to give, but if you have no combs and are compelled to put an empty frame in place of the full one, so that the bees have to build comb, we would not advise repeating the operation oftener than once a week.

In this way you can increase your colonies very fast, if you have provided queens for the new ones in nucleus hives as directed last month—being careful to feed sugar syrup liberally in all rainy weather or when honey is not secreted in flowers.

If this way is considered too troublesome, you can divide each of your ten colonies at once in a way we have often described as nearly copying natural swarming. It is this: "Take from a hive a frame of brood and the queen. Put them into an empty hive, filling the space in the new hive with combs, if you have them; if not, with frames. Set this just where the old hive stood—moving the other three or four yards away from it. You then have in the new hive the queen with the main force of bees able to work and they will fill up so rapidly that in three weeks you can take combs from it to form new colonies. The old hive, even if compelled to rear a queen for itself will do well, as it retains most of the brood, and if a queen be given it, you will find it soon in condition to spare combs for new colonies.

To the second class, those who wish for the greatest amount of honey, we can only say: Use the extractor and in this way keep the hive supplied always with empty comb. You will then have no trouble about swarming. If you wish for box honey, still empty combs below with the extractor often, keeping the boxes on and the full force of workers in the hive. There is no surer road to profit than this, if your colonies are strong. These rules apply to the swarming season whether that comes in April or May, as in the South, or in the month of June, as in this latitude, or in July as it does in sections farther north. In July number, our "hints" we hope will guide to successful management later in the season.

The A B C of Bee Keeping.

We often receive letters from those beginning to keep bees, complaining that we are not plain enough in our directions and asking that we give the "A B C" of bee keeping. To all these we answer that we try to make ourselves understood,

and to give, each month, hints adapted to all who have not more knowledge on the subject than ourselves, but if we were to adapt ourselves to the comprehension of those who are just beginning to keep bees, we should find room for little else. For these there are text books and works on bee keeping that make matters simple and easy, and these are sold so cheaply that no one should own a colony of bees, without buying one of them. This journal, while it seeks to give information on all points connected with bee keeping, cannot in any sense take the place of a book for beginners.

Notes AND Queries

Which is the best knife for uncapping, without heating the knife?

Winder & Murphy both have knives that uncap nicely in warm weather without heating.

I want to know how I can secure frames filled with straight comb?

That is my great desire, for this season I have ten good colonies, but no spare comb.

E. B.

There is no way so sure as to put an empty frame into a strong colony between two straight combs in this month. Move the combs apart the right space and put your frame in, and keep on removing combs and putting in frames. You can use this comb in building up other colonies as directed in this number. Bees are natural enough to "abhor a vacuum," and space thus made will be filled as speedily as possible.

1st. Does the bee make honey that is poisonous? If so, what season of the year, and what flower or flowers is it made of?

2d. What is your opinion of the orange flower for honey? also yellow jasanine? We consider the yellow jasanine a very poisonous flower.

3d. Is the swamp magnolia a good honey flower? Also the queen bay.

What is your opinion of the swamps and glades of Florida for an apiarian? Are summers too hot? Are they too long? giving the moth a longer time to do its destructive work?

4th. Is it necessary to give bees salt? If so when, how often, how much, and for what is to be given?

By the way, we have in this region a new (to us) enemy to the worker bee. It is a large fly or bee. It resembles a hornet in some respects, and bumble bee in others.

It has, I think, six legs; two are used as catchers or holders. The legs are fuzzy or hairy and long. It secretes itself on a limb, rail, or anything to rest on and hide. A grapevine is a great place for them to hide on and as the loaded bee comes home, the fly darts at the bee like a hawk would a chicken and gathers with his two grabbers, or front legs, and holds it fast, then bores his long bill into the bee and pumps out the honey, lets go of the bee and takes his stand for another. I don't know whether the bees dies or not.

As he is a new comer against us, and without a home, name or reputation to recommend him to us. I have given him the name of a good many representatives who come among us without a home or letters of credit to pierce us with high taxes, and after they have got all, to leave us to bleed and die. The name I think being appropriate, it is "carpet bagger."

Will this name do? Have you a like enemy of bees with you? If so, where did it come from, and how must we manage to destroy it?
J. W. M.

