

# Chicago, Ill., January 6, 1886.

# AMERICAN ISHED Issued every Wednesday by MAS G. NEWMAN & SON UBLISHERS. 923 & 925 WEST MADISON-ST, CHICAGO, ILL. At One Dollar a Year. George Neighbour & Sons, London, England, are our authorized agents for Europe. Entered at the P.O. as Second-Class matter.

Vol. XXII.

#### TO CORRESPONDENTS.

- The Subscription Price of the Weekly BEE JOURNAL is One Dollar a year.— New Subscriptions can begin at any time. Single Copies, five cents each.
- OUR NEW CLUB RATES are: \$1.90 for two copies (to the same or different post-offices); \$2.75 for three copies; \$3,50 for four copies; and for five or more copies, 80 cents each.
- Foreign Postage.-To all countries in the Universal Postal Union: 50 cents extra. To all countries NOT in the Universal Postal Union, \$1.00 more than the price of subscription.
- Sending Money.—Remit by Express, Post Office Order, Postal Note, or Bank Draft on New York or Chicago. If neither of these can be obtained, Register your Letter, affixing stamps both for postage and registry, and take a receipt for it; Money, sent thus, is AT OUR RISK, other-wise, it is not. Do not send checks on local banks, which cost us 25 cents each, at the banks here, to get them cashed.
- Postage Stamps of any denomination may be sent for fractions of a dollar; or where Money Orders cannot be obtained, stamps for any amount may be sent.
- Subscription Credits.—The receipt for money sent us will be given on the address-label of every paper. If not given in two weeks after sending the money, write to us, for something must be wrong. Do not wait for months or years, and then claim a mistake. The subscription is paid to the END OF THE MONTH indicated on the wrapper-label. This is a continual statement of account.
- Advertisements for the next Weekly BEE JOURNAL must reach this office by the Saturday of the previous week.

Blessed Bees, by JOHN ALLEN. – A romance of bee-keeping, full of practical information and entbusiasm. Price, 75c.

The Hive and Honey-Bee, by Rev. L L. LANGSTROTH.—The work of a master, and will always remain a standard.—Price \$2.00.

Dzierzon's Rational Bee-Keeping-A translation of the master-piece of that most eelebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Bee-Keepers'Handy-Book, by HENRY ALLEY.—This book contains 270 pages, and is a complete Manual of Bee-Keeping. Price, \$1.50.

Bee-Keepers'Text Book, by A.J. -Revised and enlarged. Price, \$1.00. J. KING

Extracted Honey; Harvesting, Handling and Marketing.— By CHAS. DADANT & SON.— Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the man-agement of bees. Price, 10c.

**Dzierzon Theory.** — The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samnel Wagner. Price, 15c.

Dictionary of Practical Apientiture, by PROF. JOIN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE. Details his management of bees. Price 50 Price 5c.

Foni Brood, by A. R. KOHNKE.--Its origin and cure. Price, 25c.

Kendall's Horse Book .- No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all discases in a plain and comprehensive manner. It has many good recipes, etc. Price, 25c., in either English or German.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Scribner's Lumber and Log Hook.-Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price. 35c.

Fisher's Grain Tables. - For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

etc. Price, 40c. How to Propagate and Grow Fruit, hy Charles A. Green, contains over 50 illus-trations and two colored fruit plates. It contains 64 pages. Price, 25 cents. Previous to the publication of this book, there was no work on the propagation of small and large truits which could be pur-chased for less than \$3.00, therefore the masses have been without a guide in this important branch of fruit-growing, and know very little abont propagating. The price of the book places it within the reach of all. Further than this, the book gives the latest and most approved methods found in no other publication. This book tells HOW TO PROPAGATE Straw-berries, black raspberries, red raspberries.

This book tells HOW TO PROPAGATE Straw-berries, black raspberries, red raspberries, blackberries, currants, gooseberries, grapes, quince, peach, apricot, plum, cherry, pear and apple: also GENERAL RULES for propa-gation, with illustrations showing how to bud hear to gracit how to propugate from bud, how to graft, how to propagate from layers, stools, inarching, with fall instruc-tions for grafting the grape. It tells how to lay out a garden or fruit farm—how to plant, lav cultivate trim, etc.

Moore's Universal Assistant, and

Gomplete Mechanic. Complete Mechanic. Enlarged Edition – con-tains over 1,000,000 Industrial Facts, Calch-lations, Processes, Trade Secrets, Legal Itoms, Business Man. The work contains 1,016 pages – is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man or Farmer. By mail, in fine eloth, \$2.50.

The A H C of Carp Culture, is a neat pamphlet of about 100 pages. It explains the simplest, cheapest and most effective system of carp culture, and being written by Mr. Milton P. Pierce, of Philadelphia, Pa., Secretary of the American Carp Cultural Association, it cannot fail to be of inestima-ble value to all interested in the "finny tribes." Price, 40 cents.

The A B C of Potato Culture ; "how to grow them in the largest quantity, and of the finest quality, with the least expenditure of time and labor." The book is not only a valuable one to potato-growers, but a great part of it applies to the management of almost any crop on the farm, especially to the preparation of the soil, manures, etc. Price, 40 cents.

"Farmer's Account Rook," contains 166 pages, printed on writing paper, ruled and bound, and the price is \$3.00. We will club it and the Weekly BEE JOURNAL for a year for \$3.00. If you want it sent by mail, add 20 cents for postage.

henol for the Cure of Foul Brood. -By Prof. Frank R. Cheshire, of London, England. Price 10 cents; 32 pages.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. Price, for the Weekly or Monthly, 75 cents each. They cannot be sent by mail to Canada.

Photographs of Rev. L. L. Langstroth, Baron of Berlepsch, or Dzierzon, 25 c. each.

Occupation for Invalids,	Care of Teeth,
Superflunus Hair,	After-Dinner Naps,
Restaring the Drowned,	
Preventing Near-Sight-	Malaria) Affections,
edness,	Croup-to Prevent.

#### IT TELLS HOW TO CURE

Black Eyes, Boils, Burns, Chilblains, Cold Feet, Corns,Coughs, Cholera, Diarrhoe L, Diphtheria, Drs-entery, Dandruff, Dyspepsia, Ear Ache, Felons, Fetid Feet, Freekles, Hendacbe, Hiccourh, Hives, Hoarseness, Itchinz, Indamed Breasts, Ivy Polson-ing, Moles, Pimples, Piles, Rheumatism, Kingworm, Snoring, Stammering, Sore Eyes, Sore Mouth. Sure Nipples, Sore Throat, Sun-stroke, Stings and Insect Bites, Sweating Feet, Toothache, Ulcers, Warts, Withoping Cough, Worms in Children. Price nnly 25 Cents. Sent by Mail, post-paid.

THOS. G. NEWMAN & SON

923 & 925 West Madison Street. CHICAGO 11 L.

A Bright New Year, and a snnny track, Along an npward way,

And a song of praise on looking back, When the year has passed away,

And golden sheaves, not small nor few ! This is onr New Year's wish for you !

The Year 1886 has come, and with this issne the AMERICAN BEE JOURNAL COMmences a new Volume. During the past year we have endeavored to conduct the BEE JOURNAL with a view of doing the "greatest good to the greatest number"never losing sight of the interests of producers as well as consumers. The past must be the gnaranty for the future. Our motto is "Excelsior," and "progress" and "improvement" are our watchwords. The price of the JOURNAL is reduced to one dollar a year, but it will not be any less valuable to its readers, nor will any less expense be incurred in its production. The entire gain will be to its patrons, and they are appreciating this by sending in more and larger clubs than ever before.

It is to the interest of every bee-keeper that his neighbor bee-keepers are educated especially as to marketing honey, that they may have the boney in attractive shape, and to know its proper selling value before attempting to sell it. This may prevent their spoiling of bis market by ruining the prices or disgusting purchasers.

We desire not only that every present subscriber will promptly remit for the coming year, but also that each one will convince his bee-kceping friend or neighbor that it is to his interest to join in a club, at least of two, and thus spread the light of its torch, so that so many more may be benefited thereby.

Should Any One get this number of the BEE JOURNAL who does not want to continue taking it, please send ns a Postal Card and say so, giving name and address. Do not send the number back, for we have no means of knowing to whom it was sent, if the wrapper-label is gone.

"Peace be within thy walls, and prosperity within thy habitations," was written anciently as a salutation—and it is a suitable one for our New Year's salutation to every house into which the JOLENAL shall enter.

The BEE JOURNAL has been favored with prosperity sufficient to allow of its subscription price to be reduced by one-half—aud this, too, even in the midst of disaster to many bee-keepers, and for two years a partial (to some, total) failnre of the honey crop. While some of the newer bee-papers have ceased to exist on that account, the old standard-bearer of bee-culture has stood like a bulwark against which the storms have beaten, and is still freely acknowledged to be the leading apicultural periodical in the World. It circulates in every State, Territory and Province of North America, as well as in Enrope, Asia, and Australia.

Mr. C. J. Sperry, of New London, Minn., died on Dec. 25, 1885, at 5 a.m., aged 55 years, and was buried on Sunday, Dec. 27, with Masonic honors. He was associated with Mr. L. Chandler in business connected with the "North Star" Bee-Hive. He kept bees for many years, and was very enthusiastic. The *Expositor* at New London, Minn., gives the following concerning his life:

About 1859 Mr. Sperry, with others, settled near Diamond Lake, only to be driven from his home by the merciless savages in the memorable year 1862, but returned thereto in 1865. In 1867 Mr. Sperry became associated with Samnel Adams, Wm. Wright, and Louis Larson in the improvement of the water power here, by the building of the dam and the first mill, still standing on the west side of the river, in the construction of which latter Mr. Sperry's mechanical genius became an indispensable factor, having been confided to his entire management. In this enterprise, while there were occasional changes, Mr. Sperry retained his original one-fourth interest which passes unimpaired to his family.

In his death this community loses one of its most respected citizens: and the family a wise counsellor and kind father. He repeatedly held important trusts, always accepting them in full realization of the responsibility imposed, and discharging them with conscientious regard to the public welfare. In 1881-82, he was Chairman of the Board of Supervisors for the county, aod served also as a Justice of the Peace. He was also the first sheriff of Monongalia county, by appointment of Gov. Ramscy. His family will have the sympathy of their many friends whose loving efforts were so generonsly bestowed.

Mr. O. M. Brown, of Winchester, Va., died after a short illness on Dec. 14, 1885, of pneumonia, in the 71st year of bis age. His son, Mr. J. Few Brown (also an apiarist), writes as follows concerning his father: "He was a very systematic and enthustastic bee-keeper, and everything about his apiary of 40 colonies is of the very best quality, and in perfect condition, every hive and rack put together with screws and uniform to perfection." His funeral was very largely attended.

The Champlain Valley Bec-Keepers' Association will hold its 12th annual convention at Middlebury, Vt., on Thursday, Jan. 21, 1886. We have received a very neat four-page Programme. Any one interested can get a Programme by addressing the Secretary, Mr. R. H. Holmes, Shoreham, Vt. Premiums are offered for exhibits.

A Correspondent in low writes us that Lizzle Cotton's agent is in his neighborhood selling to the "old fogies," a new strain of bees, which she claims will never produce any drones. Those who know anything about bees will not be fooled by such nonsense, but such "agents" only work among those who are ignorant concerning bees. If no drones are produced, how will young queens become fertilized? As soon as the original non drone-producing queen dies (if such existed), the "strain" would have run out—having strained itself to death.

James Heddon, Dowagiae, Mich., has placed on our desk the Prospectus of his new book, "Success in Bec-Culture," and Catalogue of Supplies for 1886–30 pages.

The First Convention of the beekeepers of America washeld at Cleveland, Ohio, on March 15, 1860; nearly 26 years ago. We have prepared a history of the inception, formation, and organization of the North American Bee-Keepers' Society, together with a digest of the proceedings of all its meetings from its inaugnration, with a full report of its last meeting at Detroit, Mich. This we are now publishing in pamphlet form. It will be ready in Jannary, and will be sent postpaid for 25 cents. We will *present* a copy of it to any one sending ns a club of two subscribers for one year, with \$2.00

We have Received from the Publishers. a copy of Number Five of the new series of Recitations called "THE EUREKA RECITA-TIONS AND READINGS." It contains over fifty pieces, designed for children from six to fifteen years of age, and also a large collection for adults. Those interested in providing an entertainment should have this collection. Each one contains 128 pages, with nearly one hundred selections, and is bound with a handsome cover, printed in four colors, and will be mailed to any address, postpaid, on receipt of twelve cents in stamps, or one each of the five numbers for fifty cents, by J. S. OGILVIE & Co., the publishers, 31 Rose Street, New York.

**Dr. G. L. Tinker**, New Philadelphia, O., has sent us a copy of his Price List for 1886, of the "Victor Hive," Sections, Queens, Bees, etc.—16 pages.

It will be Wisdom to investone dollar for the Weekly AMERICAN BEE JOURNAL for 1886. With its weekly visits every subscriber will be kept posted with all the apieultural news of the day.

New Subscribers are coming in rapidly -for this our thanks are tendered to the friends of the AMERICAN BEE JOURNAL, who are exerting their influence in its behalf. We should thribble our list at the present low rate of one dollar a year. It is a popular price, and we find the reduction a popular thing with all bee-keepers.

The American Agriculturist and the Weekly BEE JOURNAL for IS86 will both be sent for \$2.25, or with the "Family Cyclopaedia" or "Law Book," for \$2,65.

**REPLIES by Prominent Apiarists.** 

# Stimulative Feeding.

Query, No. 176.—Somme blooms 3 weeks after white clover. Is it advisable to practice stimulative feeding between the two erops 7—Doc, Missourl.

Not unless the flow from sumac lasts two or three weeks.—W. Z. HUTCHINSON.

No; sumae blooms here about July 10, and the clover does not cease to yield neetar till about this time.—G. L. TINKER.

It would hardly be necessary for so short a time.—A. J. COOK.

Yes; if sumac yields abundantly, and there is a dearth of flowers between white elover and sumae.—C. C. MILLER. t

I have never found it so in this locality.--G. M. DOOLITTLE.

We think that this is a mistake; sumac usually blooms during white clover or immediately after. At any rate it would be a mistake to feed a colony if the hive is already full, even if only to stimulate.—DADANT & SON.

It would do no good, in my judgment. You could not increase the fieldworkers by stimulative feeding in so short a period of time. As you describe the two harvests in your locality, your bees ought to be in the very best condition to reap the sumae harvest.—G. W. DEMAREE.

By no means, in this locality. Before pleurisy-root and red clover filled the "gap" between basswood and buckwheat, boneset, goldenrod, etc., we used to have a complete honey-dearth, and then was the time our queens deposited their greatest number of eggs daily.—JAMES HED-DON.

## Material for Packing Hives.

Query, No. 177.—Which of the following is the hest for packing bees for winter: wheat, onfs, buckwheat or clover chaff; forest leaves or old rugs ?—J. W.

I should prefer wheat chaff.— W. Z. HUTCHINSON.

I prefer a cellar.-C. C. MILLER.

I use fine, dry basswood sawdust. Next I should choose buckwheat chaff.—G. M. DOOLITTLE.

I presume that clover chaff is a little the best, but I do not think that there is much difference.—A. J. COOK.

Forest leaves; of the four kinds of chaff, there is little difference. As to the old rags, that would depend upon the amount of rags to the pound.—G. L. TINKER.

l prefer cloth of any kind, to anything else. Oat-chaff is the best absorbent, but it retains the moisture more tenaciously than does wheat chaff. I never tried buckwheat chaff. -G. W. DEMAREE.

Woolen rags or waste would probably be best. We use leaves. They are the cheapest and most easily secured here. If chaff is to be used, we would use oat-chaff, or even oatstraw.—DADANT & SON.

If I had not abandoned out-door wintering, I should pack my hives with any one of the materials mentioned that I could get with the least expense and trouble.—JAMES HED-DON.

# Dots on Italian Queens..

Query, No. 178.—Are the 2 or 3 little black dots, sometimes found on the upper side of the abdomen of Italian queeus, any indication of their purity? If not that, what do they indicate ?—W. R.

My best queens have no such dots on them.—G. M. DOOLITTLE.

I think that such dots are not important or significant.—A. J. Cook.

No. They are no sure indication of anything whatever. The purity of a queen cannot always be ascertained by her looks. Look at her bees.— DADANT & SON.

I think not; if they indicate anything it is a trace of black blood. At all events, in those cases where the little black dots amount to black stripes there is no doubt of it.—G. L. TINKER.

I have sometimes thought that they indicated impurity, but I have not observed closely enough to know.—C. C. MILLER.

The little black dots have nothing to do with the purity of Italian queens, unless they are splotches of broken bands around her abdomen. I have noticed that rings or bands indicate impurity of blood in Italian queens, but not so with Cyprian and Syrian queens.—G. W. DEMAREE.

# Syrian and Italian Bees.

Query, No. 179.—1s the Syrlan strain of bees, or any of its crosses, any improvement upon the Italian bees, in the production of either comb or extracted honey, or us a general-purpose bee?—A. G.

My experience with the Syrians is limited, but 1 think that 1 should prefer them crossed with the Italians, to having them pure. 1 prefer Italians to Syrians.—W. Z. HUTCHINSON.

From my own experience l should say no; but I should not think it full enough to be entitled to much weight. In some localities they may be very valuable.—C. C. MILLER.

Crosses with other races have generally been productive of great vigor and extra working qualities; but often the crosses have not proved

more amiable than the average hybrids. With selective drone and queen breeding, I think that the improvement that has been found in many instances may be perpetuated. -G. L. TINKER.

I have tried Syrians and have liked them very much. Not having Italians all the time with them. I could hardly compare them. They do breed faster, and, so far as I have seen, they are as good in every way as Italians.  $-\Lambda$ . J. COOK.

In my opinion no improvement can be made by crossing the Italian race, except the benefits to be derived from the introduction of fresh blood from other strains of yellow bees; and the same results may be had by crossing Italians with Italians of remote families, with the advantage of having your bees pure.—G. W. DEMARE.

I early decided not to bring Syrian or Cyprian blood into my apiaries until I could be convinced by the reports of the fraternity at large that they were superior to our best Germans and Italians; consequently, as yet, I know nothing about them from experience.—JAMES HEDDON.

I much prefer the Italian bees to Syrians. A cross between the two might be an improvement, were it not that the cross could not be told from the pure as to its markings, and from this would come utter confusion of the races.—G. M. DOOLITTLE.

#### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

# The Hibernation of Bees.

### DR. G. L. TINKER.

During December I have made numerous observations on this subject, and I conclude that those who say that "bees never hibernate," have overlooked some of the most interesting and important facts hearing on the wintering problem. When the Rev. W. F. Clarke first gave us his theory of hibernation, it seemed to excite the amusement of bee-keepers rather than to cause a sober conviction that it involved any truth worth thinking about. J am now able to say that if we ever expect to winter bees scientifically perfectly—we must provide them with conditions and surroundings that they may hibernate from the beginning of winter to the time when instinct prompts them to begin breeding; then hibernation must necessarily cease.

My bees begin to breed in February. after the first good flight; sometimes they begin as early as February 1, and again, not until the last of the month. Bees in-doors, or where they are un-able to take flight, may not begin breeding till late in March. Early breeding is, therefore, a nominal circumstance, but one which may be delayed indefinitely by taking all bee-bread from the bees. Experience, however, has shown that it is not wise to do this if we expect to get enough bees to secure an early harvest. In this, as in many other things, the chances are that it is the early bird that gets the worm. The correct policy would seem to be to favor early breeding as much as possible, even if we get a great many bees that we shall be obliged to feed for a few days before the expected honey-flow. I have never yet had too many bees in my hives by June 1, and J never expect to have.

To promote early breeding, reason would dictate, and experience has shown, that the bees should be placed in such conditions that we may raise the temperature about them to  $50^{\circ}$ , and possibly higher, without permitting it to fall back to a low temperature until the bees have become strong in numbers. Whether we can best secure these conditions in a cellar, bee-house, or chaff hive, is still an

open question, with the weight of argument against the chaff hive.

Probably few have considered the close relation that exists between vigorons and healthy colonies at the beginning of spring breeding, and the strong colonies that we want on June

1. My belief is, that we shall not be able to winter bees perfectly until we shall master the problem of hibernation—until we shall secure to them that perfect rest in early winter which is conservative of their vital forces, up to the time when they should begin to breed. If they are exhausted in any way before this time, our hopes of strong colonies and tons of honey will be defeated to the extent of that exhaustion.

I believe that I was the first to point out the fact in the columns of the AMERICAN BEE JOURNAL, that restless bees in winter confinement suffer a waste of tissue, and require not only bee-bread, but honey in large amount. With the restlessness and active waste, the bees are weakened and worn out, only too often, before it is time to commence breeding, when, if they had been able to hibernate up to this period, and subsequently had been properly warmed up to aid them in brood-rearing, they would have survived for active service until late in May and June. I have known old bees to survive and do good service until June 15.

What hibernation is, and how it can be secured, will appear from the following :

On the morning of Dec. 7, the temperature in this locality fell to 8° below zero. During the day I carried 17 colonies in single-walled hives into the cellar, which is 25x35x8 feet, has no ventilation, and is perfectly dark. The thermometer registered 41° above zero. About 10 p.m. I went down into the cellar with a lamp to see what they were about. The entrances being large (34-inch deep), I could see the bees clustered on the bottom of the combs in every hive, and the eluster extended to the bottom-board. They had not a particle of top ventilation and were contracted on from 4 to 7 frames, being mostly on 5 Victor frames. The light was turned up to burn very brightly so that I could see, if possible, their respirations. To my surprise, they all appeared as if dead; they were entirely motionless, and the closest examination showed no per-ceptible respiration. After a few minutes, now and then one would draw its abdomen forward as if disturbed by the light, and then straighten out again; then all was motionless as before. Thus I con-tinued to examine each colony of bees for several minutes, but found after about 10 minutes, with the light about 10 minutes, with the light shining close and full upon them, that they began to move about, and to respire once or twice at long intervals.

From this time on, I frequently examined them and at all times of the day and night. So long as the temperature remained at  $40^{\circ}$  to  $42^{\circ}$ they remained thus undisturbed by the light; but when the temperature was above or below this point, they did not bear the light well, and almost

instantly began to move about, and occasionally one would come out of the hive. At  $35^\circ$  and  $37^\circ$  the bees were restless under the light; at  $41^\circ$ they were least so. I then made up my mind that this was the point of temperature at which they most perfectly hibernated.

For a wider range of observations 1 now went to the colonies out of doors; 16 of them were on Gallup frames and were clustered up so high that I could not see them. The balance were on shallow frames and among them were three contracted on 4 and 5 frames in which I had an unobstructed view. On None had upward ventilation. these, the observations were all made after night, using for the purpose a small lattern furnishing a light as bright as the lamp. The weather being variable, I was able to make all needed observations. I found that when the mercury stood at 40° to 42the bees were all hibernating and acted the same in all respects as did those in the cellar. At 32° they were impatient of the light; at 20° they were uneasy and many respiring; and at 9° they were restless and moving about lively, as well as respiring. Below 20° all signs of hibernation apparently had ceased. How it was in the double-walled hives I do not know, as I could not see the bees. but I believe that it would take a much lower temperature to interrupt libernation than in these three singlewalled hives.

When the temperature went above  $45^{\circ}$  the bees begun to show signs of activity; at  $50^{\circ}$  they had ceased to hibernate and began to respire; and at the approach of the light they moved about freely.

My observations three years since were made late—in February—and I now think that the bees were then breeding, as on every occasion they were seen to be respiring, but most of them very slowly. The temperature of the cluster was higher—about 900 ascertained by a number of tests with a good thermometer. The temperature in the hives now in my cellar, I found to be 54° among the bees at the lower part of the cluster, when the temperature of the cellar was at 40°. The center of the cluster could not have been very much higher than this, so they could not have been breeding. I therefore believe that the thermometer will prove a reliable guide in determining whether the bees are hibernating or breeding at any given time.

Some are inclined to think that the temperature of the bee-cellar should be high—about 50—all winter. Mr. Doolittle has said that he would consider it a great acquisition if he had a bee-cellar that he could keep at 55° without artificial heat. Now, as a matter of fact, I think that few bee cellars can be kept above 45° without artificial heat; but as a certain degree of cold is essential to hibernation, and that about 41°, what more can we ask? Somehow, I am becoming impressed with the idea that a great part of our wintering troubles comes from upward ventilation in hives. The great success of Mr. Ira Barber, in wintering, may be due to

the fact that he gives his bees no top ventilation, and the further fact that his bee cellar will not likely average above  $45^{\circ}$ ; it certainly will not, if he applies no artificial heat.

If the most perfect hibernating conditions exist at  $41^{\circ}$ , that is the temperature which the bee-cellar should have in early winter. When breeding begins, then artificial means of heating to  $50^{\circ}$  or  $55^{\circ}$  will materially aid the bees in their work, and, I am thinking, may come to be an indispensable measure with all progressive apiarists.

Feeding Bees, the Honey Market, etc.

#### G. W. DEMAREE.

The questions, how to feed bees, when, and how much to feed them. have been thoroughly discussed in all the bee-periodicals; but there is matter of interest connected with this subject that seems to have been overlooked—in fact, neglected. In the past, our fathers knew but little about feeding bees even when they knew that the bees were in a starving condition. I can remember 40 or more years ago, when my father was anx-ious about his bees, one winter, and feared that some of the "swarms" would starve, and I remember that he fed them loaves of corn bread. The loaves or pones of bread were split in the middle, and then the fresh bread was saturated with sugar syrup, or rather, with wet sugar. The bees pulled through the winter all right, if my memory is not at fault; of course it was mostly the sugar that saved the bees.

It is a fact, that very few people 40 years ago knew that sugar would answer as a substitute for honey, for winter stores for bees. Those bee-keepers who are old enough to remember back through all the years of progress in this science, will agree with me when I say that apiarists at the first fed their bees sugar as a substitute for honey; in later years some began to claim that sugar syrup was as good as honey for winter stores. This is as far as any of the works on bee-culture have gone, so far as I have examined them on this subject. But now in the last few years, there are some who seem to be interested in sugar, or are carried away by some hallucination beyond the comprehension of most people, who vehemently insist that nothing but sugar syrup is safe food for bees in winter. What are the facts in the case? I have only to ask intelligent bee-keepers to ex-amine the bee-papers for reports of successes and failures in wintering bees during the past hard winter, and form their own judgment. I do not fear the result. The God-given food for bees—*pure honey*—has no superior as a food for bees—or man.

Of course, I do not pretend to say better than the purest sugar. Though weigh much with some people, but my ducted : While I believe that the we should admit that pure sugar is advice to beginners is, don't be caught bees were created for the fertilization

just as good, and as safe to winter our bees on, there is no good reason why bee-keepers should so forget their own interest as to build up the sugar-trade at the expense of the honey market, and thus bring ruin on the bee-interests of the country. A certain supply-dealer quotes sugar for feeding bees at 7 to 71/2 cents per pound, and somewhere else quotes extracted honey as low as 4 cents. Nothing could better illustrate the downward tendency of the honey interests.

I contend that a good article of dark extracted honey, such as is quoted at 4 to 5 cents per pound, is the cheapest and best food for bees that can be had; and it is a suicidal policy to pay a higher price for sugar and have so much cheap honey hanging on the market to drag down the price of the white grades more desirable for table use. I could not be influenced in this matter by immediate personal interest. I produce none but white honey and can sell all I can produce at from 10 to 1212 cents per pound at my honey store-rooms. I speak in behalf of the honev-trade.

Some years ago the glucose fraud threatened the very life of bee-culture. In the first place it appeared as a food for bees. We all know what a determined effort was made to ruin the honey-trade by thrusting glucose in its different forms in the faces of beekeepers. It required years of per-sistent exposure of the fraud, to rid the bee-interest of this vile nuisance. And now we are to be beset with the sugar-trade! If the money that has been spent for sugar with which to feed bees, had been laid out for the darker grades of honey, there would have been a lively movement in the honey market, and the lighter grades of honey would have advanced in price, and instead of a dead honey market there would have been a more hopeful feeling among bee-men generally.

I know of but one remedy for our ruined honey market, and that is to stop the sugar business, and feed our bees on their own products. Hereafter I shall buy honey to feed my bees and leave the sugar market to take care of itself. Much has been said about co-operation-let us have a little practical co-operation in this direction. The one hundred thousand dollars or more paid for sugar-much of it adulterated at that-the past fall, would have helped out the draging honey market surprisingly. It is to be hoped that the practical lessons of the coming winter will be heeded. If I was as sure that contemptible selfishness will not eventually destroy the bee-business, as I am that time will prove that honey is the best food in existence for bees, I would rest content.

#### REVERSIBLE FRAMES.

I want to say a word about the utility of reversible frames. This idea is likely to be pushed as never before-patent interests will push it regardless of its real merits. Expe-rience of years with a thorough knowl-

in the trap. Let me here prophesy that when the great "blow" is over, the thousands of reversible frames that are now being pushed into use will stand *unreversed*.

# Pollen carried from Flower to Flower.

#### 17-G. M. DOOLITTLE, (40-95).

In a paper published a few years ago, a copy of which I chanced to pick up lately, I found these words: "Pollen is borne from flower to flower

on the breeze as well as on the bodies of insects; in fact, that appears to be nature's prime method of conveying the fertilizing germs from the anthers of the staminate to the pointals of the pistillate blossoms." While in another column of the same paper I find this: "Honey is a vegetable production, appearing in greater or less quantities in every flower that nods to the breeze, or kisses the bright sunlight. It is secreted in the flower for the purpose of attracting insects, thus securing the complete fertilization of the female blossom.

Now while both of the above are Now while both of the above are true in the main, yet when applied to certain plants and trees they are not true; neither is it true that "every flower that nods to the breeze" secretes honey. There are some points in this matter which either I or other writers fail to understand, and as it has a direct bearing on our pursuit (bee-keeping) perhaps a short pursuit (bee-keeping), perhaps a short article to draw others out at this time of lawsuits against our industrious little insects, may not be amiss.

I understand that the first purpose for which the honey-bee was created, was for the fertilization of flowers, while the storage of honey was only for the preservation of the life of the bee, so that the perpetuation of the species might continue for this pur-pose (fertilization of plants); that man, after a period of time, found that have been used and thus being more and thus being used and the purpus that honey was good, and thus utilized the product secreted by the flowers and stored by the bee, to become his food, while the bees perished from such colonies as were robbed by man; that, as the years went by, man learned that the bees would store more honey than their wants required, so surplus apartments were furnished the bees, which were removed when filled, thus leaving enough in the hive or home of the bee to supply all its needs; and that from this surplus came the honey of commerce and our industry of beekeeping.

If I am correct in the above (and I believe I am), the people of the world have the bee-keepers to thank for bringing the bee from its primeval home (the bollow tree, especially as our forests are being thinned out), and scattering it broadcast throughout the land. to fertilize the millions of tlowers which otherwise would produce no fruit.

of flowers, yet I also believe that not over one-half of the different species of plants and trees require the aid of the bee to fertilize their flowers, and that only those which require the aid of the bee secrete any honey; hence I said that it was not true that every flower secreted honey. In this we see the wisdom of the Creator—bees created to fertilize flowers which could not be fertilized in any other way, and honey placed in these flowers to draw the bees to them. Thus we have the clover among grasses secreting honey, while the timothy, orchard, red top and other grasses do not secrete honey, for they are fertilized by the "breeze."

All the fault I have to find with the first author quoted, is that he represents that both the breeze and the bees may be needed to fertilize the same and all plants; while I believe that plants and trees which can be the aid of the bees, and that those requiring the aid of the bees cannot be fertilized by all the breezes which ever blew. To be sure, bees collect pollen from many flowers which do not require their aid, but, as I said before beyong is only searched by before, honey is only secreted by those which do. Take the flower of the squash for instance: Gregory, who is certainly good authority, tells us that squashes can only be fertilized bo the aid of bees and insects, and proving the same by giving experi-ments tried where fine netting was placed over the female flowers on certain hills, when not one of the flowers thus treated produced a squash; while other hills near them gave a good crop. Any one, looking at a squash flower, will at once come to the conclusion that it is impossible for the wind to carry the pollen from one flower to another; hence we find it secreting honey to attract the bees.

Prominent among this class of flowers which needs the bee to fertilize them, we have the clovers, fruit-trees of all classes, basswood or linden, buckwheat, and fall flowers generally. Of the class that does not need the aid of the bee, I will mention grasses of all kinds growing in this locality (except the clover), grain of all kinds (except the buckwheat), and many of the trees in the forest, such as beech, ash, elm, etc. We the grain I would include corn. With know that some writers tell us that bees get honey from corn, but after a careful watch for nearly a score of years, I have failed to find a single bee containing any honey in her honey-sac while at work gathering pollen from corn tassels. If the stalks are bruised or cut in any way, sometimes there is a sweet substance that exudes, which the bees get, but this cannot properly be called the secretion of nectar.

In the above I have given my views regarding the matter, and stand ready to be corrected by any who can show that I am wrong. I am no botanist, therefore I cannot give a scientific article on this subject; but if there losses in former years were due to are any good botanists among the readers of the AMERICAN BEE JOUR-NAL, I, and I think that all of its afraid that they would starve in win-plained that the queen did not do

readers, would be pleased to hear from them on this subject. Borodino, O N. Y.

Read at the Detroit Convention. Selling and Shipping Bees by the Pound.

### E. M. HAYHURST.

The possibility of shipping bees without hives or combs, was first brought to the attention of the beekeepers by an editorial in *Gleanings* for May, 1879. In this editorial, Mr. Root suggested the use, as a shippingcage, of a common dish-screen, pro-vided with a wooden bottom and supplied with candy and water. Soon after reading this, I prepared a half-pound of bees and a queen, as thus suggested, and sent them to Mr. Root as an experiment. They were re-ceived without the loss of a single bee. This settled the matter with me, that bees could be sent safely in this way, if all the conditions were right.

I sent a number of half and onepound packages that season, with good success. The dish-screen was soon abandoned for the much more convenient section-box and wire-cloth cage, as advised by Mr. Root in Gleanings for June, 1879. Here I would like to call attention to the fact that our common friend, Bro. Root, is father of this business, and that nearly every advancing step made by his now healthy "youngster," has been made at his suggestion.

Without detailing to you the many heavy losses and great discourage-ments which I met with during the following three years, and owing to which I very nearly abandoned the business as ruinous, I will state that I now have the matter so well under control that it is as safe and profitable to me as any other department of beekeeping.

I still use the well-known section-cages, each being crated so as to protect it somewhat from accidents. When a number of packages are to be sent to one address, several of them are placed in one crate; I have sent as many as 25 one-pound packages in one crate, but generally 1 divide large shipments into crates containing 12 or 15 packages. These crates are so arranged as to admit of ample ventilation for each package of bees.

For feed, I use the "Good" candy. made of the best pulverized sugar and clover or basswood honey. This candy enables us to dispense with the water which was necessary with the can-dies formerly used. When the bees are not likely to be confined more than 24 hours, no feed is really necessary, although a little candy is put into all cages, to guard against pos-sible delays. The proportion used for long distances is about 4 ounces of candy per day for each pound of bees.

I now think that most of my heavy

ter, that I would feed them all the honey that they would take, after they were caged; notwithstanding the well known fact that bees when gorged with sweets are much more likely to become panic-stricken when confined, and disgorging, smother themselves. On the other hand, I now use every precaution possible to prevent the bees from filling themselves while being caged. Bees caged without a queen have this same tendency to panics, and will often run themselves to death ; hence I send no more bees without queens.

Next to over-feeding, perhaps the greatest cause of losses is the exposure of the bees to the hot sunshine by the carriers; on this account I place conspicuous cautionary cards on each crate, calling attention to this fact. I also send printed "Directions" attached to each crate, for the benefit of the purchasers, many of whom are quite inexperienced in handling bees; these are very necessary, but do not always save the bees. One friend wrote me this season that I had failed to put queens into 4 or 5 packages sent him; he said: "I know this to be so, because all of the bees clustered in one place." Further correspondence developed the fact that after preparing his five hives as directed, he turned all the bees loose at once by throwing them into the open air, expecting each nucleus with its appropriate queen to find the hive intended for it! Another friend lost 3 out of 5 nuclei by turning them into hives containing their full complement of combs, smeared and be-fouled by the bees that died during the winter, and without giving them any brood to care for. Only two of the lot had grit enough to stay in their new quarters and clean up.

In regard to the profits to be derived from the business: After an experi-ence of seven years, I believe that when we can retail extracted honey at home for 8 or 10 cents per pound, we cannot afford to retail our bees for less than \$3 per pound, in May, and assume all the risks now required of the shipper. Probably the persons most benefited by the business, are those who have trouble in introducing queens, and they are not few; to such it is certainly a very great ad-vantage to buy a half-pound of bees with each queen, so as to enable them to obtain the improved kinds without the risk of introducing. These little nuclei can be made working colonies at once, by giving them 2 or 3 combs of brood and stores (without bees) from other hives. By adding other combs of brood as fast as the bees can care for them, they can be quickly built into full and profitable colonies : indeed 2 or 3 combs of brood and stores, is help enough in ordinary seasons, if the bees are purchased early, and in extra good seasons a half-pound of bees with a good queen will often grow into a fine colony for winter—a small beginning, but not quite so helpless as the one made by

very well—in fact, had deserted her hive. It seems that he had put her with the few bees sent with her in the mailing cage, into a large, cracked box into which he had fastened a oneno honey. He said that there were just 9 bees with her, and that he thought 4 of these were a plenty to stay with the queen while the other 5 went out to gather honey and wax !

At the risk of incurring the charge of being "enthusiastic" in regard to the immense profits to be derived from purchasing bees by the pound, I will close by giving an extract from a letter received from an Iowa customer; it sounds a little extravagant, but it is by no means an uncommon report—he probably had an extra good run of honey. Here it is : "I kept 11 of those one-pound nuclei, put each into a full-sized

chaff hive with empty combs; this is all the help they had, except a little feed when they first came, and a little foundation. They filled up their hives, increased to 20 good, strong colonies, and gave me about 400 pounds of nice comb honey. A swarm from one of them took the first pre-mium (\$10) at our District Fair."

Kansas City,+o Mo.

For the American Bee Journal. Northeastern Kansas Convention.

The annual meeting of the Northeastern Kansas Bec-Keepers' Asso-ciation was held in the Court House at Iliawatha, Kans., on Dec. 11, 1885, Pres. J. W. Margrave in the chair. The minutes of the previous meeting were read and approved, after which experiences in keeping bees were exchanged, which was interesting to all.

Mr. H. J. Ward gave his method of producing comb honey. The colony should first be in good working con-dition—strong in bees—as soon as possible. He prefers to have them swarm, as he can get more honey from the first or prime swarm than from a colony that does not swarm. He hives the swarm on combs or full sheets of foundation, or puts them in with a weak colony. He places the section-cases on immediately, and uses a slotted honey-board; as but few queens go through the two beespaces to lay in the sections, he thinks that a bee-space should not be more than 5-16 of an inch. He uses tin separators, and puts full sheets of foundation in the sections.

Mr. M. J. Dickason said that the production of extracted honey is more profitable than comb honey, as he can get from two to three times as much extracted honey as comb honey, and at no greater expense or labor. By way of example he said that two 2trame nuclei, being last spring as nearly equal in all conditions as possible, both having productive queens and active workers, were built up and seemed to work with equal vigor; one of them produced 35 pounds of comb boney, which at 20 cents per pound amounts to \$7; the other pro-duced 140 pounds of fine extracted

honey, which, at 10 cents per pound, amounts to \$14, or if retailed at 15 cents per pound, would amount to \$21, or three times as much as the first colony.

Mr. J. W. Margrave made a few excellent remarks on marketing honey. He would first try to have the home market consume all that he could produce. Comb honey should be in one-pound sections, and extracted honey m attractive packages from 1 to 10 pounds each, and be peddled the same as market gardeners peddle their produce. When people refuse to buy, he would leave a sample of honey and Leaflets, "Why Eat Honey," and "Honey as Food and Medicine," and then he would be almost sure of a sale the next time. Once a customer, always a customer if honey is sold at a reasonable price; if held so high as to be considered a luxury, but few sales will be made. He said that bee-keepers should combine and hold honey of the same grade at uniform prices, and prevent a glut of honey in the home markets.

Mr. H. J. Ward does not believe in combinations, and said that only poor boney can glut the market. He sells all the first-class honey that he can produce, at a fixed price, and sells no inferior honey. In this way he has built up a reputation for honest goods, end does not need to reduce his price in order to sell.

Mr. T. B. Dickason, in speaking of wintering bees, said that the best place is the cellar, and that enough is saved by cellar-wintering to more than pay the cost of handling. If no cellar were near, he would raise the hive on a section-case so that if dead bees should fall they would not clog the entrance, and also to give better ventifation. He would invert a honey-board over the hive, place a porous cloth on the honey-board, and then a section-case, and fill the case with leaves or chaff; also give outside protection. He put his bees on shelves in a cellar, so that any one hive could be moved independently of the rest. He raises the hive on a band 2 inches high, and turned the entrances to the wall to exclude light, puts on an in-verted honey-board to give double bee-space over the combs, and leaves the hive-cover on if the temperature of the cellar is at  $40^{\circ}$  or less.

Messrs. J. A. Johnson, J. W. Mar-grave, C. B. Weaver, and others, protect their bees on the summer stands.

The question arose as to how much honey is needed to winter the average colony, the opinion prevailing that 25 pounds is little enough; and as to best method of increase, natural swarming was prefered.

Mr. C. B. Weaver asked, "In what sized sections is the nicest combs secured?" He favors the  $4\frac{1}{4}x4\frac{1}{4}$  and

Messrs, T. B. and M. J. Dickason also prefer that size. They dispense with separators, and get nice, straight, well filled combs, which average about 12 ounces, and more of them are sold at 15 cents than full pound sections at 20 cents. They thought that being narrower, they are filled and sealed much more quickly, and nice worker-comb and clover honey for winter. I increased my apiary to 108 colo-nies, which are on the summer stands,

are consequently more salable than combs in 2-inch sections, which are apt to be bulged.

Mr. H. J. Ward uses tin separators and wide sections, and likes them very much. He never used the narrow sections.

An election of officers was then held resulting as follows : President, Hiram J. Ward, of Farmington, Kans; Vice-President, J. A. Johnson, of Everest; Treasurer, T. B. Dickason, and Sec-retary, M. J. Dickason, of Hiawatha.

A motion then prevailed to send a condensed report of the meeting to the AMERICAN BEE JOURNAL and to Gleanings, after which the convention adjourned to meet upon the call of the executive committee.

M. J. DICKASON, Sec.

How I Managed my Bees last Season.

#### JNO. A. THORNTON, (74-108).

On June 1, 1885, I had 74 colonies of bees, some in splendid condition and some in poor condition for honey-gathering. Forty of the best ones were supplied with surplus arrangements for producing comb honey; the balance for extracted honey. Thirty-three of the colonies worked for comb honey cast one swarm each, while only one colony cast a swarm of those that were worked for extracted honey, and that was caused by the removal of their queen and not getting another properly introduced.

The yield of clover honey ceased on July 1, and during the forepart of June the weather was very bad for honey-gathering, so I secured only about 2,000 pounds of white honey; the basswood failed altogether.

During the latter part of August, and until Sept. 1 or 2, it was cool and rainy, but when nice weather came again, the bees commenced work, and filled their brood-chambers and stored 2,000 pounds more of surplus honey of good quality and light in color, and for which I always secure

as good a price as for clover honey. From the 40 colonies worked for comb honey, I secured only 1,800 onepound sections suitable for market, while from the 34 weak colonies, and increase, were taken something over 2,200 pounds of extracted honey. swarms were left on the old stands with the brood-combs removed, and supplied with empty frames or full sheets of foundation. Right here let sheets of foundation. Agint here let me say that the swarms that were lived on empty frames stored the most honey in the sections, at the first; but when the fall yield came, the ones that were hived on full sheets of foundation, stored almost all the crop in sections, while those swarms that were hived on empty frames stored nearly all the honey below, and built about one-half of their frames full of drone-comb, while the colonies supplied with full sheets of foundation had their frames full of

and prepared by confining each colony board on each side, and 3 or 4  $\frac{1}{2}$  inch sticks crosswise of the frames on top, with old carpet for covers, and the upper stories half full of leaves or chaff, which completes the inside. The outside packing consists of four sticks 2 feet long,  $\frac{1}{2}x^2$  inches wide, driven into the ground back of the hive, and filled with straw between them and the hive, with a tight cord around all.

# Bee-Keeping in Central Illinois. WILLIAM CAMM.

The winter of 1884-85 was a very hard one on bees here. The severe cold weather continued so long with-out intermission, that bees could not move from the cluster, and so they starved to death after exhausting the honey in the frames upon which they were clustered. My own loss was over half, though I had 59 colonies left out of 113; yet those that survived were so weak that many of them were mere nuclei when the honey season opened in the spring. There was little honey until June;

and by the time bees were strong enough to swarm, the season closed. We had only 3 weeks in which any the crop was light. I increased my apiary, by natural swarming, to 96 colonies, and took about 800 fbs. of comb honey and 700 fbs. of extracted honey.

Last winter my bees were well quilted down, but extra frames were not taken out, and many of my hives have 13 or 14 frames. This winter 1 reduced the larger hives to 8 or 9 frames and packed between the divi-sion-boards and the sides of hives with dry leaves. Yesterday, (Dec. 18), bees flew freely from hives faced to the south and a large number of dead ones were thrown out.

Excepting melilot, my experience with honey-plants was not satisfac-tory this year. Catnip and figwort vielded honey as long as they bloomed, but their season seemed shorter than usual, and where I had taken so much pains to get them set a few years ago, they were scattering and made a poor, stingy growth. Golden honey-plant seemed to gain, but just before it came into bloom the old-fashioned black beetle with white stripes, that destroyed our potatoes forty years ago, came and left only bare stalks. This will probably account for its not be-ing found wild here, as we have a plant on our hills that looks almost exactly like it, and upon which bees work some, although insects injure it; also, they do not kill it as the beetle did Dr. Tinker's favorite.

My honey was all sold upon my local about one week later than the season with a like bees for profit, and work my owing largely to the small quantity produced. There is a demand for all we can produce, but this demand is not effective; that is to say, those and we were not treated to another

who would be our best customers are not able to buy because their wages are not in proportion to their needs.

We could insure good seasons for honey every year, if we could induce the same improvement of the land that has been made in machinery with which to work the land. When we do this we shall employ so much labor upon the land that the demand for honey will be far greater than it now is, and the increased yield of the land would insure the payment of such wages that the demand would be effective. With other industries beekeeping must share the vicissitudes of climate and social conditions, and with all other industries we are vitally interested in knowing whether we can improve our climate or better our social conditions.

I purchased, over a year ago, a foot-power saw, and have found it a won-derful help to me. I understand filing and setting saws and the use of tools for wood-working generally, so that I may have succeeded better than many others would. At first my saws seemed to wabble slightly and cut rough, but after setting, filing, and linishing with the hone myself, I turned off work that some carpenters refused to believe had not been planed; and from no regular hive factory have I ever received work so smooth, true and exact, as I can get from this saw. Murrayville, +oIll.

For the American Bee Journal.

The Honey Season of 1885.

#### J. M. HAMBAUGH.

My loss of bees last winter was about 30 per cent. I wintered 65 colo-nies in a house, or enclosure, constructed of straw, slough grass, and fodder. I gave them a flight on Jan. 1, and diarrhea was prevalent among many. I placed them on the summer stands on Feb. 27; there was then but 9 dead colonies, but diarrhea was very prevalent throughout the entire yard, and the snow was soon made as yellow as saffron for quite a distance, from their feces, and a horrible stench arose from the yard. Sealed brood and larvæ was found in many of the hives; and while some made headway in building up, many dwindled away and died, ere the weak could be re-cruited from the strong colonies, and I have found that it is poor economy to tear down the strong to build up the weak colonies, where the per cent. of weak ones is equal to that of the strong. It is better to double up colonies, where the production of honey is the object in view. Less colonies and more bees is by far the most logical conclusion.

It was about April 1 before the bees from soft maple, and the bloom throughout the entire season was about one week later than the season

scourge of honey-dew, which then was very abundant here.

In order to retrieve my losses to some extent, i bought about 35 colo-nies of bees in box-bives, and transferred them. The complete upsetting of their household affairs was so great that they did not recover sufficiently to make the season profitable, but I am looking for better results another year.

I commenced the season with about 86 colonies, and with the exception of so colonies, and with the exception of about 20 colonies, they were in rather poor condition. They increased to 103 colonies, by natural swarming, and I obtained about 3,500 pounds of extracted honey, and 1,000 pounds of comb honey. The largest yield of any one colouy was 201 pounds. Italians one colony was 204 pounds. Italians and hybrids were far in advance for the production of extracted honey. In every instance where the production exceeded 25 pounds, they were pure Italians or hybrids. Eighteen colonies produced upwards of 75 pounds each, and 6 produced over 100 pounds apiece; but to take the entire yard throughout, there was about a half crop harvested. I have Italianized and hybridized the greater portion of my home apiary, and intend to get rid of the blacks another year if possible.

There is a universal complaint of "no honey" this season, here, and because my success looks large in the eyes of some, the cry of adulteration still goes abroad. Will the people never learn that the specialist bee-keeper has great advantages over the old-fogy class?

# The Albino Strain of Bees.

#### S. VALENTINE,

I notice that in the answers to Query, No. 171, Albino bees are dis-cussed, and Mr. Pond says: "The term 'Albino' is a misnomer, as applied to the bees so-called." I claim that the term "Albino" is as applicable to insects as to animals, and if so, it is appropriate and properly applied to bees. If Mr. Pond will refer to my article on page 199 of the BEE JOUR-NAL for 1882, on "Albino Bees—Why so Called," he will see why they are called Albinos.

Mr. Harrison, editor of the American Bee-Keeper in 1881, asked why all the white hairs turned buff or yellow, when the Albino bees became a few days old; and said that if such was the case, he thought it knocked all the "Albino" out of them. I do not think so, for I cannot see any Albino in such bees to "knock out." I admit that all who use the term "Albino" for yellow, will have some "knocking out" to do, for the term "Albino" was never intended for light-colored Italians.

apiaries for a livelihood. I am not prejudiced against any variety of bees, and whenever I thought there

was not slow to invest in it. I have spent hundreds of dollars, together with a great deal of time, and many hours of thorough experimenting with bees, and I am satisfied that the Albino bees have the preference.

The Albino queens are very prolific. breeding up early in the spring, and more readily supersede their failing queeus. I frequently find both mother and daughter laying in the same hive; the workers are good honey-gatherers, and for beauty and gentleness they are not excelled.

For the American Bee Journal

The Secretion of Wax by Bees.

E. B. SOUTHWICK, M. D.

I notice that in the answers to Query, No. 164, nearly all speak as though the will was the supreme power that governs all actions, when the will is but a slave to circumstances regulated by the emotions.

None of those who replied to the Query, gave the proceedings on the part of the bees in secreting wax and making comb. (though doubtless they were all familiar with it), so I will give my description of it, which is as follows:

When bees lack for room to store honey or to rear brood, and have room for more comb, some of the bees fasten themselves at the upper part of this room, in two separate places, then others fasten to them by grasping their bodies or legs, and hanging down others fasten to them, and so on until they form a string-or two strings-as long as they want to commence with; then the lower ends are brought together and held by the bees, thus forming a part of an elongated circle. The younger bees generally do this, not because they are more fit for it, but because the older bees are more fit for something else. The bees that are free then commence feeding those in the string to the utmost of their ability, and to consume this food which brings into action a set of secreting organs similar to our sudorific organs, and they secrete from the circulation a substance that is indigestible and worthless in the system, and throw it out on the surface. These and throw it out on the surface. the free bees take off in the form of thin scales, sometimes thicker and sometimes thinner, according to the time the organ has been at work and the amount and quality of the circulation.

When one of these scales is taken off, another commences to form, and so continues as long as the bee is Kept in that position and properly fed. That this process is exhaustive— very much doubt, as nothing is taken from the circulation that would strengthen or nourish. These little scales are then made into comb. If they are too thick for the place where the bees want to use them, they draw them out thinner; if too thin, they are pressed together.

Whether the position of the bees helps the secretion or not. I am unable

to say; but I think that the forming of the semicircle is for the purpose of having them near where the wax is wanted. When regularly fed, this secretion is thrown off in the feces. and is about all there is of pure honey that is not used in nourishing the system.