We have no poisonous honey at the North and no reports, as yet, of any stored at the South, and our own opinion is that bees do not gather anything poisonous. The orange blossom is reported as rich in a delicious honey, have never tasted it. Yellow jasmine is also named as furnishing some honey, but of peculiar flavor. We hear little about the other flowers named. Will some Southern bee keeper report? We believe nothing but bees are necessary to make the glades of Florida as famous for honey as Southern California. Salt is given to bees, and they take it. We cannot say that it is necessary. Some of our best bee keepers do not use it. We never have heard of the insect you describe, but are greatly interested in your account. Will Prof. Riley or Prof. Berry look into this "carpet bagger" matter and report.

In the JOURNAL, I see directions to close all upward ventilation in honey board as soon as the severe winter weather is over, but I also see that the best way to feed is from the inside of the hive, how can both be done? Also to keep them well supplied with water. I have tried giving it to them from both in and out side of the hive, sweetened and without, but I cannot get them to take that all, though I see them apparently hunting it in damp places. Mine are in a box hive with movable frames, but through ignorance the frames were put too near together, and they are now one solid mass, but a strong swarm and as cross as bees can be, I cannot make them anything else.

I lost a nice swarm in the winter in a Langstroth hive, for this reason—I cannot feed them under the honey board. Am now feeding in sugar syrup put on sponges, which is the most satisfactory way I have yet found. Will it do to stop feeding as soon as the first bloom, such as box wood and Missouri currant comb. Everything is very late, but I see they are carrying some pollen now.

Do you give alsike clover seed this spring?

Is it as good for stock as the common red clover, and how late will it do to sow?

How late in the month will it do to send, that it may be answered in the next No.
London Grove. JANE MAULE.

All ventilation can be closed by a quilt laid over the frames. When bees are to be fed, on top of the quilt, a small hole can be made in it through which the bees can pass to the feeder. Some of the feeders are made so that a small pipe goes into a hole in the quilt through which the bees seek the food.

As your bees do not take the water, they probably get it in some hollow log, or a springy place. They prefer it in that way when they can get it.

We would advise you to transfer the bees from that hive where the frames are too near together, as soon as honey is abundant.

We would feed the bees in bad weather until white clover comes. They get very little honey in the early bloom that you name, probably because at that time the weather is not favorable for the secretion of honey.

We do not give alsike seed away this year. It is considered even better than red clover for stock.

Queries ought to reach us by the 15th of one month to be answered in the next number.

MRS. TUPPER: The bees I purchased of you a year ago have done well. They increased to three very large swarms last year, and gathered about 28 lb of honey each.

I put them in the cellar under our living room, Nov. 14, and took them out the first week in April. There was about a pint of dead bees on the bottom of each hive. They had used only 5 lbs. of honey each. They are increasing rapidly now and gathering honey. I found another colony yesterday. The progeny of the queen you sent me seems to be true every time, three gold bands and no degeneration.

I don't feel quite satisfied with the hive I have. It is better adapted to brood raising than storing honey, I think. It contains 9 frames 12x12 inches, but the bees show signs of swarming when full below, rather than work in boxes.
J. L. FRENCH.

We are always glad to hear good reports of the bees we send out, and are sure that will be the case if care is taken.

The hive we sent them in, is, in our opinion, the best made, either for box honey or for the extractor. You must have brood raised if you wish to get honey; and hive adapted for brood raising is what you want. Put the boxes on early this year, fastening comb in each one; when they begin to work in one box, put on another, and give the queen room for broods by using the extractor, or taking out a comb often. There is no better hive than the one you describe.

Bee-Men in Council.

KALAMAZOO, May 6th, 1875.

The second semi-annual session of the Michigan Bee-Keepers' Association convened in Corporation Hall at 2 o'clock p. m. President Bidwell in the chair.

The Secretary read a report of the previous meeting, which was read and then approved.

After the transaction of business relative to the affairs of the Association, the programme of the session was taken up. The first topic, "Wintering Bees," was introduced by a paper from Frank Benton, of Knoxville, Tenn., read by the Secretary. The advantages accruing to the "Sunny South," as a winter resort for the apiculturist was considered at length, with the conclusion that the migratory system of bee-keeping might be made both pleasant and profitable. The paper elicited considerable inquiry relative to the cost of transportation and other necessary expenses when the topic was discussed at length.

T. F. Bingham—I put 150 stocks into winter quarters in January. When put in, the combs were frosty and soon thawed out, creating a bad smell, reminding one of the old dysentery times. They commenced to dwindle down, and when carried out in March, I had 113 in good condition. Have a distant hope of saving two stocks, my present number.

A. C. Balch—Did your bees commence rearing brood in winter quarters?

T. F. Bingham—They did, largely, as I have always found them to do when they die of disease. I winter in a house above ground, ventilated above and below; temperature from 7 to 45 degrees above zero; bees did not die in the hive. When they die out of doors, I find them in a cluster in the hive. Had abundance of honey in close proximity to the bees.