Sherman. ~ Mich.

For the American Bee Journal.

# Bee-Keeping in Florida. JOHN Y. DETWILER.

Allow me to enquire as to the loca-tion, in South Florida, of Mr. H. G. Burnet, whose communication appeared on page 683 of the BEE JOUR-NAL for 1885. From his communication, 1 am led to believe that the honey locality of New Smyrna, Volusia Co., is much excelled; for during my residence in Florida I have failed to learn of a locality where the winter can be spent in hiving swarms and extracting honey; except it is from hives that the ants have caused the bees to swarm out, which would necessitate re-hiving them. I should like to hear further from Mr. Burnet, who evidently has a desirable locality, providing he has available transporta-

tion for the honey when harvested. I would say that, in the mangrove belt of Volusia county, the season extends from March until August, with a drouth during April, during which time feeding must be kept up. I have met several individuals who came here believing that bees gather enough honey daily to keep them going during the winter. This is a mistake; and those who ship bees either in full colonies or nuclei should see that each colony has sufficient sealed stores to subsist upon for at least 60 days. Feeding has a tendency to cause robbing, which, in this locality, is to be dreaded, as it fre-quently causes the entire apiary to become demoralized, except during a honey-flow. If Mr. B. will kindly state the source from which the bees gather honey, and the quality, he will confer a favor, and as well as prevent individuals from coming to Florida to engage in the active duties of the apiary during the winter months, except it be in his locality; for they will certainly be disappointed in the man-grove district of Volusia county.

In this connection I may say that comb honey is very liable to sweat, crack and become sour, from the dampness of the climate, and that those who change their location to any part of Florida, from the North, cheveld tote this matter into exceeded should take this matter into consideration before making too large an investment in supers and sections for the production of comb honey. To those who come here to "astonish the natives" with their superior skill and abilities, I have nothing to say; to those who are willing to profit by the experience of others, I would say that a little attention given to the methods practiced by resident apiarists will insure success, or at least prevent loss until experience is gained.

New Smyrna, OFla.

#### Convention Notices.

The annual Convention of the Indi-ana State Bce-Keepers' Society will be held at Indianapolis, Ind., on Jan. 20 and 21, 1886. The meetings of this Society have been very successful in the past, and the coming meet-ing promises to be still better. The meeting will be held in the rooms of the State Board of Agriculture, viz., Dairying, Wool-Growing, Swine-Breeding, Poultry-Raising, etc. Re-duced rates are offered at Hotels, and every-thing possible will be done to make the meeting entertaining and instructive. A very complete program is being prepared, with ample time to discuss the important subjects of particular interest to bee-keep-ers. A cordial invitation is extended to all bee-keepers, with the hope that they will at-tend, and thus make the Convention of still greater importance. greater importance. FRANK L. DOUGHERTY, Sec.

The annual neeting of the Cortland Union Bee-Keepers' Association will be held in Union Itali at Cortland, N. Y., on Jan. 12, 1886, at 10 a.m. It is hoped that all inter-ested in apiculture will make an extra effort to be in attendance at this meeting. Those unable to attend this meeting are requested to send to the Secretary, reports of their aplaries from May 1, 1885, to Dec. 1, 1885. W. H. BEACH, Sec., Cortland, N. Y.

The next meeting of the Maine Bee-Keepers' Association will be held at Skow-hegan, Me., on Jan. 19, 20 and 21, 1886. The Maine Central R. R. will sell tickets at one fare for the round trip. The Grand Trunk R. R. will sell tickets at the same rate to Lewiston, Me., to all who attend the meeting. Bec-keepers everywhere are cordially invi-ted to be present. WM. HOYT, Sec.

The Northern Ohio Bce-Keepers' Association will hold a meeting in the Baptist Hall, in Wellington, O., on Friday, Jan. 8, 1886. A special effort will be made to secure a full attendance. H. R. BOARDMAN, Sec.

B<sup>\*\*</sup> The annual meeting of the North-western Illinois and Southwestern Wiscon-sin Bee-Keepers' Association will be held in Freeport, Ills., on Tuesday, Jan. 19, 1886. JONATHAN STEWART, Sec.

The annual meeting of the Champlain Valley Bec-Keepers' Association will be held in Middlebury, Vt., on Jan. 21, 1886. R. H. HOLMES, Sec.

(27) The Northeastern Ohio and North-western Pennsylvania Bee-Keepers' Associa-tion will hold its seventh annual convention at Meadville, Pa., on Wednesday and Thurs-day, Jan. 20 and 21, 1886. C. H. COON, Sec.

The Eastern New York Ree-Keepers' Association will hold its annual convention in Agricultural Hall at Albany, N. Y., on Tuesday, Wednesday and Thursday, January 26-28, 1886. The first session will begin on Tuesday, at 2 p.m. All interested in bee-keeping are requested to attend, and bring apiatrian supplies for exhibition. The pro-gramme will consist of cssays on important subjects, discussions, etc. E. W. Philo, Sec.

#### -----System and Success.

2 All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are as follows :

The larger ones can be used for a few colonies, give room for an increase of numbers and still keep the record all together in one book, and are therefore the most desirable.

#### Local Convention Directory.

IT order to have this table complete, Secretarles are requested to forward full particulars of tlme and place of future meetings.—ED.

Testing the Hibernation Theory.— S. McLees, May, o+ Mich., on Dec. 12, 1885, writes:

On Dec. 3 I put 34 colonies of bees in the cellar; one I left on the summer stand, to test the hibernation theory. One colony increased to six. They gathered 1,200 pounds of honey during the past season. I have given them no upward ventilation. Their combs are well filled with honey, and I left some pollen in each hive. Of the result I will write to the BEE JOURNAL next spring.

Bees in Good Condition.—John Rey, East Saginaw,⊙ Mich., on Dec. 21, 1885, says:

My bees have had a fine flight today, and they appear to be in good condition. They did not spot the snow any, and I think that they will winter better than they did last winter. At least, everything seems to point in their favor, so far.

Good Results-Wintering Bees.-Ezra J. Cronkleton, Dunlap,+o Iowa, on Dec. 26, 1885, writes :

I commenced the season of 1885 with 10 colonies of bees, increased them to 16, and obtained an average per colony of 108 pounds of surplus honey in one-pound sections. My honey was produced by the wideframe system, and it was very nice and straight, and all the boxes well filled; but I shall use the Heddon system next season. As I am a student in apiculture, and not an experimenter, I adopt what I think is best as fast as my judgment dictates that it is best. I have handled bees only two seasons, and I think that I have met with very good success, having made but few blunders. I winter my bees in the cellar, very similarly to Mr. Ira Barber's plan. I was very successful last winter, and my bees are in fine condition so far this winter. I take more trouble upon myself than Mr. Barber teaches, for I lay laths on top of the brood-frames, then a muslin sheet, and then a soft, woolen blanket. After that I put on the surplus arrangement and crowd into it a cushion made of forest leaves, and of course it rests on the blanket; at last I put on the cap. I keep the temperature at 50°. I take out 2 frames, leaving in 8. This plan is old, but it seems to be successfull.

**Bee-Keeping on the Frontier.**— Joseph Myers, Alma, QNebr., on Dec. 21, 1885, says :

1 came to this place in April, 1884, bringing 4 colonies of bees with me. The people here said that they would starve, but in 1884 they increased to 7 colonies, and produced about 75 pounds of excellent honey. I had them in a cave last winter, and they wintered all right. During the past season I have increased them to 12 colonies, but lost 1, so I have only 11, which are in good condition, and I obtained over 100 pounds of honey, some of which I sold for 40 cents per pound. I believe that this will be a good honey country when it once becomes settled with people, and more clover is sown. Bees do well on buckwheat; I believe it yields more honey here then it does in Illinois, where I came from.

#### Bees are Quiet.—Titus C. Wilsie, Brandon,o+Wis., on Dec. 28, 1885, says:

I have 10 colonies of bees in the cellar. The past season was a very poor one, and I think that if bees have not been fed considerable for the winter, the loss will be heavy. We have had very warm and pleasant weather for the past week, for this season of the year, but the bees are quiet and appear to be all right. Last winter I put 33 colonies into winter quarters—some in the cellar and some were on the summer stands—but I lost all but 7 of them. I think the cause was diarrhea. The loss of those in the cellar and those out-of-doors would average about the same. Mr. B. Jenkinson, of this place, did not lose a colony out of 48, and he wintered them in the cellar. It is something I cannot quite understand, for my cellar is dry and well ventilated.

**Poor Season for Honey.**—Dr. H. Besse, Delaware,⊙ O., on Dec. 28, 1885. writes :

My bees are nicely packed away in the cellar and bee-house, where the temperature is from  $40^{\circ}$  to  $46^{\circ}$ . I put them in on Nov. 14–133 colonies in all, leaving one colony on its summer stand, as an indicator to let me know when it is time to put the rest out m the spring. This has been a very poor season, so much so that I had to teed my bees over five barrels of sugar in order to furnish them enough stores for winter. The last severe winter destroyed the white clover, and we have no basswood here, so it was the poorest season ever known in this part of the State; but I hope that we will have a good season next year, for the ground is literally covered with young white clover that will bloom next season. I should not know how to do without the BEE JOURNAL.

The Weather, Cellar-Wintering, etc.—Eugene Secor, Forest City, & Iowa, on Dec. 22, 1885, writes :

Winter has come (and gone, apparently). About Dec. 4, the first cold wave reached us, suddenly and severely. The temperature on one or two mornings was as low as 12 - below zero. Six to 8 inches of snow fell. The last few days have been mild, the snow is nearly all gone, and the frost is about out of the ground. A part of my bees have been in the cellar seven weeks. The temperature of the cellar is  $45^{\circ}$  to  $50^{\circ}$ . It has no ventilation except an inside door occasionally opened at night. My bees have natual stores entirely. Please allow me to congratulate yon on the continued excellence of the BEE JOURNAL. The last number, containing so much of interest concerning the late North American Bee-Keepers' Convention was worth more than the sum asked for an entire year's subscription.

**Favorable Winter**, ctc.—13—J. F. Logsden, (55—90), Barton,⊷ Md., on Dec. 26, 1885, writes :

The winter so far has been very favorable for the successful wintering of bees in this locality. During the last of October and the first of November I packed 90 colonies with forest leaves, and they are wintering nicely. They all had a nice flight on Dec. 23 and 24; to day the mercury is at 40° Fahr. The past season was rather poor, but I increased my apiary to 90 colonies, and my largest yield from one colony was 160 pounds of extracted honey. My erop consisted of 1,700 pounds of comb honey in boxes, and 1,000 pounds of extracted honey, mostly disposed of in my home market. My average price for comb honey is 17 cents per pound, and for extracted, 14 cents per pound.

The Season of 1885.—Wm. Morse, Rockford, & Ills., on Dec. 26, 1885, writes :

I commenced the season with 36 colonies of bees, 18 of which had been wintered in the cellar, and 18 on the summer stands, packed in chaff. Those wintered in the cellar increased to 31 colonies during the season, and produced 512 pounds of honey in one and two-pound sections; those wintered on the summer stands increased to 36 colonies and ten 3-frame nuclei, and produced 954 pounds of honey. I also obtained from my apiary about 250 pounds of honey in partly-tilled sections. In the middle of September I began preparing them for win-

ter, reducing them to 56 colonies and six 3-frame nuclei. I fed them 120 pounds of granulated sugar made into syrup; also the 250 pounds of honey in the partly-filled sections, uncap-ping what was sealed, and putting the sections on top of the frames. On Oct. 16 I packed them all in chaff, for the winter, on the summer stands. have recently disposed of all of my bees, fixtures, etc., on account of my advanced age (80 years), poor health, and failing eye-sight.

Bees had a Nice Flight. - J. G. Norton, Macomb,+o Ills., on Dec. 29, 1885. savs :

Bees are in fine condition at present. I have 50 colonies that I hope to winther safely in my usual way—with chaff packing. They all had a good flight on Dec. 20.

Bees Wintering Finely. - James Heddon, Dowagiac, 9 Mich., on Dec. 24, 1885, writes:

Among other wise sayings uttered at the late Convention at Detroit, Mr. at the late convention at Detroit, Mr. Ira Barber said: "The wintering problem is solved." I have no doubt of that fact, and, like Mr. B., f think that the main factor in wintering is temperature; outside of that, the question of food—the question being as to whether or not it be free from nitrogen, via floating pollen. Floating pollen would be consumed in any temperature, but pollen in the form of bee-bread, only after exposure to a low temperature. My bees are all passing the winter in apparent quietude and health, and while I hope for successful wintering with those upon natural stores, I feel sure of perfectly wintering those upon stores of all sugar syrup.

Good Yield of Honey.-4-Vira Swartwood, Clearfield, 9 Iowa, on Dec. 18, 1885, writes :

The last winter left its mark on the bee-keepers here, most of whom lost all, and the rest a part of their bces. We succeeded in saving 16 colonies out of 23 that were packed in dry-goods boxes on the summer stands, and all were in fair condition. They were a month later than usual in building up last spring, and as we have not been accustomed to having white clover around us in sufficient quantity for a honey crop, we made no attempt to get our bees in readiness for one, but to our surprise the few bees that we had, worked early and late during the clover season, bringing in a goodly amount of surplus, and showing us how much might have been gathered had we only been ready for it. The last two weeks in July and the first one in August drained the brood-chambers of all their honey, and the bees took a large amount from the sections for food, making one feel that it would be something to be thankful for if they could just gather enough for their winter stores. But the remainder of August and the month of September

left us satisfied with the result of the honey season for 1885. We sold 2 colonies before the season commenced, and from the remaining 14 we took 1,900 pounds of honey in sections, all nicely capped, and 300 pounds in frames, which we gave them because we ran out of sections, and thought that the season was too nearly gone to get more. Our average from 14 colonies, spring count, was 157 pounds per colony.

Preparing Bees for Winter.-W. Mason, Fillmore,+o Ind., on Dec. 25, 1885 savs

Winter has again returned, and I fear that all the bees are not cared for as they should be. If it is important that the hogs have warm pens, and other stock comfortably quartered for winter, why not the bees, too? But the "pets" are much neglected ! On Nov. 19 my bees and hives were all carefully weighed and noted, all colonies being in fair condition. stored all but one colony in my bee-house on Dec. 5, holding a tempera-ture of  $40^\circ$ . The one left out is to test, if I can, the difference of indoor and out-door wintering. The mercury has not, as yet, marked very low; on Dec. 7 it was 5° below zero. 1 notice in the last paragraph of my article, en page 744 of the Ber JOURNAL for 1885, that it reads, "I have 2-inch auger holes on either side of the lid for ventilation in winter," etc., in-stead of, "I have 2 one-inch auger holes on either side of the lid," etc., as 1 meant to say.

### Not Discouraged Yet,-Geo. W. Morris, Cornishville, Ky., on Dec. 29, 1885, says:

The past season, although the poorest for honey since I commenced beekeeping S years ago, has not yet rid me of all my enthusiasm. I began the season with 17 weak colonies, increased them to 20 strong colonies, and sold \$6 worth of queens. My bees are now in good condition for wintering on the summer stands. Although having read several of the best beebooks, yet I am very much indebted to the AMERICAN BEE JOURNAL for my education in bee-culture.

#### Honey as Food and Medicine.

27 To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and seatter them plentifully, and the result will be a DEMAND for all of their crops at remnnerative prices. "Honey as Food and Medicine " are sold at the following prices :

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of houey, will sell almost any quantity of lt.

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Jan. 4, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.-The market is without special change since last quotations. White comb honey in one-pound sections brings 156416c. A little fancy sells at I7c. in a small way. Dark comb honey scall slowly. Nearly all of the white comb honey scomes from the East. Extracted is held firmly at from 6@8c. BEESWAX.-25c. It. A. BURNETT, 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY.--The market for comb honey is very flat and inactive, which we attribute to the con-tinued warm weather, and prices are ruling cor-respondingly. We quotons, 14,015c; the same in some flat.-b, prissed sections, 136,14c; the starsed 2-lbs, 126,15c, Buckwheat honey in 2-lb, sections, 0640c; in 1-b, sections, 116(2c, Ex-sections, 0640c; in 1-b, sections, 116(2c, BEESWAX-Prime yeilow, 25628c; MCCAUL& HILDRETH BROS., 34 Hudson St.

#### ST. LOUIS.

IIONEX.-The market is quict and the demand light just now. We quote prices as follows:-Choice comb honey, 10@12c. Extracted, in bar-rels, 44%3cc. Extra fancy of bricht color and in 1-lb, packages, ½ advance on above prices. D. G. TUTT & Co., Commercial St.

#### CINCINNATI.

CINCINNATI. HONEY.--There is a very slow demand from manufacturers, for extracted honey, with a large supply on the nurket, while the demand is very good or clover honey in square glass jars. Prices toull on unlities are low and range from 48%c a ib. and arrival the start of a clocke comb honey in small sections, which brings 12605c. per lb. EEESWAX.-Good yellow is in good demand, and arrivals are tait. at 20692c. per lb. C. F. MUTH & SON, Freeman & Central Ave.

#### CLEVELAND.

HONEY.—The market is not quite as active as it has been, owing, no donbt, to msoy altractions of the Holiday Senson. Best white, 1-lb, sections sell at 15c, and 2-lbs, for 130-14c, but there is not so much sale for the latter. Second grade honey is duit at 120-33c, 01d white, 100-12c. Extracted, 700-8c, per lb. BEESWAX.—Very scarce at 2200-25c. A. C. KENDEL, 115 Ontarlo Street.

#### KANSAS CITY.

HARSECTIT. HONEY.-The demand for boney begins to sag under the present comparatively high prices, and recent warm weuther, though choice 1-10. sections are still scarce and pretty well taken up at 16007c. We think, however, that the top is reached and any change will be lower prices. Two-1b. sections are selling at 12½015c. Extracted, dark, 466 cts.; while, 76%c. BEESEWAX.-22½@25c. CLEMONS, CLOON & Co., cor. 4th & Walnut.

#### BOSTON.

110NEY.-It is selling very well but prices are very low, and we are often obliged to shade our prices in order to make rates. We quote comb honey in 1-1b. sections at 14%16c, and 2-1b. sec-tions at 12%14c. Extracted, G&MC. BEESWAX.-30 cts, per lb. BLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

HONEY.-Choice comb honey is in light supply and is bringing tim itsures. There is a fair move-ment in best qualities of extracted at steadyrates. We quate as follows: White to extra white comb, 10%12%c.; nmbcr, 7@%c. Extracted, white liquid, 54/@54/cc.; light amber colored, 4½%44%c; amber and candied, 4%c; dark and candied, 4%44%c. BEESWAX.-Quotable at 23%25c, wholesale. O, B. SMITH & Co., 423 Front Street.

923 & 925 West Madison St., CH1CAGO, 1LL.

THOMAS G. NEWMAN & SON. PROPRIETORS

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

To Correspondents. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

" Don't Stop "-that is what many write to us about their papers, when their time is nearly out. One subscriber says: "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It runs out with this month; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

Are you Entitled to a pension? You may be and may not know it. If you examine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

Beeswax Wanted .- We are now paying 24 cents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be put on every package to prevent mistakes.

-----

When renewing subscriptions please send an extra name or two with your own and secure a premium. We have some colored Posters, which we will send FREE, to put up in conspicuous places. We will with pleasure send sample copies to any one who will try to get up a club.

Preserve your papers for reference. If you have no **BINDER** we will mail you one for 75 cents, or you can have one FREE If you will send us 4 new yearly subscriptions for the BEE JOURNAL.

Many Thanks are due foour friends for sentling us so many new subscribers, when renewing their own subscriptions. The reduced price for 1886 has caused quite " a boom," and is a popular move in every sense of that word. As we do not wish any one to work for nothing, we have concluded to offer prominms for new subscribers for 1886. for in order to compensate for the reduction of our price to \$1.00, we should at least thribble our present subscription list.

For 1 new subscriber for a year (besides your own renewal) we will present you either of the following books-25 cents each.

For 2 new subscribers-any 2 of the books. For 3 new subscribers—all 3 of them; or the Western World Guide & Hand-book.

- For 4 new subscribers-Bees and Honey, (\$1.)
- Gaskell's Haod-book of Useful Information —a very handy book of 64 pages.

Architecture Simplified ; or, How to Build a Dwelling-house, Barn, etc., giving plans, specifications and cost-60 pages.

Look Within for 5,000 faets which every one wants to know-75 pages.

A few Binders for the Monthly (two eolumns on a page) are left. We will mail them for 30 cents each, to close them out. They are not large enough for either the Weekly or the Monthly of the present size -three columns on a page.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one ean afford to do without it. We will present a Hinder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few hours, to get subscribers.

2007 Our rates for two or more copies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

The Guide and Hand-Book, is a book of ready reference and an encyclopædia of everything desirable to know. As a guide to the home-seeker, it is invaluable. Its contents are partially given on page 16, and will convince any one of its value. We do not think any of our readers can afford to do without it. As a book of ready reference we find it of great value in our library. We will send the Weekly BEE JOURNAL for a year and the Guide for \$1.30

Agents can sell the Guide and Hand-Book like "hot-cakes." Send us an order for five copies (with \$2.50) and we will send you the Weekly BEE JOURNAL free for a year. This is a rare opportunity to get the Weekly BEE JOURNAL without cost !!

Losi, from the Michigan State Fair, about Sept. 15, a bee-hive stamped with my trademark : "Tetft's Summer and Winter Bee-Hive, with O. K. Reversible Frames." The reward offered is, the hive; that is, if the parties who have it wish to use it. I will send them the balance with instructions how to use it. The hive was a present to Prof. A. J. Cook.-J. W. Tefft, Collamer, N.Y.

The Time for Reading has now come. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books and can fill all orders on the day they are received.

107 Sample Copies of the Ree JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview by sending the names to this office. or we will send them all to the agent.

## NEW BOOK---JUST OUT.

# Success in Bee-Culture. JAMES HEDDON.

Mail him a postal for his

CIRCULAR for 1886

containing Prospectus and Price of Book; Cuts and Prices of his New Reversible Hive, as well as his modification of the Langstroth Hive and other Implements for Bee-keepers.

# Honey for Sale.

He still has on hand a quantity of well - ripened, bright BASSWOOD extracted HONEY, at the following low price, for CASH with the order:

100	Pound	Kegs	(net)	each.	 	•••		<b>\$8</b>	00
50			4.6	· · · ·	 •••	•••	••••	4	00

Free on board CARS, and no charge for kegs. Shipments prompt.

He also has on hand several thousand pounds of mixed honey, of about equal parts of basswood and fall flowers, which may be called AMBER HONEY, that he will sell as above, at 1 cent less per pound.

JAMES HEDDON, Address.

DOWAGIAC, Cass County, MICH.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

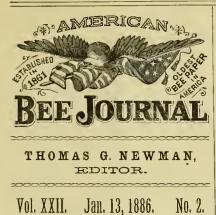

CARDEN

## Fruit-Farm & Apiary FOR SALE CHEAP!

96 ACRES, hill-land, % well-stocked with apples, manual fruit, in fine bearing condition. The remain-der is in pasture, grass, grain, etc. Aplary contains 140 ITALLAN COLONIES in Langstroth hives. Bee-house and all modern appliances for aplculture, in as good location for bees and honey as eas be found. Good th-room house, beautifully located, commanding a view of the city, river and surrounding country. New barn and ont-buildings, eistern, never-failing aprings, etc. Reasons for selling—age and ill-health.

EDITORIAL

"Excellence or Cheapness, Which?" may be answered thus :

"Economy always pays; The man who saves is wise; And those content with *must* to-day, Will surely one day rise."

We have Received a very good photograph of Mr. Heddon, and placed it in the BEE JOURNAL Album, kept on our desk for the examination of visitors.

Mr. Otto Kleinow says that he presented the bouquet of flowers to Mr. A. I. Root, at the Detroit Convention, mentioned on page 794 of the BEE JOURNAL for Dec. 16, 1885.

Mr. S. N. Clark, of Delavan, Wis., who was well-known to our readers as a correspondent, is dead. We have written for particulars, and as soon as they are received they will appear in the JOURNAL.

**Prof. A. J. Cook** has been appointed by President Cutting, of the North American Bee-Keepers' Society, a committee to confer with the Department of Agriculture at Washington, in reference to National apiculture. President Cutting says:

l have appointed Prof. A. J. Cook a committee to confer with the Commissioner of Agriculture, with reference to Appiculture and the U. S. Department of Agriculture.— From my personal knowledge of Prof. Cook's fitness for this position, I think he will accomplish much good for this Society.

To Ohio Bee-Keepers.—Dr. H. Besse, ex-President of the Ohio State Bee-Keepers' Association asks us to give the following notice. It camea day too late for our last issue, and it is therefore of but little use new:

As the time for holding our annual State Bee-Keepers' Convention is nearly at hand, I take the liberty to say that we will have a meeting at Columbus, on the 12th and 13th inst, and all interested in bee-culture are invited. Such will call at the Farmers' Hotel, when they will be instructed as to place of meeting. Important business will be transacted.

The United States Apicultural Station at Aurora, Ills., in charge of Mr. N. W. MeLain, is a grand step in the right direction, by the United States Government. In a New-Year's letter to the AMERICAN BEE JOURNAL, Mr. McLain remarks as follows :

DEAR MR. NEWMAN :-- J am diligently at work "plowing the ground," preparatory to the experimental work of the coming year. Ob, what a big field it is; and yet it is rich and problems. I hope that we may both see our work prosper, and bring forth gratifying success during the year upon which we have entered.

I will have a copy of the Annual Report of the United States Department of Agriculture mailed to each member of the North American Bee-Keepers' Society as soon as issued.

I wish to congratulate you, Mr, Editor, upon the enterprise you have shown in giving such a complete and accurate report of the proceedings of the annual meeting of the North American Bec-Keepers' Society. It is an excellent piece of reportorial work, and should be duly appreciated by your readers. I wish you and the AMERICAN BEE JOURNAL a "Happy and prosperous New Year."

We would thank Mr. McLain for his endeavors to aid the pursuit of bee-keeping by his many very interesting experiments, and we fully endorse what Brother Root says in *Gleanings* eoneerning it, which is as follows:

One of the many treats to which we listened at the Detroit Convention was the papers from Prof. McLain, whom we have before mentioned as employed by the Government, to test disputed matters in beeculture. A very elaborate experiment was made to ascertain whether bees can puncture grapes. Not only were grapes innumerable provided, but many colonies of bees. The decision was in the negative.

The decision was in the negative. We are pleased to mention that he has also succeeded in fertilizing queens by mechanical means. It is true, this has been accomplished before; but the Professor will probably soon he able to give directions so that any ordinary bee-keeper can manage the process with but little risk of failure. We have reason to feel thankful toward the U.S. Government for having furnished the means for such experiments; and we also rejoice that we have secured the services of so able a man. He promises to furnish articles for the different bee-periodicals in due season.

"Success in Bee-Culture, as practiced and advised by James Heddon," is the title of a pamphlet on bee-culture just received. It consists of 128 pages; is well-printed on good paper and illustrated. It covers the whole field of practical apiculture, and is intended for specialists and those who keep bees for the money to be obtained from the business. In his preface the author says:

In the delineation of methods of management, and of implements and devices, appertaining thereto, it has been my constant aim to present such only as will approximate uniform and unvarying success, as nearly as possible, when the requisite conditions have been complied with, and thereby obviate the disappointments and vexatious losses, resulting from the complicated and impracticable in both management and utensils. In short, the instruction herein given, is from the dollarand-cent basis — the financial results to accrue therefrom, and not from the vagaries and incensistencies of empiricisms, aiming to present the new and useful rather than mere repetition of the old.

At this season of the year we are too busy to read a book through and review it (that we shall do hereafter), but after reading several chapters we are sure that its perusal will handsomely *pay* every honey-producer. It can be obtained at this office for 50 cents.

More Misrepresentations About Comb Honey.—The Advance, a religious paper of this eity, dated Dec. 31, 1885, contains the following misrepresentations about comb honey being manufactured, etc., etc., signed "R. W. :"

The time was, until recently, that if one got honey in the comb, he was sure about it. But all that is changed. Men have learned not only to manufacture the comb much more rapidly and cheaply than the bees can do it, but now fill it, capping the so-called honey-cells by machinery, and sell it at a lower figure than any at which the real honey can be produced. Some of our readers know unserupulous men in the country who having bought a few hives of bees, almost immediately began selling great quaatities of honey in the comb. They procured it from the manufacturers of the adulterated article, but any one familiar with the taste of the real honey easily detects the frand. I went to one grocer in this city, who had recently purchased from Ohio, a thousand pounds of what he bonestly supposed real boney, and convinced him in five minutes that almost the entire quantity was made up of syrups, deftly secured in the comb. He simply said, "What are we coming to?" We have no State laws sufficiently guarded in their provisious to reach these rascals, and punish them as they deserve.

The author of the article is the Rev. Robert West, who has heen deceived by that "scientific pleasantry" (lie) of Prof. Wiley, and has unwittingly reiterated the falsehood —giving it a fresh impetus, greatly to the injury of the industry-of bee-keeping. As "Manager of the National Bee-Keepers" Union," we have requested the author to publish a full retraction and apology in the Advance, or take the censequences of a lawsuit. That is the only way to counteract such misrepresentations and falsehoods.

New Price-Lists have been received from the following persons :

A. I. Root, Medina, O.-40 pages-Bee-Keepers' Supplies of all Kinds.

Paul L. Viallon, Bayou Goula, La.-16 pages-Implements for the Apiary.

I. R. Good, Nappanee, Ind.-1 page-Italian Bees and Queens.

C. W. Costellow, Waterboro, Maine-16 pages-Apiariau Supplies.

James Heddeu, Dowagiac, Mich.—30 pages —Prospectus of his New Bock, "Success in Bee-Culture "—price 50 cents.

D. Landreth & Sons, Philadelphia, Pa.-98 pages-Seed Catalogue.

E. R. Badger, Rochester, N. Y.-16 pages-Incubator and Broeder.

Any one desiring a copy of either of them, ean do so by sending a postal card to the address as given above.

The Cincinnati Illustrated Graphle, of Jan. 16, will contain a double page illustration of the Cherokee Nation, again brought so prominently before the public by the leasing of six million acres of their land. Pictures will be 'given of Chief Bushyhead and other prominent Cherokees, and of their principal buildings. Accompanying this pictorial effort will be a full and interesting history of the Nation, by the well-known author, John R. Musick.

If You Want a handsome Calendar for 1886, get Hood's Household Calendar. You may search for dars, but you will not get one more artistic, more beautiful, or more convenient than that issued by the proprietors of Ilood's Sarsaparilla. Ask for it at your druggist's, and if you cannot get it there, send 6 cents for one copy, or 10 cents for two, to C. I. Hood & Co., Lowell, Mass.

# Early American Apicultural History.

### FROM 1860 TO 1871.

The Early History of Bee-Keepers' Societies in America is very interesting, and we feel sure that the following condensed history, covering a period from 1860 to 1871, will be devoured by thousands of our readers with considerable relish. It is condensed from hundreds of pages in the early volumes of the AMERICAN BEE JOURNAL, and many other sources :

#### First Bee-Convention.

The first Convention of the bee-keepers of America was held at Cleveland, O., on March 15, 1860. The following persons were then elected as officers :

President—Prof. J. P. Kirtland. Vice-President—Wm. M. Cunningham. Corresponding See'y—E. T. Sturtevant. Recording See'y—A. Kirkpatrick. Treasurer-E. Gallup.

The first question discussed was: "What is the best mode of wintering bees ?" The Rev. L. L. Langstroth was present, and advocated cellar-wintering. Others favored burying them in clamps. The subjects afterwards engaging their attention were ventilation of hives, feeding bees, robbing, feeding rye flour for pollen, Italian bees, swarming, beehouses, etc.

When this Convention was held there were no periodicals devoted to the pursuit of bee-culture in America, and the report of the Convention was published in the "Ohio Farmer." Mr. Samuel Wagner started the Monthly AMERICAN BEE JOURNAL in the following January (1861), and in the March number of the BEE JOURNAL he re-published the proceedings under the heading of the "First American Bee-Keepers' Convention," and editorially remarked as follows :

"We take pleasure in placing on record "We take pleasure in placing on record in our columns, the proceedings of the first American Bee-Keepers' Coovention, which met at Cleveland, O., on the 15th of March, 1860. The time is approaching March, 1860. The time is ap when bee-culture will occupy a higher position than it has yet held in this coun-try, and when it will be interesting to trace back its history to those pioneer movements which conduced to revival and progress."

#### The Second Convention

was held in Cleveland, O., on March 14, 1861, President Kirtland in the chair. The discussions were mostly on the adoption of the movable-frame hives, and a resolution was passed welcoming the advent of the AMERICAN BEE JOURNAL, and recommending it to all bee-keepers. This meeting was adjourned to Nov. 21, 1861, when a semi-annual meeting was inaugurated.

#### The Third Convention

was called to order by President Kirtland on Nov. 21, 1861, and the members dis-cussed many important matters, among them wintering, feeding, and handling bees.

On account of the Civil War, attention was called from the pursuit of bee-keeping, the AMERICAN BEE JOURNAL was suspended for 4½ years, and we know of no Convention of bee-keepers of any importance until 1866.

#### Other Conventions Organized.

The Wisconsin Bee-Keepers' Associa-tion was formed in Madison in 1866.

On Oct. 4, 1867, the "Northwestern" was organized, in Des Moines, Iowa, on the State Fair Grounds, about 150 beekeepers being present; no business of any importance seemed to have been done. R. R. Murphy was elected President, and M. M. Baldridge, Secretary.

The Kentucky Bee-Keepers' Association was formed at a Convention held in Lex-ington on Nov. 20, 1867. Dr. John Dillard was elected Pres., and W. Spencer, Sec.

The Michigan Bee-Keepers' Association was formed on April 7, 1869. Mr. E. Rood was elected its first President, and Prof. Was elected its first President, and Froi. A. J. Cook its first Secretary. The first Convention lasted two days, and the dis-cussions extended over nearly the entire field of the apicultural pursuit. Its second Convention was held on Sept. 21, 1869, and Mr. A. F. Moon was elected President. Both meetings ware held of Lagroon Mich Both meetings were held at Jackson, Mich.

The Ohio bee-keepers met in Convention at Toledo, O., on Sept. 15, 1869, and ad-journed to Cleveland at the call of the Secretary, Mr. J. F. Martin. The Cleve-land Convention was held on Jap. 14, 1870, when it was desided to held append when it was decided to hold annual sessions thereafter. This was the con-tinuation of the first American Bee-Keep-ers' Society (formed in 1860), and the President, Dr. Kirtland, and Secretary, E. T. Stucture, the secret secr T. Sturtevant, were re-elected.

The Chautanqua Co.(N.Y.) Bee-Keepers' Association was organized on Jan. 29, 1870, by adopting a constitution and by-laws and electing T. S. Moss President, and C. E. Benton, Secretary and Treasurer. It was decided to hold the first annual Convention at Mayville, on Sept. 20, 1870.

The Northeastern (New York) Bee-eepers' Association was instituted in Keepers' March, 1870; but we can find no minutes of that meeting: A semi-annual session was held at Utica, N. Y., on Sept. 27 and 28, 1870. At this meeting it was agreed to institute a National Convention, and a call was issued for such to be held at Cincin-vation in Weberger 2021 nati, O., in February, 1871.

The Michigan Bee-Keepers' Association net at Lansing on March 23, 1870. Presi-dent A. F. Moon strongly urged the formation of a National Bee-Keepers' Society, and several letters were read from prominent aplarists, urging the formation of such a Society. After con-siderable discussion the following was unanimously adopted :

"WHEREAS, The subject of a National Bee-Keepers' Association was much talked

of at our last gathering ; and "WHEREAS, In our judgment, the time for the same is fully come ; therefore

"RESOLVED, That we issue a call for a National Bee-Keepers' Association to be held in the city of Indianapolis, Ind., on the loth and 11th of August next."

The date was afterwards changed to Dec. 21, 1870, as will be seen by the following, which is copied from the AMERICAN BEE JOURNAL of February, 1871:

#### North American Bee-Association.

On Feb. 10, 1870, Prof. A. J. Cook, Secretary of the Michigan Bee-Keepers' Association, issued a circular, which he mailed to the members of that Association, to the prominent bee-keepers of other States, Oxford, O., be and to the press, inviting everybody interested to meet at Lansing, Mich., on the 21st of March, for the purpose of ensning year.

discussing special questions on the subject of bee-culture, prominent among which would be the holding of a National which would be the holding of a National Bee-Keepers Convention, at some central point during the year. On the day an-nounced, the Convention was held at Lausing, and the question of holding a National Convention was discussed with the wildest enthusiasm. As was antici-pated, the discussion resulted in a call to pated, the discussion resulted in a call to the bee-keepers of America for a National Convention, to be held in Indianapolis, Ind. The location was happily chosen, and has given very general satisfaction, it being centrally located, and readily acces-sible by a complete net-work of railroads.

Accordingly, on Dec. 21 (the day finally fixed upon), a large number of the most prominent and enterprising of bee-keepers of the United States and Canada, met in convention at the House of Representa-tives in Indianapolic and hold being tives, in Indianapolis, and held six sessions, the last one ending at midnight sessions, the fast one entring at infinite on the 22d of Dec., 1870. Every seat in the honse was occupied; the States rep-resented being Indiana, Illinois, Michi-gan, Ohio, Wisconsin, Kentucky, Iowa, New York, Tennessee, Missouri, and Pennsylvania. Delegates were also present from Utah and Canada. On the whole, it is safe to assume that never in the history of America has bee-culture been represented in a Convention by so large an assemblage of wide-awake, large an assemblage of wide-awake intelligent, and enterprising bee-keepers.

The Convention was called to order at 10 a.m., by A. F. Moon, President of the Michigan Bee-Keepers' Association, who was elected temporary President, and M. M. Baldridge, of Illinois, temporary Sec.

On motion of Dr. Bohrer, of Indiana, a committee of one member from each State committee of one member from each State represented, was appointed to prepare a Constitution and to nominate officers, viz: Z. S. Richardson, of Indiana; Ezra Rood, of Michigan; D. L. Adair, of Kentucky; M. L. Dunlap, of Illinois; Aaron Bene-dict, of Ohio; Adam Grimm, of Wiscon-sin; Elisha Gallup, of Iowa; Dr. T. B. Hamlin, of Tennessee; Robert Bickford, of New York; W. D. Roberts, of Utah Territory; Daniel McIlvain, of Pennsyl-vania; J. L. Smith, of Missouri, and Wm. F. Clarke, of Canada. F. Clarke, of Canada.

This committee reported a Constitution which with a few amendments was adopted; and recommended the following as officers during that meeting :

President—A. F. Moon. Vice-Presidents—Elisha Gallnp and Dr.

G. Bohrer.

Secretary—N. M. Baldridge, Assistant Sec'y—Wm. F. Clarke. Treasurer—N. C. Mitchell.

The report was adopted, and President Moon thanked the Convention for the honor conferred upon him, and expressed the desire that it might be the means of promoting the best interests of the Association, and bee-culture generally.

The exhibits at this Convention were : Is movable-comb hives; 3 cages for ferti-lizing queens in confinement; 3 queen nurseries; 2 bee-feeders; 1 trap for eatch-ing queens and drones when leaving the hives; 1 wax-extractor; and 4 machines for extracting honey from the combs.

The election of officers for the ensning

year was then announced as in order. On motion of R. C. Otis, of Wisconsin, the Rev. Mr. Langstroth was made an honorary member of the Association.

honorary member of the Association. In view of what Mr. Langstroth has already done in promoting the interests of bee-keeping, not only in this but in other countries by the introduction of an improved system of bee-management, Mr. Otis moved that Rev. L. L. Langstroth, of Oxford, O., be crowned with the honor of being the President of the North Ameri-can Bee-Keepers' Association for the ensuing year

The motion was warmly seconded, and there being no other nomination, Mr. M. L. Dunlap moved that President Moon be authorized to cast the unanimous vote of the Association.

The motion prevailed, and the tellers announced the result of the ballot. On motion the Secretary was instructed to notify Mr. Langstroth of his election.

On motion of Mr. W. F. Clarke, the Constitution was amended so as to pro-vide for three additional/Vice-Presidents, making the number five instead of two.

The following officers were unanimously

elected : Vice-Presidents—Wm. F. Clarke, Ont. ; Dr. T. B. Hamlin, Tenn. ; Rohert Bick-ford, N. Y. ; Elisha Gallup, Iowa ; A. F. Moon, Mich.

Secretary-M. M. Baldridge, St. Charles,

Ilis. Treasurer-N. C. Mitchell, Indianapo-

The following resolution was adopted : —RESOLVED, That the Executive Com-mittee be instructed to publish the pro-ceedings of this Association in pamphlet form at the earliest practicable day, pro-yided the funds will warrant, and that the Secretary forward a copy to each member as soon as published.

The following were admitted as honorary members:

Samuel Wagner, editor of the AMERICAN BEE JOUENAL, Washington, D. C.; M. Quinby, author of "Mysteries of Bee-Keeping," St. Johnsville, New York; E. S. Tupper, Brighton, Iowa: Rev. John Dzierzon, Karlsmarket, Lower Silesia, Germany: A. Schmidt, editor of the "Bienen-Zeitung," Eichstadt, Germany; L. Gerster inventor of the Way, Evtrator Berne, Switzerland; T. W. Woodbury, Mount Radford, Exeter, England; Major Von Hruschka, Germany, inventor of Mel-Extractor.

As the Rev. L. L. Langstroth was not present, he was notified of his election as President, and accepted it, adding that he hoped "that the interests of practical and scientific bee-keeping may be greatly advanced" by the organization.

The topics discussed were: Managenent of an apiary; diseases of bees; Italian and Egyptian bees; swarming and increase by division; queep-rearing; bee-pasturage; transferring bees; marketing honey ; comb foundation, etc.

The Convention adjourned to meet in Cleveland, O., on Wednesday, Dec. 6, 1871, at 9 a.m.

#### American Bee-Keepers' Association.

The Cincinnati "Gazette" remarks as follows:

"Various States of the Union, either singly or two or three of them united, have formed bee-keepers' associations, but hitherto no national association has existed in this conntry. The impetus given to bee-culture by the discoveries of Huber, The impetus given the distinguished Geneva apiarist, at the the distinguished Geneva apiarist, at the close of the last century, has sent hun-dreds into that pursnit. The progress of skill and knowledge in it has not lagged behind the advance made by science and skill in other departments of knowledge and industry since the blind Huber died. The necessity of associated action and effort for the benefit of bee-culture has been widely felt and that feeling has been manifested in forming numerous local associations. associations.

"About a year ago, two of these associations, at nearly the same time, conceived the idea of issuing a call for a convention to form a national organization. One of them was the Michigan, the other the Northeastern Bee-Keepers' Association. The North American Bee-Keepers' Asso-ciation, organized at Indianapolis last

December, and the American Bee-Keepers' Association, organized here, are the ers Association, organized here, are the results of calls issued by the above local bodies respectively, viz : the Michigan and the Northeastern. Between these associations there has been some con-troversy—with but little, if any, ill feeling —as to the claim of priority in issuing the call for the National Convention. "The Convention called by the Michigan

The Convention called by the Michigan Association met in December last; that called by the Northeastern Association is the one in session now in this city. Both associations have the same man, the Rev. L. L. Langstroth, of Oxford, O., for Presi-dent. Many members of the Association formed vasterday are members of the formed yesterday are members of the North American formed at Indianapolis. Mr. Langstroth, of the former body, in retiring from the active duties of the chair turing from the active duties of the chair last evening, called to officiate as Chair-man of the American, the Rev. Mr. Van Slyke, of the Northeastern Association. The union of the two National Associa-tions at their next meeting, which, for both, is at the same time and place, is a moral certainty." moral certainty."

About 150 delegates from various States assembled in Convention at f p.m., and an organization was effected by electing Rev. Wm. F. Clarke, of Toronto, Chairman.

Gen. D. L. Adair, of Kentucky, moved to adopt a Constitution, which he pre-sented, and make this Convention an Association, to be known as the Ameri-can Bee-Keepers' Association. This was objected to a sumplication in

This was objected to as needless, since we have already a North American Bee-Keepers' Association. Mr. H. A. King, of New York, fayored Gen. Adair's motion. This would be the first step toward uniting the North American. Association and the one proposed to organize here.

Dr, Bohrer. of Indiana, a delegate to the Convention that met at Indianapolis, Dec. 21, 1870, spoke in favor of maintaining good feeling. He desired that there should be but one Association, i.e., the North American or the American, as should be agreed

Mr. R. C. Otis, of Wisconsin, moved, as an amendment to Gen. Adair's motion, to appoint a committee to negotiate for union with a like committee of the North

American Bee-Keepers' Association. Mr. H. A. King, of New York, moved to amend the amendment, that the Conven-tion should first organize by adopting a Constitution, and then propose a union.

By carrying the previous question, the debate was cut off.

Mr. King's amendment to Mr. Otis' amendment was adopted.

The "American" Society organized by adopting a Constitution similar to the "North American," adopted at Indianapolis, and elected the Rev. L. L. Langstroth President, Rev. H. A. King, Secretary, Gen. D. L. Adair, and L. C. Waite Assistant Secretaries, N. C. Mitchell, Treasurer, and 15 Vice-Presidents.

The Rev. L. L. Langstroth took the chair, but being feeble, he called the Rev. E. Van Slyke, Vice-President for New York, to preside.

Rev. W. F. Clarke, the retiring tem-porary President, offered the following resolution, which was unanimously resolution, adopted: "RESOLVED, That this Association,

"RESOLVED, That this Association, when it adjourns, adjourn to meet at Cleveland, O., at 9 a.m., on the first Wed-nesday in December, 1871, at the same time and place as the North American Bee-Keepers' Association ; when, pro-vided the other organization shall instruct its officers to do the same, the officers of this heady shall resident with a view of there bee-Keepers' Association; when, pro-vided the other organization shall instruct its officers to do the same, the officers of this body shall resign, with a view of there this Society."

and then consolidating both associations into one.

On motion of Mr. Peck, amended by Mr. Clarke, Mr. King, Mr. Peck and Mr. Otis were appointed a committee to confer with a similar committee appointed by the North American Bee Keepers' Asso-ciation, with a view to a union of that with this organization, and report the same to this Association.

The topics discussed were : Winter nanagement of bees; artificial swarming; prevention of natural swarming; Italian bees vs. hybrids and black bees; hin-drances to bee-culture; drones; houey-plants; introducing queens; extracted honey, etc.

Mr. E. Gallup read an essay entitled, "Successful bee-keeping in a nut-shell.

"Successful bee-keeping in a nut-shell." The following were made honorary members: T. W. Woodbury, Mount Rad-ford, England; F. W. Vogel, Lekman-shofel, Prussia; Rev. Georze Kleine, Luethorst, Prussia; Andreas Schmidt, Eichstadt, Bavaria; Rev. John Dzierzon, Carlsmarkt, Silesia; Baron A. and Baro-ness L. Von Berlepsch, Munich, Bavaria; Prof. C. T. E. Von Siebold, Munich, Bavaria; Maj. F. Von Hruschka, Dolo, Italy; Dr. A. Dubini, Milan, Italy; Vis-count De Saliceto, Milan Italy; A. S. Packard, Salem, Mass.; C. V. Reily, St. Louis, Mo. Louis, Mo.

Statistics: 120 bce-keepers reported that they owned 5,051 colonies of bees; and the honey produced amounted to 83,065 pounds, and the average price it sold at, was about 30 cents per pound. Beeswax,1,046 pounds-4,612 colonies were in movable frame hives, and 439 in boxhives.

The Rev. L. L. Langstroth was the recipient of an expression of the gratitude of bee-keepers (in the shape of a wellot bee-keepers (in the shape of a well-filled purse), and, by manimous vote, he was accorded the special privilege of speaking when, and as long as he chose to do so, on any subject. He solved many knotty questions, and often "poured oil on the troubled waters."

This Association adjourned to meet with the North American at Cleveland, O., on Wednesday, Dec. 6, 1871, at 9 a.m.

#### The Two Associations Consolidated.

Pursuant to adjournment of both, the "American" and "North American" Bee-Keeners' Associations met in joint session Keepers' Associations net in Joint session at Temperance Hall in Cleveland, O., at 10 a.m., on Dec. 6, 1871. The President of both societies, the Rev. L. L. Langstroth, being absent on account of illuess, Vice-President W. F. Clarke called the meeting to order, and, by unanimous vote, both associations were dissolved for the pur-person of convolution. pose of consolidation.

Moses Quinby was elected temporary chairman, and Rev. H. A. King temporary secretary.

By vote, all the officers of the dissolved associations present, were created a comassociations present, were created a com-mittee to present a constitution for perma-nent organization. This committee were: Rev. W. F. Clarke, Dr. G. Bohrer, A. F. Moon, Dr. T. B. Hamlin, S. Hoagland, Aaron Benedict, L. C. Waite, Gen. D. L. Adair, and N. C. Mitchell. The committee reported a Constitution, which was then maximum advantad unanimously adopted.

The following were elected a committee on honorary members: Messrs. Root, Moon and Bohrer. Their report was adopted. It read thus:

"Such persons as were made honorary members of both the North American Bee-Keepers' Association, held at Indiana-

The Society then proceeded to the election of officers for the ensuing year, which resulted as follows :

President-M.Qninby, St. Johnsville, N.Y.

President—M. Quindy, St. Joinsville, N. 1. Vice-Presidents — Aaron Benedict, O.; J. E. Hetherington, N. Y.; E. J. Peck, N. J.; Seth Hoagland, Pa.; D. L. Adair, Ky.; T. B. Hamlin, Tenn.; G. Bohrer, Ind.; Ezra Rood, Mich.; M. M. Baldridge, Ills.; R. C. Otis, Wis.; J. W. Hosmer, Minu.; E. S. Tupper, Iowa; S. A. Stillman, Mo.; L. J. Dallas, Kans.; W. D. Roberts, Utah; W. F. Clarke, Ont.; Hugh Cameron, D. C.

Secretary—H. A. King, N.Y. Recording Secretary—A. J. Cook, Mich.: Correspond-ing Secretary, A. I. Root, O.; Treasurer, N. C. Mitchell, Ind.

The following business committee was appointed to serve during the session : Messrs. Clarke, Waite, Adair, Hoagland, Hosmer, Moon, and Mrs. Tupper.

Dr. Bohrer, of Indiana, offered the fol-lowing resolution, which was adopted :

RESOLVED, That the proceedings of the North American Bee-Keepers' Association North American Bee-Keepers' Association held at Indianapolis, and the American Bee-Keepers' Association held at Cincin-nati, also of this session of the North American Bee-Keepers' Society, be pub-lished in pamphlet form, and a copy sent to each member of this Society free of charge, the expenses to be paid out of the funds in the treasury funds in the treasury.

Mr. Rood, of Michigan, offered the fol-

Mr. Rood, of Michigan, ohered the fol-lowing, which was adopted : RESOLVED, That a committee on publi-cation, consisting of Messrs. Addar, Mitchell and King, be appointed, and that they be empowered to employ assistants in reporting.

It was resolved, that when this Society adjourns it will adjourn to meet at the city of Indianapolis, Ind., on the first Wednesday in December, 1872, at 10 a.m.

The meeting was pleasant and instructive, tive, and great harmony prevailed. Among others, the following resolutions were passed unanimously: -

were passed unanimously: -WHEREAS, Millions of wealth have been annually lost to the people through igoor-ance of bee-culture; and WHEREAS, It is the desire and object of this Society to enhance improvement and prosperity in this regard; therefore, RESOLVED, That we earnestly recom-mend the appointment of an apiarian professor in each of the Agricultural Col-leges on the Continent, and that we respectfully call the attention of State and other executives to this subject. other executives to this subject. RESOLVED, That the Secretary be in-

RESOLVED, That the Secretary be m-structed to forward copies of these reso-lutions to the Governors of all the States, Territories & Provinces in North America. RESOLVED, That the thanks of this Society be tendered to our worthy Presi-dent, Mr. M. Quinby, for the satisfactory manner in which he has presided over our meeting meeting.

The topics discussed were: Why do The topics discussed were: Why do bees swarm? why do bees rear queens? artificial swarming; can swarming be prevented? best method of handling bees to prevent anger; bee-pastnrage; bee-keeping experience; transferring bees; honey-dew; extracted honey; comb honey; marketing honey; controlling the fertilization of queens; mortality among bees; wintering bees; feeding bees with rye meal.etc. rye meal, etc.