C. I. Balch—Did your honey granulate?

T. F. Bingham—It did not.

H. E. Bidwell—What kind of honey did you winter on?

T. F. Bingham—Boneset, mostly. The quality was very good; at least, people in Chicago like to buy it in glass boxes.

L. H. Albright—Winter in an out-door cellar, in eight-inch frames. They have all come out in good condition. Put them in December 1st; give hives no upward ventilation; leave entrance open below; do not disturb the bees after putting them in; temperature above freezing.

A. C. Balch—Did your bees have brood when set out?

L. H. Albright—They did, especially the stronger colonies.

H. E. Bidwell—Are your bees black or Italians?

L. H. Albright—All black bees.

A. C. Balch—Do you extract honey?

L. H. Albright—Never. Raise all box honey; sources of supply are white clover, basswood and boneset principally.

A. W. Davis—Do you get any raspberry honey?

L. H. Albright—Not of any account.

H. E. Bidwell—Bees use raspberry honey in rearing brood, seldom storing it in the combs.

Julius Tomlinson—Will the President give his experience in wintering in the cold-frame.

H. E. Bidwell—I wintered 80 stocks in cold-frames, and am only sorry that I did not winter them all in the same manner; left the balance on summer stands; they wintered well but didn't spring well, as they "got sick."

Julius Tomlinson—How often do you allow them to fly in winter?

H. E. Bidwell—Once in two weeks; keep the temperature above freezing point; have discovered but one case of dysentery in the cold-frame.

Julius Tomlinson—Had 26 good colonies last fall in five-inch hives, two sets of combs; wintered out-of-doors and they have dwindled down to 15; much of the time they were well banked with snow.

H. E. Bidwell—Did they occupy the upper set of combs?

Julius Tomlinson—Some did, others did not; bees mostly black and hybrid; had plenty of empty combs for bees to cluster in.

Ezra Rood—I have wintered in a great variety of ways; used to succeed admirably in nearly all ways; now they usually die; had a good cellar, dry and well ventilated; mercury stood at from 42 to 45 degrees; the atmosphere was pure and good; lost three-fourths of my bees in the cellar; used to think that I could "run bees" to my satisfaction, but now—run them into the ground; its a disease—dysentery—that kills our bees; don't think that cold weather raises the mischief, as bees are wintered in Russia and other cold climates without material loss.

H. E. Bidwell—Did you give upward ventilation?

Ezra Rood—Some hives I did, others not; saw no difference in results.

E. J. Oatman—How was your cellar ventilated.

Ezra Rood—By tubes running above in each corner; also have the bottom ventilated.

E. J. Oatman—Did you keep a record of the temperature?

Ezra Rood—Yes, and am very careful not to let it go below 40 deg. or above 45 deg.; but suppose it should freeze in the cellar? If the mercury did not go below 20 deg. even, we should not regard cellars of much value.

E. J. Oatman—Extracted stores in August and fed 25 pounds of sugar syrup; put quilts on top and at end of frames; when cold weather comes, put them in the cellar and keep them quiet. Do not put them out in spring until warm settled weather. If cold comes again, hustle them in again; leave off cap of hive but give no upward ventilation; mercury ranged from 32 to 46 deg.; lost eight out of 110 stocks; prefer sugar syrup to honey, and old to new combs for wintering.

T. F. Bingham—Your stocks had young bees in the fall?

E. J. Oatman—They did; especially those that built new combs late, and died the worst.

T. F. Bingham—That hurts the "old age" theory. How have your bees "sprunged."

E. J. Oatman—Well, for the most part. Have had to double up some of the weaker ones.

T. F. Bingham—I have doubled up over a hundred.

E. J. Oatman—We did not double up in that style. Was obliged to reduce six stocks to one, however—bees that were put in the

cold-frame and bumped their brains against the glass. Stocks that were perfectly healthy when put into the cold-frame hadn't a single bee left in less than two weeks.

Julius Tomlinson—How would it have worked to put bees in the "frame" in March and allowed to fly?

H. E. Bidwell—I tried about 80 at that time and injured them. Do not think it advisable. They should be put in in the fall.

Julius Tomlinson—Would not a single tier in a narrow frame be better?

H. E. Bidwell—I think it would be as well, perhaps better.

James Heddon—I have tried the cold-frame. A tree shaded one corner, and the bees tried to get out and cluster upon it. I think there should be nothing above the frame, except blue sky.