Addresses were given as follows: Gathering the nectar, and how to market it, by President Quinby; popular bee-keeping, by Rev. H. A. King; prize poem, by Rev. W. F. Clarke; the experiences of a beginner, by Mrs. Savery; bee-keeping for ministers, by Rev. W. F. Clarke; re-constructed comb, by Gen. Adair; honey from the linden, by Le Roy Whitford.

Adjourned to meet at Indianapolis, Ind., on Dec. 4, 1872.

**REPLIES by Prominent Apiarists.** 

# Moving Bees.

Query, No. 180.—When is the best time to move an apiary of 75 or more colouies from Wisconsin to the western part of Iowa ?—N. S.

I should prefer the month of May.-G. M. DOOLITTLE.

In April or May would be an excellent time.—A. J. Cook.

In early spring, say a week or two before apple bloom.-DADANT & SON.

Under ordinary circumstances perhaps the spring.-C. C. MILLER.

I would say move them as soon as they have a general spring flight.-G. W. DEMAREE.

Early in the spring, and before there is much brood in the combs.-G. L. TINKER.

In the spring, before the colonies become populous, the combs full of honey, and the weather hot—say in May.—W. Z. HUTCHINSON.

In the late spring just after breed-ing has become well started, and before the combs become heavily loaded with honey. The reasons will be obvious to any one, even of small experience.—J. E. POND, JR.

"Much depends "-cool (not cold) weather, light hives, little brood, that the bees have had a thoroughly cleansing flight before starting, and may have the same soon after landing, are all favorable conditions in connection with the "time to move."-JAMES HEDDON.

# Sections without Separators.

Query, No. 181.—What is the best width for a one-piece section to be used without separators, so the bees will not build combs between the starters ? and will such sections hold one pound when filled ?-E. T

I prefer to use separators.-G. M. DOOLITTLE.

One and three-fourths to 2 inches; the latter will weigh about I pound.-DADANT & SON.

One and 5-12 inches, or 7 to the foot, is perhaps the best. The weight will vary slightly.—A. J. COOK.

I think that I should prefer sections 1½ inches wide. They will hold one pound if large enough, but not if they are 41/4x41/4.-C. C. MILLER.

After using sections of different widths for 3 years, I have about settled down to sections that are  $4\frac{1}{4}x4\frac{1}{4}x7$  to the foot either with or without separators. When well filled these will hold one pound, when no separators are used.—W. Z. HUTCH-INSON.

The best width for sections without separators is 1% to 1½ inches. I have POND, JR.

had many sections of these widths, nearly 6 inches square, built very true and regular without them. A section 4x5 inches will hold very nearly a pound.—G. L. TINKER.

After trying sections of different widths I prefer a section 134 inches wide with a scant %-inch opening, fitted closely in a case without separators. In a good season this size section will very nearly average a pound. There is really no such a thing as a "pound section"—there is always some variation in their exactweight.-G. W. DEMAREE.

About 15% inches; they will not contain a full pound, as a rule. Sections 134 inches in width will average one pound when filled, and work well when used without separators. I should not think of using wider sec-tions unless I used separators, and I prefer sections 1% inches wide in my locality.—J. E. POND, JR.

Careful and extensive experience has caused me to decide in favor of a section whose width is scant  $1\frac{3}{4}$ inches, or "7 to the foot." I use them of that width, and  $4\frac{1}{4}x4\frac{3}{4}$ inches square, both with and without separators; in either case they aver-age as nearly one pound gross as any size I can get.—JAMES HEDDON.

# Introduction of Virgin Queens.

Query, No. 182.—Is the introduction of virgin queens generally practical ?—C.

Not with me.—G. M. DOOLITTLE.

I think that it depends somewhat upon circumstances and the man.-C. C. MILLER.

Not unless they are just from the cell.-A. J. Cook

With me it is; but it depends upon how, where and when they are in-troduced.—H. D. CUTTING.

I think that it would be fair to say both "yes" and "no." It is with "some folks."—W. Z. HUTCHINSON. It is with

Not generally, but under many circumstances it is. It often requires much care to avoid loss, even with laying-queens.—G. L. TINKER.

I believe that it has been a common practice to introduce virgin queens when "just hatched," for many years. But the successful introduction of virgin queens of several days old is a more modern practice, and is not "generally practical," for the want of "general" knowledge as to the modus operandi.-G. W. DEMAREE.

Yes, it is with me. We must introduce to nuclei either these or cells. and I am most successful with the virgin queens, for I lose not more than one in ten.-JAMES HEDDON.

I should say not. As yet, however, the matter has not been sufficiently tested to allow of positive assertions. I have no trouble in introducing them, but I cannot see any gain made by so doing. I am positive that it will never pay a purchaser to buy them at any price, no matter how low .-- J. E.

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is located near the centre of the State named:  $\delta$  north of the centre;  $\varphi$  south;  $\circ$  east; \*O west; and this 6 northeast; >> northwest; >> southeast; and 9 southwest of the centre of the State mentioned.

For the American Bee Journal. Standard of Excellence for Honey.

### REV. O. CLUTE.

Absence from the State prevented Absolve from attending the regular meet-ing of the Iowa State Bee-Keepers' Association at Des Moines, in Sep-tember last. In my absence I was made a member of a committee to prepare a standard of excellence to guide judges in awarding premiums on bees and honey at Fairs.

I have not seen that any such I have not seen that any such standards have been prepared and adopted in other States, and it seems to me a difficult task to prepare such standards in such a way as to make them really valuable and acceptable. In the case of honey I suppose that the point on which a decision about the points on which a decision should turn are, first, flavor, second, color, and third, condition in which it is put up. Now as to flavor: It is an old proverb that "there is no disputing about tastes." Tastes differ as much as complexions do. Some people like white clover honey best, some bass-wood, some heart's ease, some other brands. I have sent samples of white clover and of heart's-ease honey at the same time to the same commis-sion dealer, not naming the honey myself, but simply saying that I could furnish either quality, and orders have come back for the heart's ease in preference to the white clover, showing that at least some experts prefer the heart's-ease. I think it will be a little difficult to decide which flavor is "the best"—which shall be "the standard."

Then as to color, probably many will say that the crystal clearness and light color of the best white clover and basswood is to be desired. Well, such honey is certainly very beautiful. But why is light color necessarily any better than a tint? Light butter is not looked upon with favor. In butter, a rich yellow color is looked upon as so desirable that even the most rep-utable dairymen resort to artificial coloring to produce it, and by aid of this coloring they are able to make June butter in January. I have seen goldenrod honey whose rich, yellow, amber color was a great deal more beautiful in my eye than the best basswood honey I eversaw. Probably the combs with honey. The queen beautiful is provide the combs with honey. The queen beautiful is provide the combs with honey. The queen beautiful is provide the combs with honey. The queen beautiful is provide the combs with honey. The queen beautiful is provide the provid

a good many others would be of the same opinion. There will, hence, be some difficulty in fixing on a particular shade as being the standard by which all honey is to be judged.

Probably the only satisfactory solu-tion of this difficulty will be found in classing honey as "white clover," "basswood," "buckwheat," "heart's-ease," "goldenrod," etc., endeavorease," "goldenrod," etc., endeavor-ing to make as many classes as there are distinct kinds of honey; then offer premiums on each class of honey, and endeavor to establish a standard color and a standard flavor for each class. But even this will not be an easy task. It would be a good plan for some of

our eminent bee-keepers to give in the BEE JOURNAL a statement of their views on this subject. I may have time soon to say a word on a standard of excellence in bees.

For the American Bee Journal.

## Bee-Keeping in Cuba.

#### A. W. OSBURN.

I received a letter from a reader of the AMERICAN BEE JOURNAL, in which he asked: "How do you man-age your bees in Cuba, to obtain such large results of extracted honey per colony?" Now, so much depends upon the circumstances that surround us at the time, that nothing more than a general idea can be conveyed in a short article.

As the reader is probably aware, our main honey-flow comes in December and January, and to get bees in condition to store honey in the winter, requires different treatment from what is necessary in the summer months. We expect our flow from the bell-flower to begin the last of November or the first of December, so we must begin preparations for this month in advance—and here comes the rub; our dry season (or honey-dearth) has our dry season (or honey-dearth) has only just closed when the barvest of bell-flower is at hand. This may seem strange to some, but the bell-flower, being one of the morning-glory family, is a trailing vine and a deep-rooted plant, and is not materi-ally damaged by the short drouth; but the bees have not bred up strong during dry weather and to make during dry weather, and to make matters still worse, the nights through November are usually cool, that hav-ing a tendency to make the queens desert the brood-chambers and go above. So we have a double trouble, i. e., bees not very strong, and breeding in the top boxes.

During the last of November the colonies are all examined, what sur-plus honey they have is extracted, of those that are full of brood below and ore broading characteristic in the are breeding above, the brood in the top box is looked over and a sealed sheet placed on the outside next to either side-wall of the top box, and the centre is lilled with freshly-ex-

will not go to the outside of the hive to lay in these combs, and the center combs, she is as completely shut off from laying above as though she was really confined below.

We have now accomplished two very important steps towards success. viz., first, breeding in the upper story is prevented, and second, by placing the brood to hatch on the outside, the bees will store there just as readily as in the centre, which you know they will not leave empty while the outside ones are being filled.

In every large aplary there will be a few colonies that do not prosper as well as their neighbors; all these on the first of November are confined to the brood-chamber and their top combs given to those that can use them. Now that we have the weak colonies on as few combs as they can them we can; all we can do with them during November and Decem-ber is to take what honey they store. It is now of no use to try to make them build up to strong colonies, for they will not do it until February, when they will breed all they need to: but during December and Jannary we keep the brood together, and do not spread it, for the space would only be filled with honey, and the force of nurse-bees divided to the detriment of all concerned. By extracting the honey every week, and giving them no more combs than they can manage, very good results can be realized from a colony that is not strong enough to occupy 2 sets of combs. From our strong colonies we extract the honey every 5 or 6 days, thus keeping the combs empty, and by this constant ehanging, we get not only pretty nearly double the amount of honey, but the queen is left no chance to breed in them.

In conclusion I have only to say that after having spent many years in apiculture as a specialty, I have learned that the apiarist must become acquainted with his location, and know what to do, and when and how to do it. More times his to do it. Many times he must use his own judgment about what kind of treatment the bees require, then go about it and give them that, and do not wait. Bee-men, like poets, "are born, not made." No rule or course of action can be laid down that can be followed out in detail in all localities. Cuba, W. I.

### For the American Bee Journal.

Bee-Keeping in Northeastern Mo., etc.

#### OTIS N. BALDWIN.

This is not a very good location for bee-culture, as regards honey production, and therefore I would not advise any fortune-hunters to come here to start an apiary. During the year 1883 bees did well here, as was universally the case. This was what I call a bad streak of good luck, or vice versa; for

No doubt tain sea of apiculture. many dreamed of the untold fortunes they were soon to receive from the labors of the bees, but in 1884-85 the honey crop here was very light, bees have barely stored enough (generally speaking) to live on, and many have even starved; besides, the winter of 1884-85 was ruinous, fully one-half of all colonies here having perished, and what did survive came out in the spring so weak that it took all the white clover season to build them up.

I have been a constant reader of the AMERICAN BEE JOURNAL, and I have read the discussions with great interest, especially as regards size of hive. I think that the size of hive depends very much upon the locality. For instance, in a great honey-yielding dis-trict I think that a 10-frame hive would be the proper thing, for in this case, where honey is constantly coming in, the swarms are necessarily larger, as the queen is kept constantly laying, and with 7-frames they would do nothing but swarm, which, to my notion, would be the ruination of a honey crop; but in a place like this. where bees only gather honey from June 10 to June 25, and from August 10 to August 25, ordinarily, we have no use for hives larger than 8-frames; and I believe that 7 are better.

I am rather inclined to Mr. Heddon's views, all things considered, and I believe that the same amount of money invested in small hives will be more remunerative, taking one season with another in districts like this; but if you are in a great honey-producing section, and want to average 400 lbs. per colony. I agree with Mr. Dadant in using a 12-frame hive.

Yesterday I took my bees out of the cellar for a flight, having been con-fined 60 days, and on examination I did not find more than a handful of dead bees in 28 hives ; to-day they had a good flight, and now I will put them back.

Clarksville, & Mo., Jan. 1, 1886.

# The Insect-Wax of China.

#### C. THEILMANN.

The following is taken from the Acker and Garten-Bau Zeitung, of Milwaukee, Wis., that paper having taken it from the Hong Kong Daily Press. It will probably he read with much interest by many readers of the AMERI-CAN BEE JOURNAL. The article is as follows:

"It is quite a new fact that the Chinese insect-wax is being exported ; no wonder that it is generally little known. This wax is mainly com-posed of wax-acid combined with Oxide of Cerotyl, and is used in England in the manufacture of the best land in the manufacture of the ost tapers which are at present too costly for general use. There are nearly 500 tons of beeswax imported into Eng-land yearly, and as Chinese insect-wax can in the highest degree be appropriated the same as beeswax, it will bespeak a great future.

tention of the French Government, which has made trials in Algeria to climatize the insects and their mothertree there; also the director of the Kew Gardens, Sir Joseph Dalton Hooker, has had his attention drawn to their produce, and has applied to Sir Harry Parks for better informa-tion about the insect and its white wax, and to learn more about the insect and wax-trees, and last, about the wax product. Sir Harry Parks gave the commission to Mr. Hosie, to visit the wax-producing territory of the Chinese Province, Szetschnen.

" Mr. Hosie thereafter traveled and searched in June and July, 1884, the interior of Szetschnen, studied the case at that place, and made a report thereof to the English Government, which report was published in the second Chinese Bluebook of 1885. This report is positive, and explains fully, though the writer has classified it in a way that is rather hard to understand, having classified it in four rubrics, viz.: 1. The insect-tree. 2. The insect. 3. The wax tree. 4. The wax. It looks as if some parts of the Province of Szetschnen were extraordinarily favored for the industry; likewise the Chien-chang-valley, the Chin-wie-territory, and the neighborhood of Chung-ching where the tree in which there is suspected Ligustrum Luzidum, is growing wild.

"Mr. Hosie failed to give the correct situation of these places, but we find in Playfairs' (Cities and Towns of China), that all the vicinities where the tree grows in profusion, and where the above industry is in its full bloom, lies between the 29th and 30th degrees north latitude, and 103 to 104 east longitude. In the aforesaid districts there is great activity in scraping the pea-like outgrowths or galls, off the limbs of the insect-trees, to export them to the different places-Szetschnen and other provinces, especially to Hunan and Kweichow. Each of these galls contains a little colony of very small, brown insects, which look like small lice, and each of them has six legs and a pair of antennæ which are of wedge form; sometimes they have also a small white cocoon which contains a bug, called ' buffalo-beetle, which also has six legs and a long trunk that is armed with a pair of pincers.

"These galls are yearly (during the latter part of April) taken from the limbs of the insect-trees, and 20 to 30 pieces rolled in the leaves of the woodoil tree and tied with rice-straw, or they are put in paper packages which weigh about 12 Chinese ounces, and are valued from ½ to I tael. The buy-ers of these galls, which are posses-sors of wax-trees in Szetschnen or other provinces, take these packages with the galls and hang them on the bushy twigs of the wax-tree, after making some rough holes in the leaves for the progress of the gall inhabitants. Mr. Hosie does not give the name of this tree; he left that part to the director of the Kew Gardens, to The whom he sent parts of the tree. "Within the past few years the wax-tree is thought to be au asb and Chinese insect-wax has drawn the at- is called *Traxinus Chinensis*.

"Mr. Hosie observed, as soon as the gall packages were hung amongst the twigs, the following :

"Each gall contains a live ' buffalobeetle' which bores a hole in the bark of the gall through which the larva escapes. At first they are unable to fly, and for sometime stay in company with some 'buffalo-beetles' of both sexes on the bushy twigs of the waxtree, and after they get wings they lay small eggs and deposit them on the twigs. Afterwards the wax-insects crawl through the holes which was made by the 'buffalo-beetle,' and crawl rapidly on the twigs of the about 13 wax-tree; after a stay of about 13 days on the leaves of old twigs, and after they have shed their coat, they climb to the tender twigs where they settle on the under side to fasten their mouths in the bark whereby a liquid gushes forth and incrusts the twig with a thick layer of wax. Mean-while, the eggs of the 'buffalo-beetle' hatch out also, and these insects are called the wax-hounds which follow the wax-insect for their prey; the latter are destroyed by the wax-grower. In about 3 months the wax crust is about 1/4 of an inch thick, and the twigs are then cut off, the wax picked off by hand and thrown into boiling water, and the melted mass is mould-This is the wax for the trade. ed.

"The twigs are also boiled to be entirely cleared of the wax. The insects which sink to the bottom while it is boiling, are pressed out and given to the hogs for food. The owners of the wax-trees have but little expense, and the industry, on the whole, is very profitable. In good years, a package of Chien-Chang galls costs about  $\frac{1}{2}$  of a tael, which produces from 3 to 4 catties of wax. Its present price is 40 taels per pikol. Iu unfavorable years not more than one cattie of wax from a package of galls is expected, whereby the wax-industry stands a great deal of risk, where the owners of the wax-tree does not also have the insect-trees, and rears the insects himself. We mentiou that the latter is known to the entomologists as Tatalimbata."

Thielmanton, ~Minu.

For the American Bee Journal.

# Bees and the Fruit-Growers.

### C. H. COGSWELL.

While attending the meeting of the Illinois State Horticultural Society, at Centralia, Ills., during the present week, I took occasion, in the interest of bee-culture, to inquire of some of the fruit-growers for their opinions and observations as to whether bees were in any way the natural enemies of fruit-growers. The unanimous ex-pression, so far as I obtained it, was in favor of the bees. All admitted that, at times, bees work largely on the juices of frnits, but none believed that they puncture the skins of grapes or other fruits.

In some localities in the southern part of the State, much complaint was made against birds, particularly

the cat-bird and oriole. One fruit-grower, in one of the lower counties, was said to have expended 200 pounds of shot on them. No complaint was lodged against the honey-bees. When other and better forage was scarce, they worked freely on grapes and other sweet fruits which had been punctured by birds, or which had burst their skins from diseased or luxurious growth. Such fruit, it was admitted, was of little value if not sucked out by the bees, for it would speedily decay or dry up.

A public expression of the Society might be valuable. Perhaps it has already been given, but I have not noticed it in former reports.

Virden, 9 Ills., Dec. 11, 1885.

# For the American Bee Journal. Location vs. Cost of Production.

#### C. W. DAYTON, (116).

On page 728 of the AMERICAN BEE JOURNAL, for 1885, C. P. Dadant says that I "suggest very correctly that if the honey crop lasts only 20 days, there is no need of having any larger hives than the queen can well fill with brood between the winter and the few days previous to the honey crop." In this it is evident that he made a misequals 37 days, which, added to 20, equals 37 days—about the length of time which is required to get bees from freshly laid eggs, into the fields as honey-gatherers.

Mr. Dadant also asks if the honey crop, throughout the Northern States, lasts only 15 or 20 days, as it does at times in my location. It will be found that I did not say that I had known the honey crop to last not more than 15 or 20 days in any location, but what I did say is this: "Provided the honey harvest lasted not more than 15 or 20 days, as that from white clover has been known to do, it would be wisdom to shut down on brood-rearing 15 or 20 days before the arrival of the honey harvest." From the sentence, "The harvest." From the sentence, "The honey harvest generally does not last more than 3, 4, 5, and occasionally 6 weeks, or 42 days," written by Mr. Chas. Dadant near the top of page 774 of the AMERICAN BEE JOURNAL for 1885, 1 infer that in his (C. P. Dadant's) location, the honey crop has been known to last not very much more than that length of time; and that 28 days is not very far from the average. That is how the honey harvest lasts in Illinois.

Mr. D. A. Fuller, on page 762 of the same volume, says : "I do not see how location can make any difference, as a large swarm is better at any time than a small one." Does Mr. Fuller fail to see how an average swarm at the beginning of the honey harvest may be equally as profitable as a larger swarm in the middle of the honey harvest? Can he get large swarms as early in the season as average ones, or does he have to hold his colonies back in the spring, in order to keep them from getting too strong? But perhaps Mr. Fuller is comparing large swarms with swarms of about the size that in mind. let us study briefly the nature

the third or fourth swarm from a colony generally is. Now I do not think that Messrs. Heddon, Hutchinson, or any one else, have expressed a liking for swarms of that kind, and though the hives used by them have been called small, it was not because they were too small for average colonies at the average time of the beginning of the honey harvest, in average locations throughout the Northern States; nor have they been called small hives because there was anything "teenty-taunty" about them, but because they are a shade smaller than some other hives which are in use, and because their size is best suited the wants of an average colony of bees when viewed from a dollar-andcent stand-point.

I am aware that in a hundred colonies there are exceptions of perhaps 10 weaker and 10 stronger colonies than the average, and that one is necessary as a help for the other in making all colonies average.

While dealing in facts, we might say that it is a close, if not a desper-ate, race we will run if we make the colonies average 8 solid combs of brood by the beginning of the honey-flow. Yes, in my locality I have known whole apiaries to occupy 15 or 20 days of a heavy yield of honey from white clover, in gathering strength to be able to decently take advantage of a 4 or 5 days' flow of honey from basswood. In a case of this kind it is probably needless to say that the large swarms would not be very numerous, and it need not be an aplary of small (average) hives either.

Bradford, & Iowa.

#### Read at the Detroit Convention.

# The Pollen Theory.

## A. J. COOK.

The pollen theory as I understand it, stances bees may winter with less liability to diarrhea, disease and death, in case there is no pollen or bee-bread in the hive to serve as winter food.

There are reasons drawn from experiment, I think, for the belief.that facts sustain the theory. For several years we have tried to arrange our bees so that some should have abund-ance of pollen in their hives, while others should be destitute of the same, making a careful record in each case. While we have never lost a colony by diarrhœa during these experiments, we have had several cases of such disease, but never in colonies where the pollen was all excluded. In truth, the main portion of the diarrhetic exereta is almost always-if not always -composed of pollen grains, thus showing that pollen was present, if not the cause of the trouble. Careful examination of bees from colonies with no pollen-some dead, others alive and lively, show little and frequently no pollen in their intestines.

of food, and see whether or not physiological science has any facts or suggestions to offer us regarding this question.

There are four kinds of food, each of which probably enters more or less largely into the food regimen of all animals. Of these the inorganic, such as water, lime, chloride of sodium, or common salt, etc., are important as entering into the structure of organs; preserving the requisite consistency of tissues, and in aiding the vital processes. Thus it is necessary that blood, or the nutritive substance of the animal body, should be liquid. A large proportion of water keeps it so; hence, what wonder that water is so essential to life, and so craved and sought after by most animals. In all vital activity, osmosis-or the passing of liquids through animal membranes, is all important; common salt pro-motes this osmosis, and thus it is that salt has such saving properties. Hence those of you who believe so heartily in giving water to bees may still rejoice in that you are improving the blood of your pets, while those who take pleasure in adding salt, may exult as you affirm, "here goes for osmosis!" These inorganic elements are usually obtained in sufficient quantities in the general food, though water is generally required in larger quantities and must be had in addition, separately, to secure the best health and greatest strength. We have all seen bees sipping water, and often in such places as to suggest that the addition of salt is very welcome to them. All kinds of food are required in greater quantity when the vital ac-tivity is increased, hence our bees will need more water as breeding, storing, or other work is increased in the hive.

The second kind of food is known under the term carbo-hydrates. It includes all the sugars and starch. As starch, when eaten, is changed under the influence of a ferment, into sugar, we may well consider it with the sugars. The carbo hydrates consist of oxygen, hydrogen, and earbon -the two former in proportion to form water. It is a matter of common ob-servation that when the carbo-hydrates enter largely into the food, the animal is apt to gain rapidly in fat. We are not sure that the sugars are changed directly into animal fat, possibly they serve so admirably as food, that they produce such an excellent condition of the animal system, that all the food is utilized, and a surplus is at hand which is stored up as fat. May be the nitrogenous food as well as the sugars aid in forming the fat of the body; in either case the food must be chemi-cally changed in that wonderful laboratory, the animal organism. The fact remains that much sugar in the food promotes the deposits of fat. We all know how the feeding of corn increases the fat, and does not the fact that corn contains over 67 per cent. of starch, which when eaten and digested is all changed to sugar, enforce the position here taken? Again, when animals hibernate, or when they are long sick and take no food, the stored fat is used up. Thus, if this stored fat can for a time serve the purpose of

all food, it is not unreasonable to conclude that all organic food may under the best conditions be converted into fat. We positively know that animals inay eat all muscle—as beef's heart— and yet the liver will form glycogen, which in turn becomes liver sugar, and, as we have seen in the marvelous economy of the body, sugar promotes the formation of fat, it may be that all food under the best conditions conduces to the storing up of fat, and that sugar powerfully aids to bring about just this most favorable con-These carbo-hydrates are dition. often styled the heat-producing foods. I think this term false and misleading. It is probable that all food, of which these sugars are an important part, are to nourish or to build up tissues and carry on the organic proces-ses. This vital work generates heat. Heat is incidental. Nutrition is to build up and keep the body in work-ing condition; in doing this the body is kent warm is kept warm.

We have seen that stored fat in animals that hibernate, and in case of disease, will alone serve to keep up the nutrition. We have also seen that these carbo-hydrates conduce more than other food to the formation of this fat. Is it not scientific then to urge that the pure carbo hydrates are the best food on which to winter our bees? And this is enforced. I believe. by experience and by nature as well, for I doubt not but that in most cases in nature, almost the entire food of bees while they are quiescent in winter, is honey.

Let me state further that cane sugar which composes from one to eight per cent. of honey, when eaten by any ani-mal, man included, is changed in the stomach to a sugar much like, if not identical, with honey. The bees do the same with nearly all the cane sugar or nectar, or with most of the cane sugar when they feed upon it. Hence it is more than likely that honey is one of the most healthy and nutritious of all our sugars; that the bees have done for us what we would have to do for ourselves had we eaten the cane sugar. Who has not found that honey seems to go further, and satisfy more quickly, even than cane sugar when eaten on our tables? One more point, common glucose, or grape sugar,—I now mean the artificial pro-duct produced by the action of sulphuric acid on corn starch-honey, and liver sugar are usually all called glu-cose or grape sugar by chemists. They are chemically identical, and give the same reactions with the copper salts which they all reduce, which fact furnishes one of the best tests for these sugars. Yet I do not believe they are the same. Physiologically they seem quite different. Why, when we eat glucose, is it changed to glycogen in the liver and then to liver sugar, unless the latter is more easily assimi-lated? Why do bees thrive on honey, and die when fed the artificial glucose? Why do bees refuse to eat artificial grape sugar when honey or nectar is to be had? All these facts seem to indicate what I believe to be true, that physiologically honey, starch, glu-cose and liver glucose are really dif-buminoids in the food.

ferent. Taste and vital action are nicer chemists than our scientists, and detect differences which the latter as vet fail to recognize. It is possible that honey and liver glucose are identical. The fact that both arise in the animal body under the influence of the digestive ferments would make this view plausible.

The third group of food elements consists of the fats. The higher animals obtain these largely in all vegetable and animal food. While the fats, also called by some the hydro-carbons, consist of the same chemical elements as do the carbo-hydrates, the oxygen is far less in amount. Actual experiment has shown that higher animals thrive poorly without some of this kind of food. Its value is far-ther attested by the appetite which craves fat, especially if the weather is cold. Bees get some of this kind of food in their pollen. It seems quite likely that the stored fat of the body may come in part from the fat eaten, though this is not certain. It is certainly true that all does not, as animals are often known to store much more fat than is taken with their food. It is quite likely that most fat eaten goes to serve the current needs, while some of the carbo-hydrates and the nitrogenous food, and quite likely some fat is, through the wonderous economy of the vital organism, changed into and stored up as fat. That nitrogenous tissues may be robbed of their nitrogen and further changed into fat, is proved by disease where fatty degeneration is noticed. This may occur in all orgaus. In some cases, as in fatty degeneration of the heart, almost pure muscle is transformed into fat. Bees get but little fat in their food, and so this group of food elements interests us less than do the others.

The albuminoids or nitrogenous food elements make up our last group. These have, in addition to the oxygen, hydrogen and carbon-nitrogen. AH protoplasm or active vital tissue, whether animal or vegetable, consists largely of this nitrogenous material. But as all organs get their substance from the food, it becomes evident that the albuminoids are absolutely essential in food. Higher animals get this albuminous food in all vegetables, in muscle, eggs, cheese, etc. Bees also get it from vegetables, usually from honey which contains from .2 to .6 per cent. albuminoids and from pollen, often from fungoid spores, and occasionally from various kinds of flour or meal. This kind of food must furnish the elements for building up all the protoplasms of the body which form a large proportion of all the We have vital organs and tissues. already seen that some of this nitro-genous food may be transformed into fat.

As no animal can possibly be developed from the egg to adult life without this albuminous food, and, as in all vital action, some of this material in the body is used up and must be restored, it follows that brood-rearing in the hive and activity of the bees necessitates the presence of these al-

As honey contain no albuminous food, except the pollen in it, it follows that bees must have bee-bread to rear brood, and also to preserve their organisms intact during the busy part of their existence. To say that bees may breed with no bee-bread, or that the active workers need none, is to say that you can have an ocean without water, a desert without sand, or bricks without clay

We know that hibernating animals, and animals long sick, often fast for months. Yet here the vital forces must be kept up and must have nour-ishment. We have seen that in such ishment. We have seen that in such cases the fat is used up, and without doubt the protoplasm in muscle and time time times yield up of their other inactive tissues yield up of their substance to furnish the small amount of albuminous nutriment needed. If we could keep our minds and bodies wholly inactive, we should need but little nitrogenous food.

We may conclude then, reasoning from real hibernation, where animals are wholly inactive, from cases of long sickness, and from higher animals in a state of quiescence, that our bees during their winter quiet in cellar or clamp, when the vital activities are at a minimum, have enough of the albuminoid elements in blood and tissues and may thrive on a pure car-bonaceous diet. Analogies, as pointed out, make the hypothesis tenable.

Again, bees are naturally very neat and do not void their excreta in the hive except under the severest stress of circumstances. I have more than once gathered all the refuse under a full colony of bees at the close of the of a long winter's sojourn in the cellar, and found almost no nitrogenous matter. If, then, bees are to be forced to long confinement, we should spare no pains to secure the greatest possible quietude. Just the proper tempera-ture, I think, will, under favorable circumstances of food and air, secure this quiescence. But in case the temperature or ought else should irritate, then it were better that no pollen should be eaten, for without it breeding, which demands great activity, would be impossible, and in its absence the active digestion necessary to liquify albuminous food would be avoided. It is a generally recognized fact that an inactive life needs little, and is better with little albuminous food. Indeed, albuminous food, as we have seen, subserves the vital activities; of course, then as we reduce these, we reduce the required amount of nitrogenous aliment.

Again, the indigestible portion of the carbonaceous food, especially the carbo-hydrates, is very slight. Not so with pollen. We can readily see then that where the feces are to be retained in the intestines as long the pollenaceous food would be or might be irritating, and were better withheld.

We thus see that from experience, from analogy, and from what we know of foods and the vital activities, we may well believe that our bees were better off in many cases were pollen absent from their winter aliment.

Agricultural College, Q Mich.

#### For the American Bee Journal.

# The Marshall Co., Iowa, Convention.

The Marshall County Bee-Keepers' Association met at the Court House in Marshalltown, Iowa, on Oct. 17, 1885, President O. B. Barrows in the chair. The minutes of the April meeting, as published in the AMERI-CAN BEE JOURNAL, were read and approved.

The subjects, "Fall and winter care of bees," and "Care and sale of honey," were discussed. It was the general impression that all should work together in keeping up the price of honey, and also should endeavor to put up honey in neat packages, and pay no attention to the jammed up mess that is offered for sale in tubs, boxes, etc., at just any price that a huyer feels disposed to give. The consumers, as a rule, will give double for comb honey in nice, straight combs in one and two-pound sections, than they will for honey of various grades and cut out in all kinds of shapes. We must not put our firstclass honey on the market to compete with this class in price.

with this class in price. A number of the members made their reports for the past season, but this is omitted at this time, as we desire to get a more complete report at our next meeting.

The subject for discussion at the next meeting will be "Spring management of bees," and the following members were appointed to read essays: L. Coeper, "Honey-plants;" G. W. Keeler, "Extracted honey;" W. P. Covey, "Comb honey;" and Mrs. J. M. Van Meter, "Bee-keeping."

ing." The convention then adjourned to meet at the Court House in Marshalltown, Iowa, on Saturday, Jan. 16, 1886, at 10:30 a.m.

J. W. SANDERS, Sec.

# OUR CLUBBING LIST.

We supply the American Bee Jonrnal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

### Local Convention Directory.

1886. Time and place of Meeting.

- Jan. 13–15.–Nebraska State, at Lincoln, Nebr. W. F. Wright, Sec., Johnson, Nebr.
- Jan. 16.—Marshall Co., at Marshalltown, Iowa. J. W. Sanders, Scc., LeGrand, Iowa.
- Jan. 19.-N. W. Illa. & S. W. Wis., at Freeport, Ills. Jonathan Stewart, Sec., Rock City, Illa.
- Jan. 19-21.-Maine, at Skowhegan, Me. Wm. Hoyt, Sec., Ripley, Me.
- Jan. 20, 21.—Indiana State, at Indianapolia, Ind. F. L. Dougherty, Sec., Indianapolia, Ind.
- Jan. 20, 21.—N. E. Ohio & N.W.Pa.,at Meadville,Pa. C. H. Coon, Sec., New Lyme, O.
- Jan. 21.-Champlain Valley, at Middlebury, Vt. R. H. Holmes, Sec., Shoreham, Vt.
- Jan. 23.-Hancock County, at Findlay, O. S. H. Bolton, Sec., Stanley, O
- Jan. 26–28.–Eastern New York, at Albany, N. Y. E. W. Philo, Sec., Halfmoon, N. Y.
- Feb. 4.-Wisconsin State, at Madison, Wis. Dr. J. W. Vance, Sec., Madison, Wis.
- Feb. 3.-N. É. Michigan, at East Saginaw, Mich. W. Z. Hutchinson, Sec., Rogersville, Mich.
- Apr. 27.—Des Moines County, at Burlington, Iowa. Juo. Nau, Sec., Middletown, Iowa.
   Oct. 19, 20.—Illinois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.
- 1. S. Halloangh, Sec., Spring, His.

time and place of future meetings .- Ell.

No Sign of Disease.—R. F. Holtermann, Fisherville, Ont., on Jan. 4, 1886. says:

My bees (in clamps) had an opportunity for a flight on Dec. 30, the weather being sufficiently mild, but only the very strongest availed themselves of the warmth. I consider this a very favorable omen; if the others had been restless they doubtless would have shown themselves. Those flying showed no sign of diarrhea.

Mild Weather, etc.--John Morris, Mauston,⊙ Wis., on Jan. 1, 1886, writes:

The winter, so far, is getting to be what I would call a very mild one, and it should make bee-keepers happy. Wisconsm is not so bad after all, but when she does her best we generally shrink before the wintry blasts. To get the AMERICAN BEE JOURNAL for one dollar a year seems like getting a good paper for half what it is worth. The questions that are answered in the Query Department alone make the paper worth more than the subscription price to any one having a few or more colonies of bees. They cannot well afford to get along without it.

**Good Swarming Season**, etc.-W. G. Russell, Millbrook, Ont., on Dec. 31, 1885, writes :

 a long bin or house. Last winter I lost only 7 light colonies out of 84. The past season has been only a medium honey season, but an extra good swarming season. We have had an open, warm fall, and we have had only about ten days of sleighing so far this winter. It all went off about a week or ten days ago, and has not returned yet. Bees are flying a little to-day. The temperature is about 48<sup>3</sup>.

Bee-Keeping for Women, etc.--Mrs. Dr. E. H. Mason, New York, N. Y., on Jan. 1, 1886, writes :

I am still engaged in bee-culture, and must insist that it is a pleasant occupation and healthful for women. I still own property in Vincennes, Ind., and I go there the last of April to set my bees to work. I manage them entirely myself all summer. On Sept.I I prepare them for winter under water-proof sheds, facing them south, with a close board-fence at the back. I allow them to fly when it suits them, and forbid my tenant to even go into that part of my premises. I think that the reason I am so successful is that I put my bees up in September, and never allow them even to be jarred or moved until spring. I have always managed my bees that way, and I have never had them freeze even in the coldest weather. I have at present 80 colonies. I have resided in New York from September until April, for the past three years, so I am a citizen of the East for eight months of the year, and a citizen of the West the balance of the year.

Light Honey Crop.—H. N. Graves, Palmyra, Wis., on Jan. 1, 1886, says :

On April 8, 1885, I took 10 colonies of bees out of the cellar, 5 of which died with "spring dwindling," and 2 more were robbed, so that left me 3. I bought 15 colonies more, and have had very good success, considering the season. It has been very rainy, and the honey crop was very light. I put 40 colonies in the cellar on Dec. 6, 1885. My crop consisted of 700 pounds of comb honey, from 18 colonies, spring count. I have sold all my honey at 15 cents per pound at home.

My Experience in 1885.—S. J. Church, Cedar Rapids,  $\circ$ + Iowa, on Jan. 4, 1886, writes :

I commenced the season of 1885with 78 colonies, some of which were very weak, but the most being in fair condition. My winter losses were 6 in the cellar and 9 after putting them on the summer stands on April 1. After a few days I moved them about  $\frac{3}{4}$  of a mile, into an orchard of apple and cherry trees. They built up finely on fruit-bloom. On June 1 the white clover began to open a little, and it bid fair to be a large crop; also the basswood was very promising; then came a fearful hail-storm that cut everything down clean, trimmed the fruit-trees and basswood badly, and the clover looked as if the life had been pounded out of it; and when I "viewed the landscape o'er," and saw the desolation, my hopes were com-pletely blighted, but in a few days the clover started up and bloomed so that 1 got about 1,000 pounds of honey by July 10. Then the bees got some honey from basswood outside of the track of the hail-storm. It has been a hard honey season for me. My increase of colonies was 32, mostly by natural swarming. After doubling up some colonies 1 had 105 left, nearly all of which were in good condition to put into the cellar for winter, which I did on Dec. 7. They are now in a very quiescent state, at a tem-perature of 46<sup>2</sup>. During the season 1 took 1,500 pounds of extracted honey and 200 pounds of comb honey. MV expenses were \$126.95 and my receipts \$132.48.

Hives from Artificial Stone.-John Turnbull, La Crescent, Minn., writes thus concerning a new material for making hives :

I have been keeping bees for 18 years, but I never gave them much altention until about 2 years ago. now have 22 colonies in the cellar. 1 have learned more about bees in the few months since I have been taking the AMERICAN BEE JOURNAL, than I had ever learned in all my life up to that time. I recently had a conversation with a stone-firm here, about making bee-hives out of their arti-ficial stone. They said that such hives would be much better than wooden ones, as they would not be affected by the hot sun in summer, and as the material is a non-conductor of heat, neither would it be affected by the cold. Hives con-structed of such material would be light and durable, and a hive of the Langstroth size would weigh about 30 pounds, and cost 30 cents. 1 intend to give them a trial. I would be pleased to hear through the columns of the AMERICAN BEE JOURNAL what our practical bee-keepers think in regard to stone houses for our bees.

Reversible Frames, Section-Cases, etc .- T. M. Coleman, Glendon,+olowa, on Jan. 4, 1886, writes :

In the report of Mr. Jeffrey, of Connecticut, on page 821 of the AMER-ICAN BRE JOURNAL for 1885, I notice that he says, " One aparist has tried the 1%-inch wide end-bar, with re-versible wire," etc., and I would like to know more about them. I am puzzled to know how to reverse frames, hives, and section-cases, in the best manner. I use a Simplicity hive of the Langstroth size, 14 inches wide, 9 frames,  $\mathcal{J}_{0}^{-}$ -inch top and end bars sawed out of plastering lath, and spaces between the frames filled with sticks sawed off of lath used for frames. The ends of the hive are rabbeted, and have tin strips for the frames to rest upon. When thering up I take the sticks out and place another bive, or half hive for sections, on top; all have square joints, and no fasten-

ends to keep them from warping. They are dressed and painted on both sides, but have no fastenings, thus making the cheapest and simplest hive lever saw. But I want some way to invert frames and cases for sections, and Mr. Jeffrey's plan scems to me the best I have heard of, but I do not understand the "reversible wire " nor " Quinby standing frames," or how they could be used one time as standing frames and at another time as banging frames. I have kept bees for 3 years, have read hooks and papers, and have learned enough to make me anxions to know more. Last winter 1 lost 17 colonies out of " cave 29 in an outside cellar or Now 1 where it froze considerably. have 24 colonics in good, warm cel-lars, and 1 obtained 4,164 pounds of honey from them last season, about half of it being comb honey and the balance extracted honey.

Colonies Packed for Winter, etc.-Robert Osborne, Danville, o+ Ills., on Dec. 31, 1885, writes:

In the fall of ISSI 1 had 74 colonies; I sold 6, and started in the winter with 68–59 packed on the summer stands, 2 without packing, and 7 l put into the cellar. When the time came that bees could make their living again, i had 48 colonies left, i. c., if 1call every one that had a queen a colony, but there was quite a number that were very small nuclei colonies that required lots of help to get them ready for the honey-flow, which was good in this locality, while white clover and basswood lasted. By July 20.1 had increased my apiary to 87 good colonies, and had taken 2,000 pounds of comb honey in 1 and 124 pound sections, and 1 had extracted t,000 pounds. The bees did not do much in the sections after that, but stored everything full in the broodchambers. My honey crop for 1885 amounted to 2,300 pounds of comb honey, 1,400 pounds of extracted honey, with an abundance to carry the bees through without feeding sugar. I have 60 colonies packed on the summer stands, and 27 colonies and 1 nucleus in the cellar under the house. I have sold nearly all of my comb honey and about half of the extracted.

The New Bee-Disease, - W. B. Thorne, Glenn, & Kans., on Jan. 4, 1886, writes :

As I asked Query, No. 133, it might be well if I should report progress concerning the bees there mentioned. About 3 weeks prior to the meeting of the "Western Bee-Keepers' Association," held at Independence, Mo., on Oct. 15 and 16, 1885, 1 determined to try and see if the stores that the colony had was the cause of the malady. I took the stores from them and gave it to another colony that was in a healthy condition; no injurious effect- resulted therefrom. I then gave the diseased colony sugar stores; ings of any kind. The top and bottom boards are alike, ts inches wide and 24 inches long, with cleats only on the in a wagon, to the savants, for treat-

ment ; but no one could prescribe for them. I was not in a mood to drive with becoming respect to a colony of bees; however, contrary to my ex-pectations, after the good shaking up of a 40-mile ride, they improved very rapidly, and are now tucked up snugly in the cellar, and I expect to get them through the winter in good condition. They however kept a few drones up to the last examination, which I made about Dec. 15. My advice is to take bees to your local conventions, if you have any that are troubled with the new malady; and if you have no dis-eased bees to take, do not let that detain you from attending, for there is money in it.

#### Convention Notices.

FWT The annual Convention of the Indiana State Ber-Keepers' Society will be held at Indianapolis, ind., on Jan. 20 and 21, 1886. The necetings of this Society have been very successful in the past, and the coming meeting promises to be still better. The meeting will be held in the rooms of the State Board of Agriculture, and its one of a series of meetings held by the different Societies of the State, which pertain to the specialties of Agriculture, via., Darying, Wool-Growing, Swine-Breeding, Pontry-Raising, etc. Reduced rates are offered at Hotels, and every-thing possible will be done to make the meeting entertaining and instructive. A very complete program is being prepared, with ample time to discuss the important subjects of particular interest to beckeepers, with the hope that they will attend, and thus make the Convention of still greater importance. The annual Convention of the Indigreater importance. FRANK L. DOUGHERTY, Sec.

The annual meeting of the North-[47] The annual meeting of the North-western Hilnols and Southwestern Wiscon-sh flee-Keepers' Association will be held in Freeport, His., on Tuesday, Jun. 19, 1886, JONATHAN STEWART, Scc.

" The annual meeting of the Champlain Valley Ree-Keepers' Association will be held in Middlebury, V1., on Jan. 21, 1886, R. H. HOLMES, Sec.

277 The Northeastern Ohio and North-western Pennsylvania Bee-Keepers' Associa-tion will hold its seventh annual convention at Mendville, Pa., on Wednesday and Thurs-day, Jan. 20 and 21, 1886. C. 11, COON, Scc.

\*\*\* The Eastern New York Bee-Keepers' Association will hold its annual convention in Agricultural Hall at Albany, N. Y., on Tnesday, Wednesday and Thursday, January 26–28, 1886. The first session will begin on Thesday, at 2 p.m. All interested in bee-keeping are requested to attend, and bring quartan supplies for exhibition. The pro-gramme will consist of essays on important subjects, discussions, etc. E. W. PILLO, Sec.

137 The Hancock County Bee-Keepers' Association will meet at Findlay, O., on Sat-urday, Jan, 23, 1886. S. H. BOLTON, Scc.

\* Tho Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, His. on Tuesday and Wednes-day, Oct. 19 and 20, 1886.

### J. M. HAMBAUGH, Sec.

Association will meet in the State Capitol at Madison, Wis, ou Feb. 4, 1886, at 9 a.m. All who are interested in bee-kceping are invi-ted to attend. The meeting will be held dur-ing the sessions of the State Agricultural Society, and bee-kcepers who are also inter-ested in toples relating to farming will have an opportunity to hear them discussed. Any bee-kceper having anything new in the management of bees are requesited to bring it along for exhibition. Persons paying full fare coning, may obtain a return ticket at-one-fifth of the regular rate. J. W. VANCE, Sec.

THOMAS G. NEWMAN & SON. PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

#### ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

'To Correspondents. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

....

" Don't Stop "-that is what many write to us about their papers, when their time is nearly out. One subscriber says: "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It runs out with this month ; but don't stop sending it. i will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

The Time for Reading has now come. The iong winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books and can fill all orders on the day they are received.

\_\_\_\_\_

Beeswax Wanted .- We are now paying 24 cents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be put on every package to prevent mistakes.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheop that no one can afford to do without it. We will present a Hinder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few hours, to get subscribers.

1397 Our rates for two or more copies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Jan. 11, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CITICAGO.

HONEY,-There is an easier tone to the comb boney narket, and prices are fully one cent per pound least than at last quotations, lice, being the price for white comb boney in 1-ib. sections, and some extra nice brings 162. This is owing to small lots coming into different commission honses, and all being enger to seli, they underbid regular honey houses in order to do so Extracted honey brings BEESWAX.-246266, BEESWAX.-246266, II. A. BURNETT, 161 South Water St.

#### NEW YORK.

HEW FORK. HONEY,-The market for comb honey is very flat and inactive, which we attribute to the con-tinued warm weather, and prices are railing cor-respondingly. We quote as follows : Fancy white comb in 1-lb, playsed or unglinssed sections, 13644c, the same in 2-lb, slassed sections, 14645c, and in un-glassed 2-lbs., 12645c. Buckwheat honey in 2-lb, sections, 56410c, in 1-lb, sections, 11642c. Ex-tracted - white clover, 6%48c, thuckwheat, 5%6%c, BEEESWAX-Prime yeilow, 25628c. MCCAUL& HILDHETH BROS., 34 Hudson St.

#### ST. LODIS.

HONEY.-The market is quiet and the demand light just now. We quote prices as follows:-Choice comb honey, 10%12c. Extracted, in bar-rels, 42%5c. Extra fancy of bright color and in No. 1 packages, 14 advance on above prices, BEESWAX.-Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCENNA'PL.

CINCINNATI. HONEY.—There is a very slow demand from munufacturers, for extracted honey, with a large supply on the market, while the demand is very good for clover honey in square glass jars. Prices for all qualities are low and range from 4646 a li. Supply and demand is fair for choice comb honey in small sections, which brings 12615c, per lo. BEESWAX.—Good yellow is in good demand, and arrivals are fair, at 29822c, per lb. C. F. MUTH & Son. Freeman & Central Ave.

#### CLEVELAND.

HONEY.—The market is not quite as active as it has been, owing, no donbt, to many attractions of the filoiday Searon. Best white, 1-1b, sections sell at 15c, and 2-1bs, for 13%14c, but there is not so much sale for the latter. Second grade honey is dull at 12%33c. Old white, 10%12c. Extracted, 7% per net h aFC, per lb. BEESWAX.-Very scarce at 22@25c, A. C. KENDEL, 115 Ontario Street.

#### KANSAS CITY.

HONEY.-Sales are extremely light and prices are very low. Choice comb honey in 1-lb. sections brings 14615c; 2-lbs., 12613c. Dark fail honey 1 to 2 cents less. Extracted honey is very dulland of slow sale. We had to unload a lot of very fine ex-tracted honey this week at 5c, and stocks continue to accumulate. BEESWAX.-Searce and higher-22625c. CLEMONS, CLOON & CO., cor. 4th & Wainut.

#### BOSTON.

HONEY,--It is selling very well but prices are very low, and we are often obliged to shade our prices in order to make rates. We quote comb honey in 1-b. sections at 149(16c, and 2-lb. sec-tions at 12%14c. Extracted. 6%4c. BKESWAX.--30 cls. per lb. BLAKE & HIPLEY. 57 Chatham Street.

#### BAN FRANCISCO.

110NEY.-Choice comb honey is in light samply and is bringing firm figures. There is a fair move-ment in best qualities of extracted at steady rates. We quote as follows: White to extra white comb, 10% 12% c; amber, 76%. Extracted, white liquid, 54% 54% c; light amber colored, 4% e4% c; amber and eandled. 4% c; dark and candled, 4% 44% c. BEESWAX.-Quotable at 2% 2% c, wholesaile. O. B. SMITH & Co., 423 Front Street.

Are you Entitled to a pension? You may be and may not know it. if you examine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1,30,

197 Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview by sending the names to this office. or we will send them all to the agent.

The Guide and Hand-Book, is a book of ready reference and an encyclopsedia of everything desirable to know. As a guide to the home-seeker, it is invaluable. Its contents are partially given on page 32, and will convince any one of its value. We do not think any of our readers can afford to do without it. As a book of ready reference we find it of great value in our library. We will send the Weekly BEE JOURNAL for a year and the Guide for \$1.30

Many Thanks are due to our friends for sending us so many new subscribers, when renewing their own subscriptions. The reduced price for 1886 has caused quite " a boom," and is a popular move in every sense of that word. As we do not wish any one to work for nothing, we have concluded to offer premiums for new subscribers for 1880, for in order to compensate for the reduction of our price to \$1.00, we should at least thribble our present subscription list.

For 1 new subscriber for a year (besides your own renewal) we will present you either of the following books-25 cents each.

For 2 new subscribers-any 2 of the books. For 3 new subscribers-all 3 of them; or the Western World Guide & Hand-book.

For 4 new subscribers-Bees and Honey, (\$1.)

Architecture Simplified ; or, How to fluild a Dwelling-house, Barn, etc., giving plans, specifications and cost-60 pages.

Look Within for 5,000 facts which every one wants to know-75 pages.

Kingsley, of Bossier Parish, La. It is made entirely of wood, and is simple and durable.

To any One sending us one new subscriber with their own renewal (with \$2.00), we will present a copy of the new "Convention History of America."

We are Now Deinged with correspondence, and we are several days behind with our answers to letters upon multitudinous subjects, and shall not be able to "catch up" for several days yet. Our correspondents will please exercise a little patience. We shall "get there," we hope, this week.

Mr. C. F. Muth, the popular honey merchant and supply dealer of Cincinnati, Ohio, took his son into the business as a partner on Jan. 1, 1886, as will be seen on page 48 of this issue. The BEE JOURNAL wishes the new firm success.

The President of the North American Bee-Keepers' Society has given some hints to the Vice-Presidents on page 42. It will be necessary for them to act at once, for the meetings of the managers of Fairs will soon take place. Let there be good bee and honey shows everyhere. They help honey consumption by informing the public concerning the desirability of eating honey.

**Some Fool** in Hudson, Mich., having read Bro. Root's offer, in *Gleanings*, of \$1,500 for a sample of the artificial combhoney said to be "made and filled with glucose by new machinery" (*a la* Wiley), sent to this office for a sample of it, and without waiting for a reply, wrote to Mr. Root, accepting his offer. We wrote him that it was a "hoax;" that "there was no such thing made," etc. Had he waited for our reply, he would not have dared to accept Mr. Root's offer. "The fools are not all dead"—here is a genuine sample of the modern "go-ahead" class. A Brief History of the North American Bee-Keepers' Society, with a digest of its 15 Annual Conventions, and a full Report of the Proceedings of the 16th Annual Convention held at Detroit, Mich., on Dec. 8 to 10, 1885. This is the title of a new pamphlet of 64 pages just issued at this office. Price, 25 cents.

To compile this history and digest of all the past meetings of the Society, has taken much time and labor, and we have no doubt but that it will be duly appreciated by the apiarists of North America. The following is a portion of the "Introduction :"

Life is too short, and Americans are too busy to spend the time necessary to delve into a multitude of volumes in order to post themselves on the general history of the past in reference to the formation of Societies of Apiculture. They havelong needed a digest of Convention History in general, and of the Continental Society in particular. They want to know what was done, and what subjects were discussed at the former meetings. Heretofore this could only be ascertained by carefully examining over 20 volumes of the AMERICAN BEE JOURNAL, and other papers; and some of these are possessed by comparatively very few of the apiarists of to-day.

In the following pages, we have endeavored to supply this want by stating the place and time of each meeting of the Continental Societies during the past 25 years, and naming the principal officers elected, as well as to note all the business of importance transacted.

We have also mentioned all the subjects discussed, and enumerated all the essays read at each meeting; so that the history is complete, without a broken link, so far as it can be ascertained at the present time, and we feel sure it will now become a book of reference in our National gatherings.

Frequently have the members of the Society voted to have the proceedings published in pamphlet form, but so far the Society has done it but ONCE, and then only published one-third of what was voted to be done, by publishing the report of one convention instead of three.

In 1877 the publishers of the AMERICAN BEE JOURNAL issued a pamphlet of 32 pages containing a report of the Convention of that year. They also publish this pamphlet at their own expense, and have published a report each year, varying from 4 to over 40 pages, in the AMERICAN BEE JOURNAL.

Only a few years ago, at one of the annual meetings, no one had even a list of the officers for the year, (the Secretary being absent); at other meetings, persons were elected to fill offices not warranted by the Constitution, which had been amended, re-amended, and the amendments entirely lost sight of. There will be no excuse for such things hereatter; if this panphlet is consulted, confusion will be avoided.

The organization of Societies are of immense advantage to our pursuit, and help to obtain for if that recognition which it richly deserves among the productions of America. They open up avenues of trade for honey by informing consumers concerning its excellence for medical and mechanieal purposes, confectionery, table use, etc.

They help producers by looking after their interests in the use of the mails for the transmission of bees to all parts of the world, and the use of the railroads for the shipping of honey and getting it into the proper elassifications, etc.

This pamphlet also contains engravings of the principal honey-plants, and portraits of the Rev. L. L. Langstroth, of Ohio, and Moses Quinby, of New York; two of the pioneers who helped to revolutionize American apiculture, and usher in a new era.

A Revolution in Bee-Culture is what the Rev. W. F. Clarke predicts for the new system of managemont as given in Mr. James Heddon's new book. It is evidently a veritable "new departure," and something worthy of the attention of all honey-producers. Some have but little doubt of its being second only to the invontion of the movable-frame hive and system of managemont invented by the Rev. L. L. Langstroth; and say, if the adoption of movable-frames created a revolution in the methods and management 30 years ago, surely invertible hives, and consequent ease of manipulation by hives instead of frames, will cause a second revolution.

Without endorsing the system of management, we must accord to the inventor the acknowledgement that it is *new* and *original*. So far as we know, no one has ever before advocated the making of the brood-chamber in two sectional parts, in order to obviate the necessity of the continual handling of frames. If this system shall prove to be all that is claimed for it—*it will* cause a revolution in bee-management 1 To handle hives instead of frames will certainly lessen the labor, curtail the expense of honey-production, and add much to the pleasure of keeping bees.

Scores of prominent apiarists are investigating the matter, and many have already endorsed it, in the main. Some have raised objections to the practice of reversing brood-combs, but, as we understand it, Mr. Heddon's system is to interchange the broodcombs in horizontal sections, and thus accomplish nearly all that reversing combs would do, but doing it without inverting a cell.

We must say that we are considerably captivated with the system, as detailed by Mr. Heddon in his book, and shall investigate it further, as soon as we can procure a hive. Our readers will be informed concerning the conclusions we have arrived at in a future number of the BEE JOUNNAL perhaps next week.

Mr. S. X. Clark, of Delavan, Wis., died of beart disease on Mareb 17, 1885. He went to work in his shop on that morning apparently as well as ever, and Mr. J. S. Wright writes us that he found him there, one hour later, dead. Mr. Wright should have made this public long ago, and then he would have been enumerated in the roll of "Apicultural Necrology," read at the late Convention at Detroit. Mr. Clark was one of the *fathers* of the North American Bee-Keepers' Society; an enthusiastic apiarist, and a good man generally.

Dr. Tiuker bas sent us a sample of his new "side-passage sections." They are very nicely and accurately eut.

The Canadian Duty on Beeswax.— On page 819, Mr. Holtermann refers to this matter. We asked Mr. D. A. Jones to explain the matter, which he does as follows:

"We referred to the duty being removed from *Bees* (uot beeswax), and we have been mis-reported. Some effort was made at a late session of Parliament to have the duty taken off of wax, but owing to the fact that the matter was brought before the committee appointed to revise the tariff, at too late an hour, the change could not be made."

**REPLIES by Prominent Apiarists.** 

# **Oncen-Nurseries.**

Query, No. 183 .- Is the queen-nursery practical? I mean, is it used by the majority of queen-breeders and honey-producers, or only in oceasional instances? Are there real advantages in it ?-D

I use it and value it highly.-G. M. DOOLITTLE.

Yes, and by some it is used with excellent success, if not by the ma-jority. Yes, there are advantages in it.-A. J. COOK.

It is a great convenience. It is used by manyqueen-breeders, whether by a majority or not I do not know; but few except queen-breeders need it.-W. Z. HUTCHINSON.

It is doubtful if the queen-nursery is better than the lamp-nursery; in either case the queens will hatch out all right if the cells are left with the bees until they are ripe; *i.e.*, until they turn reddish brown at the tip, which is from 1 to 3 days before the queen emerges.—G. L. TINKER.

A great many of such things de-pend upon our babits, perhaps even upon prejudices and whims. I have apon prejudices and whiths. I have never had a queen-nursery, yet I know many good bee-keepers use them, and it is quite possible if I once used one I should think I could not get along without it.—C. C. MILLER.

It depends upon what you mean by "the queen-nursery." If you refer to the modern nursery, made of cages adjusted in a case or frame, so as to be hung in the hive, it is practical and practicable, though not in use by a maintering of queen hereders. Hugh a majority of queen-breeders, much less honey-producers. It takes time to introduce generally any good thing. To me there is real advantage in its use. When I have spare queen-cells I can save them by transferring them to the nursery. It is costly to rear queen-cells as they should be reared, and it pays to save them when rearing queens for sale.-G. W. DEMAREE.

It is practical, and is used by many able apiarists. As to whether so used by the majority, is a question for the census taker. There are real ad-vantages in it, to the breeder of queens m large numbers, but not in my judgment to one who desires to rear only a few queens for home use in a small apiary.—J. E. POND, JR.

I believe it is. I do not know whether a majority of queen-breeders nse it or not, but if the majority do not, they seem to me to be where I was when I did not use it. It not only more safely hatches the queen-cells, but more uniformly and surely, for it preserves a more uniform and proper temperature than is the rule within hives.-JAMES HEDDON.

# Laving Workers.

Query, No. 184.-Are laying workers feeundated ?-F. K.

No.-C. C. MILLER.

Of course not. They cannot be.-DADANT & SON.

No.-A. J. COOK.

Not by the direct intervention of the male. Some of us believe that the causes which produce the effects we see in the laving-worker and the unfecundated queen, are reproduced periodically in some way not now fully understood. What a field is open here to the student of nature.— G. W. DEMAREE.

No.-II. D. CUTTING.

A single instance only, to my knowledge, has ever been given of a worker having copulated with a drone. This case occurred in the old country, and is well authenticated. do not believe that fecundation could follow such copulation. As in Query, No. 185, it would require far more, space than can be spared to give a philosophical answer. The text-books on bee-keeping all explain the subject quite fully.—J. E. POND, JR.

No.-G. L. TINKER.

No.-G. M. DOOLITTLE.

Yes, any worker-bee that lays eggs is fecundated by something. I have no idea, however, that they are ever fecundated by drones, as are queens. As of Query, No. 185, my belief is formed from the statements of those who have made the matter a study.— JAMES HEDDON.

No.-W. Z. HUTCHINSON.

# Eggs that Produce Queens.

Query, No. 185 .- Are queen eggs, when first laid, male or female ?-T. F.

Yes.-C. C. MILLER.

Yes, male or female, of course ; but a differential diagnosis would floor me. If the querist has reference to a change of sex by the worker bees, I would say it is never effected.—G. L. TINKER.

Female.—A. J. COOK.

An egg that produces a queen is a female egg when laid.—W. Z. HUTCH-INSON.

Female.-II. D. CUTTING.

I have not made, and am not competent to make examinations that amount to proof. I leave this to our entomologists and chemists, and take their word for it. Should they err, and inadvertently deceive me regarding this matter, such deception would not lessen my honey crop.-JAMES HEDDON.

"Much depends." As a rule, eggs deposited in worker-comb are female, and those in drone-comb are male. There are exceptions to this rule, however. To explain fully would

require a long article, and as such explanation will be found in any of the text books, I refer T. F. to them. -J. E. POND, JR.

Female, if worker eggs are such.-G. M. DOOLITTLE.

If there was any such thing, prop-If there was any such thing, prop-erly speaking, as a "queen egg," I would say that it must of necessity be a female egg, because it produces a female of the highest order. There can be but the two kinds of eggs in the hive—male and female. The one kind produces the male or drone, the The same female, queen or worker. The same female egg that will pro-duce a worker, which is an undevel-oped female, will produce a queen when the conditions are right accord-ing to actually mathed of duclaring ing to nature's method of developing the queen.-G. W. DEMAREE.

To make the question more' intelli-gible, we would take the word "queen" out of it; then we would answer, the eggs are male when unimpregnated, and female when im-pregnated. In one word the answer is "parthenogenesis." Read a bee-book for an explanation of this word, which would be too lengthy here.— DADANT & SON.

#### Convention Notices.

The annual meeting of the Champlain Valley Bee-Keepers' Association will be held in Middlebury, Vt., on Jan. 21, 1886, R. H. HOLMES, Sec.

237 The Northeastern Ohio and North-western Pennsylvania Bee-Keepers' Associa-tion will hold its seventh annual convention at Meadyrille, Pa., on Wednesday and Thurs-day, Jan. 20 and 21, 1886. C. H. Coon, Sec.

The Eastern New York Bee-Keepers' Association will hold its annual convention in Agricultural Hall at Albany, N. Y., on Tuesday, Wednesday and Thursday, January 26-28, 1880. The first session will begin on Tuesday, at 2 p.m. All interested in bee-kceping are requested to attend, and bring apiarian supplies for exhibition. The pro-gramme will consist of essays on important subjects, discussions, etc. E. W. PHILO, Sec.

IT The Hancock County Bee-Keepers' Association will meet at Findlay, O., on Sat-urday, Jan, 23, 1886. S. H. BOLTON, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. M. HAMBAUGH, Scc.

The annual Convention of the Indiana State Bee-Keepers' Society will be held at Indianapolis, Ind., on Jan. 20 and 21, 1886. The meetings of this Society bave been very successful in the past, and the coming meeting promises to be still better. The meeting will be held in the rooms of the State Board of Agriculture, via., Dairying, Wool-Growing, Swine-Breeding, Poultry-Raising, etc. Reduced rates are offered at Hotels, and everything possible will be done to make the meeting entertaining and instructive. A very complete program is being prepared, with ample time to disenss the important subjects of particular interest to be exkeepers, with the hope that they will attend, and thus make the Convention of still greater importance. FRANK L. DOÙGHERTY, Sec. The annual Convention of the Indi-

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colouies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark O indicates that the apiarist is located near the centre of the State named: δ north of the centre; 9 south; O+ east; • west; and this of northeast; o northwest; • southeast; and 9 southwest of the centre of the State mentioned.

For the American Bee Journal

# Mr. James Heddon's Bee-Book.

### WM. F. CLARKE.

It is entitled "SUCCESS IN BEE CULTURE; as practiced and advised by James Heddon, Dowagiac, Mich."

The appearance of this work marks a new epoch in bee-literature, and heralds a revolution in bee-culture. These are strong words, but they are well-weighed, and thrown fearlessly down in the arena of public debate. Any gladiator, who is disposed so to do, is welcome to pick up the gauntlet for a friendly tilt over them. "" Come on, Macduff."

Hitherto we have had only primary text-books in apiculture. I do not dis-parage them—far from it. They are excellent and valuable, as are the various issues of the first six books of Euclid in mathematics; but we have long needed something for the more advanced class of bee-keepers. Now we have it. Mr. Heddon's book does not jostle any other. It occupies a niche of its own. The tyro cannot understand it. A man must be a long way ahead of the *pons asinorum* in apiculture, or he had better let this book alone. Above all things, let no novice presume to criticize it!

Among the first things that strike one in reading these pages, is the transparent frankness of the author. Evi-dently he has no secrets. He owns his great indebtedness to others for ideas and suggestions. These have passed through his mental mint, been tested practically, and are now issued, along with his own original conceptions, in the form of gold and silver coin for free circulation among bee-keepers. There is a cool audacity as well as a charming frankness about this which I admire. It is like a general revealing his plans and tactics, and then saying to all comers, "I am ready to try conclusions with you at any time or place." It is a question, not of superior knowledge, but superior skill. The "hest man" will "win." This is to run the race of life on the fairest and most honorable principles conceivable.

At a time when the honey market is

apiarists tell us they can hardly pro-duce honey at a profit at all, it is a real boon to have a practical and successful producer come forward and tell us how to minimize cost, and lessen labor. This, Mr. Heddon does with a minuteness of detail and force of reasoning which carry conviction right home. It is not too much to say that we have here a new and original system of bee-culture. I frankly own that it has burst upon me as a welcome and glad surprise.

Mr. Heddon's new book and new hive must be judged together. When, at the Detroit Convention, I listened to his description of the hive he had invented and recently patented, I was interested in some features of it, but the thing as a whole did not take any special hold of me. There were so many things at that memorable meeting calculated to set one thinking ! began to revolve that hive in my mind on the return journey. First one feature of it, and then another loomed up, each pleasing and satisfactory, under if this is that ideal hive I was dreaming about so often last sum-mer!" When the circular arrived, giving descriptions and illustrations of the hive, I said, "Eureka!" in earnest. And now that I have got the book I am ready for the spring campaign !

In common with many others, I have become sick of such everlasting manipulation of frames, lost faith in any and every system of management that involves a constant disturbance of the brood-nest, and when I wrote that "rime" for the AMERICAN BEE JOURNAL, entitled, "A discontented bee," I felt that there was more truth than poetry in it. The idea of manip-ulating lives instead of frames, though it may seem very simple to some, and superficial thinkers may hastily conclude that there is nothing in it, is just going to revolutionize bee-keeping, and "don't you forget it," Mr. Pooh-pooh, whoever you are !

I intended to review Mr. Heddon's book, but I find that I can only call attention to it just now. I do not en-dorse it all, by any means. There are many things in it from which I dis-sent, and I shall do so, giving reasons therefor, in due time, in the AMERI-CAN BEE JOURNAL. I felt it, however, a simple, as it is a very pleasant duty, to put on record my sense of the great service which Mr. Heddon has rendered to the interests of practical apiculture in the publication of this volume. Let this acknowledgment embrace that other bee-keeper of large experience and eminent ability who has contributed many of these well-filled pages, and to whom Mr. Heddon constantly refers as "My Friend," because "he is somewhat averse to publicity." This title is only a kind of bee-veil, however, which does not altogether conceal the wearer. It is rare sport when two such Nimrods go out to hunt! If one misses, which he rarely if ever does, the other is sure to hit, and most of the game has two rifle balls in it !

because he and I have fought so many hard battles on the printed page. We still disagree as to some phases of "the pollen theory," and I scarcely think he has done full justice to my theory of hibernation in the chapter on that subject, but I too have faith in "Father Time" and can afford to wait. It is gratifying to know that we are both in pursuit only of the truth.

It may be that some one who reads quainted with me, will say, "What a big puff!" Now, I have been an editor for many years, and as such 1 have written all sorts of articles on all manner of subjects, but there is one thing I have never yet penned, and that is---" a puff." It is 22 years since in all that time I have never had "an axe to grind" for myself or any one else. I have never been the hired scribbler for any man, clique, ring, or party. I have several times given of-fence by declining to write up merely personal and selfish interests. I once sacrificed a tempting and prominent position because I could not and would not write "to order." I can honestly say, that in all my rather voluminous contributions to the apicultural periodicals, I have never written a line except in the interest of the general bee-keeping public. This article, bee-keeping public. This article, whatever its errors or defects may be, is a spontaneous tribute to what I regard as real merit.

Guelph, Ont.

For the American Bee Journal. Small Hives vs. Large Hives, etc. W. Z. HUTCHINSON.

Labor is the most expensive factor in the production of honey; and if, by having 60 hives instead of 40, the labor is thereby sufficiently lessened, there will be more profit even if 60 small hives do cost more than 40 large ones. Perhaps some will wonder at my assuming that the labor will be less with many small hives, than with few large ones; if the large hives are so large that one man cannot handle them with ease, and two are required, or else one man gets a lame back by handling them, the 60 lighter ones may be handled with less labor than the 40 heavier ones. Let us not forget the time is rapidly approaching when we shall manipulate hives more and frames less, and when this time comes the advantages will all be in favor of the small hive.

On page 774 of the AMERICAN BEE JOURNAL for 1885, Mr. Dadant says, that the man with the small hives will have more increase of bees, and consequently his expenses for new hives will be greater. Granted; but is not this increase worth hiving? If we eannot afford hives for our bees, we might as well "hang up our fiddle."

With the exception of one season, when the honey-flow was early and of short duration, I have received more low, and the prospect is that it may go yet lower—when some prominent I in praise of Mr. Heddon's book, store than from a colony that did not swarm;

and other bee-keepers have had a similar experience. But let us suppose that less honey is secured when a colony sends out a swarm; will not two colonies in place of one compensate for the lessened yield of honey and for the hives in which they were hived? If they will not, then the colony from which the increase sprang was obtained at a loss.

Mr. Dadant speaks of the greater number of surplus-cases that are needed with small hives, and argues that more work will be required to manipulate them. With small, light cases, nearly all the bees can be shaken out when taking off surplus honey; with large cases this cannot be done, as the cases are too heavy, and slower methods must be resorted to.

In Mr. Dadant's computations he said that there were a certain number of bees on each comb, and he told us how many combs there were. He now savs that he puts on surplus-cases, and of course these cases must be filled with bees, which reduces the number of bees quite materially upon the broodcombs; and when we take these bees from the surplus-cases and a large part of them from the brood-combs, in the shape of a swarm, and put them into a new hive, the brood-nest of which has been reduced more than one-third, he will readily see that the surplus-cases are as well filled in the new as they were in the old hives. Mr. D. must make some new computations, if he adds a surplus apartment to draw off some of the bees, for as they now stand, they are incorrect.

He speaks of the increase of work occasioned by the removal of the surplus-cases to the new hives. This is but the work of a moment, and, even if it were more, it hardly seems fair to pick out one particular instance in which the work is increased; we must look at things in the aggregate. Beekeepers are willing to work when the work will increase their profits more than any other thing they can do; they are also willing to use more costly implements, or employ capital in any manner when the expenditure is certain to increase the profits more than anything else they can do. These re-marks will also apply to the time spent in hiving swarms; the remarks in regard to furnishing hives for increase will also apply here. If we cannot afford hives, and the time for putting our bees into them, then "good-bye," bee-keeping.

Mr. Dadant's 5th paragraph is not exactly clear to me. If I understand him aright, he would say that I do not have two queens until the young queen commences laying. True, nor do I have any use for her, as by the Heddon method of preventing afterswarms the old colony is kept so reduced in numbers that but little brood could be cared for if there were a queen. By the time she begins laying the bees have hatched in sufficient numbers to care for her eggs, and there is no danbarrow the brood-nest being filled with honey, because it is now reduced to only 5 combs, and, with a young queen just beginning to lay, it is the disposition of the bees to give her an abundance of room; they will even remove | erers."

the honey from the brood-nest to the sections to give her room.

Mr. Dadant's experience, as given in the 6th paragraph of his article, in regard to small hives being filled with honey to the exclusion of brood, in the same proportion as large ones are, is exactly opposite to mine. This is the point that has been the very pith of all these arguments, viz., that with a small brood-nest the queen would occupy all, or nearly all, the cells in the brood-nest to the exclusion of the honey, which would of necessity be stored in the surplus apartment, whence it could be removed and sold at the highest market price. Mr. Dadant now says that there is nothing in this; that the amount of brood in a hive is in proportion to the size of the hive. I can best answer this asser-tion by quoting Mr. Dadant's own words. In his 8th paragraph he says: "Those who use large hives know which queens are the most prolific." True; that is the point exactly. When we have a prolific queen the large brood-nest is nearly filled with brood; but what happens when the queen is not prolific? Why, "5 to 20 pounds of the choicest honey is stored in the brood-nest." This is the manner in which those who use large hives learn which are their most prolific queens. How else can they learn it? But, as though "to make assurance doubly sure," Mr. D. in his last paragraph says: "Those who employ small hives do not know their most prolific gueens." Of course not; and why not? Simply because all of the broodnests are full of brood, they being of such capacity that an ordinary queen can keep them full and more too. Mr. D. thus refutes his own arguments.

### PROLIFICNESS OF QUEENS.

Although this subject is of sufficient importance to deserve a discussion by itself, I here desire to say a few words about the extra prolifeness of queens. I do not think that it is desirable, and I would not breed for it. My small hives settle the question to my entire satisfaction. At the season when I wish my hives full of brood they are full, all of them; hence I have no use for very prolific queens, as the hives are rather below the capacity of the average queen.

Aside from this, however, I value quality (in bees) above quantity. I agree entirely with Mr. O. O. Poppleton, when he says, on page 120 of the AMERICAN BEE JOURNAL for 1884: How very common it is to notice two colonies in the same apiary, in the same kind of a hive, with about equal numbers of bees and brood, and, so far as the bee-keeper can see, in equal conditions every way, yet while the one gives a large amount of surplus honey, the other gives little or none. This is one of the most common experiences in bee-keeping, and shows conclusively that while a good queen is one of the essentials in successful honey-production, it is far from being the only one." Farther along in the same article Mr. Popple-ton says : " My colonies that contain extra prolific queens are very rarely indeed among my best honey-gath-

I cannot conclude this article withont thanking my opponent for the gentlemanly manner in which he has presented his arguments; there have been no "quibblings," nor "eva-sions;" and should he finally succeed in convincing me that he is right, I should not feel in the least chagrined, as no man need blush to have an error pointed out by Charles Dadant. Rogersville, & Mich.

It is rather amusing to observe the different ideas on the wintering problem; so many specialists have the best plan, and nearly all differing, notwithstanding that the experiments are made in the same latitude. One says that the only proper method is on the summer-stands, and they never have any loss, except those colonies having inferior queens. Now note the margin for a plausible excuse, for the reports of those same parties would indicate that from 25 to 90 per cent of their colonies had inferior queens. One of those summer-stand advocates, living at our county-seat, out of 230 colonies lost all but 45, and he still contends that out-of-doors is the natural element of the bee.

Another good plan that we are ad-vised to try, is to suspend the helpless little creatures in mid-air, with plenty of breeze from below so that they may sleep or hibernate. If I under-stand this system correctly it is too expensive to be of value to any except those having plenty of ready money. However unreasonable this system may appear, it is beginning to have advocates of marked ability; but my experience will not admit of my coinciding with the hibernation theory. I have examined my bees repeatedly with the thermometer ranging at various degrees of temperature, and I always find them easily aroused.

I gave my plan of wintering bees more than a year ago, which for me dispels all fears as to wintering them safely, and I notice that Mr. Heddon and Mr. Barber are advocating the same plan, except that the requisites are not the same with us all, for I have no ventilation pipes, no cushions or sticks under the guilts, and I take nothing but the brood-chamber in the cellar, with the quilt sealed tightly. I have them tiered up 3 hives high, and to-day (Jan. 9), while the temperature is 15° below zero, I would like to take the summer-stand advocates into my cellar, where the temperature is never below  $40^\circ$ , and note the joyful hum and perfect condition which can only be attained in a moderate temperature.

1 do not crave an argument with any one-what I state in regard to my own apiary is not theory, it is simply facts. This is my third season in win-tering bees in the cellar, and I have not lost a colony, either with or with-out on inferior success. out an inferior queen. I do not care whether a cellar is wet or dry, so that it is warm. I know of two different

apiarists who tried the cellar last win-ter, and lost all their bees. Upon ascertaining the condition of their cellars, I learned that they were not only wet but frequently cold. That I claim is worse than the poorest of outdoor wintering.

When Mr. Heddon answered the query on page 820 of the AMERICAN BEE JOURNAL for 1885, as to the proper size to have the hive-entrances in winter on the summer-stands, he spoke my sentiments exactly when he jocosely replied that he should pick up the entrances (taking the hives with them) and place them in a good cellar. I do not remember whether he said a warm cellar or not, but if he did not, he meant it. Those are just my ideas, backed by satisfactory experience.

In conclusion I would say that all who like can freeze their bees into submission, but as for me I prefer to provide them with good, warm quarters, and no matter what the condition of the atmosphere outside may be when a visit is made them they will greet the visitor at the entrance with a joyful hum.

Sharpsburg, Ill.

For the American Bee Journal Curious Freaks of Bees. C. W. DAYTON, (116).

Early in the season of 1883, as soon as the young bees began to play freely before the hives on sunshiny days, I noticed on the ground before one hive, that there remained a large number of bees that did not get back into the hive. At this time there were bees scattered about 2 or 3 rods from the hive, but not more than 3 or 4 in any one place. About the middle of the summer I superseded the queen in that colony and this in due time ended all peculiar actions of the bees, until the next spring, when I found another colony in the same attitude, except that the bees, when they remained out, did not scatter themselves over so much ground, but remained nearer the hive, and when night came they huddled together in the hollows in the ground, some of which hollows contained a quart or more of dead bees that had accumulated there in the course of a week or less. The queen in this colony remained unchanged, and last spring (that of 1885), two colonies of this kind were found, both of which are now in winter quarters.

The affected bees appear to be just as well developed as any bees, but they run from the hive generally holding one wing out of place, as if it had been broken or bent out of shape. The bees do not seem to die because of affliction but from exhaustion or the chill of the night. Notwithstand-ing the great loss of bees from these colonies the queens were so prolific as to build them up to ordinary colonies, one of which gathered about 80 pounds of honey.

In case of these colonies while about

that show symptoms as described. 1 do not mean to say that one-half of the bees, young or old, in these colonies at any and all times are like those described, but one-half of the bees which are of the right age to take their first flight are of this kind, and these, taken the season through, would equal one-half of all the bees hatched. Though I never have reared a queen

or made any increase from such colonies, every spring I find one more colony of this description than there was the fall before.

#### Read at the Detroit Convention.

# The Production of Comb Honey.

### G. M. DOOLITTLE, (40-95).

It has been announced that I am to lead in the discussion regarding the production of comb honey. Before doing so I wish to quote the words found on page 723 of the AMERICAN BEE JOURNAL for 1885: "Long articles seldom profit those who have to do with them. Life is short; time is short; moments are precious." Especially is this last true at a bee-convention, and many a person has become tired on account of the long essays read at the same. What we want is animated discussion, rather than long essays, no matter how ably written. Therefore the best part of this essay will be its brevity.

There are four things of importance in the production of comb honey: First, a good queen; second, the get-ting of the bees at the right time to gather the harvest; third, a skillful apiarist; and fourth, the right kind of a hive.

I put the queen first, for the whole of bee-keeping centres upon her. Without a queen it would be impossible to produce a pound of comb honey; hence it becomes apparent that the better the queen is, the more honey we obtain. When we come to fully realize the great value of really good queens, we shall have less queens which cost the apiarist nothing. I wish to leave the impression that good queens cost something, and are valuable in proportion to the pains taken in rearing them.

I put the getting of the bees at the right time to receive the harvest sec-ond, for this is paramount to all else in the production of comb honey—ex-cept the queen. Unless we can have the bees in our colonies by the tens of thousands at the right time, the flowers will bloom in vain, as far as filling our sections with honey is con-cerned. When all realize the second proposition, and work for the same to its fullest extent, oue-half of the colonies will gather as much surplus as the whole do under our present management.

I place a skillful apiarist third, as he is only second to the bees and queen, and unless he is skillful enough to do things at the right time and in the right place, both bees and flowers will one-half of the bees appear as bees be in vain, as far as getting a good Secretary, Mr. R. H. Holmes. Shore generally do, there is the other half yield of comb honey in sections is Premiums are offered for exhibits.

concerned. The apiarist must study hard, work early and late, and "leave no stone unturned" that will produce a pound more honey, if he is to be successful in producing comb honey at the present low prices.

I place the right kind of a hive fourth, for this comes last in the cate-gory of our subject. To be sure, bees will store honey in a nail-keg, but the day of putting honey upon the market in the shape it must present if taken from such a repository, has passed away, so that if we would realize the most from our bees and our labor, we must get our honey stored in neat and attractive receptacles. The live that will admit of getting the largest number of bees in the right time for the honey harvest, and then get "all hands" to work in the surplus arrangement as soon as the harvest arrives, is the one to use. We could divide and sub-divide these four headings, especially the last three, yet the above four fundamental principles would not be changed. I therefore leave the subject for your decision. Borodino, ⊙ N. Y.

E. W. Thompson-Is it profitable to fill sections full of foundation ?

J. B. Hall-After many experiments I have decided that it is.

II. R. Boardman-During the past season I hived 100 swarms with no foundation in the brood-nest, excepting starters. I have no data to show whether or not it was a profitable experiment, but I was well pleased with the results. I cut out the new comb from the brood-nest, leave it lying upon the grass until the eggs, if there are any in it, have lost their yitality, then I fasten this new comb in the sections instead of foundation. The honey is beautiful and tender, but will not bear shipment so well. J. B. IIall—I have tried this plan of

hiving swarms without foundation, but I get too much drone-comb. W. Z. Hutchinson—Are your brood-

nests large or small? J. B. Hall-Large.

W. Z. Hutchinson—That explains it. I hive my swarms upon only 5 Langstroth frames, and not more than one comb in 25 is drone-comb, and this occurs only when the queen is an old one.

H. R. Boardman-I was surprised at the small amount of drone-comb built in my frames. My swarming and hiving were managed upon the Heddon plan.

G. M. Doolittle-Comb foundation gives honey greater strength, but this strength impairs its eating verv qualities.

C. F. Muth-There is no necessity of using foundation heavy enough to detract from the palatableness of our comb honey.

'The Champlain Valley Bee-Keepers' Association will hold its 12th annual convention at Middlebury, Vt., on Thursday, Jan. 21, 1886. We have received a very neat four-page Programme. Any one interested ean get a Programme by addressing the Secretary, Mr. R. H. Holmes, Shoreham, Vt. For the American Bee Journal.

# A Visit to Dr. Tinker's Apiary.

## J. A. BUCHANAN.

As there are no good apiarists with-in many miles, and being anxious to compare notes, I decided to visit some bee-keeper of prominence. The an-swers given to questions in the Query Department of the BEE JOURNAL by Department of the BEE JOURNAL by Dr. G. L. Tinker, being so much in harmony with my views, I decided to visit him and make his acquaintance. I did so last September; and after introducing myself and receiving a pleasant welcome. we were soon "among the hives."

The apiary was a model of neatness: all the bives are new and faultless in construction. As the frames all rest on metal, rabbets, they may be renoved without irritating the bees. No quilts are used over the brood-frames, which are made of white poplar. The top-bars, I think, are I inch wide, and the spaces closed by the use of smooth, square sticks cut from white poplar, which leaves a clean white surface, making the use of the close-fitting honey-board easy.

The Doctor is a machinist, and has excellent machinery for cutting out hives, sections, etc. The beautiful sections made from white poplar are the acme of perfection. The "Im-proved Victor" is made and used at the Doctor's apiary. Its distinguish-ing feature is continuous passage-ways; the sections are but 1½ inches wide, and a honey-board made of very thin, strong slats of the same width as the top-bars of the brood-frames and resting directly on the same. Small saw cuts are made in the edges of the slats, forming a honey-board, into which are inserted long strips of per-forated zinc. There is no trouble about putting on the cases of sections, as they are pushed to place from the end of the hive, without danger of killing bees; when adjusted there are no bee-spaces, and there is no chance for brace-comb building, and where starters have been put into the sec-tions with care, the combs will be perfectly built. The sections are brought down as close to the broodframes as possible, leaving no chance for waxing or propolizing the sections; there are no bee spaces or "loafing-grounds." The queen can see to the top sections, but cannot get up there to lay any eggs.

It may be asked, can more honey be secured by this arrangement than by the use of the zinc honey-board with two bee-spaces intervening? A single experiment made in my apiary last season leads me to doubt. In putting on the zinc honey-boards and sectioncases at the beginning of the honeyyield last season, in one hive I put 3 zinc honey-boards; then the case of sections. Did the bees go up into them at all? Oh, yes; they did, and finished them in good style as quickly as any other; and best of all the combs were of snowy whiteness; but much depends upon the strain of bees.

Some years ago there was every possible effort made to bring the sections close to the brood-nest, and the thickness of the tops of the brood-frames was reduced until they were unable to sustain any considerable weight, which soon became crooked and unsightly. However, it was not long until it was discovered that when brought so close to the broodcombs, especially when old and black, there was more or less dark wax used in building the combs, and also greater liability of the queen's enter-ing the surplus receptacles; hence the invention of the zinc honey-board with its break-joint, double-bee-space features. It may be, by using the continuous passage-way system, having the perforated zinc for the bees to work through, they might stop at the gate long enough to clean off, before entering the parlor; but I am inclined to think that I should prefer to have some more space between the departments.

A word about the Doctor's Syrio-Albino bees: Without smoke or protection of any kind, many of the hives of full colonies and nuclei were opened and inspected without in the least anoying the bees. These bees are beautiful, and the queens are large and prolific. The Doctor's method of securing large queens is by cutting a twig from a young basswood tree and pointing it so as to be able to remove a larva from a well-advanced royal-cell, and in its stead placing a very young larva taken from a worker-cell. He remarked that he had discovered this some time ago, and herein lies his secret of securing perfectly-developed queens. But the plan was not new to me, for 10 or 12 years ago I described the same process in *Gleanings*; but as the Doctor had never seen nor heard of it, the discovery was also original with him. Holliday's Cove, 5 W. Va.

For the American Bee Journal.

Carbonate of Soda for Bee-Stings, etc.

#### MRS. DR. E. H. MASON.

The sting of the bee being an acid poison, the antidote for it would be carbonate of soda. The moment one is stung he should put his finger-nail close under the point of the sting, so as not to press on the upper part of the sting, and draw the sting out. Then apply a strong solution of soda swelling, and if it is a child or a nervous person that is stung, apply the soda several times. If stung very badly, or many times, dissolve a half-tea-spoonful of soda in a little water and drink it.

The above antidote is also good for stings of wasps, yellow-jackets, bumble-bees and hornets; and where per-sons have over-eaten of honey and are taken with cramps and pain, a half-tea-spoonful of soda and ten drops of peppermint dissolved in a wine-glass of warm water, will give relief at once. It will be found that mostly where bee-stings have given trouble,

has been the result of injudicious treatment of incompatible and poisscratching the wound into swelling and inflamation, sores and blood poison, more from the poison of fingernails than from the stings. In cases where one cannot apply the proper antidote, just pull out the sting and never touch, rub, or think of it, and in time it will get well of itself.

Persons of pure, active blood and steady nerves are but slightly affected by a bee-sting. For myself I would much prefer the clean sting of a bee, to the virus-soiled spear of a Jersey mosquito, which might inoculate one with the poison virus of many sick and diseased bodies, and which is always in waiting for one with its poison-soiled spear; whereas from the bee one gets nothing but clean, pure bee virus which is a preventive of rheumatism. The bee never stings but the one time, whereas the mosquito can spear all summer.

New York, N. Y.

Notwithstanding the increasing favor shown cellar-wintering, there are many who, for various reasons, will continue to winter their bees on the summer-stands, using chaff hives or packing-boxes for extra winter pro-tection. There is little doubt but tection. There is little doubt but that chaff hives would entirely supersede packing-boxes, were it not for the acknowledged inconvenience of performing many of the needful manipulations during the busy season, necessitating either the removal of the brood-frames, or the entire "ark." Time and strength are both too valuable to be needlessly wasted, and as several bee-keepers have expressed themselves as being pleased with my arrangement of chaff hives for sum-mer use, I will describe it.

The brood-chambers of my hives are made without bottom, the ends being <sup>7</sup>/<sub>8</sub>-inch thick and the sides <sup>5</sup>/<sub>2</sub>-inch. They are 9<sup>7</sup>/<sub>8</sub>-inches wide inside, hold-ing 7 Langstroth frames, which, by the way, are as many as can be used of comb honey is desired. The stand is sufficiently large to allow a space of 3 inches on all sides of the brood-chamber, and has 2 entrances cut through the floor as long as the hive is wide inside, so that the bees enter the hive from beneath. Two of the four pieces forming the sides of the bottom stand are placed slanting, for alighting-boards leading to the en-trances. Upon this stand, resting in rabbets, are two sections and a pitchroof forming an outer-case, both the sections and roof being rabbeted on all four sides, allowing the use of one or more sections equally well. Thus you see I have a complete doublewalled hive, the outer case of which can be removed at pleasure.

This outside case and stand is identical with those used by Mr. A. E. Manum, with the exception of the double entrance, and known as the Bristol Langstroth hive. The 3-inch space surrounding the brood-chamber is packed for winter, and the entrance is adjusted with slides to suit the ideas of the hee-keeper regarding bottom ventilation.

Now for the summer management: During the spring the back entrance is kept closed, and previous to the with the two sections of the outer-case, are removed, and the roof used for shading. The outer cases may remain, however, if the bee-keeper prehave them out of the way. When a colony swarms, the brood-chamber is simply pushed around at right angles to the former position, even with the back of the stand and covering the back entrance only, which is now opened. A new brood-chamber is now placed over the front entrance, in which the swarm is hived. We now have two hives on the same stand placed back to back, each having a separate entrance, one facing south, the other north. After six days this north or old colony is moved to a new stand (Heddon's method), and the other brood-chamber is turned back to its original position, both entrances now opening into it. Thus you see I save all that lifting and "moving a little each day," as described by Mr. Heddon, while to the bees no visible change has been made in the outside appearance.

In forming nuclei, rearing queens, dividing or doubling up colonies, the experienced apiarist will readily see the many advantages possessed by this arrangement. While I believe, as stated in my article on page 709 of the AMERICAN BEE JOURNAL for 1885, that "a small, light hive, designed to be used on the tiering-up principle,' and allowing expansion and contrac-tion with little labor, will eventually supersede the cumbersome hives in use at the present time; and also that these little hives will be placed in cellars during winter, yet, for the many who will continue the use of the Langstroth frame and out-door wintering, I offer the above suggestions, hoping they may receive as much comfort from their practical use as I have during the past few years. Haverhill, 6 Mass.

For the American Bee Journal. Bee-Keeping in Nebraska, etc. REV. G. T. WILLIS.

I do not think that it will pay to keep very many bees here, as the country is new, and farmers have not given much attention to sowing white clover yet; still, I must have some bees, as much real pleasure would be lost without them, and I must have the American Bee Journal so I may know what is going on in the api-cultural world. I was very much in-terested in the report of the recent convention held at Detroit, Mich.; in

fact, I am always deeply interested in any and everything that pertains to apiculture. Allow me to say a few additional words in regard to Mr. D. S. Given, who was mentioned in that report. I lived within one block of him for several years before he went to California, and learned from him my A B C of apiculture. Any infor-mation that I desired or help needed, he was always ready to give freely. have never known a more kind-hearted, generous man. I knew when he was working to make his foundation press, as he made no secret of it, and I am inclined to think that his close application to the work of get-ting up his press hastened on the dread disease (consumption), of which he died. A faithful Christian, gener-ous and noble-hearted, with many friends and comparatively no enemies, enthusiastic in the pursuit of Apicul-ture—his name will go down to posterity as one who did much to advance its interests. Ile and I were among the first to try the experiment of using fine wire in foundation; and how we almost cried "Eureka!" when we discovered how nicely and perfectly the bees would draw out the founda-tion over it. I feel pretty sure that this was what suggested to him the idea of constructing the dies so as to make the foundation and press the wires in at the same time; and those who have used his press can testify how well he accomplished his purpose. I think that all who are en-gaged in the pursuit owe him a lasting debt of gratitude. Gibbon, ⊙ Neb.

#### For the American Bee Journal.

## Degree where Hibernation begins.

### C. P. HEWETT.

After carefully reading Dr. Tinker's article on "The Hibernation of Bees," on page 5, I would say that I have been experimenting for the last 3 seasons to find that point where hibernation begins. In order to do this I built a cellar so arranged with ventilators that I could close or open them to regulate the temperature. I started in with a temperature of 46°, but I found that was high and dropped it to 44°, then to 42°, and there I found the bees quiet and not disturbed easily. I have held the temperature for the last 39 days between 40° and 44°, and I find that there is perfect hibernation. On Jan. 10th the thermometer indicated  $18^{\circ}$  below zero, and to-day  $16^{\circ}$  below; the temperature in my bee-house has been  $42^{\circ}$ .

I give my bees upward ventilation in the hives, but I shall close them down about the first of March to start down about the first of March to start the bees to breeding. Bees did noth-ing here last season, and were put into winter quarters in a rather light condition. I have not lost a colony in winter quarters for the last 2 years, but I have wintered bees in a lower temperature than I am doing this winter.

I am now wintering 74 colonies. I keep a thermometer hanging in my

bee-house and take notes every morning. I take no pollen from my bees. I like to see them carry it in. I think there are a great many false charges made against it.

Kingston, ⊙Wis.

# Rhode Island Bee-Keepers' Society.

The bee-keepers of Rhode Island have organized under the name of "The Rhode Island Bee-Keepers' Society.

The Society's object, as stated by the by-laws, is to advance scientific and practical apiculture, to suppress the production and sale of adulterated honey, and to create a greater demand for pure honey. No person who pro-duces or sells adulterated honey can become a member, and a member found guilty of either, will be expelled and debarred forever from member-

and departed forever from memor-ship. The officers of the Society are as follows: President, Dr. C. D. Wig-gin, of Providence; Vice-Presi-dent, Geo. C. Greene, East Green-wich; Treasurer, Arthur C. Miller, Barrington; Secretary, Geo. A. Stock-well, Providence; and the Executive Committee consists of the Vice-Presi-dent Secretary and Mr W. O. Sweet dent, Secretary, and Mr. W. O. Sweet, of West Mansfield, Mass.

GEO. A. STOCKWELL, Sec.

For the American Bee Journal

## Honey-Plants of Texas.

#### W. S. DOUGLASS.

About Feb. 1 the little bees begin bringing in pollen from the elm, then honey from wild-peach, which is very plentiful here, and then comes tamepeach, plum and willow. In March honey is gathered from black-haw, red-haw, etc., all of which yield a good supply. In April we have rat-tan and persimmon, for the yield of which there are never enough bees. In May elder and horse-mint bloom, and if the weather is suitable the hives will soon be overflowing with beautiful honey. The flow from horsemint generally continues for 45 or 50 days, provided it rains every 10 or 12 days, as is usually the case here in

May. Wild China yields honey at the same time, and the swamps are cov-ered with it. In June, horse-mint, which generally blooms until the 15th. which generally blooms until the 15th. cotton, wilding or crab-apple, and dog-wood; in July and August we have cotton, dog-fennel, meadow-pine and witch-hazel. In September smart-weed, wild-sage and rag-weed bloom; in October and November wild-sage, privet-bush, and many others yield honey. I have mentioned only the principal ones that yield honey in this locality, and all of these, if the weather is favorable, yield an if the weather is favorable, yield an abundant supply. I would be pleased to hear from others on this subject who live in this State. Lexington, Texas.

# For the American Bee Journal. Organization for Mutual Protection.

#### W. H. STEWART.

"All are but parts of one stupendous whole, Whose body Nature is, and God, the soul."

To secure the highest and best good of humanity, "governments are formed among nen." Fortunate is he, or she, who is a citizen of this, the grandest and best government ever formed on earth. The union of States and territories is the surety of our National longevity and greatness. These States and territories " are but parts " of the Nation, of which we may well be proud. It is equally true that each of the States and territories are politically, socially, and financially prosperous just in proportion as the citizens therein are united in the support of the highest and best common good.

Again, it is true, that the highest and best good of the individual is found only in the good of all in com-mon. Individuals " are but parts of one stupendons whole,"whose body the Nation is, and good, "the soul." All are aware that the highest and best good of the hand cannot be sustained if it be amputated from the body; and continued dismembering, would destroy the body.

The above are self-evident truths; nations, or societies built upon any other foundation than truth will be "found wanting." Among the "thou-sand and one " nations that have been organized, none have as yet given general and perfects at is faction; yet, by and through each organization some truth has been evolved; and when a truth or real good is born, it " comes to stay." Truth and good are principles; principles are immortal—they never change, never die. Errors and evils are change, never the. Errors and evils are changeable conditions, there-fore temporary, lasting only for a time; and in the march of human events, they are left behind.

At the formation of our Govern-ment, all the good and truths then known and understood, were embodied in our Constitution; and yet many mistakes were made which were to be rectified by coming generations. Individuals, families, and organized societies, are the living fountains from which all political, social and financial good must flow; and as an individual stream from an individual fountain, and running in a lone channel, would soon be dissipated by evaporation, even so are the efforts of lone men lost, and the only hope for strength and success must be based upon organization and union; like the little streams that unitedly form the mighty river.

In animal life there is ever a manifest struggle for life, and in that struggle the fittest survive while the struggle the fittest survive while the others perish. Many of the lower forms of life were conscious of this truth many ages before Darwin wrote, and led by their instinct or consciousness, organized in flocks, herds, and colonies, as do the "little busy bees," showing conclusively that

the index-finger of natural law points in the direction of organization for mutual protection.

This law "lives in all life, extends through all extent,

Spreads undivided, operates unspent."

The division of our Nation into Slates, gives it strength, not weak-ness. These States again divided and subdivided into other countless or-ganizations, and all founded on the principle of mutual protection, proves that truth and justice "operates un-spent." Recognizing these truths, the many trades and useful industries have organized their several Unions for mutual protection, and all seem to prosper much better than when the several individuals stood (or fell) alone.

With these truths and facts before us, and in full view of surrounding circumstances that threaten to outlaw bee-keeping, is it not surpassingly strange that men who manifest a good degree of wisdom on other subjects, should be so slow to join the National Bee-Keepers' Union ? The production of honey adds to the wealth of any nation; it brings one of the most useful and desirable resources of Nature within reach of all, bringing with it health and happiness. We have only to unite, and each become a part of one grand whole (the Union), and we will soon see that our noble pursuit will "spread undivided, and operate unspent;" for "united, we stand; divided, we fall." Orion, 9 Wis.

For the American Bee Journal Prizes for Honey and Bees at Fairs.

-----

#### HINTS TO VICE-PRESIDENTS.

During the first three months of the year, the premium-lists for County, State and District Fairs are usually made up. The Vice-Presidents of the National Society should therefore soon commence their work.

I would respectfully suggest that they communicate with the different Official Boards of the Agricultural Societies in their respective States, and endeavor to induce them to offer appropriate prizes for BEES and HONEY at the Fairs for the coming season.

The following, or something similar to it, would be well to recommend in the line of prizes:

Best colony of bees in observatory hive; best display of comb honey; best display of beeswax; best honey-; best display of beeswax; best honey-ex-tractor; bee-hive for all purposes; and largest and best display of apiarian implements.

Each vice-president and secretary of State and local societies will under-stand the requirements of their locality, and act and govern themselves accordingly.

#### H. D. CUTTING,

Chairman of Executive Committee. Clinton, 9 Mich.

#### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regu-

lar price of both. All postage prepaid. Price of both. Club The American Bee Jonrnal ......1 00.. 

AGF The Seventeenth Annual Conven-tion of the New York State Bee-Keepers' Association (tormerly the Northeastern) will be held in Rochester, N.Y., on Feb. 16, 17 and 18, 1886. This will be one of the largest meetings ever held in the State. A 16, 17 and 18, 1886. This will be one of the largest meetings ever held in the State. A large number of our most experienced bee-masters will take part in the discussions, and several essays will be read from a number of our most practical apiarists throughout the country. The programme is complete. If you are young in the work you can not afford to stay away—if older, you may give some good hints, if you get hone. We wanta good display of all kinds of supplies and fixtures. We have a room on purpose for exhibits, and any goods sent to the Secretary in care of the "Na-tional Hotel," Rochester, N. Y., will be placed on exhibition, and either sold or re-turned to the exhibitor, as directed. Re-duced rates at the hotels have been secured, also rates on some of the railroads. Alt will have to pay full fare one way—return ticket at 1-3 fare by presenting certificate from the Secretary, who will furnish them on apirone for each one of the solitor dise from the Secretary, who will furnish them on application. We want an active vice-president in every county in State. Please hanne one or send the hame of some one, for your county.

F. C. BENEDICT, SEC.

#### Honey as Food and Medicine.

27 To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and seatter them plentifully, and the result will be a DEMANO for all of their crops at remunerative prices. " Honey as Food and Medicine " are sold at the following prices :

Single copy. 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page. "Presented by." etc. (giving the name and address of the beckeeper who seatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of houey, will sell almost any quantity of it.

1 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.-ED.

Weather in the South, etc.-9-Oscar F. Bledsoe, (75-140) Grenada, & Miss., on Jan. 11, 1886, says:

We are having zero weather here now. The mercury was 4° below zero on the morning of Jan. 9-the coldest weather ever known here in the mem-ory of "the oldest inhabitant." I ory of "the oldest inhabitant." I fear that it has played havoc with the nuclei colonies. I am trying to win-ter them in order to preserve the fine tested queens. I cleared \$400 in cash from my bees last year, besides the increase—a result that I consider good. I am aiming higher this year. May the AMERICAN BEE JOURNAL be crowned with success and useful-ness the present year as in the past. ness the present year as in the past; and may the foundations of bee-cul-ture become more firm as a steady, remunerative pursuit!

Bees Doing Well.-S. L. Sherman, Oskaloosa, 9 Iowa, on Jan. 1, 1886, says:

The past season was rather poor for bees here. There was no fall honey. One year ago I began the winter with 83 colonies of bees, and on May I, 19 of them were alive, most of them having only a handful of bees. I have increased them to S3, by the nuclei system and natural swarming, and obtained 500 pounds of extracted honey and 200 pounds of comb honey in sections. I now have 60 eolonies in a cave, 20 in the cellar, and 3 outside packed in leaves; all appear to be doing well. I use the Langstroth frame. I sold my honey at 12½ and 15 cents per pound.

New Honey-Plant.-Hiram Chapman, Versailles, 9 N. Y., on Jan. 2. 1886, says :

In the report of the Detroit Convention, under the head of "Pasturage for Bees," I noticed my honey-plant described as resembling plantain. If described as resembling plantally. If you would have an opportunity of ex-perimenting with this plant, I will send you some specimens of it which will blossom next summer. Mr. L. C. Root, Prof. McLain, of the United States Apicultural Station at Aurora, UL and others will wish my aniary Ill., and others, will visit my apiary next summer and thoroughly investiand report at the convention to be held at Indianapolis, Ind., next fall.

[We would have no opportunity of testing it here.—ED.]