E. J. Oatman—Would the glass placed in a horizontal position give enough heat?

H. E. Bidwell—It would not.

James Heddon—Have had much trouble in having bees cluster on the glass in the cold-frame.

E. J. Oatman—By putting mosquito netting on the under side of the glass, I prevented clustering on the glass, and all attempts to commit suicide by bumping their brains out against it.

James Heddon—Have wintered fifty-one swarms in good condition and am at as much of a loss to know why, as I was when I lost so heavily, heretofore. I set them out in March, and they had a good two days fly. Think a partial fly only an aggravation. Credit my success in a measure to the Italian bee. Do not think that rearing brood early is desirable. It expends the vitality of the bees without a proper recompense. Do not use any quilts whatever. Prefer a good, plain board. They are less cumbersome, and I think, just as good. There is something more important than quilts that is at the bottom of our success. The same is true of ventilation. I have stocks in hives that are badly cracked, so that it snows and rains in them, yet they are strong and healthy. They are tough and you cannot kill them.

C. I. Balch related instances of how bees have wintered well in one season and nearly all died in others, under the same apparent circumstances. How can we account for it, unless it be a disease?

The next topic, "Building up Colonies in the Spring," was then taken up.

T. F. Bingham was called upon to give his experience. He said that in consequence of having met with a serious calamity, his usual buoyancy of spirits had departed, and he did not feel like talking. It's no use to build up colonies, except to have them die.

E. J. Oatman—Has any one used quilts stuffed with bran, on hives?

Julius Tomlinson—I have, and find they accumulate considerable moisture, especially at times in spring.

T. F. Bingham—I would advise you to send that item to *Gleanings*. A. I. Root has been trying to invent a watering-trough for his, and this, no doubt, will fill the bill. It can be used in connection with those beautiful tin corners. 'Tis just the thing.

A. C. Balch related his experience in rearing queens. Preferred to remove a queen from a full colony, and when the cells were nearly mature, insert them in other colonies. Queens should be started from larvæ not over two days old, less would be better. Ex-

changing combs is better than cutting out queen cells. Early in the season is a much better time than later.

C. I. Balch stated that he had eggs removed from inserted comb to other combs developed into queens. Some were very good, were prolific for nearly five years, while others were valueless. Have raised queens in October that proved hardy and prolific. There is a vast difference in different strains of stock. The only way to winter successfully is to make good woolen shirts and drawers for the "pets."

E. J. Oatman gave his experience in detail in getting worker combs built in the fall. Remove all brood combs except two or three containing capped brood, and fill up with empty frames. Fed a quart of syrup to each hive at night. Fed 500 pounds of C sugar, and obtained worker combs, 11x12 inches, at a cost of 20 cents each.

C. I. Balch—It has been stated as requiring 25 pounds of honey to make a pound of comb; Does it require as much syrup?

E. J. Oatman—I cannot state; only two or three hives built any drone comb.

A. C. Balch—Did the bees have any drone comb when they commenced building the comb?

E. J. Oatman—They contained none.

T. F. Bingham—Were the bees gathering honey at the time?

E. J. Oatman—Enough for breeding purposes, but not to store any.

Julius Tomlinson—What is your experience in getting comb from honey as gathered by the bees?

E. J. Oatman—Anything but satisfactory; have always got a too large proportion of drone comb. They do not build near as rapidly as they do when fed on syrup.

Julius Tomlinson—By taking away all full combs of honey I got worker combs built at one side of an upper story.

T. F. Bingham exhibited specimens of artificial comb, made of paper and coated with wax. Bees store honey in it readily.

C. I. Balch—Will they brood in it?

T. F. Bingham—I didn't ask so much of them.

James Heddon—I want to get an artificial comb that the queen won't look at, even. Such a comb would be valuable.

T. F. Bingham—To get honey, use a box to hold three combs, keep black bees, be careful to commence on the right day of the week, observe the changes in the moon, and if it rains honey and the bees don't get their backs up, we are all right; but if they do, ours are down.

A committee of three, consisting of James Heddon, T. F. Bingham and H. A. Knapp, were appointed to draft resolutions, when the convention adjourned until evening.

EVENING SESSION.