Bees in Good Condition.-Arthur E. Ault, North Liberty, Clowa, on Jan. 9, 1886, writes :

Last winter was the most severe one ever known for bees in this locality. I had 25 colonies packed in chaff on the summer-stands, 13 of which died with diarrhea and spring dwindling, in the spring, and several of the re-maining 12 were quite weak. I worked my bees almost entirely for increase, and I now have 37 colonies. White clover was badly winter-killed in this county, and basswood yielded but little honey; however the fall flow of honey was good. Buckwheat, goldenrod, heart's-ease, and the asters yielded exceptionally well. My bees are all packed in chaff, being supplied with natural stores, and seem to be in good condition. They had a partial flight on Christmas. The AMERICAN BEE JOURNAL grows better and better.

Reversible Hives.-W. Z. Hutchinson, Rogersville, & Mich., on Jan. 9, 1886, says :

I want to say a word about the utility of reversible hives. They will likely be pushed as never before, but pushed upon their real merits—regardless of patent-rights. The experience of one season with reversible hives may not weigh much with some people, but my advice to beginners is, begin with rewhen the great "blow"—of opposi-tion—is over, the thousands of ordi-nary movable frames that are now being pushed into use, will stand— aside for *reversible hives*.

Quietude in the Apiary.-John Reynolds, Clinton, 9 Me., on Jan. 6, 1886. writes :

Fifty fittle churches without any steeples, each with pastor and people. music, prayer, sermon, doxology—all combined. The apiary is now at rest, and in contrast with the hum of the "little busy bees" through the hot summer, nothing is now heard from them (nor should be), except a low distant waterfall as it vibrates upon the frosty air. I have 50 colonies of Fifty little churches without any

bees, all well provisioned for their winter's nap. Last season I increased my apiary from 27 colonies to 54, with a total of 2,250 bs. of surplus honey taken, mostly in 1-th. boxes, excepting 200 bs. of extracted. The season of 200 hss, of extracted. The sensoh of 1884 was a hard one on our bees. I had to feed both the blacks and Italians, and obtained no surplus. We have just had a week of warm weather, the snow being all gone, with southeast wind and some rain. The frost is out of the ground almost enough to plow. What effect, at this date, it will have on the clover roots remains to be seen.

Keeping Bees in a Barn .- Noah Field, Spencer, 9 N. Y., Jan. 8, 1886, says:

Last spring I bought a colony of bees in a box-hive from a neighbor. It produced one very large swarm. I kept them in a room upstairs in my wagon-barn. Each hive has a slanting bottom-board, and a sliding door that I can raise when I wish to clean out the dead bees. I place the hives 2 feet from the floor and 3 feet apart. I cut openings in the side of the barn just the size of the fronts of the hives, and place the honey-boxes on top of the hives in the room. I got 28 fbs. of honey from the 2 hives. They are in a cellar for the winter, have a plenty of honey stores, and so far they are doing first-rate. I think that the slanting bottom-board is a great benefit, for the bees can take everything so easily downhill to the entrance. also have a piece of glass in the back of each hive a piece of glass in the back of each hive through which I can see the bees pass into and out of the hive. All who have seen where I keep my bees think that it is a nice place.

Home Demand for Honey.-P. J. England, Fancy Prairie, Olll., on Jan. 12, 1886, says :

On June 1, 1885, I had 25 4-frame nuclei, which I increased to 27 colonies, and secured 1.500 fbs. of extracted honey, every ounce of which is sold. Of course we can build up a home de-mand ! Use a No. 1 article of honey for bait, and people will be caught.

Bee-Keeping in Texas. - C. M. Davis, Denison City, & Texas, on Jan. 7. 1886, says :

I have kept bees for at least 20 years, and I take a great interest in the business—in fact I find much pleasure in it also. I am in the north-ern part of Texas, and it is a very poor place for the bee-business, on account of so much drouth. A number of parties that have invested quite

for the last few years has yielded but little honey. I have kept bees quite profitably in Maine, but I fail to do so here. I am looking for a good location in Florida for bee-keeping, near a city, where I can have an orange orchard and good facilities for transportation.

Blasted Hopes.-Dr. C. C. Miller, Marengo, & Ill., on Jan. 9, 1886, writes:

Isn't it strange that bee-papers publish so many successes and keep quiet about the failures ? This thing is all wrong, and you should at once correct it, Mr. Editor, by establishing a corps of 15 or 20 traveling assistant editors to visit every bee-keeper who has not sent in a favorable report, and find out how much of a failure he has made. As I have failed to make a living this year with my bees, and would like to earn something without doing much for it, I will agree to be one of the number, at a salary of \$2,-500 per annum, you to pay all travel-ing expenses. I would not, of course, be expected to travel in unpleasant weather. If you accept my liberal offer let me know by return mail.

P.S.-As the snow-drifts are too deep for traveling at present, I should like my time to count from this morning. Will you furnish satchel to carry reports in?

P.P.S.-In case you shouldn't send me or any other traveling man this way after it, here is my report:

		, Fall 1884	
**	• 6	Spring 1885.	179
66		Fall 1885	
No,	ths. hon	ey—about	1,700
Yie	ld per co	olony	9½ tbs.

[Well, Doctor, we confess that it is a poor report, but perhaps a report for 10 years would show better. Try it. We do not think it would pay us to hire many at the salary you mention. But your "irony" is a stinging rebuke to the chronic fault-finders. We publish just what reports are sent to the BEE JOURNAL, without asking whether they show success or failure. In fact, we very seldom even read them, before passing them over to our clerk to be prepared for "the Press," and all that he does to them, is to try to make them readable and appear creditable in public. " Chronic kickers" are a nuisance, but they exist in every department of life.-Ep.]

Sugar Syrup for Winter Stores. -Miss H. F. Buller, Campbellford, Ont., on Jan. 7, 1886, writes :

I am glad to see that some of our prominent apiarists are calling the attention of their fellow apiarists to the mistaken policy of feeding their bees on sugar syrup for winter stores, to the great and obvious detriment of the honey market. If, as it is stated, honey that has been extracted will granulate in the combs if fed back for winter stores, should any colonies re-

quire feeding, as most seasons some will do in every apiary, still that is no reason for feeding sugar alone, as a small proportion of it mixed with the honey will, I believe, prevent granulation, or candying. Last season, when there was so much honey-dew, I fed each colony a few pounds of granulated-sugar syrup, and I think that it was a benefit; at any rate my bees wintered very well. The honey of the past season was of very fine quality, and for what feeding I had to do I used the darkest honey I had, with only a little syrup added, and so far my bees seem to be wintering even better than I ever had them; and though it is a long time till spring, vet I shall be very much surprised, as well as disappointed, if they do not come out all right.

Bees Flying on Christmas.-Dr. H. R. Dorr, (9-14), Worden, 9 Ills., on Jan. 2, IS86, writes :

One year ago last November I began the winter with 13 good colonies of bees, packed in chaff in double and single walled hives, with plenty of natural stores. I lost 4 colonies in wintering, 3 having starved or frozen to death, as some will have it, and one being queenless I count as lost. I began the season of 1885 with 9 colonies, and increased them to 14, by division. I am now wintering them all on the summer stands, packed with corn-cobs and hay-chaff on the sides, and on top I use corn-silk in-stead of cushions. The hay-chaff scattered over a layer of cobs fills up the unevenness and packs closely. From the above number of colonies extracted 900 pounds of honey, a little more than half of it being from clover, and the rest from heart's-ease. I also have about 200 pounds of comb honey in frames, and about 100 onepound sections partly filled. I sold 25 one-pound sections at 15 cents each. In recapitulating I find that my crop of honey is 1,200 pounds for the year 1885, not counting their winter stores which amount to at least 450 pounds. My bees were flying on Christmas day and cleaning house.

#### Convention Notices.

25 The Wisconsin State Bee-Keepers' Association will meet in the State Capitol at Madison, Wis., on Feb. 4, 1886, at 9 a.m. All who are interested in bee-keeping are invi-ted to attend. The meeting will be held durwho are interested in the meeting will be held anr-ing the sessions of the State Agricultural Society, and bee-keepers who are also inter-ested in topics relating to farming will have ested in topics relating to hear them discussed. an opportunity to hear them discussed. Any bee-keeper having anything new in the management of bees are requested to bring it along for exhibition. Persons paying full fare coming, may obtain a return ticket at one-fifth of the regular rate. J. W. VANCE, Sec.

The Northeastern Michigan Bee-Keepers' Association will hold its 4th annual meeting on Wednesday, Feb 3, 1886, in the Common Conneil Rooms at East Sagnaw, Mieb. The Sherman Honse, one block from the place of meeting, will entertain those present, at \$1.00 per day. Saginaw people are working hard to make the meeting a sweeess. Let ns all go and show them that we appreciate their efforts. W.Z. HUTCHINSON, Sec. The Northeastern Michigan Bee-

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Jan. 11, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO

HONEY.—There is an easier tone to the comb honey market, and prices are fully one cent per pound less than at last quotations, 15c, being the price for white comb honey in 1-lb, sections, and some extra nice brings 16c. This is owing to small lots coming into different commission houses, and all being eager to sell, they underbid regular honey houses in order to do so. Extracted honey brings 66% ac per lb. houses in Section 56 (482) and 56 (482) and

NEW YORK. HONEY.—The market for honey continues dull, and prices are ruling lower; however, if the cold weather continues, it may improve the trade in a short time. We quote as follows: Fancy white comb in 1-b, paper cartons, 13(a)16c; the same in 1-b, glassed sections, 12(a)13c; the same in 2-b, glassed sections, 12(a)13c; the same in 2-b, glassed sections, 94(a)1c, and in un-glassed 2-lbs, 11(a)12c. Buckwheat honey in 2-b, sections, glassed, 9C; in 1-b, sections, glassed or unglassed, 10(a)1c. Extracted—white clover 64(@RC; buckwheat, 54(@Nec. BEESWAX.—Prime yellow, 26@28c. MCCATL & HILDRETH BROS., 34 Hudson St.

#### ST. LOUIS.

110NEY.-The market is quiet and the demand light just now. We quote prices as follows:-Choice comb honey, 10@12c. Extracted, in har-rels, 44@5c. Extra facey of bright color and in No. 1 packages, 14 advance on above prices. BEESWAX.-Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEY.-There is a very slow demand from manufacturers, for extracted honey, with a large supply on the market, while the demand is very good for clover honey in square glass jars. Prices for all qualities are low and range from 468c, a lb. Supply and demand is fair for choice comb honey in small sections, which brings 12@35c, per lb. BEESWAX.-Good yellow is in good demand, and arrivals are fair, at 20@22c. per lb. C. F. MUTH & Son, Freeman & Central Ave.

#### CLEVELAND.

HONEY.-The market is not quite as active as it how in a second state is not quite as a cure as the second structure of the Holiday Season. Best white, I-ib, sections sell at 15c, and 2-ibs, for 13@if4c, but there is not so much sale for the latter. Second grade honey is duit at 12@if3c. Old white, 10@if2c. Extracted, BEESWAX.—Very scarce at 22@25c. A. C. KENDEL, 115 Ontarlo Street.

#### KANSAS CITY.

HONEY.-Sales are extremely light and prices are very low. Choice comb honey in 1-lh. sections brings 14015c; 2-lbs., 12013c. Dark fall honey 1 to 2 cents less. Extracted honey 1s very dull and of slow sale. We had to unload a lot of very fine ex-tracted honey this week at 5c., and stocks continue to accumulate. BEESWAX.-Scarce and higher-22@25c, CLEMONS, CLOON & Co., cor. 4th & Walnut.

#### BOSTON.

HONEY.—It is selling very well but prices are very low, and we are often obliged to shade our prices in order to make rates. We quote comb honey in 1-lb. sections at 14916c, and 2-lb. sec-tions at 12014c. Extracted, 683c. BEESWAX.—30 cts. per lb. BLARE & RIPLEY. 57 Chatham Street.

#### SAN FRANCISCO.

HONEY.-Choice comb honey is in light supply and is bringing firm figures. There is a fair move-ment in hest qualities of extracted at steady rates. We quote as follows: White to extra white comb, 106124c.; amber, 768c. Extracted, white hquid, 54654c; light amher colored, 44644c; amher and candied, 4%c; dark and candied, 4644c. BEESWAX.-Quatable at 23625c, wholesale. O. B. SMITH & Co., 423 Front Street.

Are you Entitled to a pension? You may be and may not know it. If you examine the Guide and Hand-Book you will soon find ont. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

BUSINESS MANAGER.

Special Notices.

The NEW Heddon Hive.—We have made arrangements with the inventor, by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat. Further announcement will be made hereafter, giving prices, etc.

THOS. G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL.

23 Onr rates for two or more eopies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

To Correspondents. — It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

"Don't Stop "—that is what many write to us about their papers, when their time is nearly out. One subscriber says: "This has been a year of disaster, and it is not convenient forme to send you the money now to renew my subscriptiou. It runs out with this month; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

The Time for **Reading** has now come. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books and can fill all orders on the day they are received.

and the second second

**Preserve your papers** for reference. If you have no **BINDER** we will mail you one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so *cheap* that no one ean afford to do without it. We will present a **Hinder** for the BEE JOURNAL to any one sending us fnur subscriptions--with \$4.00direct to this office. It will pay any ono to devote a few hours, to get subscribers.

**Beeswax Wanted.**—We are now paying 24 eents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be pnt on every package to prevent mistakes.

Agents can sell the Guide and Hand-Book like "hot-cakes." Send us an order for five copies (with \$2.50) and we will send you the Weekly BEE JOURNAL free for a year. This is a rare opportunity to get the Weekly BEE JOURNAL without cost 1 1

Some sent fraction of the BEE JOURNAL will be sent frace upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview by sending the names to this office, or we will send them all to the agent.

The Guide and Hand-Book, is a book of ready reference and an encyclopædia of everything desirable to know. As a gnide to the home-seeker, it is invaluable. Its contents are partially given on page 48, and will convince any one of its value. We do not think any of our readers can afford to do without it. As a book of ready reference we find it of great value in our library. We will send the Weekly BEE JOURNAL for a year and the Guide for \$1.30

Many Thanks are due to our friends for sending us so many *new* subscribers, when renewing their own subscriptions. The reduced price for 1886 has caused quite "a boom," and is a *popular* move in every sense of that word. As we do not wish any one to work for nothing, we have concluded to offer premiums for *new* subscribers for 1886, for in order to eompensate for the reduction of our price to \$1.00, we should at least *thribble* our present subscription list.

For I new subscriber for a year (besides your own renewal) we will present yon either of the following books—25 cents each.

For 2 new subscribers-any 2 of the books.

For 3 new subscribers—all 3 of them; or the Western World Guide & Hand-book.

For 4 new subscribers-Bees and Honey, (\$1.)

Gaskell's Hand-book of Useful Information —a very handy book of 64 pages.

Architecture Simplified ; or, How to Build a Dwelling-house, Barn, etc., giving plans, specifications and cost-60 pages.

Look Within for 5,000 facts which every one wants to know-75 pages.

A few Binders for the Monthly (two columns on a page) are left. We will mail them for 30 cents each, to close them out. They are not large enough for either the Weekly or the Monthly of the present size --three columns on a page.

Frank Leslie's Popular Monthly for January, 1886, has articles and illustrations hy a host of persons eminent in literature and art, and covers a wide range of subjects. It is essentially the Popular one of our monthlies, suiting the tastes of the many. Christian Reid, the favorite American novelist. contributes a short story, "A Match-making Scheme ;" Brander Matthews, the standard dramatic authority, writes of the "Kembles :" Etta W. Pierce, too well-known to need praise, hegins a very attractive serial entitled "Daughters of Cain," laying the seenes in cultured Boston and the eattle ranges of the West. Henry R. Dorr, of a family of writers, tells of "Bermuda," tempting readers to visit "storm vexed Bermoothes." Miss Lily Higgin, a favorite with American readers, draws "The Upper Ten Thousand in England." Noel Ruthven tells the story of "Opera in New York ;" Vernon Lee gives "Tuscan Notes." W. E. McCann, Mrs. Sarah K. Bolton, and I. V. Crawford supply stories and sketches. Published by Mrs. Frank Leslie, 53, 55 and 57 Park Place, New York city, at 25 cents a number, or \$3.00 a year, postnaid.

96 ACRES, hill-land, ½ well-stocked with apples, peaches, pears, plums, quinces, grapes, and small fruit, in the bearing condition. The remainder is in pastnre, grass, grain, etc. Apiary contains 140 ITALIAN COLONIES in Laogatroth bives. Bee-bouse and all modern appliances for apiculture, in as good location for bees and honey as cao be found. Good 10-room bouse, beautifully located, commanding a view of the city, river and surronnding country. New barn and out-buildings, cistern, never-failing spriogs, etc. Reasons for selling-age and ill-bealth.

1Att S. A. STILLMAN, LOUISIANA, MO.

1886. ITALIAN QUEENS. 1886. 6 Warranted Queens for \$5.

Write for circular, No circulars sent this year unless called for. J. T. WILSON, 3Ctf NICHOLASVILLE, Jessamine Co., KY.

# THE VICTOR HIVE

Is pronounced by competent aplarists to be the Best Hive for comb boney. It is operated on a new principle, the passace-ways being continuous through perforated zinc to the sections. Our dovetailed White Poplar Sections, with or without side passagee, canot be excelled in accuracy or amothness. They are as nearly perfect as can be made. Sumple of the new sections for 2 one-cent stamps. Catalogue on application.

· Address, DR. G. L. TINKER, 3Dtf NEW PHILADELPHIA, 0H10.

OR THE

# **BEES** and **HONEY**.

to issue their Catalogues, should be careful to get the prices of Books and Periodicals correctly stated. We notice that several which have already appeared, give wrong prices for Books, and also for the AMERICAN BEE JOURNAL. It would be better to omit mention of them entirely than to quote them wrongly. It would save trouble and annoyance.

J. W. Powell & Son, says a local paper of Mankato, Minn., report having 195 eolonies of bees, which produced 7,000 pounds of honey; of which they shipped 5,000 pounds to Iowa, Dakota, etc. They are among the largest and most successful beekeepers of the State.

G. B. Lewis & Co., of Watertown, Wis., had an exhibit of sections at the Detroit Convention, but by some "oversight," no notice was taken of them by the committee on exbibits. Of course it was unintentional on the part of the committee. We give this item to repair, in some measure, the omission, and we are sorry Messrs. Lewis & Co. dld not mention it soon enough to have a note made of it in the body of the pamphlet.

A Brief History of the North American Bee-Keepers' Society, with a digest of its 15 Annual Conventions, and a full Report of the Proceedings of the 16th Annual Convention held at Detroit, Mich., on Dec. 8 to 10, 1885. This is the title of a new pamphlet of 64 pages just issued at this office. Price, 25 cents.

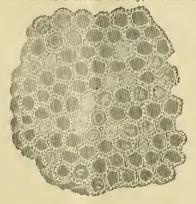

To compile this history and digest of all the past meetings of the Society, has taken much time and labor, and we have no doubt but that it will be duly appreciated by the apiarists of North America.

This pamphlet also contains engravings of the principal honey-plants, and portraits of the Rev. L. L. Langstroth, of Ohlo, and Moses Quinby, of New York ; two of the pioneers who helped to revolutionize American aplculture, and usher in a new era.

Petrified Honey-Comb.-Mr. John G. Ridenour, of Elida, O., on Dec. 21, 1885, seut us a plece of petrified comb, and remarks as follows concerning it :

I send you a piece of petrified honey-comb I send you a piece of petrified honey-comb for the AMERICAN BEE JOURNAL MUSEUM. This petrification of honey-comb was found on the banks of the James river in Mon-tana, by a friend, who said that he knew what it was as soon as he saw it, by its shape and resemblance. He thought he must have a piece for me, as he knew of no one else that had as much curiosity for small things in an apiary as 1 have. Hold the broken side to the sun and turn it to and from you, and you can see the sparkling diamonds. diamonds.

It is evidently fossil coral, and not petrified comb. It would be proper to call it honey-comb coral. We have several specimens in our Museum already, and this is

added to the number. Prof. Cook, in his Manual, says :

The animals of which these were once the skeletons, so to speak, are not insects at all, though often called so by men of con-

all, though often called so by men of con-siderable information. The species of the genus Favosites first appeared in the Upper Slurium rocks, eulminated in the Devonian, and disappeared in the early Carboniferous. No insects appeared till the Devonian age, and no Hymenoptera-bees, wasps, etc.-till after the Carboniferous. So the old-time Favosites reared its linestance columns and helped to build islands and continents untold accord reared its himestane columns and helped to build islands and continents untold ages— millions upon millions of years—before any flower bloomed, or any bee slpped the precious nectar. In some specimens of this honey-comb coral, there are to be seen banks of cells, much resembling the paper cells of some of our wasps. This might be called wasp-comb coral, except that both styles were wrought by the self-same animals. animals.

New Price-Lists have been received from the following persons :

The Queen Decides. - Recently the Louisville Medical News appeared with an editorial on the "Cause of Sex," assigning it to the male and female, according to their respective emotions, etc. Dr. G. P. Hachenberg, of Austin, Texas, who has one of the most extensive aplaries of the South, took issue with the views advocated in the edltorial, and in a communication to the editor. advanced the following peculiar theory :

advanced the following peculiar theory : It appears to me that we can only pass judgment on such intricate subjects, by reasoning from analogy. To do this, in this case, the male never has anything to do in determining the sex. The male only imparts its own species, and a part of his individuality, and nothing more; and the intricate process of determining sex de-volves on the female alone. That either sex may have some of the features of either parent, is no argument against these views. But for proof: The female bee, usually called the queen, has sexual commerce but once in her life, and for years afterwards, in her propagation, she determines the sex through a choice of her own. If the queen-be is the key to unlock this mystery of mimal life, then the physiological evolution that determines the sex, is solely centered in the female. For a wise purpose, the gift of the queen, that is, the potency of her own choice, has been denied to the latter to determine the sex of her gestation, yet still emotional influences on her part are not a foreign necessity. Evidently the local effects of the spermatezon is an important factor in regulating these emotions ; these with local and constitutional conditions, in the aggregate, favor the evolution of sex, either one way or another. I think it well to study the subject from this stand-point.

Appreciation of the AMERICAN BEE JOURNAL for 1886 is so often expressed by our correspondents, that we could not find room for one in a hundred, but the following are a fair sample of all of them :

J. E. Pond, Jr., Foxboro, Mass., writes: "I am proud of the JOURNAL as an Ameri-can production. It, if possible, grows better and better: at any rate 1 am pleased to find that reduction in price is not followed by reduction in labor or falling off in merit."

Chas. II. Wiele, Stoddard, Wis., writes : "It onas. 11. Wiele, Stoddard, Wis., writes: "It is but a little money for so many valuable articles, I would not be without it if it had been *raised* in price, instead of being re-duced."

W. J. Cullinan, Mt. Sterling, Ills., writes: "I have received the BEE JOURNAL and your book, 'Bees and Honey,' and I consider both invaluable to every one engaged in progressive bee-culture. With the book I am more than pleased."

W. A. Pryal, humorist of the Oakland, Calif., Express, is authority for this "funnydote :"

"London has a regularly incorporated association, the object of which is the protection of the butterfly. The society should also encourage the baking of the buckwheat cake, which, according to the old joke, makes the butter fly."

Now, by all means, let a society be formed for the propagation and consumption of the flap-jack, for it will be the cause of making the honey tly, too. The bee is not the only insect that apiarists take a great interest in, as will be seen by the above.

A Correspondent sends us the following inquiry. As he is a very young man perhaps we may pardon him for this time, if he will promise not to do se any more. It is almost too pun-ny to be funny :

Query-Did not the paper read by Prof. Cook at the Detrnit Couvention come nearly "putting a bead on" (Heddon) the pollen theory?

**REPLIES by Prominent Apiarists.** 

# Wintering Bees in a Pit.

Query, No. 186.-About Dec. 1 I put my bees into a pit 3 feet deep, and put cloth in the bottom. I placed 1-inch blocks under the corners of the hives, packed corn-fodder between the hives and the sides of the pit, that a cover of boards. Over the boards I put another cover of straw. The bees keep up a continual hum. By letting a ther-mouncter down through a box which con-nects with the bottom of the pit, I find that the temperature varies from 35° to 45°. Will it do to leave them there for the winter? -J. R., Dec. 24, 1885.

Yes, if it keeps dry in the pit. At any rate do not take them out till a warm day .- DADANT & SON.

I have had no experience in putting bees in pits, but I think that I would leave them just where they are.—H. D. CUTTING.

should rather the tempe \_ture T would remain evenly at 45°, but 35° to 45° is as well as I could control my house-cellar in which I have wintered hees successfully. A continual hum is always heard in a cellar containing bees, and if of the right kind, it denotes that they are wintering well. -G. M. DOOLITTLE.

Unless they could be placed in a higher temperature, I would not disturb them; and even if they could, I doubt the advisability of disturbing them, especially if the temperature does not fall lower than 35°.-W. Z. HUTCHINSON.

If you had said that the temperature varied from 40° to 45°, I should say all right. I do not like it as low as 35°. In making a pit, why not make it all under ground and cover it so deeply that you can keep the temperature from 45° to 48°? Do not fear a little gentle hum; it is a note of contentment.-A. J. Cook.

I have had no experience in this kind of wintering, but I should think that the temperature might answer. If the "continual hum" be from a large number of colonies, and resembles the sighting of the wind among pines, I should not be afraid of it; but if it be a continual "zip, zipping," I should feel a little uneasy.—C. C. MILLER.

I do not like your repository at all; however, if I was in your place, I should pile on more straw or earth, or something to raise the temperature about 10<sup>-</sup>, and keep it more uniform. Bees may become noisy and restless in a high temperature, and no diar-rhea result; but if from a low tem-perature, "look out."—JAMES HED-DON.

The experiment of keeping bees in clamps during the winter months has ing them now would create, will the plan detailed by Mr. Frank been tried with more or less success. inevitably injure them greatly by While I do not think that plan the breaking up their clusters, and caus-

best, I should advise in this case to leave the bees alone and not disturb them at all, for fear that disturbance would cause great excitement and injure them more than to leave them where they are.—J. E. POND, JR.

"The continual hum" began with the packing, and they keep it up because of the great excitement and disturbance it occasioned. They disturbance it occasioned. They were aroused from the condition of hibernating sleep which they had en-tered on Dec. 1, and it will now be doubtfol if they will doubtful if they will get settled so as to enter it again. I think that they will be as safe where they are as anywhere. Dec. I is too late to pack hees in this latitude. They cannot be packed even in October without some disturbance. But the rustling of a lot of corn-stalks in packing would thoroughly arouse them at any time. All operations about the hives in the fall should be conducted as quietly as possible, and all jarring carefully avoided.—G. L. TINKER.

# When to Move Bees.

Query, No. 187.—Would it be safe to move my 23 colonies of bees 30 miles in January, on a sled? or would it be better to move them in the spring, on a wagon, after they have had a cleansing flight?—W. G.,

Move them in the spring.-II. D. CUTTING.

The latter way would be my choice. -JAMES HEDDON.

I should prefer the latter method.--C. C. MILLER.

I should prefer to wait until spring. Bees can be moved as safely on a wagon as on a sled.—G. M. Doo-LITTLE.

I should wait until spring; still I am not certain that moving them in winter would injure them.-W. Z. HUTCHINSON.

I have known it to be often done with no harm, but theoretically I should prefer to wait till spring.-A. J. Соок.

I cannot speak for your climate, but I used to select a time when snow was on the ground to go into the hills hauling them on a sled over the roughest road imaginable, without any apparent injury to the bees. They were in boxes and "gums," and were confined by tying a coffee-sack over the open ends of the "gum." This was 25 years ago.—G. W. DEMAREE.

You had better move them in the spring. We tried sleds to our hearts' content. The jarring is not contin-uous, but very hard when there is any, unless the sleighing is extra-ordinarily good. Besides, it excites the bees and does them no good.— DADANT & SON.

Wait till spring, by all means. Any disturbance of a nature such as mov-

ing them to eat disproportionately, or die out in detail.—J. E. POND, JR.

Bees may be safely moved on a sled in January, if extra precaution is taken not to jar them in handling or moving. If it was more convenient for me to move them now than in the spring, I would do it, although the spring is the best time usually to move bees. The moving of bees in winter should be intrusted to no one but an experienced apiarist, one who can handle hives of bees as no one else can.—G. L. TINKER.

# Cleansing Foul-Broody Hives.

Query, No. 188.—My bees have the foul brood, and I expect to use phenol at once to cure them. I cured one of the worst cases I had last summer, by using Mr. Doolittle's plan. I would be satisfied with his plan if there was an easy way of disinfecting or purifying the old hives, which I am not able to throw away; I have no kettle large enough to boil a whole hive, and it is a hig job to knock a hive to pieces and boil each piece. Is there any way of washing out the old hives with carbolic acid water so as to purify them Y I suppose I have 25 colonies that are affected, but I wish to feed phenol in honey and water to all, so as to cure it throughout my entire apiary of 120 colonies. —Texas. Tevas

When you have them cured by the use of phenol, tell us all about it in the BEE JOURNAL.—G.M.DOOLITTLE.

I should think that the farmers living near you keep something to scald their hogs in. Here I could borrow a "hog-box," *i. e.*, a large box with a sheet-iron bottom, so as to be set over a furnace. In such a boiler you could boil two or three hives at a time. Quick-lime added to the water would make it more effective. -G. W. DEMAREE.

You can use a sponge and apply the solution, but be extra careful to saturate every spot. I would prefer a kettle or tank and give them a good boiling. If you are very careful and will do your work well, you can cure it.--H. D. CUTTING.

I have never seen a case of foul brood, but if phenol is effectual, why not paint the hives with a solution ?--C. C. MILLER.

I cannot say, but why not try washing the hives well with either carbolic acid or salicylic acid dissolved in alcohol? I presume this would disinfect the hives.—A. J. Cook.

We are no authority on this, having never seen a case of foul brood. Several French apiarists claim to have cured foul brood by smoking the bees and hives with dried thyme.--DA-DANT & SON.

It seems to me that it would cost less to procure a kettle or pan that would hold a part of a hive at a time, than to use as much carbolic acid as would be needed. A pan two feet square and 4 inches deep, would scald every part of my bive by turning the parts.—JAMES HEDDON.

pure carbolic acid, and if it will cure the disease, it will, I should judge, effectually cleanse an infected hive, if thoroughly applied to *every* part.— J. E. POND, JR.

I think that it would be useless to wash out the hives with carbolic-acid water, at least with a 5 per cent. solution. A good atomizer, like the little "Gem," I should think would be effectual in cleansing hives used with a mixture of eqnal parts of phenol and alcohol. I have used so strong a mixture in the sick-room, but it is a little too pungent. In my practice I have found one part each of carbolic acid, alcohol and water used with the atomizer to be highly effectual in the sick-room in destroying the contagion of typhoid fever, scarlet fever, and diphtheria. My experience has led me to think that if the mixture were used in school-rooms in localities where epidemices of the two latter diseases prevail, there would be no need of closing schools, and the epidemics would soon abate. Perhaps the same strength of mixture would be strong enough to cleanse hives of the germs of foul brood,—G. L. TINKER.

#### OUR CLUBBING LIST.

We supply the **American Bee Jonrnal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

# System and Success.

23" All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are as follows:

The larger ones can be used for a few colonies, give room for an increase of numbers and still keep the record all together in one book, and are therefore the most desirable.

Any person not a subscriber, receiving a copy of this paper, will please consider it an invitation to become a subscriber to it.

**Explanatory.**—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of eolonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark  $\bigcirc$  indicates that the apiarist is located near the centre of the State named:  $\eth$  north of the centre;  $\blacklozenge$  south;  $\circlearrowright$  east;  $\circlearrowright$  west; and this  $\circlearrowright$  northeast;  $\circlearrowright$  northwest;  $\circlearrowright$  southeast; and  $\blacklozenge$  southwest of the centre of the State mentioned.

For the American Bee Journal

### Comb Honey vs. Extracted Honey.

#### 17-G. M. DOOLITTLE, (40-95).

On page 759 of the AMERICAN BEE JOURNAL for 1885, under the above heading, Chas. Dadant & Son, by an overhauling of my report on page 709 of the same volume, endeavor to prove that Doolittle was not correct in his estimate, that with extracted honey at 8 cents per pound, comb honey could be produced at 12 cents per pound, with equal profit to the apiarist. Messrs. Dadant & Son should be credited with great tact and skill, for certainly such is shown in their weaving the many minor points in my report into their fabric in such a way as to point toward their 20 cents per pound for comb honey, instead of 12 cents as I put it. Well, I am very glad that they gave as that article, for it gives me a

Well, I an very glad that they gave us that article, for it gives me a chance to explain farther regarding that report, than I otherwise should have done, and in doing so I will leave them as near the 20 cents per pound for their comb honey as I possibly can and keep truth on my side.

In my report found on page 709, which helped them to draw their conclusions, I gave the number of colonies of bees that I had to start with in the spring, as 40. Twenty of these were good to fair, 10 rather weak, and 10 very weak. Of these, 25 were set apart for comb honey, 2 for extracted, and 13 (the very weakest) for queenrearing; hence I had 20 good to fair colonies and 7 weak ones producing honey, 5 of the weak ones being worked for comb honey, and 2 for extracted. Without farther explanation all would expect that the 20 good colonies gave more of the comb honey in proportion to their number, than did the weak ones, while the facts in the case are that 2 out of the 5 weak colonies worked for comb honey gave more than the average yield, one giving 139 pounds and the other 128 pounds. The reason for this is as follows:

After I had set apart only the 13 insure their wintering; thus reducing weak colonies for queen-rearing, orders began to pour in for queens to such an extent that I saw that I would be "swamped" if I did not make before it was sealed over, or in an some provision for more nuclei than I

could possibly make from those 13 weak colonies. Accordingly I began to draw bees from all of the strongest colonies, and used them for nuclei upon the plan I gave last June, taking the brood that they were hived upon from these strong colonies also. These nuclei were built up as fast as possible by giving them a frame of brood occasionally from these strong colonies, so that they constituted the larger part of my increase, as will be seen when I say that in no case was there allowed but one swarm from any of the 25 colonies, and two of them did not swarm at all. Thus we have 23 new colonies from the 25 old ones set apart for comb honey, making 48. Then we have the 13 weak colonies built up to good colonies, and the two set apart for extracted honey, making 63, while the next 32, to make the 95 reported, were made of nuclei built up, and others which were doubled up in the fall.

From the above Messrs. Dadant & Son will see wherein their last para-graph on page 760 of the AMERICAN BEE JOURNAL for 1885, has no bearing on the subject. One other item I wish to explain right here. In that paragraph they speak as though they thought that the queens that were used to produce the comb honey were crowded for room. This is a mistake, for such queens were not crowded until after the bees were produced which gather the crop. Here is where they touch on one of Doolittle's hobbies. Nearly all of those queens had 15 Gallup frames which they filled with brood and bees, so that when swarms issued they were not the little swarms that Messrs. Dadant & Son speak of as coming from an S-frame Langstroth hive, but they were rousing large swarms, only they came a little late in the season, owing to the treatment given the strong colonies which I have spoken of above.

Now comes in the crowding part. When these large swarms were hived they were given only 5 and 6 frames in the brood-chamber, while all the rest of the hive was tilled with sections. In this I believe we have one of the greatest secrets toward the successful production of comb honey. Get all the bees you can before the honey harvest, by giving abundant room for the laying-capacity of the queen, and after the honey harvest arrives contract the brood-apartment of all hives, so as to throw the larger part of this force of bees into the sections.

Again, they speak of the 2 colonies worked for extracted honey producing 388 pounds, which is correct; but unfortunately for their 20 cent-perpound theory, I found when preparing the bees for winter, that these 2 colonies had used up nearly all the honey in brood-rearing that I had left in their hives when taking away the 200 pounds from them, so I had to give them 50 pounds of the removed 200 to insure their wintering; thus reducing the 388 pounds to 338 pounds. Then the 188 pounds of this 338, which was taked with the extractor, was taken before it was sealed over, or in an unripe state, as I wished it for a particular use, and did not care to have it stay in the hive until it was ripened, as I always insist in having it when it is for market. This would make a reduction of the amount, or of the value (one being equivalent to the other), but I will only call this part to offset the one cent per pound that they give as the value of the washing of the cappings for vinegar. As their was no cappings, of course I could not wash them. When I do have them I never wash them, for the low price of cider-vinegar in this locality, together with the cost of the barrel, makes it unprofitable to do so, especially as we can with a solar waxextractor entirely separate the honey from the wax or cappings.

Another thing: I am not ready to admit that it takes any less labor or capital, all things considered, to run an apiary of a given size for extracted honey, than it does for comb honey; and I have been carefully experimenting on this point for the past 12 years, producing some of each kind of honey nearly every year during that time. When Messrs. Dadant & Son produce comb honey in sufficient quantities, and become expert so that they can remove all the surplus honey from 90 colonies in 3 hours, as does Mr. A. E. Manum and others here at the East, they will speak less of the extra work required in producing comb honey. So, then, if we call the labor equal in producing both kinds of honey, and offset the 2 colonies producing the 388 pounds of extracted honey with the 2 weak ones worked for comb honey which gave 270 pounds, we shall have about this result: Each colony worked for extracted honey produced 169 pounds, which, at 8 cents per pound, amounts to \$13.52. This divided by 135 pounds (the amount of comb honey given by each of the two weak colonies), gives about 10 cents as the comparative cost of comb boney, which is the estimate given by Mr. Pond in answer to Query, No. 153. If we divide the \$13.52 by the 119 pounds of comb honey given on an average throughout the apiary, we shall have about 11½ cents as the comparative cost of comb honey, which is about what I gave in my answer to Query, No. 153. Now, if we count the increase given by the 2 colonies worked for comb honey (which was two fine swarms) against no increase from the other, there will be but little difference in the comparative price per pound between the two.

However, I will not multiply words, but simply say that after 12 years of careful experiment regarding the production of both comb and extracted honey, I find that when thoroughly ripened by the plans given by Messrs. Dadant & Son, I get, on an average, one-half more extracted honey than I do comb honey, with about an equal expenditure of capital and labor on each. For this reason I answered Query, No. 153 as I did, and I am still of the opinion that the answer "8 cents and 12 cents per pound" as the relative cost of producing extracted and comb honey, is nearly, if not quite, correct.

Borodino, ON. Y.

# The Night is Still.

The Century.

#### EDITH M. THOMAS.

The night is still, the moon looks kind, The dew hangs jewels in the heath, An ivy elimbs across thy blind And throws a light and misty wreath.

The dew hangs jewels in the heath, Buds bloom for which *the bee* has pined; I haste along, I quicker breathe, The night is still, the moon looks kind.

Buds bloom for which the bee has pined, The primrose slips its jealous sheath, As up the flower-watched path I wind And come thy window ledge beneath.

The primrose slips its jealous sheath— Then open wide that churlish blind, And kiss me through the ivy wreath ! The night is still, the moon looks kind.

# For the American Bee Journal Infallible Queen-Introduction,

#### JOHN NEWITT.

So much has been said and written on queen-introduction, "safe," "direct," and otherwise, that the subject would seem to have been thoroughly exhausted; and still successful introduction of queens is only looked upon as "luck" work, if I may judge by the remarks of Mr. James Heddon on page 732 of the AMERICAN BEE JOUR-NAL for 1885, and others.

The greatest amount of harm has been done by bee-keepers making hasty assertions formed on some observation which they did not comprehend, and these statements repeated time after time until they are accepted as truth. For instance, how many times are we told that old, queenless bees will not accept a stepmother ? and yet to such, no matter how old or how long they may have been queenless, I can introduce fertile queens as quickly as I can drop them at the entrances of the hives containing such bees. Could anything be more simple or easy ?

It is well known amongst bee-keepers, that bees will not accept another queen while their own is in the hive, nor as laid down by Huber, for 24 hours after her removal; I have observed, which I believe has never been noticed by any one else, that when bees have started queen-cells, they look upon them as their own queen, and will not accept an alien, particularly while they are *unsealed*, and this is the "rock" where so many are lost.

Huber says that bees will accept a strange queen and treat her as their own if she is presented to them at the end of 24 hours; this system is practically like the one of Mr. J. E. Pond, Jr., and if the new queen is caged at the time of removal of the old one and not kept caged longer than 30 or less than 24 hours, no failure will ever occur. I make this as a positive assertion, providing the releasing is done between 24 and 30 hours after removal of the old queens; after 30 hours

queen-cells will be started, then all the "difficulties" begin. If every queencell is cut out, when the bees miss them, and before they start fresh ones, they will at this point accept the queen; but not when cells are started again. The older the bees are, the more eager are they to begin fresh cells, hence the saying, "Old bees will not accept an alien queen." So anxious are old bees to rear another queen, that if one is caged in a queenless, unsealed and broodless hive, they will carry eggs dropped by the caged queen and rear queens from them. Those scientists who doubt that bees can steal or carry eggs to rear queens from, had better try this experiment, when I venture to think their stock of knowledge will be increased. But with bees in this state it is almost impossible to get the strange queen accepted; I have tried on one case for 16 days.

Some years ago, when thinking over the question of queen-introduction, I reasoned thus: "When bees are queenless and have no means of rearing another queen (say their own was a virgin and lost on her wedding-trip), has Nature, in her great econom-ical laws, ordained that their generation shall die off and not save themwhich might come to them, say one lost in taking her bridal trip?" The more I thought of this, the more un-natural and repugnant to all her other laws, it seemed to me; so, as I had a stock at the time, which had been queenless two months, I decided to try the experiment. Robbing was rife at the time in the neighborhood, and when I dropped a fertile queen amongst them, the "guards" pounced on her as a robber; but oh, my, their astonishment! they immediately set up a peculiar hum and formed a halfcircle round her, and conducted her into the hive, when she commenced laying. I have repeated the experiment so often with all kinds of queens, useing imported ones of priceless value, without a single failure, that I may be pardoned for saying that this system of mine is "infallible." The "Law" to bear in mind is this : "The bees must have been queenless at least 30 hours, and have no means to rear another." This law holds good even if laying workers are present, unless they have begun laying, so that the bees of any hive found to be queenless, will accept another without any caging; so also one in which all the queen-cells are cut out on the 9th day, or one where a virgin queen was lost on her bridal trip. The knowledge of this law also enables me to prove in a few seconds whether a hive is queenless or not, without having to hunt up the queen; for, if queenless, they will accept a queen with a joyful hum; if not, they will " ball " her.

I find this system invaluable in the fall, for it very often happens that we want to replace old queens with young ones, or we may have our most valuable queens in colonies that we would rather they did not pass the winter in, and would like to exchange them with others. Now with this system, all we have to do is to take the queen from

the other stock, cage her in a mailing cage, where she will be safe for a week or so; in two days I catch my most valuable queen and drop her at the entrance of the hive from which the other was removed, providing the weather is warm; if it is cold, I drop her in under the quilt, amongst the In two more days I take the bees. one from the mailing-cage and give her in the same way to the other hive. Of course care is required that neither of the hives contain brood or eggs, which can be noted when removing the queens, which is not probable in the fall; but if they do, the combs containing the brood or eggs must be given to other hives in exchange for brood or eggless ones.

My first publication of this system is in the *British Bee Journal* for July 1, 1883, page 83; but bee-keepers do not seem to have "grasped" the value of the idea yet; or perhaps I ex-plained it too *briefly* for any one to comprehend it An or word of Ma comprehend it. An ex-pupil of Mr. D. A. Jones, of Beeton, Ont., paid me a visit last fall, to see bees migrated to the heather and returned, to whom I showed its practical workings; old queens were removed, and any time when convenient after 2 days, young ones were allowed to run in at the entrance or dropped in under the quilts, and others exchanged. He expressed his astonishment and delight with the process, which he said "licked" all the plans of queen-infroduction that he had seen or heard of in the New World. I call it "Hew-itt's Direct System" of queen-introduction-direct because the queen alone is given direct because the queen alone is given direct and at once, without any caging; and strictly speaking, it is the *only* direct system extant. Reaumur's and Huber's are direct in a degree, while Simmins' is not direct in the least, as a comb of brood and honey covered with bees has to be given as well; while the plan is not even new, having long been used in this country.

The first system of queen-introduction was given by Reaumur 100 years ago, his plan being to confine the bees in a box and then after awhile give them the strange queen; almost exactly as Mr. Doolittle does in mak-ing and uniting nuclei. Huber, under date of Aug. 30, 1791, criticises this plan, and while he admits its truths he maintains that the bees are not in a natural condition. Just so! the bees are lost, with no queen or means of rearing one, hence they will *infallibly* accept another after 24 hours; which I am sure Mr. Doolittle will have found to be so. Thus it will be have found to be so. Thus it will be seen that Renumur's plan is my system in embryo; but by the law I give, it can be varied to suit all conditions and circumstances.

It will be seen that we have three infallible ways of safely introducing *fertile* queens, (1 do not in the slightest way allude in this article to introducing virgin queens), and if any failure results it will be on account of not keeping to the rules. For instance : Some direct caging queens 3 days or more; with such advice the wonder is that any are accepted—certainly none will be with old bees; if only

young ones are in the hive, then queen-cells are not usually started for 5 days, when it will act; hence the advice to move the stock to a fresh stand, to draw off the old bees, under the belief that they alone are dangerous; while as a matter of fact the old bees, if caught on broodless comb and kept queenless, will after 30 hours invariably accept any fertile queen at once, if given uncaged, when brood can afterwards be added if wanted.

I am not making this public in haste, as I have for years been testing this great natural law that I have discovered; those who are inclined to doubt its truth, should notice the commotion and noise at the entrance of a stock of bees that are queenless, and hav-ing no means to rear another, which noise and commotion I believe is made to attract a strange queen to them. Anyhow, I have had 2 colonies re-queen themselves so, and a friend of mine had one also. Every bee-keeper should note the peculiar hum they make when a fertile queen is given them; it is something like the swarming-hum, so near as I can discribe it, but still it is distinct in its peculiarity; however, every bee seems to know that a "mother has come, and begins "clapping" its wings for joy, or it may be to welcome her; whatever it is, in my opinion it is the most poetical phase of the natural history of bees, and I want every bee-keeper to test it for himself.

Now, readers, you all at some time or another want to change your queens; so carefully study this article and you will find it worth all you have ever paid or are likely to pay for the AMERICAN BEE JOURNAL. If any-thing is not sufficiently clear, I will try and make it so. Tell all, next try and make it so. winter, how you like it. Sheffield, England.

By request of Mr. Hewitt, we have printed the word "stock" for "colony," where he had so written it. We prefer the word colony, but defer to the wishes of our correspondents when they express a decided preference, as does Mr. Hewitt; lest we should Newman-ize it, as one correspondent expressed it, when mentioning our changing of his verbiage in this respect. Having adopted a nomenclature of terms in bee-keeping. should we not always try to be consistent therewith ? When a departure is made from that, we make a note of it.—ED.]

# The Hibernation of Bees.

#### WM. F. CLARKE.

#### Editor American Bee Journal:

The accompanying article will appear in the February number of the Rural Canadian. Will you kindly make room for it in an early number of the AMERICAN BEE JOURNAL, and permit me to say that a multitude of claims and calls forbids my noticing the matter just now in a shape more suitable for your columns? By so suitable for your columns? By doing, you will greatly oblige, WM. F. CLARKE.

Guelph, Ont., Jan. 19, 1886.

The able and unanswerable article of Dr. Tinker on the hibernation of bees cannot but produce a profound sensation among intelligent bee-keepers. In a private letter, which I take the liberty of quoting, the Doctor says: "You will notice that I do not says: "You will notice that I do not make use of the word 'quiet,' or 'quietude,' because I think the con-dition the bees pass into implies something more than is expressed by those terms. I shall be pleased, if, after reading my article, you would put in a disclaimer that you are not satisfied with that word to express the actual condition. In my opinion only the word hibernation is applicable."

Many a time and often since this controversy began (about 18 months ago), I have felt like making a clean sweep of "quiet," "quietude," "qui-escence," "torpor," "semi-hibernation." and all other words having any ambiguity about them. From the first I have felt as Galileo did about the true theory of the solar system, but, without access to a scientific library, and with the most meagre opportunities for experimenting, modesty forbade assertiveness. only man in the bee-keeping fraternity who made any pretensions to scientific acquaintance with entomology, treated the whole affair with contemptuous dogmatism, and would not even in-vestigate the theory. I broached it with the simple and reasonable request that bee-keepers would experiment in regard to it. So far as I know, Dr. Tinker is the first who has done this with any thoroughness, and it has been wholly of his own accord. The result is, complete demonstration There are more to follow. "They are coming, Father Abraham, 300,000 strong !"

I have no hesitation in accepting Dr. Tinker's article in its entirety, with the exception of what he says as against the chaff hive," and I merely "ask leave" to let that point rest in abeyance until next spring discloses the result of experiments now being made. Meantime, our best thanks are due and are hereby presented to the worthy Doctor, and the disclaimer he suggests is gladly made. Hence-forth, "mBERNATION" is the word, and none other, that we accept, for, in truth, it is the only term known to science, which is applicable to the case.

<sup>27</sup> The Wisconsin State Bee-Keepers' Association will meet in the State Capitol at Madison, Wis., on Feb. 4, 1586, at 9 a.m. All who are interested in bee-keeping are invi-ted to attend. The meeting will be held dur-ing the sessions of the State Agricultural Society, and bee-keepers who are also inter-ested in topics relating to farming will have an opportunity to hear them discussed. Any bee-keeper having anything new in the management of bees are requested to bring it along for exhibition. Persons paying full fare coming, may obtain a return ticket at one-fifth of the regular rate. The Wisconsin State Bee-Keepers' one-fifth of the regular rate. J. W. VANCE, Sec.

# Pacific Rural Press. Sknuks in the Apiary.

#### WM. MUTH-RASMUSSEN.

The skunk is one of the recognized enemies of bees, and, like most of them, is nocturnal in its habits. The first indication that the bee-keeper has of the visits of a skunk is, that the front of the hive and the entranceboard is blackened as if smeared over with mud, which had afterwards been carelessly wiped off. This is done by the skunk's scratching on the hive with its paws to incite the bees to come out. As it is not strong enough to knock the hive over, like a bear, and get at the honey itself, it is con-tent to eat the bees for the sake of the honey they may contain, although I doubt not that it frequently swallows a highly seasoned morsel.

On closer examination, a hole will generally be found scooped out in the ground in front of the hive, and more or less dead and dying bees, some-times as much as a handful will be found lying in the hole. It has been said that the skunk manages to get the bees entangled in the hairs of its large bushy tail, and slashing it around in the hole kills or cripples the bees before it proceeds to eat them. As it always leaves a number of bees, many of them still kicking, in the hole, it may be surmised that either it does not take much to satisfy the skunk, or else, getting more stings it has had enough. However, if a skunk is allowed to visit the same bive several times in succession, it is obvious that it will not take it long to seriously depopulate the colony, more so as its visits are most frequent during the winter, when the bees are not breeding.

A large dog will easily kill a skunk, and some dogs take naturally to that kind of game, while others are loth to tackle a skunk after they once have gotten a dose of its perfume. Skunks may be shot on moonlight nights if the bee-keeper watches for them, but in either case they are apt to leave their scent, which will adhere to the locality for a number of days. The better way is to trap them in a com-mon box-trap with a sliding-door.

The trap may be haited with a piece of old, tough comb or a rag smeared over with thick honey, or with a piece of fresh meat tied securely to the trigger. It should also have a small opening in the top, closed with a shutter, through which it may be seen if it is which is in the trap. If a skunk is caught, carry the trap to a pond or a large, water-tight box; immerse the trap and weight it down with a heavy stone, so that it will be filled and thoroughly covered by the water. If the trap is handled carefully, without shaking or frightening the skunk, it will, as a general thing, not smell. -In 10 or 15 minutes the trap may be taken out of the water and the skunk buried deep enough to prevent dogs or coy-otes from unearthing it again.

As soon as the trap has been dried out, so that the door works easily, it should be set again, and works apparently better the oftener a skunk is caught in it, as the scent seems to be rather an attraction to others of the same tribe. To prevent the skunk from lifting the door and escaping, a cleat should be nailed across the bottom of the trap, just inside the lower edge of the door. If this cleat is not there, or some other device to hold the door down, the skunk can easily raise it with its long claws. Independence, & California.

## Small Hives vs. Large Hives.

#### D. A. FULLER. (80.)

I think that I can best answer Mr. Dayton, page 25, in his reference to my letter on page 762 of the AMERI-CAN BEE JOURNAL for 1885, by giving little of my experience in my own a apiary. I must acknowledge that as late as the spring of 1883 I was very much in favor of the 8-frame hive. I commenced that spring with part of my bees in 8-frame hives and part of them in the 10-frame ones. That year I commenced using the Heddon super and tiering-up system for comb honey. I found that I was getting but 28 sections on an 8-frame hive, and the lo-frame hives took 32 sections, 4<sup>1</sup>/<sub>4</sub>x4<sup>1</sup>/<sub>4</sub>x 13-16 inches. This made 4 fbs. more for the 10-frame hive, and I tiered them up 4 high; none of the S-frame hives were tiered up any higher, and a few of the 10-frame hives were 5 tiers high. But allowing them to have been tiered up the same, I had 4 more sections to the tier on the 10frame hives than on the S-frame ones, which made 16 lbs. more honey in favor of the 10-frame hives.

The foregoing was my experience for 1883 ; in the season I used but 3 8-frame hives, still determined to give them a fair trial; but the result was the same, and those other 3 8-frame hives were condemned to the woodpile. It has often been said that the strongest argument a man can use is oue that reaches his pocket, and this did reach mine, to the amount of \$2 per hive, if I compute the 16 bs. of honey at 12½ cts. per pound, which is a low estimate. Location certainly made no difference with my experi-ments as the hives stood side by side.

While tiering-up is not an entire preventive of swarming, if it is closely and carefully attended to the apiarist will not be troubled with many swarms; and if Mr. Dayton could see the swarms that do issue when a colony in a tiered-up hive does swarm, he would conclude that I did not need to compare a third or fourth swarm with an average one. In my plan of working by tiering-up, third and fourth swarms are a rarity.

Some springs I do find it necessary to feed some colonies in wet or cold spells in order to build them up to good, strong colonies by the com-mencement of the white clover sea-son. My colonies do average more

than S-frames of brood, and quite often fully 10-frames, at the beginning of white clover bloom; and my ex-perience has taught me that a large (average) hive is better than a small (average) hive. Cherry Valley, 5 Ill.

For the American Bee Journal

# Reversing the Frames.

#### J. E. POND, JR.

When the matter of reversing frames was first presented, I looked the idea over and experimented somewhat in that direction, and as I had previously met with some degree of success in reversing sections to cause the corners to be filled out. I became quite enthusiastic on the subject, and gave the opinion that they would be or should be universally adopted. A single season with them taught me that I was wrong, and that the bene-fits claimed by their use was not in accordance with natural law, and could be far more easily attained without the trouble and expense of fitting over frames, as would be necessary in order to adopt the plan.

Chief among the benefits caused by the method of reversing, is the get-ting of brood in the tops of the frames; not that I pass over that of getting frames filled out in the corners, for by use of full sheets of foundation no trouble of that kind need arise. It is, I suppose, as well known to others as to myself, that the queen will not use store-combs in which to lay her eggs, but will use only such cells as are of the regulation depth. Reasoning from this premise, and on the further ground that the attempt is always made to put honey above the brood, I decided that any plan that would keep the upper part of the comb at just the correct width, viz., % of an inch, would at once cause the cells to be filled with eggs; and as a matter of course, the stores to be deposited in the sections above.

The question then arose, how can this best be done? Shaving off the combs I found to be too much labor, but upon testing the idea of putting the frames nearer together. I found the plan was a success. If the combs are placed just so near together as to leave a bee-space between them, and allow the whole comb to be % of which wide netrophe will be found an inch wide, no trouble will be found in keeping the upper rows of cells filled with eggs, if sections are in place; and if the new top-bar of Mr. G. W. Demaree is used, no brace-combs will be needed at all, while the bees will be found to occupy the sections whenever there is any honey to be gathered and stored.

Perhaps my own experience may not be that of others; however, I would advise that a test be made in different localities, in order that the matter may be fully determined; for if it works elsewhere as with myself, time and labor will be saved, and the pro-duction of comb honey greatly simplified.

# Pollen and Bees---Misrepresentation.

### W. ADDENBROOKE.

f fully endorse the article by G. M. Doolittle, on page 6, on "Pollen car-ried from flower to flower." Most of the readers of the AMERICAN BEE JOURNAL are aware that in England, soushes cannot be raised in the open air; they are all raised in green-houses and hot-bed frames, and many hours have I worked in the garden at home in England, with a fine, long camel's-hair brush, conveying the pollen from blossom to blossom where the bees could not get to do the work; and even now in this climate, if we do not have good weather for the bees to work on the fruit bloom, and especially on red clover saved for seed, we get but a poor crop. Last year I had a good crop of mammoth clover (pea-vine) seed, while a few miles from here there was none, and I think that I owe it to my colonies of Italian bees, for they worked on it first-rate.

I think that if people would only open their eyes, and study " Nature's laws," there would be no need to fight lawsnits caused by spite or ignorance.

I was pleased to see the stand that you have taken in the BEE JOURNAL, on page 19, concerning "more mis-representations about comb honey." I think that the bee-keepers of the country are greatly interested in causing a stop to be put to all such misrepresentations, and should spare no expense to put to shame such false articles as are now published. North Prairie, ∾ Wis.

For the American Bee Journal.

Upward Ventilation in Wintering.

5-J. M. GOODRICH, (62-120).

Having read Dr. G. L. Tinker's able article on the hibernation of bees, page 5, and having found much in it that is instructive, and which I can endorse, especially the tempera-ture of bee-cellars, yet I must take exception to the remark that, "Somehow I am becoming impressed with the idea that a great part of our wintering troubles comes from upward ventilation in hives." My experience in this climate where bees must stay in the cellar about four months of the year, has led me to just the opposite conclusion after an experience of five years in cellar-wintering.

I cannot keep bees in a cellar here for any length of time without up-ward ventilation, as they will become so damp that the water will run out of the hive-entrances, and the combs will become so wet that the bees will become diseased and die. Almost every year, until this year, I have put into the cellar some colonies, from some cause either small colonies or covered with quilts (I use board-covers), without upward ventilation,

and in every case water was sure to run out of the hive in a short time; while other hives by the side of them, with upward ventilation, were all right.

In the fall of 1884 I had quite a In the fall of 1884 1 had quite a number of very small colonies—so small that they ought to have been doubled up, but I was very busy and was not aware of their condition until it was too late to unite them; thinking that they were so small that they would not need upward ventilation, I put them (16 in number) into the coller without moving the into the cellar without moving the covers forward one-quarter of an covers forward one-quarter of an inch, as in my practice for upward ventilation; the result was that every colony had water running out of its hive in a short time; and when the covers were moved forward, the water stopped compresent of the bins in her stopped coming out of the hive in less than 24 hours, which I find to be the result every time.

My conclusions are that the cellar wants but little ventilation, and outside air let into the cellar when there is much difference in the temperature, is sure to arouse the bees and do harm. But keep the entrances open, with reasonable upward ventilation so that the moisture will not accumu-late in the bive, and the bees will be all right.

Concerning the temperature of cellars: My bees will be quiet at from 40° to 43° above zero, but above that point they are uneasy, and get worse as the temperature is raised.

### Bees on the Great American Desert.

#### D. M. IMLAY.

A few years ago people said that "bees won't do any good in this country." Well, I did not dispute it, for I did not know anything about it; hut some soon began to try keep-ing a few bees, and this " Desert " will soon begin to export honey instead of importing it. In 1881 I obtained a colony of bees in a Langstroth hive (luckily), and subscribed for the *Kansas Bee-Keeper*, and afterward for the BEE JOURNAL. Then I went to school two years and did not do much with bees except to get stung and bedaubed with honey; but I will sub-mit my reports, which are as follows:

In 1881 I increased my apiary from 1 to 2 colonies, and got no honey; in 1882 I increased it from 2 to 4 colo-1882 I increased it from 2 to 1 oney. nies, and secured 100 pounds of honey. I lost one colony in the spring; I think that it was queenless, but I did not know it then. In 1883 I increased my apiary from 3 to 11 colonies, and I lost 4 colonies and bought 8. In 1884 I began with 15 colonies, increased them to 39, and secured 800 pounds of honey. I lost 8 colonies and bought 1, and 2 1-trame nuclei. In 1885 I began with 34 colonies (nominally), increased them to 70, and obtained 1,800 pounds of extracted honey, and 500 pounds of comb honey. With my present ex-perience, and with the bees in about

50 hives, I could have gotten nearly double that amount. The colonies were very weak in the spring to begin with, and they got scarcely any honey until the middle of June, and then only enough to keep up brood-rearing until about the middle of July. After that they got no more until about the middle of August, when they began on buckwheat, and from they bught heart's ease; from these two plants we get our surplus crop. I had only 3 or 4 colonies ready at the right time to take advantage of the flow, but all of these gave over 100 pounds each.

A neighbor had 10 colonies in the spring, increased them to 25, and took 2,500 pounds of honey. He said that he could have taken 1,000 pounds more, had he been at home. It was extracted before being capped, and as I handled some of it, I can say that with the mercury at 50° Fahr., I could take up 2 pounds of it on a large spoon. I would like to ask Mr. Doospoon. I would like to ask Mr. Doo-little if such honey should be left on the hive until capped before extract-ing. The honey was put in screw-top cans as soon as extracted.

I sell all of my honey in the home market, by using pails, and by the means of a sign on my shop. At a very little expense I think I can sell 10,000 pounds next year without leaving our own town, which has about 2,000 inhabitants. This matter of creating a local market cannot be too strongly urged by our lights in apiculture.

My experience in apiculture has been very limited, as I have farmed and worked at other thiugs most of the time, but I may in the near future devote my whole attention to bee-keeping. I rescued 2 colonies from the brinstone-pit, and bought 23, theu sold one, and brimstoned one that was queenless. During the fine weather in December the others fell weather in December the others fell to robbing, so my apiary now consists of 93 colonies.

Last year I had some trouble in feeding bees. Will some reader of the BEE JOURNAL say whether the following would be a good bee-feeder or not? Take a solid bottom-board and run saw cuts one-half way through the board,  $\frac{1}{3}$  of an inch wide and almost across the bottom; then if the hive tips a little forward and the feed is poured in through a slant-ing hole in the rear of the hive by means of a funnel, the syrup will run toward the front of the hive, filling the saw cuts. In this way a bottomboard could be made to hold a pound of syrup. Is it good, or not?

Last March I moved my bees about 75 yards without loss. They had a good flight the day before, and were moved in the morning and had a flight soon after; the only precaution taken being to disfigure the old place and lean something up in front of each hive.

In looking over the apiarian cata-logues that I have, I noticed that whenever anything is said on labels for honey about candying, it reads like this: "All pure honey will candy," or "It will candy on the approach of cool weather." Well, I wanted some labels, but my honey

would not candy, and I could not tell would not candy, and I could not tell my customers that my honey would not candy; so I had some labels printed with a note commencing, "If this honey candies," etc., leaving a doubt in the matter. Now I know that all pure honey will not candy on the approach of cold weather, for the greater part of mine on hand is clear vet although some has candied; and yet, although some has candied; and last year it candied more slowly still. I have known some honey to go over until June and still be clear, and that the best grades of heart's-ease honey. The neighbor mentioned above expressed his surprise at its not being solid by Dec. 1, but this was his first year in Nebraska, and will be his last, as he possessed the true Heddonian spirit and wanted to leave me the field; (but rather, he wanted to go to Kansas)

Now I have told some good things about bee-keeping in Nebraska, and I ought to tell the other side. There is nothing for bees in June, and a great many have died of starvation just as our Eastern bee-keepers were being almost flooded with white clover and basswood honey; but clover is mak-ing rapid strides for the West. Seward, Nebr.

For the American Bee Journal. Strong Colonies for the Honey-Harvest.

#### C. THIELMANN.

There is much said by some of our most able apicultural writers, about having the colonies the strongest or most populous "at the right time," or for the main honey-flow, thereby securing the most available honey harvest. This would be no secret to the majority of bee-keepers, if they could only know the time when that large honey-flow would come, or if some of the writers could tell them of its coming every year, so that they could prepare for it and have their bees strong for the harvest.

There may be some localities where the main honey-flows come regularly at the same time or about the same time of the season; but from nearly all the reports and accounts that we read, and also from my own experi-ence during the past 17 years, this rule, on the whole, has not proved to be true. The main harvest here has come only 3 or 4 times at about the same time of the year, all the others having come either before or after the above-mentioned time, though all of them began from the middle of June to the middle of August, excepting one, which began on Aug. 22 and continued till Sept. 23, and gave me a surplus of about 3,500 pounds of honey. In a number of years there was a honey-dearth, when at about the same time of other years we had the best honey-flows. One year I had to feed about 20 colonies of the less stronger ones, to keep them from starvation, with abundant white

clover in bloom, too. I am sorry to say that I have not as yet reached that excellency of api-

year, when the largest honey-flow is coming. I have learned how to win-ter my bees best, but as yet I have failed to learn when the best honey-flow will be here. I would be very grateful to any of our fellow-beekeepers if they would tell me every year when my honey-flow will be at hand. It seems to me that this is one of the questions that can no more what the weather will be in the future; therefore I think that it is best, for the majority of bee-keepers to keep their bees as strong as they can all summer, so as to reap the harvest whenever it does come; and it surely will do no harm if the colonies go into winter quarters strong in bees. I also find that the strong colonies stand a honey-dearth a great deal better than do the weaker ones; therefore I fail to see any advantage in this latitude, with so many different honey-producing flowers at times, to prevent or lessen the increase of our colonies at any time in the summer; and, as a rule, they lessen enough themselves in winter and spring. I can never get my colonies too strong, but sometimes 1 fail to have them all strong enough.

Here white clover is generally abundant, but in some years it fails to yield much honey, and other years it yields plentifully. Basswood is also abundant, and blooms about the same abundant, and blooms about the same time as it does in Mr. Doolittle's locality, but we have more failures from it than honey-flows. Corn generally comes immediately after basswood, but on an average it does not yield honey here once in 3 or 4 years. L was much surprised to read years. I was much surprised to read that Mr. Doolittle had never seen bees gather honey from corn; if he had gather honey from corn; if he had been here the past summer, I could have shown him where they gather it. My bees stored about 1,000 pounds of honey from it, with which they finished about 2,500 partly-filled sec-tions of the linden honey. It is the best and finest honey that they stored. If I mistake not, the last was the fourth season that my bees have fourth season that my bees have gathered honey from corn (any amount worth mentioning) in 17 years. It is of a yellow whitish color, and can hardly be distinguished from the color of the red clover honey. All of it was very thick, and had a fine, smooth taste and aroma, being free from any after-taste.

In the season of 1884 my bees gathand very fine honey it was, too. It was no louse honey, either; nor was it gathered from the blossoms of the trees. When I examined it I was almost convinced that what ancient bee-men have said was true, viz: "When it honeys even the stones will yield honey." The honey from the birch was gathered in June, on the young twigs at the joints or junctions where the leaves connect with the twig. There was a little leaf or cup on each side of the junction, which contained the honey. I had never noticed this before, nor did I see it

August from horse-mint. I am not able to say whether I ever got any honey from that source before that or obtained any since that with large quantities of horse-mint bloom within 80 rods of my apiary the last two seasons.

Under the above circumstances the readers can see that a certain time of the season could not be ascertained in which to have our bees in prime con-dition; nor would the subtractionplan be of any advantage, as we do not know when the main harvest is coming.

Thielmanton, Minn.

For the American Bee Journal

Ventilation and Temperature in Winter.

#### C. W. DAYTON.

As a specialist in the bee-business, I endorse nearly all of the article on page 5; however, I would differ slightly by giving upward ventilation and maintaining a temperature of 43° and maintaining a temperature of 43° or 44°. Some way or another I have failed in wintering bees without up-ward ventilation, though I have had moderate success by contracting the brood-chambers so that it would be entirely filled with bees. Virtually, this would be upward ventilation, there being a draft passing out at the bottom of the hive. bottom of the hive.

While hibernation may be (and I believe that it is) a key to the winter problem, the old difficulty remains, viz., failure in making the bees hiber-nate not only in the forepart of the winter, but in the latter part also. To make bees hibernate for a time is an easier task to perform than it is to follow them up and find out what caused them not to hibernate. Each of these tasks I think that I have to some extent accomplished, and to give an idea to what extent, I might state that in an August number of the BEE JOURNAL for 1885. I related how, in the previous fall, I prepared 60 colonies with upward ventilation and 40 colonies with upward veneticity tilation, to be wintered in the same cellar; how in mid-winter I found moisture on the under side of the covers over the cluster of the unventilated colonies; and that on May 1 the 40 colonies were nearly all dead, while the 60 remained healthy. Again, last fall I prepared 111 colonies with ventilation and 1 without ventilation, and placed it in the same cellar with the III; at this time that solitary colony is afflicted with disease, while all the others are healthy.

Let beginners not be led astray in the belief that upward ventilation or downward ventilation, high temperature or low temperature, natural or artificial stores, comprise all and the only requirements for successful win-tering, as it will be found that they are only a few of the many factors to be considered. The soonest way of finding out the necessary factors for I am sorry to say that I have not last year. as yet reached that excellency of api-culture to know just exactly every larger part of my surplus honey in lose bees with the rest of us, and

then, if they have been persevering and economical enough to have maintained a subsistence in the face of Borean winters, light crops and low prices, they will stand a chance, at least, of being able to truthfully say that they know which are the neces-sary factors in wintering, and can winter their bees successfully.

At this time it seems as though location may have something to do with the condensation of moisture. I always had supposed that the condensation of moisture was common in all countries where the wind blows and the rain falls. In the fall of 1882 1 placed in the cellar 13 colonies that praced in the cellar 13 colonies that were in large observatory hives. Through the glass I watched daily, from Nov. 9 to April 12, the actions of the bees. There was no upward ventilation given, and they had been in the cellar but a short time before the glasses were driver with weith the glasses were dripping with mois-ture, and water ran from the combs. I saw individual bees leave the cluster and sip moisture a great number of times. On April 12 but one hive con-tained live bees, while on the bottom-boards of the others there was mold, moisture and dead bees fully two inches deep, and all the characteristics of disease were present. The hive containing live bees differed from the others in having two  $1\frac{1}{2}$ -inch holes about 4 inches from the top. Were bee-keepers as apt to re-port failures as successes we would have more abundant evidence that this case is a fair example of the condition of hives where the bees die with disease.

From the writings of certain bee-keepers who winter bees with success without upward ventilation, in tem-peratures varying from  $40^{\circ}$  to  $70^{\circ}$ , it is made to appear as proper to let the bees arrange the ventilation, and store them in the store that is the store of the store them in any moderately warm repository. In my case, and as also in the case of neighboring bee-keepers, such management has always proved very disastrous. For all of our skill we can figure no difference in effects in can figure no difference in effects in warm temperatures, except as bear-ing relation to moisture. Though we have been moderately successful in wintering bees packed with some porous substance, like the inquisitive Yankee we wish to know why every one cannot winter bees successfully without upward hive-ventilation, as does Dr. G. L. Tinker, H. R. Board-man, or Ira Barber. Bradford  $\measuredangle$  Lowa

Bradford, & Iowa.

For the American Bee Journal.

# Care of Bees in Winter.

#### J. H. ANDRE.

I have noticed in the AMERICAN BEE JOURNAL and elsewhere that bees, after they had been prepared for winter, should not be disturbed until whiter, should not be disturbed until spring. Perhaps this advice will be followed by some beginners, and when spring comes, and an examina-tion of the bees is made, several colonies may be found to have died from starvation, or from some other

trifling cause which might have been easily remedied if the bees had been examined every two weeks.

My bees are wintered in a fruit-andvegetable cellar, that is visited with a light from two to four times per day. I also remove the dead bees from the hives every two weeks, and their humming may be heard at all times; towards spring it becomes a continual roaring, and yet my bees always win-ter well. I have had them breeding six weeks before they were taken from the cellar, and such colonies were the best of all. I put the most of my bees in for the winter as early as Nov. 15, last fall, and the balance 1 left out until Dec. 11, hoping that they would get a flight. Some that I had fed liberally were put into winter quarters without their young bees having a flight. This will be a test case, and if nothing prevents, I will speak of it again next spring.

Owing to poor health, and an in-ability to give my bees proper care, I found that one was queenless and had died, the cold weather of November having been too severe for their thin ranks, and the last survivors had the diarrhea. I suppose that some would say that it was pollen that caused it. What a pity it was not one of the latefed colonies, so as to make it sure.

Lockwood, 9 N. Y.

#### -----Convention Notices.

The Northeastern Michigan Bee-Keepers' Association will hold its 4th aunual meeting on Wednesday, Feb. 3, 1886, in the Common Council Rooms at East Saginaw, Mich. The Sherman Honse, one block from the place of meeting, will entertain those present, at \$1.00 per day. Saginaw people are working hard to make the meeting a success. Let us all go and show them that we appreciate their efforts. W. Z. HUTCHINSON, Scc.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. M. HANBAUGH, Scc.

Ar The Seventeenth Annual Conven-tion of the New York State Bee-Keepers' Association (formerly the Northeastern) will be held in Rochester, N. Y., on Feb. 16, 17 and 18, 1886. This will be one of the largent meetings ever held in the State. A large number of our most experienced bee-masters will take part in the discussions, and several essays will be read from a number of our most practical aplairists throughout the country. The programme is complete. If you are young in the work you can not afford to stay away—if older, you may give some good hints, if you get none. We want a good display of all kinds of supplies and fixtures. We have a room on purpose for exhibits, and any goods sent to the Secretary in care of the "Na-tional Hotel," Rochester, N. Y., will be placed on exhibition, and either sold or re-turned to the exhibitor, as directed. Re-duced rates at the hotels have been secured, also rates on some of the railroads. All will have to nay full fare one wav-retart AT The Seventeenth Annual Convenduced rates at the notels have been secured, also rates on some of the railroads. All will have to pay full fare one way—retarn ticket at 1-3 fare by presenting certificate from the Secretary, who will furnish them on application. We want an active vice-president in every county in State. Please name one or send the name of some one, for your county. for your county.

F. C. BENEDICT, SEC.

time and place of future meetings .- ED.

Bees Wintering Grandly.-J. E. Cady, Medford, 9 Minn., on Jan. 15, 1886, says :

We are snowed in up here with 2 feet of snow on the level. My bees are wintering grandly in a temperature of 48° above zero.

Bees did Well,-J. J. Hopkins, Brookside, 5 Pa., on Jan. 2, 1886, says :

My bees did very well for this neighborhood, last year. 1 had 39 colonies last spring, and I extracted 1,160 pounds of honey from 10 of them, from the balance; besides increasing my apiary to 55 colonies.

Learning by Experience.-Rev. Weisel Beale, New Madrid, Mo., on Jan, 19, 1886, says:

This is my fourth year of bee-keep-ing. I have learned some things by paying for them! Yet I feel a grow-ing interest in the business. I will ing interest in the business. I will start in the season of 1886 with 15 colonies, I had about that number last fall, but I had to part with all but 4, which I transferred to this place when I moved from Shawnee-town, Mo. I take great pride in my bees and love them. My hives are all nicely painted and equiped. About next year my experience will have ripened enough for me to pre-sume to render an onlyion on some of sume to render an opinion on some of the important questions of the day in apiculture.

Extremely Cold Weather.-G. M. Doolittle, Borodino, ON. Y., on Jan. 14, 1886, says :

We have just passed through the coldest week ever known in this locality by the oldest inhabitant. The mercury scarcely reached as high as zero during the entire week, and was as low as 15° to 30° below zero much of the time. On one day the sun shone brightly all day, but the mer-cury stood below zero all through the day. Such cold on a clear, still day was never before known in central New York.

Bees in Good Condition, etc.-P. B. Thaxton, Blue Springs. + Mo., on Jan. 18. 1886, savs :

In the fall of 1883 I bought 6 colonies of bees. I have held my own very well, having now 120 colonies in apparently good condition. I have made but little money in the business, still I am not discouraged. I have read Prof. A. J. Cook's and Henry Alley's works on bee-keeping, which I consider very good, but the AMERI-CAN BEE JOURNAL has been worth more to me than everything else. could not do without it. The article on page 6, by Mr. G. W. Demaree, is worth money to me. I am through feeding sngar syrup to my bees. All who have not done so, should read that article, and then work in the interest of the honey market, and, as Mr. Demaree says, "Let the sugar market take care of itself."

Bee-Keeping in W. Virginia.-W. B. Zinn, Holbrook, W. Va., on Jan. 12, 1886, writes:

Last spring we had a fine apple bloom here in W. Virginia, and our bloom here in W. Virgina, and on bees did finely while it lasted. They gathered some honey and got a good start in brood-rearing. After that was gone they had scarcely anything for a while. We had no white clover bloom. The past summer was too dry for bees to gather very much honey. We had some red clover that the Italians worked on. The black-gum bloom was good and the bees made good use of it. The linden-bloom was pretty fair, so the most of the old colonies gathered enough to winter on and some little to spare. I had 21 colonies last May; during the season I had 9 natural swarms and I made 13 I sold 4 colonies and 4 nuclei, nuclei. which left me 35 colonies. My swarms and nuclei did not gather any honey to winter on. In October I commenced to prepare them for winter. I doubled them back to 25 colonies, and have them all in chaff hives with chaff cushions on them. They were all in nice condition up to the past week. The bee-business has been pretty dull here for the last 2 seasons; some lost their bees last winter, and last summer being so dry, some have become discouraged. I winter my bees on the summer stands.

Heavy Frosts in Florida.-Jno. Y. Detwiler, New Smyrna, Fla., on Jan. 11. 1886, says :

The heavy frosts in this vicinty have utterly ruined our prospects for the coming crop of mangrove honey. The mercury is reported by various parties as being as low as 10° to 20° above zero. Fish have been frozen by the thousands, green turtles are desting on the surface perfectly be floating on the water perfectly benumbed, and oranges are frozen as hard as chunks of ice. There has been nothing like it since 1835, when the mangrove was entirely annihilated. On the Peninsula the mercury was 20° above zero. I will report later, as to the extent of damage, when this " cold snap " moderates.

Amiability of Italian Bees.-Peter. Billing, Pawnee City, ~ Neb, on Jan. 15, 1886, says :

I am somewhat in darkness concerning the amiability of Italian bees. I have often heard and read that Italians were more gentle than the common bee, but with me this has so far proven the reverse. About 7 years ago I began with the common bee, and soon I could hive and handle them without much smoke or protection; but after a few years they be-came hybridized, and were ugly things to handle. So I concluded to Italianize them; but the bad temper has by no means subsided. They have their 3 distinct yellow bands, are good honey-gatherers, fast to increase, and I might say moth-proof ; but wee unto the man that jars the hive or unto the man that jars the live or comb when manipulating, or crushes a bee, or blows his breath among them! for sometimes, seemingly with-out any cause, they will dash forth and attack one furiously. I would like to have some light thrown upon this subject through the JOURNAL.

The bees are evidently cross hybrids; not Italians.-ED.]

#### Decreasing Breeding, etc.-C. P. Dadant, Hamilton,+o Ills., writes :

On page 25, Mr. C. W. Dayton seems to be of opinion that the breeding should be decreased 37 days before the end of the honey harvest. Т wish to warn the reader against too early a decrease of breeding. First, young bees are needed in the hive for nurses, comb-builders, etc., till the end of the harvest, or else older bees will have to remain at home in their place. Again, apiarists never know the exact date of the beginning, much less of the ending, of the honey crop, until it has taken place. It is safe to say that the apiarist who will try to forsee the date of the closing of the crop 37 days ahead, and decreases the breeding in anticipation, will, as a rule, be unsuccessful. Again, in Illinois and many other States there Again, in are two crops-the clover crop and the summer or fall crop. Mr. O. N. Baldwin mentions them on page 24, but he thinks that they are shorter than the real average of the past 20 years. The date of these crops is not fixed, and it is very difficult to be always pre-pared just in time, unless the beekeeper remains fully prepared through the season. To sum up my views: Keep the colonies strong at all times, but have them the strongest during the flow of honey.

Red Clover Italians, etc.-Isaac M. Myers, Millersburg, & Ind., on Jan. 12, 1886, writes :

1 purchased a colony of red clover Italian hees last spring, and 1 find that they are very quiet bees, and the honey is nicer than any that I had in 1884. I got 5 colonies from the one weak one. About half of the bees of the colony were dead when I received them, and I am wintering 6 colonies of the red clover Italian bees. I think

that we should work to rear a bee that has a long proboscis, as well as for purity. Their honey is very clear and thick, and tastes nearly the same as bumble-bee honey, which is gath-ered from red clover and thistles. I find that they work largely on red clover. I will give my cure for bee-stings. I have been stung a great many times, and it swells on me nearly like a rattle-snake bite. I did use tobacco on it to draw the poison out at first, but one day I had some alum in my pocket and I thought I would try it; I found that it did not swell hardly any after I wet the alum and rubbed the place where it was stung.

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a.m., Jan. 25, 1886. {

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.—There is an easier tone to the comb honey market, and prices are fully one cent per pound less than at last quotations. 15c. being the price for white comb honey in 1-lb. sections, and some extra nice brings 16c. This is owing to small lots coming ioto different commission houses, and all heing eager to sell, they underbid regular honey houses in order to do so. Extracted honey brings 6@%c. per lb. BEESWAX.—24@20c. K. A. BURNETT, 161 South Water St.

NEW YORK. HONEY.-The market for honey continues dull, and prices are ruling lower; bowever, if the cold weather continues, it may improve the trade in a sbort time. We quote as follows: Fancy white comb in 1-b, paper cartons, 13@14c; the same in 1-b, glassed or unglassed sections, 12@13c; the same in 2-b, glassed sections, 9½@11c, and in un-glassed 2-lbs, 11@12c. Buckwheat boney in 2-lb. sections, glassed, 9c; in 1-lb. sections, glassed or unglassed, 10@11c. Extracted-white clover el/ewc.; huckwheat, 5½@646. BEESWAX.-Prime yellow, 26@28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

#### ST. LOUIS.

HONEY.—The market is quiet and the demand light just now. We quote prices as follows:— Choice comb honey, 10@12c. Extracted, In bar-rels, 4½65c. Extra fancy of bright color and in No. 1 packages, ½ advance on above prices. BEESWAX.—Firm at 22½c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEY.—There is a very slow demand from manufacturers, for extracted honey, with a large supply on the market, while the demand is very good for clover honey in square glass jars. Prices for all qualities are low and range from 48Sc a lb. Supply and demand is fair for choice comb honey in small sections, which brings 12@35c, per lb. BEESWAX.—Good yellow is in good demand, and arrivals are fair, at 20@22c, per lb. C. F. MUTH & Son, Freeman & Central Ave.

#### CLEVELAND.

HONEY.-The market is not quite as active as It has been, owing, no doubt, to many attractions of the Holiday Season. Best white, 1-1b. sections sell at 15c, and 2-1bs. for 13@14c, but there is not so much sale for the latter. Second grade honey is dull at 12@13c. Old white, 10@12c. Extracted, 7@8c, per lb.

asc. per lb.
 BEESWAX.—Very scarce at 22@25c.
 A. C. KENDEL, 115 Untario Street.

#### KANSAS CITY.

HONEY.-Sales are extremely light and prices are very low. Choice comb honey in 1-lh. sections brings 14@15c; 2-lbs., 12@13c. Dark fail honey 1 to 2 cents less. Extracted honey 1s very dulland of slow sale. We had to unload a lot of very fine ex-tracted honey this week at 5c., and stocks continue to accumulate. BEESWAX.-Scarce and higher-22@25c. CLEMONS, CLOON & Co., cor. 4th & Walnut.

#### BOSTON.

HONEY.--It is selling very well but prices are very low, and we are often obliged to shade our prices in order to make rates. We quote comb honey in 1-lb. sections at 14@16c, and 2-lb. sec-tions at 12@14c. Extracted, 6@8c. BEESWAX.--30 cits. per lb. BLAKE & RIPLEY, 57 Chatham Street.

60

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

> ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

The NEW Heddon Hive.-We have made arrangements with the inventor, by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat. Further announcement will be made hereafter, giving prices, etc.

THOS. G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL.

Cor rates for two or more eopies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

To Correspondents. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

" Don't Stop "-that is what many write to us about their papers, when their time is nearly ont. One subscriber says : "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It rnns ont with this month; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

The 'Time for Reading has now come. The long winter evenings can be utilized by reading up bee-literature. We have all the newest hee-books and ean fill all orders on the day they are received.

Preserve your papers for reference. If you have no BINDER we will mail you one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

When Henewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a Hinder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few hours, to get subscribers.

Beeswax Wanted.-We are now paying 24 cents per pound for good, average, yellow Becswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be put on every package to prevent mistakes.

Agents can sell the Guide and Hand-Book like "hot-eakes." Send us an order for five copies (with \$2,50) and we will send you the Weekly BEE JOURNAL free for a year. This is a rare opportunity to get the Weekly BEE JOURNAL without cost ! ]

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview by sending the names to this office, or we will send them all to the agent.

The Guide and Hand-Hook, is a book of ready reference and an encyclopædia of everything desirable to know. As a gnide to the home-seeker, it is invaluable. Its contents are partially given on page 64, and will convince any one of its value. We do not think any of onr readers can afford to do without it. As a book of ready reference we find it of great value in our library. We will send the Weekly BEE JOURNAL for a year and the Guide for \$1.30

The proceedings of the North Ameriean Bee-Keepers' Convention at Detroit are published in pamphlet form. A copy will be sent free to each paid-up member. All others who desire can secure a copy on the payment of 25 ets. F. L. DOUGHERTY, Sec. Indianapolis, Ind.

Knitting and Embroidery,-We have received from the publishers a handy little book, entitled "Knitting, Crocheting and Embroidery," which gives full instructions to all who desire to become successful workers in the art. It contains 70 illustrations and 84 pages, bound in paper eover. The book will be sent by mail to any address for 15 cents, by J. S. Ogilvie & Co., Publishers, 31 Rose Street, New York.

Perforated-Zinc.-We have laid in a stock of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstrotb bive-1934x1412-Price 25 cents cach.

All the Numbers from the beginning of the year are sent to new subscribers, unless otherwise ordered.

The Initial Chapters of "The Heir of the Ages," a thrilling and mysterious lovestory, by James Payn, appears in the Illustrated Graphic (Cincinnati), commencing Saturday, Jan. 23. This is said to be one of the most interesting stories ever published.

To show the high appreciation in which the Graphic is held, it may interest many of our readers to know that the Nonotuck Silk Company, famous for its Cortieelli and Florence Silks ; the Emerson & Fisher Company, large earriage manufacturers, and the John Shillito Company, all leading houses of Cincinnati, occupied the choice pages of the grand holiday number of that paper, paying the sum of several hundred dollars per page.

The Graphic will issue, on May 1, a grand mid-summer number, which will he far ahead of anything yet published.

To any One sending us one new subscriber with their own renewal (with \$2.00), we will present a copy of the new "Convention History of America."

Are you Entitled to a pension? You may be and may not know it. If you examino the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Gnide Book will both be sent for \$1.30.

237 The Eastern New York Bee-Keepers' Association will hold its annual convention in Agricultural Hall at Albany, N. Y., on Tucsday, Wednesday and Thursday, January 26-28, 1886. The first session will begin on Tuesday, at 2 p.m. All interested in bee-keeping are requested to attend, and bring apiarian snpplies for exhibition. The pro-gramme will consist of essays on important subjects, discussions, etc. gramme will consist of the subjects, discussions, etc. E. W. PHILO, Sec.

#### A FASCINATING PURSUIT.

A FASCINATING PURSUIT. Queen-rearing is a fascinating pursuit. Every bee-keeper should rear a few queens for amusement and experiment. The best method for rearing queens may be found in the third edition of **The Bee-Keepers'** Handy-Hook, a work of 300 pages and 100 illustrations. Of this treatise on bee-culture, Mr. Langstroth says: "It certainly is the best authority on this important braneh of bee-keeping. You bave done more, in my opinion, than any one else to faeilitate the breeding of eholee queens, and to simplify the process by which those who breed such queens either on a large or small scale, can make the most of all time they devote to this important branch of bee-culture." The hook is handsomely and substantially

The book is handsomely and substantially bound in cloth, and sent by mail for \$1.50

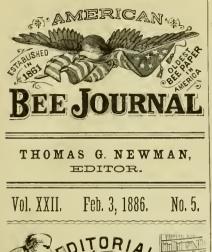

Prospectns and price-list of queens and snpplies sent free. Address,

4Etf HENRY ALLEY & CO., Wenham, Mass.

### THE AMERICAN BEE JOURNAL.

62

The Heddon Hive bas been placed in

our Museum, and we have made a pretty thorough examination of it. It suggests the handling of hives instead of frames, thus lessening the labor of bee-keeping, enrtailing the expense of honey-production, and adding to the profits of the apiarist. It and the system of management for which it was constructed, presents a "new departure" in many essential points, and will doubtless receive a thorough discussion by the correspondents of the AMERICAN BEE JOURNAL.

As it is claimed by some that the hive and system of management will cause a "revolution in bee-keeping," it becomes the prerogative of the aplarists of America to give the system a critical examination. This should be discussed in a friendly manner, with the sole object of arriving at the truth, and neither *prejudice* nor *interest* should be allowed to influence any opinion. Only a calm and deliberate discussion, *after* a thorough investigation of the merits or demerits of both the hive and system, can be of any value to apiarists generally.

The "claims" which Mr. Heddon makes on his system, are to be found on page 73, and to these the readers are referred in order to obtain a right understanding at the start.

Mr. Elias Thomasson, a bee-keeper of Louisville, Ky., and one of our subscribers, died of apoplexy at 9:30 a.m., on Jan. 11, 1886, in the 76th year of his age. After eating a hearty breakfast, be started out to give his little grandchild a ride on her sled. They went into Dobbin's drug-store to get warm. Suddenly he began to stagger, and before belp could be given him, fell upon the floor. Everything possible was done for him at once, but in a few moments he was dead.

**Two new Bee-Papers** are received :-The Bee-keepers' *Index*, an 8-paged monthly published at 25 cents a year, by W. P. Beach, Ovid, Mich. : and *Rays of Light*, a 12-paged monthly. published at 50 cents a year, by J. J. Martin, North Manchester, Ind.

The Convention Pamphlet is well received. The following is a sample of scores of letters received concerning it:

BRO. NEWMAN :--The History of the North American Bee-Keepers' Society has come to hand. I an glad you have the enterprise to put in compact form what may be very valuable for reference in the future ; and while on the subject of enterprise, allow me to congratulate you, first, on being the pioneer to publish a weekly bee-paper, and secondly, on reducing the price so that no bee-keeper can afford to do without it.--C. C. Miller, Marengo, Ills.

Yon have doue a great amount of work to produce such an important and interesting work. It should be in the library of every bee-keeper. It contains much valuable matter.—H. D. Cutting, Clintoo, Mich.

You certainly deserve much credit for crowding so much of the early history of the Society into so few pages, and those who wanted the proceedings of the Detroit Convention published in pamphlet form, can now receive it in excellent shape, and there will be no more trouble in hunting over several papers to find the whole proceedings.—W. Z. Hutchinson, Rogersville, Mich.

We commend your enterprise in getting up so valuable and interesting a work.— Clemons Cloon & Co., Kansas City, Mo.

lt is a valuable publication.-W. T. Falconer, Jamestown, N. Y.

The "History of the North American Bee-Keepers' Society," etc., is received. I am delighted to have so great amount of matter of interest, relating to apiculture, condensed into so small a space for reference. Notwithstanding I bave very nearly a complete file of the AMERICAN BEE JOURNAL, extending back to its first issue, I am none the less delighted with the "Brief History." -G. W. Demaree, Christiansburg, Ky.

You have my thanks for preparing the "Brief History of the North American Bee-Keepers' Society." It will save valuable thme in hunting up references; is well edited, and the typographical execution is excellent.—Mrs. L. Harrison, Peoria, Ills.

The Convention History is at hand. It is a very nice book, indeed, in every way, and cannot fail of being appreciated by all those interested in Conventions.—G. M. Doolittle, Borodino, N. Y.

New Price-Lists have been received from the following persons :

Deere & Co., Molioe, Ills—120 pages— Plows and Cultivators. It is an elegant production, artistically and typographically considered.

A. C. Nellis & Co., Canajoharie, N. Y.-96 pages-Floral and Garden Seeds.

Joseph Harris, Rochester, N. Y.-72 pages -Vegetable and Flower Seeds.

J. B. Mason & Sons.Mecbanic Falls, Maine. --50 pages--Italian Bees, Queens, and Apiarian Supplies.

E. T. Lewis & Co., Toledo, O.-32 pages-Honey Extractors, Smokers, Foundation, Hives, Sections, Crates, etc.

C. F. Muth & Son, Cincinnati, O.–32 pages –Bee-Keepers' Supplies.

J. T. Fletcher, Clarion, Pa.-8 pages-Bees and Poultry.

Wm. Henry Maule, Philadelphia, Pa.-56 pages-Seeds of all kinds.

Any one desiring a copy of either of them, can do so by sending a postal card to the address as given above.

**The Convention History of America** and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.15.

We respectfully call the attention of every subscriber to the seed advertisement of JAMES J. H. GREGORY, Marblehead, Mass. His large and complete catalogue is sent free.

The Rev. Robert West, editor of the Advance, of this city, to whom reference was made on page 19, in that paper of Jan. 21, acknowledges the receipt of our demaul for a "full retraction and apology," but instead of doing that, makes another charge from a correspondent who says he has "reason to believe that there was an establishment on —— street In Chicago that manufactured bogns honey," and gives this as the modus operandi:

"It was said to be done by extracting the genuine honey from the comb with the machines In common use for that purpose, then placing in a sunny room the comb, a number of shallow dishes of cheap sugar, glucose, molasses and water and a swarm of bees! It was said that the industrious bees, rather than remain idle, would go to work and place the above mixture in the empty comb, but it was of course not honey, although apparently put up in genuine packages."

The *Reverend* gentleman also alleges that he is "familiar" with the "room" where this is done, but adds that "the room is not now so sunny as it might be, and there is reason to surmise that cheaper carriers have been substituted for the bees which the writer mentions."

The first witness brought forward only says he has reason to believe that there is such an establishment, and that it was said to be done in the manner mentioned. He knows nothing about it, except hear-say, and frankly says so; but the Rev. Robert West says he is familiar with the establishment, and surmises that they have found a substitute for the bees !!

Now, Mr. West should be *honest* enough to mention the street and number, and give the name of the proprietor. This he can do, for he is *fumiliar* with the establishment! We demand the facts !! A elergyman should be *honest*; and should be ever ready to "tell the truth !!" Surmising will not do for proof.

In the first article on Dec. 31, 1885, Mr. West asserted positively that "men have learned not only to manufacture the comb, ....but now fill it, capping the so-called boney-cells by machinery," etc.; but when asked to "retract" or "prove" the assertion, he drops the "machinery" part, and elaims that the bees do the work, and are the adulterators !! He dodges the issue !

We affirm most positively that the Reverend gentleman's assertion about comb being made, filled and eapped by machinery, is a base fabrication; and we thus publicly DEMAND the proof, or a full retraction and apology ! Dodging the issue ; surmising : or bringing witnesses who "have reason to believe" this, that or the other thing ; or averring that "it was said to be done" by some unknown person, will not answer! Give us the plain, naked, absolute facts-the proof. Now it is Mr. West's turn-let him speak out ! Either prove the assertion, or prepare to defend a suit for damages done to the pursuit of bee-keeping, by his bold and base assertions !

We deprecate adulterations of all kinds, and would favor a law to put adulterators in the pillory, or flog them at the whippingpost; and we also detest those who show their ignorance at every turn, by denouncing hnnest products, and injuring an industry by their stupid or malicious blunders!

#### **REPLIES by Prominent Aplarists.**

# Origin of Honey, etc.

Query, No. 189 .- Where does the honey come from? Is it in the ground just waiting for the right kind of flowers to grow so that the atmosphere can pump it up through them? Is there any danger of its being all pumped out? Does the same combination of elements that makes plenty of honey, also make the sorghum-stalk and the sweetpotato sweet? Did you ever notice that poor honey years were poor sorghum years, and that the sweet-potatoes were not sweet? I know that it was the case here the past year. An old molasses-maker says that none of the sorgbum brought to the mill this year made more than halt a crop, and I know that our sweet-potatoes were not sweet, as in other years.-Vermont, Ills.

I will try and answer this in sections as asked: 1. From the nectar of flowers. 2. Yes. 3. No. 4. Nearly so. 5. I have never noticed any difference.-H. D. CUTTING.

Honey is made from the nectar of flowers, and is as thin as water when first collected. The nectar is a secretion by the nectarilerous glands of flowers. A proper humidity of the soil and warnith are among the conditions most essential to free nectar-secretion.-G. L. TINKER.

The honey comes from the ground the same as does the milk that Old Brindle gives. It is not unlikely that weather that would effect nectar-secretion might possibly effect caue and sweet potatoes. As I never raise cane, I am not authority on that point. When the cow pumps all the milk ont of the ground, then we may fear a dearth of nectar in the flowers. -А. Ј. Соок.

# Top-Storing.

Query, No. 190.-I am satisfied that I do not have sufficient room on top for surplus honey, and so I desire to ask whether side storage could he adopted successfully. My American hives have 10 frames, 12x12 inches. Could I not take out 3 or 4 combs at the heginuing of the basswood harvest and fill the space with sections, replacing the combs after the basswood harvest is over? Would the queen not use those sections for brood? If so, how could I prevent it ?-E., New York.

The plan could be successfully adopted, and the queen could be kept out with perforated zinc. Ilad I such hives I should change to such a style that gave an abundance of room for top storing.—W. Z. HUTCHINSON.

Look at Mr. Doolittle's articles in some of the past numbers of the AMERICAN BEE JOURNAL. He makes ponnds on each side, simultaneously a success of side-storing. 1 would with top-storage, and the side-storage

rather get new hives, if necessary, but by tiering-up you ought to be able, on your present hives, to have 200-pounds surplus room. Is that not enough ?— C. C. MILLER.

Wide-frames with sections may be used at the side of such hives in the manner indicated, and perforated-zinc or a slotted division-board used to keep out the queen. I have used just this arrangement with deep frames, but I do not like it.—G. L. TINKER.

Side-storing can be adopted, but it is not desirable; unless the sections are carried above for completion, they are not nice. The queen can be kept out by the use of a queen-excluding division-board. I think it much better to put crates of sections above, and tier up till all desired space is given,—A. J. COOK.

The queen would not get much chance here to use the side sections for breeding in basswood time. Queenexcluding metal would prevent her from reaching them at any time. I think that the removal of "3 or 4," or even 5 combs, after June 1, will be advantageous; and if once tried you will continually practice it thereafter. -JAMES HEDDON.

I should do as you suggest. With me, queens are not as apt to go into the side boxes as into those on top. Eight American frames are enough for any time of the year for a brood-apartment, and 5 would be ample when practicing the contraction method.—G. M. DOOLITTLE.

If you have not room on top, "make room ;" then if you cannot get it on top, cut down your frames. You can get honey stored in sections in the brood-chamber, but you do not want to ; at least you would not if you lived in my locality.—II. D. CUTTING.

My favorite remedy would be to get the bees out of such a hive as you describe, as soon as possible. But others will differ from me about this. With the cases I use in my apiary. either for holding sections or shallow frames, your hives could be "tiered-up" till your bees would have all the room they could utilize. "Side storing" as a system, in a large apiary is objectionable on account of disagree-able manipulation in the brood nest, and additional labor in many ways.-G. W. DEMAREE,

Side storing in American hives in sections has never been a success with myself. Perhaps it would prove more satisfactory in other localities. 1 can see no reason why room enough cannot be given by tiering up. 1 have tiered-up American hives 7 to 10 cases of sections high, and found that the bees would work well in the upper tier, if care was taken to protect them by blankets and quilts.—J. E. POND, JR.

If you use side-storing sections or crates you had better make larger hives, as your hives are not any too large for breeding. We tried side-storing for 5 years on about 60 American hives enlarged so as to take 20-

was a total failure, owing to the stor-ing of pollen in this side honey, and insufficient filling of the crates at the side unless the bees were exceedingly crowded. Your American hives ought to have 13 brood-frames; this would also increase your surplus top-room.-DADANT & SON.

# Closing in Bees with Wire Screens.

Query, No. 191.-What are your opiuious about closing bees in with wire screens? We use a modified Simplicity hive, with a portieo 3 inches deep, and when we put them into the cellar we covered the porticos with wire screens, the wire being 3 inches from the opening in the hive. We feel a little uncasy about them. There are 15 colonies. We saved 7 colonies out of 8 that were so prepared last year.-Linn Co., Iowa.

I am opposed to closing in bees, but if you keep the screen cleaned off you will have no trouble.—H. D. CUTTING.

Wire-cloth tacked over a portico would be less objectionable than to tack it directly over the entrance. I do not believe that either one is of service, except to keep out mice.—G. L. TINKER.

If the bees remain quietly in the hives without knowing that they are confined, it will make no difference; but if they discover that they are confined, and begin to worry, the results may be very serious.-G. W. DEMAREE.

I consider the screens worse than useless; just so much worse as is their cost and the labor of putting on. As a rule they will not effect the win-tering of the bees one way or the other as you have them prepared.—G. M. DOOLITTLE.

The screens prevent the dead bees from being scattered on the floor; aside from this I do not know what good they do. If they caused the bees to worry, trying to get out, I should remove them. I do not advise their use.—W. Z. HUTCHINSON.

We prefer to put the bees in the dark and leave the hives open. Those bees that go out die anyhow if confined. They leave because they are ill at ease. You may always expect to lose some bees that way in the cellar.—DADANT & SON.

I have never wintered bees in special depositories, but on principle, and from careful study of the experiments of those who have made it a success, I should advise leaving the entrances entirely unclosed, but keeping the depository completely and utterly dark.—J. E. POND, JR.

I was once in the cellar of Mr. E. D. Godtrey, of Red Oak, Iowa, and saw about a hundred colonies fastened saw about a finite colones fastened in with screens, the only ones I ever saw thus fastened. They were then in line condition, but I do not know how they came out. I wish that he would tell us. I think that I should rather have the entrances open—at have the entrances open—at least cleaned out every 2 or 3 weeks.— C. C. MILLER.

I should prefer to have nothing over the entrances. If they do get uneasy and try to get out, this will irritate them, while the fact that they can come out is not undesirable. Such a screen could serve no good purpose except to keep mice out, and if mice are in the cellar, they should be caught in a trap.—A. J. COOK.

I cannot discover as yet just what caused many of my healthy bees to leave their hives, fall, and perish on the cellar bottom. I have thought that such a device as yours (which has been used by others) might be valuable. I do not think that it can produce any bad results the way you have it arranged.—JAMES HEDDON.

**Explanatory.**—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require. This mark  $\bigcirc$  indicates that the apiarist is

This mark  $\odot$  indicates that the apiarist is located near the centre of the State named:  $\eth$  north of the centre;  $\blacklozenge$  south;  $\circlearrowright$  east;  $\circlearrowright$  west; and this  $\circlearrowright$  northeast;  $\circlearrowright$  northwest;  $\circlearrowright$  southeast; and  $\blacklozenge$  southwest of the centre of the State mentioned.

For the American Bee Journal Whom do Bee-Conventions Benefit?

DR. C. C. MILLER, (179-340).

Some time ago a prominent writer in bee-culture asked me the question, "For whose benefit are bee-conventions?" I have never seen the question answered, and I am not sure whether I can give a correct answer in full, although I have given it some thought. It is a matter, however, deserving of some attention, since the manner in which the time is occupied at a convention, depends largely upon the conception had, as to the object of the convention.

As to the importance of the manner in which the time is occupied, it is only necessary to consider the thousands of dollars which these conventions annually cost. Take the meeting of the late Detroit convention. Estimate the average traveling expense of each member at \$10; living expenses for four days (or parts of four days including coming and going) at \$1.25 per day—\$5; time lost, \$5; making \$20, probably a very low estimate; but if 100 are in attendance it amounts to \$2,000. Other conventions will cost much less, but there are a great many of them.

I suppose in the case of many individuals the pleasure of social intercourse will amply recompense all cost. I suspect, bowever, that these meetings would not be very largely attended were it not for the expectation of information to be gained.

Receiving and giving information is probably the prime object of beeconventions.

In attendance are found those who are interested to different degrees in bee-culture, from the man who makes his entire dependence upon the business for his bread and butter, to the one who has one or two colonies, to which he never has given (and perhaps never will give) much attention. I suppose it is desired that all these classes shall attend—certainly pressing invitations are given to them. Although all these different classes may find something of value in any convention, it is hardly to be supposed that the grade of information most needed by the beginner will be such as to be most valuable to the veteran.