The association was called to order promptly at 7½ o'clock, President Bidwell in the chair. The first topic, "Extracted Honey," was introduced by a paper from James Heddon, of Dowagiac, who took the ground that we ought to discourage the production of every single pound of honey which costs 50 cents to produce it, that will be a drug on the market at 15 cents. He also urged that we should pay more attention to developing a good, reliable market for our products. The relation of the producer to the "exclusive" honey dealers in cities, was considered at length, with the conclus-

ion that if we are to make money in the apiary, we must get our surplus in small glass boxes, instead of waxed barrels.

T. F. Bingham—Dadant says that if honey candies, it's pure, but we can't always wait; glucose is made from starch, treated in a retort, with sulphuric acid; this can only be removed with lime; the addition of water will lessen the acidity; substances containing tannin added to it will turn it black, but not good syrups.

A. C. Balch—According to good authority our "golden-drip" syrups are largely adulterated.

James Heddon—All honey contains acid—formic acid—as is fully demonstrated by analysis.

Julius Tomlinson—Extracted honey is finding favor in my home market, though for profit, box honey is the thing.

A. C. Balch—Even if we are compelled to use liquid honey in making vinegar, it will pay; even for the good of the bees, especially in times of great honey secretion.

James Heddon—Extracting honey to give room in the brood chamber, is giving room for more honey, rather than more brood. While Italian bees are inclined to store honey in the brood chamber, we can coax them to store honey above and out of they way. Black bees are much better, however if we can only induce them to survive our awful winters.

E. J. Oatman—What would your black bees do in a "tough" honey season?

James Heddon—About as well as Italians, better early in the season.

E. J. Oatman—In times of scarcity I have had Italians rear abundance of brood and store a little honey when the blacks were losing ground.

Julius Tomlinson—I think Mr. Balch is right about the value of the extractor in keeping the brood-chamber clear of honey.

James Heddon—And keep your surplus out of the honey boxes at the same time.

A. C. Balch—Though bees don't know much, they are not fools altogether. Honey in the hive is detrimental to brood rearing in summer, and too much of it, to success in wintering. They will store it in the brood combs in excess of what is best for their own welfare.

H. E. Bidwell—If your combs get full, raise them up and let them store in empty frames below.

A. C. Balch—And always get drone comb.

James Heddon—If I am to get box honey, and they are bent on storing in the hive, then it follows that I must wait till the hive is full below before they will store above, when I haven't the bees to do it? Such logic hurts my theories of obtaining box-honey.

T. F. Bingham—We are told that the Extractor will save our bees; but, practically speaking, our bees have all gone to—well, a warm climate. Years ago, before there was any such thing, bees wintered well. Oh, that beautiful "honey-slinger."

James Heddon—Will Mr. Burch state if he is able to keep his combs full of brood and get honey stored in boxes without the aid of an extractor?

H. A. Burch—Even Italians, properly managed, will keep the brood below, and honey above, in boxes, and two, without any aid from an extractor.

A. C. Balch—If for no other reason than

obviating troubles with the moth, I should prefer the Italian bee.

T. F. Bingham—I hope the President will rule out this Italian bee question. I have been maligned, abused and churned for daring to say a word derogatory of their merits. If Dadant hears of it he'll give us poor fellows "Hail Columbia." Let us avoid this mellow subject altogether.

James Heddon—Mr. Bingham should remember that he is at perfect liberty to express the opinions of the majority—not the minority.

A. A. Knapp preferred a hive that would admit of removing frames in the rear; thought preferable to lifting out of the top; frames are a foot square.

James Heddon—I once saw a hive on the "lake shore," while visiting H. A. Burch, that the frames came out at the rear; 'twas a nice rattle trap; it wants 26 yoke of oxen to remove frames when the bees stick them fast; have had "hive" on the brain; tested other people's hives, and experimented on my own delusions.

A. C. Balch—How would you swarm "artificially?"

J. Heddon—Drum out swarm, and put it on the old stand, removing the old hive; Use a shallow drum box with slats on the open side, and be sparing of smoke.

A. C. Balch—Oftentimes the queen don't want to go.

James Heddon—But we make them go; can get them in this way much easier and more speedily than by hunting for them. To be of value a process or implement must possess more advantages than disadvantages.

The subject of making a display of our products at the Centennial Exhibition was considered at some length. Various opinions were expressed, when the subject was finally committed to the charge of the President to act in the best interests of the Association.

T. F. Bingham read a paper on the requisites of the successful apiarian. The subject was considered from a facetious standpoint, causing considerable merriment.

A. J. Pope gave a description of Seth Hoadland's device for hiving bees. He also related instances of making bees cluster wherever desired by whistling for them.

Ezra Rood—I also tried the whistle—a regular pig-tail quirl—but failed to strike the key-note.