Perhaps it may be well, right here, to consider what are some of the sources whence one can obtain' light as to bee-keeping. I may name these : Observation, experiment and experience; conversation with, or instruction from other bee-keepers; books upon bee-keeping; periodicals de-voted specially to bee-keeping; and conventions. 1 do not now think of other sources. Perhaps the last three, or, omitting conventions. books and periodicals alone are sufficient for a tolerably full course of instruction in theoretical bee-keeping. Under ordi-nary circumstances, if a young man with no knowledge of the business, but contemplating entering upon it, should ask my advice as to going 200 or 300 miles to attend a convention, I should advise against it. He had better take the money and invest it in books and bee-papers. Let him post himself thoroughly in the several (mind you I don't say one of the several) excellent bee-books. But no matter how familiar he may be with these, there are always new things coming up, thousands of bee-keepers coming up, thousands of bee-keepers are experimenting in different direc-tions, and these things he can have the benefit of, by taking bee-papers. Indeed, if I were restricted to only one source of information outside of my own experience, I would unhesitatingly take the bee-papers. The days for the arrival by mail of my bee-papers are as distinctly marked in my mental calendar as are Saturdays in that of the school-boy; and I never expect to become so advanced in the management of bees that I shall not be interested in these printed messengers. What, then, is the need of conventions, if books and papers are so complete?

In reading a communication in a paper, no matter how fully the writer may treat his subject, there are likely to be left out points on which we would like to question him ; at a convention we have the opportunity to do this. Then, too, at a convention, aside from the social privileges, there is a sort of mental stimulus from the meeting of so many interested in the same pursuit, that seems to stir up some to bring out important facts that otherwise might never come to light. Suppose, now, at a convention some one happens in box-hives—and he considers that here is a fine chance to

gain some information, so he begins asking whether the queen or the drone lays the eggs (and I have known something not so very far removed from this to happen); how much time do you think he ought to be entitled to occupy in this way? And yet the elementary facts, such as are familiar to even those of very limited experience are just the ones which this man needs to learn, and the time of the convention could not be spent more profitably, to him, than in dealing with just these elementary matters. But Bnt if the time were taken up in this way, how many, think you, would be in attendance whose experience and wisdom would make a convention valuable? It is not probable that diverse interests will allow all to be united in their views, but looking from the stand-point of one making bee-keeping not merely a recreation, but the means of livelihood, I should say that the chief participants should be (and perhaps they usually are) those of experience, who, by a mutual interchange of thought may each give and receive information. If the inexperienced, by their attendance, can catch some of the sparks as they fly, so much the better for the inexperienced.

Whilst upon this subject I will refer to another matter that needs correction. In the report of the Detroit Convention, page 810 of the AMERICAN BEE JOURNAL for 1885, it is stated, "Only about one-third present at the meeting had become members of the Society;" that is to say, about 200 persons were there who had the full benefit of the convention and contributed nothing toward it not even the paltry sum required as an annual membership-fee. Is not this being a little too free?

Marengo, 5 Ills.

For the American Bee Journal

Preserving Bee-Papers for Reference.

#### REUBEN HAVENS.

Having been confined to my room the greater part of the time for the last three months, with rheumatism, I have improved the time in reviewing and studying up bee-culture. I find the bound volumes of the AMERI-CAN BEE JOURNAL very convenient, and intensely interesting. I have an Emerson Binder in which I preserve the numbers throughout the year, and then have them neatly bound. With the index of subjects treated, and the index to correspondents, it is almost invaluable as a book of reference. In this way I often get needed information with but little trouble, and with no delay.

In no business is the motto "Strike while the iron is hot," or in other words, do everything in its right time, of more importance than in the beebusiness; in fact, success almost entirely depends upon it. A little delay often causes heavy losses. If this view is correct, and I think every thonghtful person will accede to it, then no better investment can be made by bee-keepers than to take the old reliable BEE JOURNAL, every number of it, and at the end of each year have them neatly bound; not merely for the name of having a bee-library, but for the purpose of close and persistent study.

These thoughts have been brought ont by remarks of bee-keepers whom I have endeavored to persuade to subscribe for the AMERICAN BEE JOURNAL. One said, "I wouldn't give 15 cents for it;" another, "I think I will take it three or four months next summer;" but in every case where objection was made, there has been failure in the past, and undoubtedly will be in the future. In some cases the parties were very enthusiastic a year or two since, but now they are completely discouraged. In fact it requires some nerve to withstand the losses of the past two years, and keep a "stiff upper lip."

# Read at the New York State Convention.

# Development of the Honey Market.

#### R. F. HOLTERMANN.

Perhaps no theme, now that our bees are in winter quarters, is of greater interest to the producer of honey. I feel my deficiency in dealing with this subject, yet my labor will not be in vain if one new idea or thought is thrown out, if old ideas are more prominently brought before us, or more united efforts decided upon before the discussion closes.

Why should we cry about our markets being overstocked when all we have to do is to enlarge them, and thus increase the consumption of an article which will stand upon its own merits when once introduced? Our markets have not been fully developed, and consumption has not reached its full capacity until every man, woman and child uses this and no other sweet. What are the means to be employed? We can all suggest. Four years in attendance (generally selling honey) at the Toronto Industrial Exhibition has given me a few ideas of the difficulties to overcome.

We want to disseminate more knowledge about apiculture, not for the benefit of the bee-keeper, but in periodicals where it will reach the masses that know nothing about it: state the progress that apiculture has and is making; what vast quantities of honey are produced and consumed compared with former days, and how this progress permits of such a production. Little articles written as reading matter and news of the day, will do a vast amount of good to educate the masses to consume honey. They will be interested, and the idea of using honey brought before them again and again, will cause them to realize that if they do not use honey as a staple article they will not be up with the fashion; and that foolish feeling and idea which sets one-half the world blind to everything, can be made to work to our benefit and—for once—that of its slaves.

As soon as a new outlet is found for the sale of honey-be it to the pork-packer, tobacconist, or some other business—send an item to the paper of large circulation, stating that "pork-packers (or whoever they may be) are commencing to use honey successfully in their business, etc. If bee-keepers had the energy of the general-manager of some quack medicine, who works up such a market by judiciously appearing before the pub-lic, bee-keepers would soon find that they could not supply the demand, and as ours is an article of merit the market would not decrease. There-fore we want to do a liberal amount of advertising, setting forth the merits of this sweet above all others for children, invalids and people in sound health-something we never do except occasionally in a bee-paper, the last place it should be put to enlarge the market.

At exhibitions held in larger cities we want a large and prominent exhibit of honey and apiarian implements. Start by giving the directors a nice can of honey; they are human, and will interest themselves on our behalf as to space and general accommodation. Give our prominent people a sample if they do not buy, and after tasting they will generally leave an order and feel under an obligation to speak of the fine display and quality of your honey. Do not wait until a reporter makes himself known to you, but hunt out those of the leading papers, pave the way to their good graces by a little honey, and in that way the exhibit will receive an amount of attention by the public that it olherwise would not. Having in this way secured the co-operation of influential people and the public generally, it will soon become a habit for them to buy honey.

As to the quantity in packages: Regulate it yourself by the package you give them at first; you can come to a larger. Toronto people have been spoilt by too small a package down to a smaller, but hardly advance being placed upon the market. Five years ago we sold the bulk of our honey in 5 and 10-pound packages; a few in 2½, but the latter was the smallest. Year after year the size has decreased, and to-day it is as difficult to sell a 2½-pound, if not a 1pound package, as it was five years ago to sell a 5 and 10-pound packages. The sellers are too blame for this, not the buyers. At your exhibition you will find so many wise heads ready to condemn the whole display, because it is too large; they say, "that cannot be all honey!" but you, who listen, know that they are a class who condemn with their own ignorance as a basis. Explain to all who will listen about bee-keepers, be courteous and endeavor to create a kindly impression, and you make a step in the right direction. After the exhibitions follow them up by establishing a general agency under a man who knows what is wanted, or if circumstances permit, sell honey yourself. Visit nice, clean groceries, fruit-stores and chemists, and there arrange to set up a neat display in the window or on the coun-

ter, and leave a stock to sell from. Do not be discouraged by the storekeeper saying, "No one asks for honey;" tell him it is because they do not see it to buy; even if the party has but little push, seeing it will bring customers.

Place honey upon the market at the right time. There is no use in rush-ing it on when small fruits, etc., are abundant, and see that the display is kept up. Put your name upon every package. Whether comb or extracted honey every effort should be made to place it upon the market in as uniform and attractive a manner as possible to the eye and palate. The sec-tions should be white, clean and well preserved, and any inferior cases should be disposed of at your exhibitions by cutting from corner to corner, making four pieces, each attached to the side of a section; these can be sold upon the grounds in large quantities. Observe the utmost cleanliness with your extracted honey; seldom, if ever, extract it before it is onethird capped, then put into large, deep tanks, which will give neither taste or color to the honey, and in a few days the thin, green honey will find its way to the top, and can be re-moved; the remainder, if clover, should be sealed within a week's should be sealed within a week's time; thistle, the same; basswood a little longer, and you have an article fit for any man. Keep dark honey from spring or fall separate; never place it upon the retail market, for it blocks the mark for it blocks the way for a more desirable article. Many more valuable sugges-tions will doubtless be thrown out by the discussions; may all have a beneficial effect.

I would suggest a discussion upon the advisability of placing extracted honey upon the market in a granulated form; then we would secure a uniformity in the appearance of the article. If we do our best, it will granulate; and we would educate the public mind to the fact that if granulated it is above suspicion.

Brantford, Ont.

# Wintering Bees, etc.

#### L. H. CROWELL.

On Dec. 4, 1885, we had a furious snow-storm, and it grew quite cold, so I put my 19 colonies and 1 nucleus into the cellar; as I had not enough to fill it, I built a room 8x8 feet, independently of the cellar-walls, out of boards, and lined it on all sides within with building-paper, making it perfectly dark. A 2-inch pipe runs from the centre of the room, commencing 6 inches from the floor, which is connected with the stove-pipe above by extending it into the stovepipe 3 feet. Before I put my bees into the cellar there was a draft which would draw the blaze of a fire 2 inches to one side, so I was sure of good ventilation.

I have kept the temperature of the bee-room at  $41^{\circ}$  above zero most of the time. We had a thaw about Dec. 24

to 29, when it rose to  $46^{\circ}$ ; but I kept it there until it became cold again, by using snow and salt. The mercury is about  $3^{\circ}$  lower outside of the room. When it is zero out-doors I open the outside doors of the cellar to purify the air. My bees have been very quiet, and there are very few that are dead—not more than a quart, both inside of the hives and on the cellar floor, and they are dry, so that there is not the slightest smell from decaying bees, and there is not the least sign of bee-diarrhea among my bees.

I was much pleased with Dr. Tinker's article on the hibernation of bees, page 5, for it confirmed several observations of my own. My bees bred late in November, and they are wintering partly on sugar syrup. They have about 6 inches of oat-hulls over them. These oat-hulls I obtained from an oatmeal mill in this place; they were so clean and easy to get that I thought they would be just the thing. I never saw a hive opened until April 7, 1885, when I got 10 colonies, which I have increased to 19. I lost one by swarming out after being hived. I secured 150 pounds of comb honey. White clover did not seem to secrete any honey, and for 3 weeks in the middle of April it was so cold that the bees could not fly.

I have 2 acres of Alsike clover for next year, and I expect to sow a bushel of the seed the coming season. I am glad that you are refuting that nonsense about manufactured honey. Give them the law!

Rockford, & Ills.

For the American Bee Journal. Quinby Standing-Frames, etc. II. L. JEFFREY.

# ni h. serener.

On page 28, Mr. T. M. Coleman asks for further explanation of the reversible frame mentioned in my report on page 821 of the AMERICAN BEE JOUR-NAL for 1885. The real dimensions of the Quinby standing-frame are, two end-bars, 1½ mches wide, 11½ inches long, and ½-inch thick; the top and bottom bars are nailed  $\frac{1}{24}$ inch from the end, towards the centre of the ends. They are cut from material % of an inch wide,  $\frac{1}{24}$ -inch thick, and 16 inches long, making the inside measure  $16 \times 10\frac{1}{26}$  inches. The bottom-bar is only  $\frac{3}{26}$ -inch thick, and the trame is fastened to the bottomboard by a hoop-iron hook.

As mentioned in my report in, 1877 all of my bives and frames were in use, and of the Langstroth size  $(17\frac{5}{8}-x9\frac{1}{8})$ , with no material at hand fit to make frames of; but there were fifty or more of the above described Quinby standing-frames on the place, and by shortening the wide end-bar to  $9\frac{1}{8}$ inches, from the original  $11\frac{1}{2}$ , they were made the Langstroth depth, and by driving a stout nail in the end of the frame, it made a hanging frame with closed ends. These frames were so used for the rest of the season, and I think that in 1878 some of them were used for nuclei hives, by laying

a piece of lath on a board for each end of the frame to rest on, and with 2 of the frames together and a piece of board on each side, a string tied around, a strip of board laid on the top, a 2-frame nucleus was set up on two standing-frames; I believe that several were made by setting the frames against one side of some of the occupied hives, with a divisionboard to cover the exposed side of the combs, and a few handfuls of earth to make the entrance the right size. In 1878, if I remember rightly, some of thein were turned the bottom-side upward, to see if the bees would not fill the frame completely full of comb. The next thing was to see if they would be as likely to fill the lower corners of the frames with dronecomb, if the frame was turned bottom upward, and several trials showed that as apt as the bees are to fill out the extreme lower corners with drone-comb, just so sure they would till it with worker-comb if the frame was inverted.

Then, to try the matter further, I made 2 or 3 Langstroth hive-bodies. rabbeted top and bottom with 36-inch square cleats 1-inch apart in each end of the hive, and cut from some of my Langstroth frames the drone-comb in the lower corners. Half of the combs were hung in the bodies in their proper position, and a cleat tacked across the ends. The hive was then set up on its end, and in the odd spaces combs were inserted from the bottom; thus the combs 1, 3, 5, 7, and 9 were tops upward, and 2, 4, 6, 8, 10 were bottom upward. As soon as the hive was put in its proper position, every comb which was bottom upward was lilled out with worker-comb, and the others were filled out with drone-comb. The hive was then set upon its end again, and the combs drawn out, the drone-comb cut out, and the hive turned so as to bring the frames bottom upward, when worker-comb was built. After trying the Lang-stroth hive-bodies in 1880, 1881 and 1882. I learned that it was a positive law that the bees would move the honey to the sections from the reversed frames, when in its place eggs were deposited, actually making the colony stronger in bees and stores as the result. Thus I gained two points, viz., frames full of worked-comb, and the comb built firmly in the frame. I also received a strong hint as to how to get sections finished up and not to extract from the brood-chamber.

Now as to the closed-end frame : I observed that the combs were filled out with brood faster in the spring ; that the hoar frost did not collect on the ends of the bive and project between the combs as it did on the regular narrow end-bar frame ; that the bees were not as apt to fly out on those bright winter days because of the space between the frame and the hive; that every cold spell in the spring was not as plainly felt; and that in packing for winter the frames were pressed closely together and packed firmly, with leaves. If a hive was moved, there was no swinging of frames to irritate the bees. A comb with a queen-cell on it and a board

each side, would save a queen and much inconvenience. The nails for the projecting arms gave place to a strip of hoop-iron with a hooked end and a screw in the centre of the frame, and various other devices to invert frames, until 1885 when reversible wires were used, and so far they "fill the bill" satisfactorily, so that 1,000 pairs will be tried the coming season.

In ISS3 I made a few frames the Langstroth size, with 1%-inch endbars; in ISS4 I made a few more of them, and in ISS5 I worked them in 25 hives under various conditions, as a test for myself, and I used them with the vilest hybrids and the gentlest Italians and pure blacks to see how they worked; two or three others making similar tests with/ the same frame are satisfied, and expect to dispense with all but the reversible Langstroth frame with 1%-inch endbars. The reversible frames have advantages enough to over-balance all objections.

#### REVERSIBLE HIVES.

On page 37, Rev. W. F. Clarke says, "Come on, Macduff!" So I will, but on the same side. I have not seen a description of Mr. Heddon's hive, or know aught of it except what I learned in that article, and from *Gleanings*; and if I have a correct idea of the hive, he is not alone, as there have been several hives in Connecticut of the same principle and construction; that is, with a horizontal dividing brood-chamber. I believe that some are now in existence, one being a movable-comb hive built in 1879 or 1880, the others of older patterns. In 1878 I transferred a colony from an old hive of that plan with slotted top and bottom. The principle, though old, is susceptible of many advantages. Though I have not seen Mr. Heddon's new book or circular, yet I can substantiate many of his claims from what I have seen of the principle of the hive, and, patent or no patent, I expect to try some hives of that principle this year. Washington Depot,  $\sim$  Conn.

For the American Bee Journal.

# Mr. Heddon's New Bee-Hive.

#### G. M. ALVES.

It seems that Mr. Heddon's new hive is on a boom. Mr. Hutchinson will run all of his next season's swarms into them, while the Rev. W. F. Clarke, with his refreshing enthusiasm, predicts that a revolution in bee-keeping is impending, and with glowing words, kindred to his announcement of the hibernation theory, in true chivalric style, throws down the glove and challenges each and all comers to raise it. Now, the writer has no disposition to meet the "shining lance" of the Reverend gentleman, nor to disparage the hive, but thinks that we should not be too hasty in throwing away what we have already found reasonably good.

Perhaps those who have been trying to follow the bright inventive genius of Mr. Heddon, who at much expense of both time and money, and who have now about equipped their bee-yards with what Mr. Heddon now calls "old goods," will with despair-ing sadness realize the fact that their fertile leader has again changed ground, and asks them to again throw away the old and accept the new. Perhaps to them it will seem rather too much for conservative and plodding human nature. Perhaps they will think that Mr. Heddon is too non-conservative to make a very good leader. Perhaps there are others who think that Mr. Heddon belongs to that class of men who live for the good of posterity; that his very bright and inventive mind originates too much, and runs into devious channels to make him a man of staid convictions: that the bee-world, as well as the ontside world, require such men, but that it is posterity which soberly considers, cons over and selects for their use from the extended researches of such geniuses.

If there be bee-keepers of such opinions, shame on them all: All those who unshrewdly guessed that inventive genius had reached its acme, to be re-imbursed for loss sustained from their bad guessing? Or are those who will say that Mr. Heddon yesterday championed the hang-ing frame, and to-day chooses the Huber? that a short time since he battled valiantly with Mr. Doolittle for non-separators, and now prefers separators? Are these men to be heard? By no means! Who shall deny the right of change, or who shall cripple the wing of genius?

But with particularity to the hive, the writer propounds these questions without undertaking to answer them himself:

1. Is there not too much machinery about it?

2. Does it not require too nice mechanical work—too precise meas-urement of its details—to be readily adapted to general use ?

3. Can men who pursue bee-keep-ing for profit afford, at the present price of honey, to use \$4 hives? 4. Will not the interchange of two

shallow hanging-frame hives answer all practicable purposes of inversion? Henderson,+o Ky.

# For the American Bee Journal My Experience in Bee-Keeping.

#### A. C. FASSETT.

On page 92 of the AMERICAN BEE JOURNAL for 1885, will be found my report for 1884, stating how I built up my apiary, the kind of hive that I use, etc., and that at the time I wrote, Feb. 9, 1885, I had in all 55 colonies of bees in winter quarters—15 packed on the summer stands, and 40 in the cellar; those in the cellar were kept dry and warm. I had no thermometer that I might see how the temperature ranged, though I know that it did not freeze there : in fact, they were kept the same as I had wintered them before with scarcely any loss.

I also stated the kind of bees that I had, and that I expected to Italianize them the next season. all of Well, I did do so, and with not much trouble, either, for I only saved 2 out of the 55 colonies, and one of them had a queen that would not lay. I had all of my bees in winter quarters by Nov. 23, 1884; some became restless in February, and Feb. 25 being the first day since Nov. 23 that was warm enough for bees to fly, I took them all out of the cellar for a flight, and found 3 dead colonies. On April 5 I took them all out of the cellar to stay, and found 29 colonies dead, and also 14 out of the 15 that were packed outside, were dead. All died with the diarrhea, I think, which left me 9 rather light ones on April 5, 1885.

They then began to dwindle, and I thought that they were all going, so 1 took all I could find and put them into 2 hives-queen and all-and the result was that I saved 2; but one of them had to do all the breeding for both until one could rear a queen. 1 kept them both strong by taking brood from the old queen. I then bought one good colony and 3 Italian queens in May, and was successful in rearing queens, so that by July 1 1 had 30 small colonies, all doing finely; but on account of the scarcity of late honey, the fall breeding was a failure, so I united the colonies, and now have 17, some of which are weak. wish that some prominent correspondent would write an article on how to handle colonies that are light in both bees and stores.

I have 14 colonies in the cellar and 3 outside. I put them all into the cellar at first, but they would not keep still, so I had to take the 3 out and pack them ; up to this date (Jan. 22) I have not lost a single colony.

The Manufacture of Eggs and Combs.

#### S. F. NEWMAN, NORWALK, O.

EDITOR OF THE BEE JOURNAL.—I enclose an article on "Manufactured Eggs," the writer of which is evidently disgusted with certain editors who are constantly giving editorials on subjects about which they are totally ignorant—thus misleading the public. Recently editorials have appeared in the Cleveland Leader and Chicago Advance, both stating that honey-combs are made, filled with bogus honey, and capped, all done by machinery. A certain professor also gets a "dab" for his "scientific pleasantries." Possibly you may think the article worthy of a place in the AMERICAN BEE JOURNAL. It may be that the "traducers" of comb honey can be reached by ridicule, if in no other way. Here is the article alluded to:

#### " PODUNK CORNERS, O.

TO THE EDITOR OF THE CHRONICLE: Dear Sir:-Ilow rapt in astonish-

ment is the mind when it reverts hack over a period of 50 or 60 years, and notes the wonderful discoveries,

improvements and inventions that have been made which tend to promote the comfort, happiness and welfare of mankind. The last of all these, but by no means the least use-ful, is the remarkable discovery of a process for manufacturing artificial eggs, upon which the editor of the Cleveland Leader and Herald has quite a lengthy editorial in his paper of Dec. 16, 1885. This discovery, like many others, seems to have happened just at the time when most needed, for, as we all know, eggs are now used for many purposes for which they were not formerly used, and their increased use has so increased the price that it has become quite burdensome; but it is more than probable that as soon as arrangements can be made tor obtaining them by the new process, their price will be materially reduced so that all, the poor as well as the rich, can always be supplied with an abundance of this desirable ' fruit.

"These eggs are so perfect and so like those obtained the usual way, that it is impossible to distinguish them from the genuine, and so far as we have tested them for culinary and scientific purposes they are fully equal. The editor of the Cleveland *Leader* is mistaken in saying they can be detected by boiling, and I think he does wrong to throw any obstacle in the way of this new enterprise.

"The gentleman who discovered the process by which these eggs are manufactured, resides in this county. He is a philanthropist of the highest order, constantly seeking to do that which will benefit his fellow men. He has distinguished himself in many ways as a scientist, and probably is not excelled in that direction by any living man. When these eggs were first tested to determine their hatching qualities, it was found that they were delicient in some very important ingredients. Although the chickens were perfectly formed, their bones lacked that firmness necessary for easy locomotion. A leading physiol-ogist residing here, having been consulted, advised the inventor to mix pulverized bone with the albuminous part of the eggs. This advice was followed and worked admirably.

"There is another defect, however, which seems not to be so easily overcome. The young chickens are en-tirely destitute of feathers, and no way has yet been discovered to remedy the defect. The inventor held the theory that the feathers came from the yolk, and he thought that if a larger amount of carrots and saffron was used the feathers might be produced. I did not agree with him, for so far as my observation extended, I had never found any feathers in either of those plants, and a careful examination with the microscope failed to reveal any. The actual test of the matter proved that I was cor-rect, for however much of carrots and salfron was used the feathers were not forthcoming. We have concluded, for the present at least, to give up experimenting in that direction, and to raise only summer chickens. Without doubt, it hatching is deferred until the first of May, and the chickens housed during stormy weather, they can be raised without difficulty even if they have no feathers, and they can be killed for the early fall market.

"I think there will be a decided advantage gained in raising feather-less chickens, on account of the yast amount of labor saved in picking them, for thus we shall be able successfully to compete with farmers who raise them the usual way. We can sell them much cheaper than they can, and still make a good profit.

"It may be a matter of curiosity to the editor of the Leader to know how the life giving principle is imparted to these eggs. The human mind is to these eggs. The human mind is ever reaching forth and grasping for new knowledge. After the inventor of these eggs found that they would of these eggs found that they would answer nearly all purposes for which eggs are used, he began a series of experiments to bring them to such a state of perfection that they would hatch. He studied Huxley, Darwin and many other writers on the origin of life, all in vain, and after spend-ing much time and money in his re-searches and experiments he had nearly given up in despair, when he found a certain 'wily' professor who was an *astute* scientist, remarkable for his wonderful attainments and profound scholarship. He also possessed the remarkable faculty of perpe-trating 'scientific pleasantries' to a greater extent than any other man.

"Upon corresponding with this re-markable man, he learned that he also had been experimenting in the same direction, and had been successful; that he had actually fertilized the carrotic and albuminous substance of which these eggs are made, before it was placed in the shells, by subject-ing it to a similar process to which fish-eggs are subjected in order to fertilize them. It was only after many trials that this 'wily' professor succeeded in accomplishing his object in a cleanly way, but at last his efforts were crowned with success.

"It is wonderful to read the Professor's discription of this experiment upon this albuminous and carrotic mass. He says 'that at the very beginning of the operation the carrotic and saffronic ingredients begin to separate from the albumen and asseparate from the arbument and as-sume the spheroidal form, and in a moments the whole mass has the same appearance that eggs obtained the usual way would have, if care-fully broken and emptied from the shells into a vat. Immediately after the formation of the yolks, the lime particles commence uniting in the particles commence uniting in the form of slender white rings which float on the surface of the albumen. These rings grow both upward and downward, but more rapidly down-ward, by attracting to themselves the in the albumen; and much quicker than I can describe the operation, about two-thirds of the shells are formed, the lower ends being comsufficient plete and containing a amount of albumen to float the yolks, which at this stage of the process, as it possessed of life, glide quickly over the edge of the shells and fall into the receptacle prepared for them.

Immediately after this part of the operation is completed, the attraction of the shells for the particles of lime is transferred to their upper edge which grows rapidly until the perfect egg is formed. By a slight change in some of the manipulations, eggs can be made to differ somewhat in size.

"A stock company has already been formed, a site purchased, and as soon as the weather will admit, a building will be erected, and the eggs manufactured on an extensive scale; manufactured on an extensive scale; we expect to employ about 500 hands in the operation. We have \$2,000 worth of stock, the unsold part of which the editor of the Cleveland *Leader* can have at par. Without doubt there will be 'millions in it.'

POULTERER."

We are astonished that such papers as the Cleveland Leader and Chicago Advance should give publicity to such fabrications, particularly the Advance. a religious paper of the Congregationalists. The author of the falseboods about the manufacture of comb and filling and sealing it by machinery, in the Advance, is a clergyman, and one of the managers of that paper-one who ought to be above doing injury to an honorable pursuit, by giving publicity to such a slanderous falschood. See page 67.-ED.]

For the American Bee Journal. Things "New" and "Old," etc. JAMES HEDDON.

I wish to publicly thank the Rev.W. F. Clarke for his article on page 37, containing so many kind expressions and plain and vigorous words. It is pleasant to know that there are those with whom we have entered the arena of sharp contest in our own search for truth who still remain our friends, ever willing to give honor to whom they think honor is due. I must also thank nearly a hundred honey-pro-ducers who have privately expressed nearly the same sentiments.

I wish to publicly correct a few misapprehensions which time and nervous strength forbid my doing by private letters.

I will say first, that the new hive is not a "small one." the brood-cham-ber being equal to that of the 10-frame Langstroth hive, when not inten-tionally contracted to one sectionalcase, upon the system which I prefer,

case, upon the system which I prefer, at the proper season. 2. I find its top surface (which is the same as the standard 8-frame Langstroth hive) ample for this locality, but it can quickly be in-creased to double that surface by placing the cases side by side.

3. It is not true, as many supposed, that the hive must necessarily be reversed or any of its parts inverted. In fact, the double-interchangeable brood-chamber system is the only one well adapted to secure most of the advantages gained by reversing.

4. It is a mistaken idea that this hive and system demand fall feed-ing for winter; on the contrary it is eminently adapted to wintering bees on natural stores, and that, too, of any preferred variety, and without any tedious manipulation; all of which is fully explained in my book which is fully explained in my book.

5. Regarding the invention and patent: Several bee-keepers have written me that they have used sub-stantially the same thing; full ex-planation, however, plainly revealed a mistake, and I predict that this will be repeated in every similar case.

I wish it understood that I do not claim the use of tightening-screws of all sorts, and adjusted in all manners; nor invertible, closed-end frames in all manner of adjustments; nor two-story brood-chambers of all kinds, any more than I claim an exclusive right to the use of wood, nails or paint in a bee-hive, simply because I use them in this one; but I do claim a certain number of arrangements which I consider the very best with which to construct a hive so that any frame can be reversed at will, or any number of frames may all be reversed together at will, without any addition or subtraction of parts or extra manipulation; so that we may accom-plish the great bulk of necessary work by manipulating a number of frames at once, instead of singly; that we may cut out queen-cells or introduce the same ; shake our bees nearly all clear from the combs with a single motion; find queens almost instantly; and many other useful manipulations which I will not repeat here; in fact my claims cover any hive mechan-ically constructed like mine in one or more of its essential features for the purposes specified. We discover principles, but we patent the mechanical arrangement by which these prin-ciples are applied; not in all their details, however.

While I have not endeavored to cover all methods of constructing one brood-chamber in two horizontal sections, the idea was original with me, being the outgrowth of a conception of an improved system of management. If it is worthless, it will fall. together with my opinions regarding it; but if it is what a trial of two sea-sons compels my students, Mr. Hutchinson and myself to believe. I shall rest content with the thought of being the first to systematize it, impress it upon the minds of my fellow bee-keepers, as well as putting it forth clothed in what I believe to be the best general mechanical construction. the minor details of which may change at any time, for this invention is confined to no particular size, shape or number of pieces.

Many letters received prompts the following words of caution: Do not hastily adopt this or any other im-proved hive, at a *sacrifice*. My colo-nies in improved Langstroth hives, on straight worker-combs (a majority with reversible frames) will not be transferred soon. The new hive will be adopted in my apiaries only as fast as increase and other changes in harmony with economy will warrant. This course I consider best for all.

#### Local Convention Directory.

1886. Time and place of Meeting. Feb. 4. - Wisconsin State, at Madison, Wis. Dr. J. W. Vance, Sec., Madison, Wis. Feb. 11.-Rhode Island, at Providence, R. I. Geo. A. Stockwell, Sec., Providence, R. I. Feb. 16-18.-New York State, al Rochester, N. Y. F. C. Benedict, Sec., Perry Centre, N. Y. Feb. 17, 18.—Cedar Valley, at Laporte City, Iowa. H. E. Hubbard, Sec., Laporte City, Iowa. Apr. 27.-Des Moines County, at Burlington, Iowa. Jno. Nan, Sec., Middletown, Iowa. Oct. 19, 20.–Illinois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

1 order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings .---------------ED.

Report for the Past Season.-W. K. Williams, Buffalo,+0 N. Y., on Jan. 26, 1886, writes :

In the fall of 1885 I had 20 colonies packed with leaves in chaff hives. lost 8 in wintering and sold 2, which left 10 to start the season with on May 1, from which I had a yield of 1,500 pounds of extracted honey (all white clover and basswood) besides enough left in the combs to feed up with in the spring; and I put 20 colonies into winter quarters last fall.

Snow-Storms in Kausas.-Nathan Davis, Wyckoff, O+ Kans., on Jan. 18, 1886, says:

My bees are wintering well on the summer stands. They stored some nice comb honey in one-pound sections last summer from sweet clover. They worked on it for 6 weeks. I also gathered a nice lot of seed from it, and I think that I will sow two acres next spring. We had the worst snow-storm on Jan. 7 that I have ever seen in Kansas; the mercury was as low as 16° to 18° below zero, and the loss of stock in western Kansas is very stock in heavy, and a great many people were frozen to death.

Bee-Keeping in Nebraska.-Wm. F. Ware, (5-14), De Witt, Nebr., on Jan. 22, 1886, says:

I agree with the Rev. G. T. Willis (page 41) that it does not pay to keep many bees in Nebraska; not so much on account of the scarcity of white clover, but on account of the poor honey market. Four years ago I commenced keeping bees, and the first two years 1 sold all of my ex-tracted honey at 20 cents per pound; the next year at 15 cents per pound, and carried more than half of it until July. Thinking that perhaps comb honey would sell better than extracted, I worked my apiary for comb honey; but I find that it retails slowly at only 15 cents per pound in sections, and extracted at 10 cents per pound. of the case, projecting enough inside colony in it, and the foundation all During all the time 1 have not re- to catch the frame. I have also an right, the bees would miss their queen

ceived \$10 in cash, but took it out in goods at the store, allowing a commission of 10 to 15 per cent. for sellmission of 10 to 15 per cent. for self-ing. I have tried to make it attrac-tive by labels and packages. In the fall of 1884 I put 9 colonies in the cellar, and lost 4 in the spring, thus leaving 5, and 2 of them were very weak. During the summer I increased them to 14 strong colonies, and 25 for 250 mounds of a comb buyout and took 350 pounds of comb honey and 325 pounds of extracted. I have 150 sections of comb well drawn out for this year's work.

Report for 1885. - A. Eastman, Union, & Ills., on Jan. 26, 1886, says:

Noticing the report of Dr. Miller, page 44, showing such poor results, and as I live within 7 miles of his apiary, I thought I would report how I succeeded with my bees. I com-menced the spring of 1885 with 16 colonies, 3 of which were so weak that it took all summer to build them up; so I had only 13 that I got any surplus from. I secured 400 pounds of comb honey in sections, increased my apiary to 24 colonies, and bought 4 more, so I now have 28 colonies in the cellar. They appear to be doing well in a temperature of 42°. I sold my honey at home for 15 cents per my honey at home for 15 cents per pound, and could have sold a great deal more.

Candy for Winter Feeding.-R. Metzler, Odessa, Ont., on Jan. 20, 1886, writes:

How can I make candy to feed my bees, for laying on the frames under the cushions, so that they will be dis-turbed as little as possible?

[Use 4 parts of coffee A sugar, and 1 part of water; simmer until it becomes quite hard on being cooled; mould it into frames of one-inch thickness, and lay it on the top of the frames, using sticks underneath 1/2 inch square, to give the bees free access to it, and the heat of the hive will keep it warm and soften it.-ED.] all right.

Reversible Hives, etc.-W. T. F. Petty, Pittsfield,+o Ills., on Jan. 23, 1886, writes :

I notice on page 35 that Mr. James Heddon has a new hive, with the brood-chamber in two sections. I made a hive 4 years ago, to be used in this way, and made 75 of them last year. I move my bees in the fall to the river bottom, 11 miles away, and with the shallow frame there is no danger of the combs breaking down. The deep hanging-frame has many disadvantages, such as being clogged with honey in the top part, etc. With the chamber in two parts the top can be taken off and the honey extracted from it, and placed below without having to handle all the brood. I use the same case to hold sections with section-holders. My frames rest on metal strips nailed to the bottom end

improved section which I make by cutting grooves on the inside of the sides of the section, so a thin piece of wood can be slid in, so a tim pice of box which protects the comb from injury and dampness; on the thin wood slides all necessary printing can be done. I have thought of sending one of my hives to the BEE JOURNAL Museum, but I have neglected to do so. I will as soon as I can.

Extracted Honey vs. Comb Honey. etc.-Frank Wilcox, Mauston, O Wis., says:

Have any of the bee-keeping fra-ternity demonstrated by carefully conducted experiments how much conducted experiments more extracted than comb honey can be produced ? Comparing one apiary with another apiary will not decide it, because the pasturage will not decide it, because the pasturage will be differ-ent. Comparing 2 colonies appar-ently alike will prove nothing, be-cause the yield might have been dif-ferent had they been run for the same. Working a certain number of colonies for same and a certain number of colonies for comb, and a certain number of other equally as good colonies for extracted honey, in the same apiary during the same season, and getting the average of each, spring count, is the only method that I can think of that will give results of any value. The comparative cost of labor, material, etc., is not required in this question. Unother thought in this question. Another thought: By the laws of Wisconsin selling adulterated honey for pure honey is a criminal act. Words publicly charg-ing a man with criminal acts are actionable, in suits of libel, I believe.

Very Cold Weather. — Emil J. Baxter, Nauvoo,+o Ills., on Jan. 15, 1886, says :

My 230 colonies of bees are wintering on the summer stands packed a la Dadant. We have had very cold weather lately—22° below zero. It is warmer now, and from all appearances my bees seem to have come through the recent cold spell

A Woman's Experience. - Mrs. Sallie E. Sherman, of Salado, 9 Texas, gives the following as her experience with the use of Alley's drone and queen trap:

On March 14, 1884, my son and only child came home from College sick. which lasted 72 days; during which time my bees increased from 20 to 48 colonies by natural swarming. Had it not been for two of the Alley drone and queen traps that 1 had, it would have been impossible for me to have secured half the swarms and at the same time nursed and taken care of my son. As it was, when a swarm began to come out, I put a cage at the entrance, and by the time I could get an empty hive in place with a few frames of brood from the parent colony in it, and the foundation all wight the break merchine in the transformation

and come back pell-mell in search of her, and thus enter the new hive at once. In about 20 minutes the bees were hived and went to work at once. without further trouble or ado, and I was back in the house with my son. In hiving them thus, I moved the old hive to a new location, and put the new one in its place, and let the queen run in with the bees. It was a beautiful sight to me to see my golden Italians come pouring in a stream, so to speak, from the top of a tall elm-tree into their new hive, without any climbing of trees or sawing of limbs. without distiguring the symmetry and beauty of a favorite shade tree. had no help, except a neighbor's little boy, who, after doing his chores at home, came over and remained a few hours in the middle of the day to watch the bees and tell me when they were swarming. I would about as soon think of going back to the old "gum" as doing without the drone and queen trap.

Mangroves Frozen in Florida.-W. S. Hart, Hawk's Park, OFla., on Jan. 18, 1886, says :

We have just had a frost (mercury down to 20° above zero) that has killed a large part of our mangroves. It would be well for those apiarists who contemplate starting for this region soon, to note that the condi-tions are somewhat changed here, for the present, in their line.

Bees Bringing in Pollen, etc.-Alderman & Roberts, Wewahitchka, ~ Fla., on Jan. 19, 1886, write :

We have had the coldest winter known here for over 23 years. A great many bees are dead, but those that are living are having a good time now bringing in lots of pollen. We have about 1,000 colonies of bees, and expect a good flow of honey this season. The honey gathered here in the spring, in April and May, cannot be excelled in quality. The summer honey-flow is very good, but not as fine as that of the spring. The bloom fine as that of the spring. The bloom from which the first quality is gathered, is from gum, and is in abund-ance along the Apalachicola and Chipola rivers. The average per colony here is 8 gallons.

The Early Part of Winter .-- John Morris, Mauston. Wis., on Jan. 5, 1886. writes :

The past fall was a very mild one, with but very liitle rain indeed, so that the water in our wells was very low, and fall plowing was pretty dry work, whilst all high winds and rough weather avoided this section of the country. It can be imagined that we got along very nicely, and that every one expected an open or mild winter, which, of course, to a bee-keeper is very pleasant to anticipate. But the first week in December brought us up to the winter pitch, and we con-

ever, excepting that we had a good body of snow on the ground. But a change came over all of this; the wind veered around into the north and it appeared as though the tropical regions had swung around to the arctic side of us to give us the same soft winds, mists and fogs, and now for the last eight or ten days it would rain a while, then it would snow a little, so that sleet and snow and rain was the order of the days until again we have 5 or 6 inches of snow and ice. In future years the first part of the winter of 1885-86 in Wisconsin, will not be spoken of as being cold or the coldest.

Severe Frosts in Florida.-Jesse Oren, Hawk's Park, OFla., on Jan. 14. 1886, writes:

We had severe frosts here on the nights of Jan. 10 and 11, forming ice injuring the orange crop and stock. The mangroves are said to be destroyed, which causes the mercury of contentment to run very low among bee-men here. In February of 1835 the mercury sank to 7° at St. Augustine, making a clean sweep of all orange trees, mangroves and other semi-tropical trees. At this last freeze 18<sup>o</sup> above zero was the depres-sion at New Smyrna, 3 miles north of Hawk's Park. Mr. Rudolph Sheldon, an old settler and a first-class beeman here, says that the mercury fell to IS<sup>o</sup>, as observed by him, but that others had reported it 10<sup>o</sup> at New Smyrna. St. Augustine is 65 miles north of New Smyrna. I do not know anything about the depression at St. Augustine at this time, but if the mercury fell to 7<sup>-</sup> there in 1835, it may be near that this time. Mr. Sheldon says that he is going about 150 miles south of this place next week, to hunt  $u_{\rm P}$  a locality where the man-groves may not be killed.

How I Began Bee-Keeping, etc.-Jacob Oswalt, Maximo, & O., on Jan. 25, 1886, writes :

I have been a careful reader of the AMERICAN BEE JOURNAL for the last 3 years, and I must say that 1 have received a vast amount of useful knowledge in bee-culture from the perusal of its pages. I have had just 5 years experience in bee-keeping. In the spring of 1881 I was among my maple trees cleaning snow out of the sap-crocks, and as I was passing along I discovered bees flying on the snow; troin what our pioneer fathers used to say. I supposed that I was near a bee-tree. I looked around in the tops of several large trees, and discovered bees passing to and from the limb of a large elm tree, about 75 feet from the ground. In May I transferred the colony from the limb, without cutting the tree, and I call it my pet, or my first colony. In some future number I will describe how I transferred my first colony from the tree cluded once more to submit to the rigors of winter; yet in a few days thereafter it was as mild and fair as in Falcon chaff-hives, and doing well. to the hive. 1 now have 20 colonies of hybrid bees all snugly tucked away

so far as 1 know. Last winter I wintered 9 colonics in chaff hives on the summer stands, without losing any, and last summer I increased them to 20.

Small vs. Large Hives .- Ch. Dadant, Hamilton,+0 Ills., writes :

In closing our lengthy discussion on this subject. Mr. Hutchinson has given us victorious (?) arguments. I will cease to argue; but 1 will make a simple assertion, the correctness of which I leave the readers to judge. It is this: A method of bee-culture which forces all the honey into the which forces all the honey into the surplus apartment, whether by con-tracting, reversing, or by using too small hives, or by all these methods together, and forces the apiarist to feed back his honey till the next crop, or till winter, and for winter—such a method. Leave will power suit the method. I say, will never suit the majority of the practical bee-keepers, who will always try to leave their bees enough honey for their wants, whenever practicable.

I thank Mr. Hutchinson for his compliment, on page 38, and for his courteous manner, as an apiarist; and I hope that our amicable dispute has been of some use to others.

#### **Convention Notices.**

The annual meeting of the Rhode Island Bee-Keepers' Society will be held on Feb. 11, 1886, at Providence, R. I. GEO. A. STOCKWELL, Sec.

The Cedar Valley Bee-Keepers' Association will hold its winter meeting at the City Hall in Laporte City, Iowa, ou Feb. 17 and 18, 1886. Reduced rates are offered at the hotels. A very complete programme is prepared with ample time to discuss subjects of im-portance to bee-keepers. A cordial invita-tion is extended to all to be present.

#### H. E. HUBBARD, Sec.

Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886.

J. M. HAMBAUGH, Sec.

for The Seventeenth Annual Conven-tion of the New York State Bee-Keepers' Association (formerly the Northeastern) will be held in Rochester, N. Y., on Feb. 16, 17 and 18, 1856. This will be one of the largest meetings ever held in the State. A largest meetings ever held in the State. A large number of our most experienced bee-masters will take part in the discussions, and several essays will be read from a number of our most practical apiarists throughout the country. The programme is complete. If you are young in the work you eah not afford to stay away—if older, you may give some good hints, if you get none. We want a good display of all kinds of supplies and fixtures. We have a room on purpose for exhibits, and any goods sent to the Secretary in eare of the "Na-tional Hotel," Rochester, N. Y., will be placed on exhibition, and either sold or re-turned to the exhibitor, as directed. Re placed on exhibition, and either sold or re-turned to the exhibitor, as directed. Re-duced rates at the hotels have been secured, also rates on some of the railroads. Alit will have to pay full fare one way-return ticket at 1.3 fare by presenting certificate from the Secretary, who will furnish them on application. We want an active vice-president in every county in State. Please name one or send the name of some one, for your county. for your county.

F. C. BENEDICT, SEC.

Issued every Wednesday by THOMAS G. NEWMAN & SON, PROPRIETORS,

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

> ALFRED H. NEWMAN, BUSINESS MANAOER.

Special Notices.

The NEW Heddon Hive.—We have made arrangements with the inventor, by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat. Further annoncement will be made next week, giving prices, etc.

The book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

-----

To Correspondents. — It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have aseveral lettera (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

"Don't Stop "—that is what many write to us about their papers, when their time is nearly out. One subscriber says: "This has been a year of disaster, and it is not convenient forme to send you the money now to renew my subscription. It runs out with this month; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

When renewing subscriptions please send an extra name or two with your own and secure a premium. We have some colored Posters, which we will send FREE, to put up in conspicuous places. We will with pleasure aend sample enpies to any one who will try to get up a elub.

**Preserve your papers** for reference. If you have no **BINDER** we will mail you one tor 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

A Brief History of the North American Bee-Keepera' Society, with a digest of its 15 Annual Conventions, and a full Report of the Praceedings of the 16th Annual Convention held at Detroit, Mich., on Dee. 8 to 10, 1885. This is the title of a new pamphlet of 64 pages just issued at this office. Price, 25 cents.

To compile this history and digest of all the past meetings of the Society, has taken much time and labor, and we have no doubt but that it will be duly appreciated by the apiarists of North America.

This pamphlet also contains engravings of the principal honey-plants, and portraits of the Rev. L. L. Langstroth, of Ohio, and Moses Quinby, of New York; two of the pioneers who helped to revolutionize American apiculture, and usher in a new era.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Hinder** for the BEE JOURNAL to any one sending us four subscriptions—with \$4.00 direct to this office. It will pay any one to devote a few hours, to get subscribers.

**Beeswax Wanted.**—We are now paying 24 cents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipper should be put on every package to prevent mistakes.

Agents can sell the Guide and Hand-Book like "hot-cakes." Send us an order for five copies (with \$2,50) and we will send you the Weekly BEE JOURNAL free for a year. This is a rare opportunity to get the Weekly BEE JOURNAL without cost 11

**CONTINUES OF THE SET OF THE SET** 

**Perforated-Zinc.**—We have laid in a stock of perforated zine, for excluding drones and queens, and can fill orders for any aize of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive—1934x14½—Price 25 centa each.

All the Numbers from the beginning of the year are seot to new subscribers, unless otherwise ordered.

The Guide and Hand-Book, is a book of ready reference and an encyclopædia of everything desirable to know. As a guide to the home-secker, it is invaluable. Its contenta are partially given on page 64, and will convince any one of its value. We do not think any of our readers can afford to do without it. As a book of ready reference we find it of great value in our library. We will send the Weekly BEE JOURNAL for a year and the Guide for \$1.30

#### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

Price of both. Club The American Bec Journal ...... 100..

#### System and Success.

\_\_\_\_\_

\*\*\* All who intend to be aystematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are as follows :

 For
 50 colonies (120 pages)......\$1 00

 "
 100 colonies (220 pages)......
 1 25

 "
 200 colonies (420 pages).......
 1 50

The larger ones can be used for a few eolonics, give room for an increase of numbera and still keep the record all together in one book, and are therefore the most desirable.

. . . . . .

To any One sending us one new subscriber with their cwn renewal (with \$2.00), we will present a copy of the new "Convention History of America."

Are you Entitled to a pension? You may be and may not know it. If you examine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

Any person not a subscriber, receiving a copy of this paper, will please consider it an invitation to become a subscriber to it.

**Cash in Advance** is the rule, but no longer than six months of grace can be allowed on the small sum of \$1.00. Subscriptions may commence at any time, and discontinuances may be ordered at any time, when arcarages are paid up.

The Time for Reading has now come. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books and can fill all orders on the day they are received.

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a.m., Feb. 1, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HIONEY.—There is an easier tone to the comb honey market, and prices are fully one cent per pound less than at hast quotations, isc. being the price for white comb honey in 1-ib. sections, and some extra nice brings itc. This is owing to small lots coming into different commission houses, and all being eager to seli, they underbid regular boney houses in order to do so Extracted honey brings force to the

BEESWAX.-24@26c. R. A. BURNETT, 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY.-The market for honey continues dull, and prices are ruling lower; however, if the cold weather continues, it may improve the trade in a short time. We quote as follows: Fancy white comb in 1-ib. gassed or unglassed sections, 13@14c.; the same in 1-ib. glassed or unglassed sections, 13@14c.; and it un-glassed 2-ibs, 11@12c. Buckwheat honey in 2-ib. sections, glassed, 9c.; in 1-ib. sections, glassed or unglassed, 10@clic. Extracted-white clover 6½@8.c.; buckwheat, 5½@14c. BEEESW AX.-Prime yellow, 26@28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

#### ST. LOUIS.

HONEY.—The market is quiet and the demand light just now. We quote prices as follows :— Choice comb honey, 10@412C. Extracted, in bar-rels, 45@5C. Extra fancy of bribt culor and in No. 1 p (ekages, 14 advance on above prices, BEESWAX.—Firm at 225&c. for prime. D, G. TUTT & CO., Commercial St.

#### CINCINNATI.

IIONEY.—There is a very slow demand from manufacturers, for extracted honey, with a large supply on the market, while the demand is very good for clover boney in square glass jars. Prices for all qualities are low and ranze from 488c a ib. Supply and demand is fair for choice comb honey in small sections, which brings 12415c. per lb. BEESWAX.—Good yellow is in good demand, and arrivals are fair, at 20%2c. per lb. C. F. MUTH & SON, Freeman & Central Ave.

#### CLEVELAND.

CLEVELAND. HONEX.--The market is not quite as active as it, has heen, owing, no doubt, to many attractions of the Holiday Season. Best white, 1-ib. sections sell at 15c, and 2-ibs. for 130 eldc, but there is not so much sale for the latter. Second grade honey is duil at 120 33c, 01d white, 10% 12c. Extracted, 76 we, per lb. BELSWAX.--Very scarce at 22025c. A. C. KENDEL, 115 Outario Street.

#### KANSAS CITY.

KANSAS CITY. HONEY.-Sales are extremely light and prices are very low. Choice comb honey in 1-lb. sections brings 140.15c, 2 lbs., 1204.13c. Dark fal honey 1 ta 2 cents less. Extracted honey is very dulland of slow sale. We had to unload a lot of very fine ex-tracted honey this week at 5c, and stocks continue to accumulate. BEEESW AX.-Scarce and higher-22@25c, CLEMONS, CLOON & Co., cor. 4th & Walnut.

#### BOSTON.

HONEY.--It is selling very well hut prices are very low, and we are often obliged to shade our prices in order to make rates. We quo e comb honey in 1-b. sections at 14.916c., and 2-b. sec-tions at 12@14c. Extracted, 66.96c. BEESWAX.--30 cts, per lb. HLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

SAN FRANCISCO. HONEY.-Choice comb honey is in light supply and is bringing firm figures. There is a fair more-ment in best qualities of extracted at steady rates. We quote as tollows: White to extra white fiquid, 54% 54% : light amber colored, 45% 44%, amber and candled, 44%; dark and candied, 4% 44%, BEESWAX.-Quotable at 23% 25%, wholesaie, O. B. SMITH & Co., 423 Front Street.

#### Bee-Keepers' Badges at Fairs.

We have some ELEGANT **RIBBON BADGES,** having a rosette and gold Bee, for bee-keepers' use at Fairs, Conventions, etc. Price 50 cents each, by mail, postpaid.

THOMAS G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL.

## Fruit-Farm & Apiary FOR SALE CHEAP!

96 ACRES, bill-land, ½ well-stocked with apples, acades, peurs, pluns, quinces, grapes, and amall truit, in the bearing condition. The remain-der is in pasture, grass, grain, etc. Aplary contains 140 ITALIAN COLONIES in Langstroth bives. Bee-house and all modern appliances for apiculture, in as good location for bees and honey as can be found. Good loroom house, beautifully located, commanding a view of the city, river and surrounding country. New barn and out-buildings, cistern, never-failing springs, etc. Reasons for selling-age and Ill-bealth.

B. J. MILLEB & CO., NAPPANEE, IND.

WANTED.-Two young men to work with hees. Three hundred colonies-27 years' ex-perionce. Address. S. I. FR FEBORS. 4Atf TTHACA, WIS.

Mr. John Peacock, of Chicago, Ills., an enthusiastic hee-keeper, was run down by a train on Sunday, Jan. 31, and killed. He was buried on Thursday last, and was over 78 years of age.

The Honey Crop for San Diego County, Calif., for 1885, is reported thus: Comb honey, 1,107,000 pounds; extracted, 1,284,-500; total, 2,177,500 pounds. This is equal to 1,088 tons, or over 100 carloads of honey. At 8 cents per pound it is worth over \$178,000.

G. M. Doolittle, Borodino, N. Y., writes : "I look forward with pleasure to every Thursday night when the AMERICAN BEE JOURNAL arrives,' fresh and newsy,' and just as regularly as the day comes. I do not know hnt there could be a better Bee Journal gotten up, than the one you publish, but so far, there never has been."

New Price-Lists have been received from the following persons :

Cole Brothers, Pella, Iowa.-40 pages-Flower, Vegetable, and Garden Seeds.

Dr. J. P. H. Brown, Angnsta, Ga.-20 pages Italian Bees, Queens, and Apiarian Supplies.

Earle Clickenger, Columbus, O .- 1 page-Bee-Supplies.

Wm. Groff, Rome, N. Y.-4 pages-Com-mon-Sense Bee-Hives.

F. A. Salishury, Geddes, N. Y.—28 pages— Queens, Apiarian Implements and Supplies. J. B. Mason & Sons, Mechanic Falls, Maine. -50 pages-Becs, Queens, and Apiarian Supplies.

A, C. Nellis & Co., Canajoharie, N. Y.–100 pages–Flower, Field, and Garden Seeds. Berlin Fruit-Box Co., Berlin Heights, O.-6 pages-Berry Packages and Apiarian

Supplies.

Thomas G. Newman & Son, Chicago, Ills.-36 pages-Bee-Keepers' Supplies.

A. A. Abbott, Morenei, Mich.-16 pages-Plants, Seeds, etc.

Any one desiring a copy of either of them, can do so by sending a postal card to the address as given above.

Adulterated Food .-- The Illinois State Board of Agriculture, after a prolonged discussion, has adopted the following resolutions:

Resolved, That we respectfully request Congress to enact a law placing all dairy products and all imitations of or substitutes for the same, under the control of a com-petent Government inspector, to the end that such articles shall be branded and sold under their proper names and on their merits.

Resolved, That we respectfully direct the attention of congress to the nuwholesome adulteration of other food products, and pray for proper legislation for the adequate protection of the people from the same.

The recent Iowa State Dairy Convention at Oskaloosa, appointed persons to secure, in every county, signers to a petition to the General Assembly requesting that hody :

1. To prohibit by law the sale as butter or 2. To enact suitable penalties for the

2. To enact surface penalties for the violation thereof. 3. To appoint a dairy commissioner for Iowa, charged with the enforcement of the law, and appropriate ample funds for this

Now add honey, and all other articles of food which are so often adulterated, and let Congress prepare to defend the whole people of the United States against the nefarious schemes of adulterators. Things have been so lax, that now there is hardly an article of human food which escapes the manipulation

of these adulterating scoundrels. The "whipping-post" and "pillory" are the most appropriate punishments for adulterators.

Mr. Gustav Bolm, who was sued by fruit-growing neighbors in California for damage said to be done to raisins by his bees, and fined \$75 therefor, is preparing to appeal the case, under the direction of the National Bee-Keepers' Union. The appeal is set for next month. Mr. Bohn writes as follows about his position in the premises :

If this snit goes against us, bees cannot be there present location before my neighbors had their grape-vines set ont. I purchased the place from a bee-keeper, who kept bees on it before me. I am located at the foot of the last range of mountains this side of the desert, so all will see that I have not moved my bees here to feed on my neighbors' fruit, as was testified to by some of them who grow fruit, one of them having grape-vines in the nursery for sale by the hundred thonsand, and one having five times the number of acres set to grapes as the plain-tiffs, and but one mile from me. Those are some of my witnesses. some of my witnesses.

The Statistics reported at the Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Convention, held at Meadville, Pa., Jan. 20 and 21, 1886, were as follows :

Number of colonies fall of 1884...... 3,371 " spring of 1885...... 1,838 " pounds of comb honey, 1885..48,890 " cxtracted honey, 1885.12,240 " beeswax, 1885....... 488

The National Agricultural and Dairy Conventions, under the auspices of the American Agricultural Association at the Grand Central Hotel, New York, Feb. 16, 17 and 18, should be attended by all interested in agriculture and dairying.

Dr. J. W. Vance, of Madison, Wis., has sent us the following resolutions, which were unanimously passed at the Wisconsin State Bee-Keepers' Association, on Feb. 4, 1886, on home markets for honey :

Resolved, That the hee-keepers of this State endeavor as far as possible to create a home market for their honey, so that there will be no need of seeking city markets in which to dispose of our surplus products.

Resolved, That we thank Mr. T. G. Newman, of Chicago, for his efforts in securing re-duced rates of transportation on honey, and congratulate him upon his success.

Resolved, That we desire to express to Mr. Newman our sincere appreciation of his labor and zeal in fighting the glucose adul-terators, and bringing to light their nefarious schemes against the interests of brackmanar bee-keepers.

Resolved, That the bee-keepers of the State are urged to make more creditable exhibits at the next State Fair.

Mr. F. L. Dougherty, in the Indiana Farmer, remarks as follows :

A thorough system of management is as A thorough system of management is as necessary in beckeeping as in any other business. A hap-hazard way of doing things will never win any but meager re-turns. He who looks ahead and prepares for his work before the time for the work to be done will find the result for aveceding be done, will find the result far exceeding those of the one who waits until the work needs to be done, and then has to hurry in the vain endeavor to catch np.

This is excellent advice. If system is necessary anywhere, it surely is so in the apiary, and no one should expect success without it. Be in time ; get everything you need for the honey crop on hand in good time, and keep everything in order. You will thus have your tub "right side up" when the honey-flow comes.

The Bee is a Granger, says the Detroit Free Press, "and started the first co-operative store; established the first savings bank, and organized the first mutual-aid association." What next?

A Brief History of the North American Bee-Keepers' Society, with a digest of its 15 Annual Conventions, and a full Report. of the Proceedings of the 16th Annual Convention held at Detroit, Mich., on Dec. 8 to 10, 1885. This is the title of a new pamphlet of 64 pages just issued at this office. Price, 25 cents. \*

This pamphlet also contains engravings of the principal honey-plants, and portraits of the Rev. L. L. Langstroth, of Ohio, and Moses Quinby, of New York ; two of the pioneers who helped to revolutionize American apicnlture, and usher in a new era.

One of the Results of publishing, in pamphlet form, the proceedings of the North American Bee-Keepers' Society, is that hundreds of papers are now publishing condensed portions on each of the subjects upon which addresses were given followed by discussion. This will probably continue during the whole year, more or less, in many agricultural and other papers, and people in general will become better informed on the pursnit of honey-production. This may help to connteract the falsehoods promulgated by ignorant scribblers in many of the newspapers at the present time.

**REPLIES by Prominent Apiarists.** 

# Keeping Bees on Shares.

Query, No. 192 .- What portion of the honey produced would be a fair compensation to the renter of an apiary, supposing that I should furnish the bees, empty hives, frames, foundation, sections and crates in the flat, kegs for extracted honey, and retain the ownership of all the bees and fixtures, my share of the honey to be delivered to me [at the apiary] crated, or in kegs ?-C. B. F., Mich.

#### One-third.-G. L. TINKER.

One-half, less one-half the cost of foundation, sections, crates and kegs. -W. Z. HUTCHINSON.

One-half, if the bees are located on the renter's land, and he has to hive the swarms free of charge.-DADANT & Son.

It would depend upon the size of the apiary, and how much time the renter put in; but I will say one-half of all the honey.—H. D. CUTTING.

I should say three-fifths, and per-haps two-thirds. It is usual for the person renting to pay one-half of all the expense, and receive one-half of the honey produced.-A. J. Cook.

When I used to keep bees in that way, I received one-half the honey as pay for my work. I furnished onehalf of the sections and crates actually filled, however.—G. M. DOOLITTLE.

About one-third, or a little more. About one-third, or a fittle hole. If you would furnish everything ex-cept what is sold with the crop (crates, sections, and surplus foundation), and that furnished equally by both parties, the surplus honey might be divided equally, the increase always remaining with the apiary.—JAMES UKEDON HEDDON.

One-third of the honey produced would be about right, taking all things into consideration. This would be large wages for simply working the apiary, considering that the renter is turnished with everything, includ-ing the sections, kegs, etc., to hold his own part of the crop, were it not that he must take the greater risk as to what the honey harvest may or may not be, and must leave enough honey to winter the bees.—G. W. DEMAREE.

Several more factors are needed to make this conundrum complete-the number of colonies, condition of honey-yield (whether large or small), it. If hy portion, proportion even is meant, I am but little better off, as so much will depend upon the quantity of honey produced, and the amount of work actually done to produce it; but I would say ordinarily from  $\frac{1}{3}$  to  $\frac{1}{2}$ , with a proportion of the increase of bees.-J. E. POND. Ju.

# Catching Prime Swarms.

Query, No. 193 .- Will the following plan work all right in catching swarms? When a swarm is coming out, go to the hive with a screen something like those used over butter-dishes, etc., to keep flies off; watch for the queen, and when she comes forth, gently place the screen over her, and as the swarm is nearly or all out, remove the hive, placing another in its place, and when the bees return, liberate the queen. I meau prime swarms.-J. K., Iowa.

I think that the plan has been successfully practiced by a great many.— C. C. MILLER.

Yes, sir, a similar plan bas invariably succeeded for years in our College Apiary.—A. J. COOK.

Yes, as a rule. If the queen is kept caged until nearly all the bees are in the new hive, you will have less trouble with the plan.—G. M. Doo-LITTLE.

The plan will work if you can catch the queen. Sometimes you will see her in the headlong rush, but oftener not, especially if the entrance is large.—G. L. TINKER.

Yes, but when the swarm returns, it is not always safe to liberate the queen, as she may fly away then. If you liberate her, keep an eye on her, and if she tries to leave, keep her caged in the new hive for a few hours. –Ďadant & Son.

Yes, the plan will work all right if you can capture the queen; but it is a good deal like "catching the bird by sprinkling salt on its tail." You cannot capture the queen with any certainty in that way.—G. W. DEM-AREE.

It will depend upon how much wing-power your queen has. If you are on hand with you butter-dish (excuse me, I mean "screen"), and can put it over her, your plan will work all right if the queen goes in with the swarm.—H. D. CUTTING.

I cannot see that this plan differs (except in the manner of caging the queen), from the plan usually adopted with queens whose wings are clipped ; and I think it would be as successful as such methods usually are .- W. Z. HUTCHINSON.

The old recipe given for a rabbitstew is, "first catch your rabbit." If you are present with the screen or any sort of a queen-cage, and can catch and confine the queen, the bees will come back to her and swarm into a new hive placed on the old stand. The only trouble is in first catching the queen, which, in a large aplary, is a big job to do every time that a colony swarms.—J. E. POND, JR.

When you are on hand, implements handy, swarms prime, with little liability of several being in the air at once, the above plan often aids des-patch. Use the smallest size of butter-dish screens. I have been re-uniting. No queens were injured, aided much by also having a frame Usually the swarm would sulk or re-about 3 feet square, covered with wire-issue, and I prefer the latter of the cloth, which I placed close up in front two evils.—JAMES HEDDON. butter-dish screens. I have been aided much by also having a frame about 3 feet square, covered with wire-

of the hive when the issuing began, and forced nearly all the bees to-travel up, as they departed, thus multiplying the chances to observe the queen. Now suppose this wire-cloth was worker-passing and queen-orcholing on a frame that was a par excluding on a frame that was a partial box.—JAMES HEDDON.

# Destroying Queen-Cells.

Query, No. 194 .- Will an old queen destroy the queen-cells of her parent colouy, or any others, when both colonies-the old and the young one-are again united iu 6 or 7 days after swarming? How will the bees of the parent colony act towards the queen, when there is no alternate mixing of combs and bees ?-F. L., Mo.

I should consider it somewhat "risky."—G. M. DOOLITTLE.

I have never tried such an experiment, but I feel very certain that the old queen would be killed.-G. L. TINKER.

No positive answer can be givensometimes yes, as often no. The unit-ing will probably be possible, as it is easy to unite bees at swarming time. -A. J. COOK.

The queen will destroy all queencells that the bees allow her to reach. The behavior of the bees toward one another will depend much upon the condition of the harvest—hostile during a bad honey yield, peaceable in a good yield.—DADANT & SON.

1. In some cases the bees (hardly the queen) might destroy the queen cells; oftener I think they would swarm. 2. Generally, I should ex-pect the queen to be treated kindly.— C. C. MILLER.

I have never tried this, but I think that the old queen would destroy cells, and that she would not usually be molested; but I would not advise such a procedure.—W. Z. HUTCHIN-SON.

1. No one can tell what she will do in such a case; sometimes she will, and at other times she wont. The only way to determine is to try it. 2. If a queen has been kept out of a colony for a day or more, the bees of that colony ordinarily look upon her as a stranger, and therefore the same care should be taken in putting her back, as in introducing a perfectly strange queen.-J. E. POND, JR.

She would, if the bees would permit her to have her own way, but if the swarming-impulse is as strong as it usually is, the bees will either "ball" the old queen and kill her, or force her to go with a swarm.—G. W. DEMAREE.

You will find great variance, owing to location and seasons. Here they act differently at different times. With me it has been unvarying, that none of the bees quarrelled after such

-----

# Finding the Queen.

Query, No. 195.-I have read of so many different operations with bees, where it is neeessary to find the queen, that I write my experience and ask for a remedy for my troubles. I first smoke my becs, then open the hive, take out a frame, look it over carofully, and lay it down outside the hive, and proceed with the other frames in like manner ; then the inside of the hive will be filled in the corners, on the bottom and on the sides with a horde of bees, all excited and in motion. By this time the bees outside will have recovered from the effects of the smoke, and are ready to sting and fly about in the air, making a complete confusion of the whole job ; and the result is 1 do not find the queen.-E. A. S.

I do not smoke the bees so as to get them to running; if you do, you will always have trouble in finding the queen. Go slowly and carefully, not exciting the bees, and you will succeed better.—G. M. DOOLITTLE.

Take out the central combs first, examine them quickly—learn to tell by one sweeping glance whether the queen is on one side of a comb. Find the queen before the bees get to running all over. When a comb has been examined, place it in an empty hive.—W. Z. HUTCHINSON.

To keep them quiet keep up the smoke. When we find trouble in seeing the queen, it is often an aid to shake all the bees in front of a hive, on a board. This often saves time, and is quite sure. Shaking bees from frames seems to take the fight out of them.—A. J. COOK.

Have you carefully studied directions in the bee-books? If not, one of the first things is to commence a library. I suspect that you use too much smoke, as very little is needed a couple of puffs at the entrance before touching the hive, and 3 or 4 across the top after uncovering it. With good-natured bees in a honeyflow, no smoke may be necessary.—C. C. MILLER.

If I want to find a queen in any hive very quickly, I would not smoke the bees. The queen is nearly always found on the combs containing the brood, and on the brood itself, not on the sealed honey. If the bees are vicious, I would put on gloves and protect my face. If not smoked, the queen seldom leaves the combs on opening a hive.—G. L. TINKER.

It is plain that you lack practice, and that your bees are not pure Italians. The best chance to find a black queen is to lift a centre comb first, for she may beon it and will not have time to run off as she does when you start at the side, where she is less likely to be. Seek for her on the brood-combs. When your bees get confused, give them a good smoking, remove their hive, and shake them all on a sheet in front of an empty hive on the stand of their own. If you do not tind the queen then, you had better quit hunting for queens.— DADANT & SON.

When no robbing is imminent, I have hunted queens in the same manner. If you and your bees are "fidgity" you may not find the queen till what you describe, results. You can drive the queen and part of the bees above into a box, and then shake them upon a board, and tind ber thus. This method is also uncertain and slow. With my hive I shake the queen out at once, without removing a frame.— JAMES HEDDON.

Take out one frame, look it over carefully, then hang it outside of the hive, or inside of an empty hive. Take the next frame, look it over, and if no queen is found upon it, put it back into the hive, to one side, and go on until you do find her. You will have less trouble if you leave the frames inside of the hive. If you do not find her, go back over the frames. In looking up queens, I find the less smoke you use the easier to find them. —H. D. CUTTING.

There is no remedy. The only way to find a queen, is to hunt her up. If you cannot find her readily on the first trial, close the hive, wait an hour or so, and try again. You can if you like, shake all the bees from their combs in front of the hive, and brush out all the bees, and then pick out the queen when all are traveling back; this, however, is a tedious job, and I prefer the second trial. It is seldom, though, that I do not find the queen at the first attempt.—J. E. POND, JR.

Your experience is not peculiar; all beginners meet with the same difficulties that you mention. Use a comb-box large enough to hold a full set of combs, or an empty hive will do. Open the hive and use no more smoke than is absolutely necessary to keep the bees quiet. Remove the combs one at a time, and look them over, placing them in the comb-box till all have been examined. If the queen is not found, examine among the bees left in the hive, stirring them with a stick. If still not found, go over them again when replacing the min the hive. "Practice makes perfect."—G. W. DEMAREE.

# Hive-Entrances in Winter.

Query, No. 196.—In covering hives with outside boxes for wintering bees on the summer stauds, how should the entrances be arranged to prevent their being clogged with snow, in regions where *very* heavy snows fall ?—H. C. P.

Make your cover-box with a deep portico.—DADANT & SON.

The entrances should be protected by wide boards in front of them.—G. L. TINKER.

Stand a board up in front of the entrance, so the snow will not drift in.—II. D. CUTTING.

I stand a board from the alightingboard slanting to the hive, so as to protect the entrance from snow.—G. M. DOOLITTLE. I have no experience of late years, but would not boards leaned against the hives accomplish it? — C. C. MILLER,

Lean a board up against the hive in front of the entrance, and fill the openings at the ends of the board with straw.—W. Z. HUTCHINSON.

Snow never injures my bees by drifting at the entrances of the hives. A broad board set up against the front of the hive would remedy the evil effects, if there was any to be feared.—G. W. DEMAREE.

A slanting board can be placed against the hive. If this is as long as the hive, and pretty close to the entrance, it will serve the purpose well. If snow is cleaned out as soon as the weather warms up, it is a question if it does any harm.—A. J. Cook.

It will make little difference whether they are so protected or not. If desired, a board can be set slantwise over the entrance, but I have never found that snow clogging entrances caused any injury, as it is porous enough to give ample ventilation.— J. E. POND, JR.

To prevent clogging with snow and other vastly more important and detrimental influences, allow me to advise leaning a board up over the front of the hive, and piling all the snow over the hive, board, and all that you can find. Cover them from sight, if you have enough snow, and keep them so as much as possible.— JAMES HEDDON.

#### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

Are yon Entitled to a pension? You may be and may not know it. If you examine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

Explanatory .- The figures nefore the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark O indicates that the apiarist is located near the centre of the State named: 3 north of the centre; 9 south; 9 east; •O west; and this 6 northeast; •O northwest; • southeast; and 9 southwest of the centre of the State mentioned.

For the American Bee Journal Lengthening the Swarming-Impulse.

#### 17-G. M. DOOLITTLE, (40-95).

By reading the answers to Query, No. 173, on page 820, I notice that the lengthening of the swarming-impulse, so as to get more queens reared, is stated by some to be an advertising "trick of the trade." Some of the replies appear a little uncharitable and uncourteous, to say the least, and as I am one of those who have advertised queens reared under the swarming-impulse, I wish to say a few words on the subject, in addition to what I said on page 820, of the BEE JOUNRAL for 1885.

If any person entertains the idea that the swarming-impulse is to be commenced at will, on the first day of April, and closed on the last day of October, I will simply say that I know of no plan of doing such a feat; but I do know how to get bees to swarm 2 weeks in advance of the time they otherwise would, and keep them swarming from a month to 6 weeks later, each varying of course according to the season. So it occurs that I have had prime swarms as early as May 18, and as late as Sept. 3, although the average will be from June 10 to Aug. 20. As I keep no secrets from the readers of the AMERI-CAN BEE JOURNAL, I will tell them how it is done; but first I wish to explain why I consider queens reared under the swarming-impulse superior to those reared by the erroneously-called "artificial process."

1. The bees will not thus rear queens until all the conditions for queen-rearing are favorable; while with that method they are obliged to rear queens at the will of the bee-keeper, often under the most unfavorable conditions.

2. The queen-larva is so abundantly fed that a thrifty growth is obtained, thus giving great vigor; while by the so-called "artificial" method the queen-larva is often insufficiently fed, thus dwarfing the queen's capacity as an egg-layer. I have never cut open a queen-cell produced under the swarming impulse but what I found a lump of royal jelly left nearly as large as a pea; while I have cut scores of queen-cells produced otherwise where the strips were cut out, by

that did not have enough left in them so as to detect a particle of royal jelly. 3. My queens reared under the swarning-impulse, and those so reared that are purchased of others, have lived to be 3, 4, and some even 5 years of age, doing good business all those years; while I have never pur-chased but one "dollar" queen that lived 2 years, and three-fourths of them pever lived over 1 year them never lived over 1 year.

Now as to how I manage: In the latter part of April I select colonies having such queens as I wish to breed from, which, as a rule, I know where to find from the fall previous; and when thus selected I use every known means to advance them as fast as possible. I formerly depended upon giving these colonies frames of hatching brood, but for the past 2 seasons I have used the plan of giving caged bees, with better results. I take a cage, and from each of a number of colonies I get a pint or so of bees, until I have as many as I wish, when the cage is placed in the cellar until nearly dark; it is then brought out and placed over the selected colony in down with the colony during the the night through a hole in the quilt. In this way the colony is materially strengthened without the danger of chilling any brood. I treat only 1 or 2 colonies in this way, depending on the usual means to get the majority of them ready to swarm a little later on; but I do get these one or two to swarm two or more weeks in advance of the rest,

Next, as it comes toward the close of the swarming season, I cage the queen and hang her with the swarm having just issued, so as to keep them out as long as I desire, and be secure from their leaving for the woods, when from other colonies I get frames of hatching brood so as to fill the hive into which the swarm is put. If no honey is coming in from the field, they are fed liberally, which results in the hive being crowded with bees and stores so that in from 12 to 18 days I get another swarm from this brime swarm. This I practice only when I do not have enough queens on hand reared when the bees swarm without coaxing to supply the esti-mated demand. All queens are kept which are reared from the best colonies during the general swarming in the last of June and July, so as to save this expensive coaxing and feed-ing, so that I often send out queens in September and October that were of this sort.

Another item: I manage to get nearly double the queen-cells built by these coaxed colonies that I do ordinarily. To do this, I proceed as fol-lows: When I think that they will be about starting queen-cells, I take a frame of drone-comb (or partly such) and cut three strips out of it about 1½ inches wide, one at the bottom, one in the middle, and one near the top. Previous to this I have saved some queen-cups or embryo queencells, as I came across them in my work with the bees. These cups are

means of melted wax, when this frame coaxed. The bees seem to think that they have started these queen-cups themselves, so that I have in a few days from 20 to 30 nice queen-cells instead of from 5 to 10 as I ordinarily would.

When the colony swarms, a part of the swarm is returned so as to protect the queen-cells from any injury from in the season, the queen is taken from them and all the bees allowed to go back. If really good queens are to be reared in the hive of the parent colony, do not move this hive from the old stand, so as to hive the new colony on the old stand, as there is danger of chilling the queens in the cells.

I have now described how I proceed to secure queens which give me great satisfaction, and this method is no "trick of the trade" with me.

# Feeding Sugar for Winter Stores.

#### J. G. HARLAN, (17-32).

Allow me to join with those whohave already spoken against the ex-tensive sugar-syrup feeding. It is very obvious why this universal feeding of sugar syrup will cause still farther decline in the honey market. It will throw hundreds of thousands of pounds more honey on the market, or pounds more honey on the market, and that kind, too, that does more to-cause low prices than almost any-thing else; by this I refer to dark extracted, honey in bulged combs, broken sections, and sections not completed. Now this unsalable honey is just as good for spring, summer or winter stores as any sugar syrup; at

least it has proved so with me. This practice is also causing much distrust both among dealers and consumers, they strongly suspecting that all the honey offered, especially by large honey-producers, is more or less composed of sugar; and indeed they have some ground for their suspicious. I would make this suggestion: Put no honey on the market but the very no holey on the market but the very nicest, and in the most attractive form. Do not be in too great haste to sell. Keep honey the year round for your home trade. Work the home to the the the trade to be the only one market as though it was the only one you knew of. Do not cut on prices. Dealers in your own town can afford to pay a cent or two more per pound to have honey laid down in their stores, than to have it shipped from a distance, and paying freight and drayage. I know of honey being shipped from this county to the New York market, last fall; and I also know of a groceryman in this town that had benow chinned this winter that had honey shipped, this winter, from New York here, for his trade. This illustrates the point. Now let those who do the most writing for our bee-papers, take this matter up and give their advice to us who are in the

like the year 1880, when the late-gathered honey is very bad, we will have to extract and feed sugar, or lose our bees; but such seasons do not come very often.

My number of colonies is 32, in chaff hives, one being in the cellar; number last spring, 17; number of pounds of comb honey in one-pound boxes, 1.200; number of pounds of extracted honey, 250. I sold all of my honey at home. By the way, I think that I have the best and most con-venient chaff hive made. My number of colonies is 32, in

Union City, O+ Ind.

# For the American Bee Journal. The Oneida County Convention.

A number of the most enterprising bee-keepers of Oneida County, N. Y., met at Rome, N. Y., on Nov. 21, 1885, and organized under the name of "The Oneida County Bee-Keepers' Association," adopted a constitution and by-laws, and elected the follow-ing as officers for the ensuing year: President, R. Bacon, of Verona; Vice-President, W. E. Clark, of Oriskany; Secretary, O. J. Evans, of Camroden; and Treasurer, J. M. Resequie, of Verona; Seventaen beachageners ba Verona. Seventeen bee-keepers became members of the Association, and if the weather had been favorable, many more would have been present.

After the usual amount of routine work, which is indispensable in setting a new society on a solid footing, the subject of "Wintering bees" was discussed as follows:

Pres. Bacon-Much depends upon locality and hives, and the winters have something to do with it. Bees may be treated in the same manner two winters-the first winter perhaps they will do well, and the next very poorly. We should strike the middle line after getting all available infor-mation. Bees should be prepared for the winter, dry and carefully; they must not be shaken up. Some cellars will do for wintering bees, while in other cellars they will not do well. I cannot keep mine in my cellar. I have a frost-proof bee-house which is made double-walled, the studding being about 8 inches, boarded outside and inside, and the space of 8 inches filled with dry earth. On the outside of this again is nailed studding 2 inches thick, on which are nailed matched siding, thus leaving a dead-air space of 2 inches between the siding and with dry sawdust. I prefer to keep the temperature of my hee-house about 45°. My colonies do not consume more than from 5 to 10 pounds of honey each, in winter. My bee house more than pays for itself every season. On pleasant winter days I give my bees a flight, and I ind that they come out better in the spring than when they are not allowed to have flights.

W. E. Clark-I copied my bee-house after Mr. Bacon's, but got it so as to be a little too warm in the spring. do not wish to put my bees out till the soft maple blossoms in the spring. 1

therefore sunk my bee-house about 4 feet into the ground, and found that the bees would remain more quiet in the spring. I had no ventilation at the bottom of the bee-house last winter, and my bees never wintered better. If a bee-house has damp air in it, it should be ventilated. I elevate the lower tier of hives about an inch from the bottom-board. This arrangement, by admitting a free cir-culation of air through the hive, prevents the accumulation of mold in the hive and on the bottom-board, which would otherwise occur. The next tier is elevated about half an inch, while the upper ones need no more ventilation than the ordinary entrance. As to absorbents on the top of the hive, I use old quilts which are cut to the right size and laid on the top of the hives. Last winter I put lo colonies in with just the honey-board on top, and those wintered as well as any. I have also packed some with dry sawdust on the top *a la* Mr. Bacon; but so far as packing on the Bacon; but so far as packing on the top of the hive is concerned, I find but very little if any difference. I have never tested chaff hives, but bees cannot winter as well in them as in a bee-house. I keep the temperature in my bee-house from 45° to 48°. The great object is to keep the temperature even.

The convention adjourned to meet at Stanwix Hall, in Rome, N.Y., on Feb. 24, 1886, at 10 a.m.

O. J. EVANS, Sec.

For the American Bee Journal.

## The Hibernation of Bees.

#### PROF. A. J. COOK.

I did not intend to say more on this topic, but the well being of science, and our industry as well, makes it the duty of some one to speak; and as no other one may find time, I again take my pen.

Brother Clarke amuses me. will remember the old story of the shrewd farmer who said to his neigh-bor lawyer: "Friend, my bull has razed your fence and gored your ox to death. What ought to be done?" "Why," said the lawyer. "the case " Why," said the lawyer. "the case is plain—you must pay for the ox." "Oh !" said the farmer, "my inex-perienced, clumsy tongue has blun-dered. It was your bull that gored, and my ox is dead. "Oh !" said the lawyer, "that alters the case ma-taxialty " lawyer, " terially."

I pronounced against Bro. Clarke's theory which he first built wholly, if I mistake not, upon the statement that bees in trees in the forest do not die-which, by the way, is not at all true in Michigan. I have received a pretty severe blast of adjectives-in truth, as severe a word-flagellation as a kind-hearted, orthodox clergyman in good and regular standing would dare to give. Dr. Tinker speaks for the Dominie's pet, and as positively as I ever did, and there is no such words as " contemptuous dogmatism,"

when Bro. Clarke speaks, and which took the Detroit assembly fairly off its feet. This time the other "ox is its feet. This time the other "ox is gored." Well, it is all right: we all enjoy Bro. Clarke's enthusiasm and his charming periods, if we do not always respect as fully his opinions and theories.

More than once I have gone over the same ground that Dr. Tinker has, and have no fault to find with his admirable experiments, nor the facts which he draws from them-they are which he draws from them—they are substantially the same that I have obtained. But when this winter-quiet of bees is termed "hiberna-tion," then I do object, and I think with excellent reasons. I believe that if the Doctor will experiment with other inserts and objects his with other insects, and observe his bees longer, he will also agree with me that another word than hibernation must be used.

We find a wasp in winter, when it is very cold. The wasp hibernates. We pick it up—it does not move nor does it sting us. We watch it for hours—there is no movement. We put it where it is colder—still there is no movement. The wasp is not dead, it hibernates. Possibly it may, while in this profound coma, take some oxygen, though I doubt it; certainly it eats nothing. Now, Doctor, is this analogous to the condition of the bees in their winter quiet? If not, and the bees hibernate, what shall we call this?

Next, let us examine the bees. They are also very quiet when the tempera-ture is somewhere from  $40^{\circ}$  to  $50^{\circ}$ Fahr. I find that the temperature for this most quiet condition varies, probably due somewhat to the size of the colony, and very likely to the mois-ture in the air. The bees are not quiet like the wasp. I have marked the form of the cluster, when for some minutes I could not see the least signs of life. In an hour or two. examination showed that the form of the cluster had changed; indeed I found, by watching long enough, that we could see the outer bees push into the cluster. This, of course, is less satisfactory than leaving them and coming again to note the form of the cluster, for we might say the light irritated them. Yet the very fact that motion is induced, makes hibernation an inappropriate term to use.

I went into a large cellar the other day, with 50 colonies of bees in it. The temperature was  $44^{\circ}$  Fahr. My brother was with me. There was almost no sound, and no bees came out of the hives. If we would tap on any hive, we at once got the response in a gentle murmur, "All right." In another cellar at 41° Fahr., with a few less colonies, the bees were more noisy. As soon as we had a light in the cellar, the bees commenced flying out. Now, I ask Dr. Tinker if either of these were good examples of hiber-nation. Again Dr. Tinker says, and it is always true, that the centre of the cluster of bees was warmer than the outside. Now, if the bees are dormant—if they are fully hibernating-whence this warmth? Of course but that same gust of rapturous en-thusiasm which always wells forth of course the bees are active, must bethe heat is radiating all the time, and

They breathe and move; only, how-ever, but very little. We subjected the wasp to greater cold, and it waked not; I have found by oft-repeated ex-periments that greater cold waked the bees to greater activity. Dr. Tinker finds the same. They now breathe more, cat more, move more. Is not this curious hibernation? My not this curious hibernation ? My idea—1 think the popular idea—in truth, an excellent idea of hibernation—is stupor engendered by cold, which becomes the more profound as the cold increases. Grant the definition, and surely bees do not hibernate.

Let me ask Dr. Tinker if he would be willing to leave his bees without food, in case he was positively sure they would keep for weeks in this condition of greatest winter quiet. I certainly would not the second time. Again, the hibernating wasp did not sting when we picked it up. Try the sting when we picked it up. bee from the Doctor's "hibernating " cluster, and see if the results are the same

Now I am through ; and I shall not trespass on the space of the BEE JOURNAL again. 1 think, with this subject. I only desire that we should not use this term, when winter quiet or quiescence is just as good-I think far better-and we need this term for another phenomenon more startling and wonderful. If we use this term for bees, we may with hardly less impropriety call sleep hibernation. If our bees truly hibernated, we could withdraw food, reduce the tempera-ture, and cry "Eureka !" with Bro. Clarke, knowing that with returning warmth our bees would wake to new life.

Agricultural College, 9 Mich.

# For the American Bee Journal. The Champlain Valley Convention.

The Champlain Valley Bee-Keepers' Association met in Middlebury, Vt., on Jan. 21. 1886, being called to order by the President, Mr. II. L. Leonard, of Brandon, Vt. The report of the last annual meeting was read by the Secretary, and adopted.

A discussion was opened by Mr. E. J. Smith, of Addison, Vt., on the sub-ject of "The best race of bees for profit." Although the subject was an old one, quite a spirited discussion fol-lowed. The experience of different members varied, but the majority were in favor of hybrids for all pur-Messrs. The ground was taken by Messrs. A. E. Manum, of Bistol, V. V. Blackmer, of Orwell, and others, that there were two distinct races of black bees—the small black bee and the larger brown bee, J. E. Crane, of Middlebury, held that they were not distinct races but the difference in appearance might be on account of difference in breeding and the kind of flora upon which they fed in different localities.

#### AFTERNOON SESSION.

The Treasurer's report was called for, and showed that the expenses in-

rangements of the present meeting were more than the sum in the treasury. On the suggestion of the President a sufficient amount was collected to pay all bills and leave a balance in the treasury.

The committee on the nomination of officers presented the following as officers for the ensuing year: President, P. C. Abbey, Essex, Vt.; Vice-Presidents, W. H. Proctor, Fair Haven, D. S. Hall, South Cabot, and J. E. Crane, Middlebury; Secretary, R. H. Holmes, Shoreham; and Treasurer, J. E. Crane. On motion, the Secre-tary cast the vote of the Association for the above-named persons, and they were declared elected.

The following essay was read by Miss Marcia A. Douglas, of Shoreham, Vt., on

#### BEE-KEEPING FOR WOMEN.

It would be presumptuous for me, a novice of but two seasons' experience, to stand in the presence of these vet-erans in the field of apiculture and attempt to bring before them any-thing new or instructive upon this ancient, yet modern, theme. But I trust you will bear with me for a little, and if any errors creep in, remember that it is through ignorance.

Josiah Allen's wife says, "There are a dozen sides to everything." and I am sure that no bee-keepers would take exceptions to this assertion in regard to their business. But it is not my intention at this time to discuss more than eleven sides. for I could not profitably use more than the fifteen minutes allotted to me on the programme.

The necessary and primary elements in women to succeed in bee-keeping as in any other undertaking, is to perceive what needs to be done, and then be able to bring about the most satisfactory results with the least possible expenditure of time and labor. We must also love the bees, enjoy watching them, and strive to ascertain their requirements so as to be able to administer to their wants. The ever-recurring "cause and effect" must be traced out, and when we are able to accomplish this, amid the varied circumstances in'this intricate business, we have taken the one all-important step to success.

We are told in "Iloly Writ" that "Where no counsel is, the people fall; but in a multitude of counsellors there Surely, Solomon could not is safety." have considered that especially applicable to us—beginners in the bec-business! Why, there is such a diversity of opinions and so much contradictory advice given so freely and courteously through the various periodicals, that if we were to swallow it all and undertake to digest one-half of it, dyspeptic apiarists would be the inevitable sequel. I would not ignore all authorities-far from it; but I would carefully peruse them and extract therefrom such ideas as commend themselves clearly to our comprehension and individual need.

During my career I have been, and am still highly favored, in that I live not very far from reliable authority, and I avail myself of opportunities to curred by the Secretary for the ar- ask questions, as may be attested by

one of the brothers present. Bnt there are emergencies in the apiary that try women's souls and call for prompt action. Then every particle of "bee-lore" in our possession is mustered into service to aid in .reagement, Harriet M. Morris states that, "The being who has for generations split kindling-wood with a caseknife, driven nails with a stove-hook, and defended herself with a broomstick, may be relied upon to find a way to capture the most inconsiderate swarni that ever settled upon tree or post." Men have the advantage of us, they are such calm, moderate, deliberate creatures, and can adjust themselves so readily to circum-stances! Now we are not to suppose for one moment that our Secretary was in the least disconcerted one day last summer, if he did have nine swarms come out at once and form one grand cluster; and at another time a very aspiring colony insist upon occupying the very bighest branch of the tallest locust tree in the vard after having been offered a hive once or twice from some of the lower limbs! I think the climbing was the most trying to him, still, he is not one who would easily weary in well-doing !

The next side to be considered is that scientific bee-culture is an open field for women as well as men, and our opportunities for making discoveries and improvements are equal, and, withal, we are thought to be such ornaments or acquisitions to bee-keepers' associations that we are gratuitously voted into full membership. Now, judging from the past pre-eminent success of the score or more of women throughout this broad land, we can but take courage to press forward and make our way through this open gateway to the attainment of the same desired goal. By many it is often exclaimed mentally, if not audibly, "Oh, for an opportunity to earn money that I can call my own !" In the days of our grandmothers, country women could realize quite an income from the fruit of the spinning-wheel and loom; but that mighty motive-power, steam, has hoisted those machines to the attics, where the "young Americas" have, in play, brought them to such a state of dilapidation that but a few fragments of the originals are left to tell the story.

For several seasons past the poultry business has been quite a "fashion-able summer resort," and in many instances with good results; yet, at-tended by no small degree of uncertainty, and besides, their pasturage is much more expensive than that of the bees. If we compete with our brothers in making pantaloons or in teaching school, we are imagined decidedly out of place in demanding as much pay as is commanded by them for the same work. Several years ago, during the operation of the cheese-factory near which I live, the dividends were made out by a man, one of the directors of the company, and when it was sug-gested that a certain woman make out the dividends and receive the same remuneration, another man in protestation affirmed that her time was not

so valuable as that man's, and therefore it would be unjust for her to receive the same compensation for the work; and so that speculation came to an untimely end. But I have yet to hear of a crate of honey being shipped to any commission house at a discount because of its being produced by a woman! It is said "some women love to be dependent and to be compared to clinging vines which are lifted into the sunshine by sturdy oaks." But as far as my observation goes, that ground assumes the aspect of sinking sand; for have we not all seen trees encircled by thrifty, prom-ising bark, that were bollow at the heart? and by and by has it not been deeply regretted that self-reliance had not been planted for a trellis?

Now in this next side, notwithstanding my limited experience, I think I shall venture to discourage all ambi-tious "vines" who contemplate emother persons that expect to find a "regular bonanza;" for with the present honey-market quotations one need not anticipate very heavy returns for time and money expended.

There are disagreeable sides to every calling; therefore do not expect to find the apicultural path strewn entirely with roses. No great feats are ever accomplished without the requisite self-sacrificing patience and perseverance.

If you are one whom the bees dislike, and, as you say, will go out of their line to meet and sting you, think twice before investing your money, for it is no laughing matter if one eye, swollen and aching, of necessity, closes its doors and refuses to be on duty for a day or two, and your features are all so distorted, that to be recognized by your mother, an introduction becomes necessary! Then those busy little bees have never had impressed upon them that one day in seven was made for rest; but instead of thus appropriating it, Sunday is one of their best days, regardless of your desire to attend church; and during their busiest comes most of the centennial cele-brations and Fourth of July picnics. But it may be you deem it unjust for me to criticise the doings of these wonderful insects, still, they must bear in mind that everything under the sun must be subjected to that; and just here allow me to insert a few extracts from charges made on them by the London Sporting Times: "There is no insect more thoroughly objectionable than the bee. It is even more disgustingly active than the ant. Scientific persons are fond of telling us of the bee's tremendous geometrical knowledge, and parade in proof thereof the fact that it builds hexagonal cells, thereby packing the greatest number of cells, with the smallest possible amount of wax, within a given space. They tail, however, to notice that there is no law requiring bees to build their pre-posterously little cells. If they were really intelligent insects and knew the they would build cells holding a pound of honey each, and thus enable a

human being to eat honey without at the same time filling up the interior of his person with wax. This simple plan has never yet occurred to the bees. They go on building their anti-quated and clumsy cells without once undertaking to improve upon them. They may be intelligent but they do not improve it by adhering to a pattern of cell invented by their antediluvian ancestors. To hold up these miserly and wantonly busy insect to the admiration of mankind is a positive outrage. It is time that a protest should be made and that mankind should be needed by the plain and obvious truth that an insect which spends its whole existence in working and stinging is even more unworthy of emulation than is the mosquito or the book-agent.'

But enough of this; let us now turn to tenthly : We must not jump at conclusions before hearing both sides of the question. This occupation, if pursued legitimately and scientifically, is ennobling and leads to clearer perceptions of the useful and ornamental. and in it there is no element of degeneracy. It enlarges our minds in the reception of the truths of natural history and botany, and paves the way for a more liberal culture. It moulds character whenever the enterprise has the soul-spmpathy of the one engaged in it, and makes us all enthusiasts. It is without doubt a healthful enterprise and will afford that long-felt need of most of our American women in the country—exercise in the open air. In short, it is an honorable pursuit and a laudable undertaking.

Eleventhly: If in the face of these numerous pros and cons you can untalteringly endure the foretold pleasures and hardships, together with the not poetical, but literal "sweat of your brow," be assured that you are a fit candidate to receive a life-long certificate of admittance to the ranks of bee-keepers.

And now while we are here together comparing our ideas, let us all will-ingly submit to friendly criticism even if it does seem to upset some of our long-cherished theories. "Let the truth come to the front and stand conspicuously there; for truth will triumph whether we consent or not."

Besides the foregoing essay, others were read by V. V. Blackmer, Orwell. Vt., subject, "Is sweet clover a Were read by V. Y. Blackmer, Orwen, Vt., subject, "Is sweet clover a nuisance?" "Small packages for honey," by J. H. Martin, of Hartford, N. Y.; and "The variation of the honey season in different localities," by H. L. Leonard. The following subjects were then discussed: "The future outlook of sale and production future outlook of sale and production of honey," "The best management of bees to prevent swarming," and "Marketing honey."

The most intense interest and en-thusiasm' prevailed throughout the entire session. A prize was offered to the one producing the best essay, which was unanimously awarded to Miss Marcia A. Douglas.

There were over 80 persons present

that there were more ladies present than were present at the Detroit Convention. It was decided that the name, "Champlain Valley Bee-Keep-ers' Association," should be changed to the "Vermont State Bee-Keepers' Association.'

During the evening session reports of bee-keepers were read, which showed an aggregate of 1,652 colonies in the spring of 1885, and 2,565 colo-nies put into winter quarters last fall.

Premiums having been offered for honey-products and apiarian supplies, several articles were on exhibition. The awarding committee reported that on account of the exceptional excellence of the articles they found great difficulty in arriving at a conclusion.

The awards were as follows: Best bee-hive (complete), shipping-crate and honey-boxes, Drake & Smith, of Bristol, Vt.; best bee-feeder and clamp for boxes, D. S. Hall, of South Cabot, who also exhibited the "Heddon case;" best 10 fbs. comb honey, and best heavy comb foundation, Moody & Isham, of Weybridge: best 10 fbs. of extracted honey, R. H. Holmes. (The premium on extracted honey was afterwards given to Mr. F H. Wright, of Enosburg, by mutual consent.) Best light comb-foundation, L. O. Thompson, of Weybridge; and best display of bee-keepers' requisites, Messrs. Drake & Smith.

A vote of thanks was tendered to the Secretary for his efforts in arranging and assisting in carrying out the programme of the meeting; also to the retiring President, for the faithful manner in which he had performed his duties, and to all who had participated in reading essays or in the discussions. It was decided that the time and place of the next annual meeting be left with the executive committee.

Thus ended one of the most profitable and enthusiastic gatherings ever held in the history of the Association. R. II. HOLMES, Sec.

#### For the American Bee Journal

Small Hives vs. Large Hives, etc.

#### C. W. DAYTON.

I agree with Mr. Fuller, on page 56, that a large (average) hive is better than a small (average) hive, taking the apiary through. That he can get 10 solid frames of brood in every hive by the beginning of the honey-flow, shows that a 10-frame hive is the best for his location; while a 12-frame hive may be the best for Mr. Dadant's location, and an 8-frame hive the best for my location. There is a difference in location. I am through using divi-sion-boards both in the brood-chamber and upper story in half of the hives of my apiary. I did not use the hives of my apiary. division-board before the honey harvest to retard brood-rearing, but at the beginning of the harvest, in order to obtain honey instead of more worthless brood. On page 698 of the AMERI-CAN BEE JOURNAL for 1885. I gave my experience with different sized

hives for last season, and also told how long it takes ordinary colonies to fill 12 combs with brood. I once had some experience in hiving swarms, of the kind that breaks the limbs of the trees, that issued so late in the boney harvest as to be unable to huild comb in which to rear a sufficient amount of brood to maintain a colony. I have received the "Convention History" I have and I find that it greatly exceeds my expectations in typography as well as contents. I consider it a valuable ac-quisition, as will all who take any interest in bees. It contains the very heart of a first-class bee-book, and the second page alone is worth to me many times the price of the book.

Bradford, & Iowa.

For the American Bee Journal.

# Temperature of Bees in Winter.

### L. C. CLARK, (23-23).

I wish to add my testimony in favor of a temperature of about 40° for beecellars, and I was surprised that a temperature so high as  $60^{\circ}$  to  $90^{\circ}$ , as recommended by Mr. Ira Barber in his essay at the Detroit Convention, was allowed to pass unchallenged, and consequently is taken as the winter temperature for bees recommended by that Convention. From  $60^{\circ}$  to  $90^{\circ}$  is the temperature of an active state of existence, and we hold that the natural condition of a colony of bees, or their natural instinct, is to remain inactive or sleep during the winter season; and that this condition is best secured at a temperature of from 35° to 40°. If we examine a colony placed in so high a temperature as 60° to 90°, we will find that the bees scattered among the combs in a constant state of activity, and of course must wear out their lives in much less time than when they are kept inactive by a lower temperature.

It may be said that brood-rearing is constantly kept up in a high temperature, which may be true, but we must remember that rearing of brood largely, requires water, fresh pollen, and a chance for flight in the open air; two of these we cannot have in a cellar, and I cannot divest myself of the idea that sooner or later we will get into trouble by placing our bees in the cellar in a condition that they will rear much brood. We all agree that it requires a large amount of honey to rear brood, and it seems to be all unnatural to attempt to do so in winter confinement. I also find that when the temperature of the cellar goes below freezing, the bees at the outside of the cluster have a constant quivering motion of the body and wings, much more so than at the same temperature when out-doors. It appears that they are too cold and are trying to raise the temperature by a motion like a man with insufficient covering upon the bed-he will wake up and try to get warm. The bees are doing the same thing, and this constant mo-tion or activity will wear out their vitality at a time when there are no young bees to replace the loss.

The question is about this way: At the close of the breeding season in the fall, we have a certain quantity of bees and honey in each hive—now which shall we do, place these bees in a condition that they will sleep quietly and not wear their lives out by activity? or shall we place them in a condition of activity where they will be constantly wearing out, and constantly rearing-brood with two of the con-ditions of successful brood-rearing lacking—fresh pollen and a flight, and also water if furnished to them at all in an artificial manner?

On page 809 of the AMERICAN BEE JOURNAL for 1885, Mr. Ira Barber says at the close of his essay, "Where but few bees are kept, where I live, they have no trouble in wintering them in any cellar where vegetables will keep without freezing." Now these cellars must from necessity be kept above freezing and will probably range from 35° to 45°. And if small lots of bees winter in these cellars without trouble, why does he recom-mend a temperature so much higher for large lots of bees? Probably 19 bee-keepers in 20 pursue some other calling-generally farming-and geuerally have cellars, that will keep vegetables without freezing, and cannot conveniently adopt a temperature which would require artificial means to keep it up with small lots of bees. I cannot agree with Mr. Heddon where he quotes Mr. Barber on page 12, by saying, "The wintering problem is solved." The tendency seems to be toward cellar-wintering in preference to out-door packing, but there is a wide difference of opinion as to temperature, moisture and ventilation, and whether it is advisable to raise the temperature toward spring to en-courage breeding. These are points which we should all experiment on and observe, and now is the time of year to do so.

Granada, & Kans.

#### Convention Notices.

127 The annual meeting of the Rhode Island Bee-Keepers' Society will be held on Feb. 11, 1886, at Providence, R. l. GLO. A. STOCKWELL, Sec.

(27) The Cedar Valley Bee-Keepers' Associ-ation will hold its winter meeting at the City Hall in Laporte City, Iowa, on Feb. 17 and 18, 1886. Reduced rates are offered at the hotels. 1886. Reduced rates are offered at the noters. A very complete programme is prepared with ample time to discuss subjects of im-portance to bee-keepers. A cordial invita-tion is extended to all to be present. H. E. HUBBARD, Sec.

13. I. Hendward, Sec. 13. The New Jersey and Eastern Bee-Keepers' Association will hold their ninth semi-annual convention at Cooper Union (Room 22) in New York City, on Wednesday, March 10, 1886, at 9:30 a.m. All who are interested in bee-culture or honey are re-spectfully invited to attend. We expect a large delegation from the Philadelphia Association to meet with us, and it promises to be one of the most interesting as well as instructive conventions that this Associa-tion has ever held. A special invitation is extended to ladies, well knowing that they are by no means a small factor in our in-dustry. Beginners, it is well known, will learn more by attending one good conven-tion than a year of practical experiments will teach them. All are requested to bring something to exhibit, and if you cannot come, send us an essay to read on some live subject. W. B. TREADWELL, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886.

J. M. HAMBAUGH, Scc.

Weather, the meeting of the Marshall County Bee-Keepers' Association was postponed from Jan. 16, 1886 to Feb. 20, 1886 ; at which time the same programme will be carried out as was intended for Jan. 16. J. W. SANDERS, Sec.

The fourth annual convention of the Eastern lowa and Western Illinois Bee-Keepers' Association will be held at Moore's Hall in Davenport, Iowa, en Feb. 17 and 18, 1886. A number of prominent aplarists are expected to be present. Everybody inter-ested in bee-keeping should not fail to come, as all topics of interest to those engaged in the sale and production of honey and bees will be thoroughly discussed. Everybody present are requested to take part in the discussions. Supply dealers and those having honey and beeswax are requested to bring the same for exhibition. having honey and beeswax are required bring the same for exhibition. WM. Goos, Sec.

The Seventeenth Annual Conven-tion of the New York State Bee-Keepers' Association (formerly the Northeastern) will be held in Rochester, N. Y., on Feb. 16, 17 and 18, 1886. This will be one of the largest meetings ever held in the State. A large number of our most experienced bee-masters will take part in the discnssions, and several essays will be read from a number of our most practical apiarists thronghont the country. The programme is complete. If yon are young in the work you can not afford to stay away—if older, you may give some good hints, if yon get none. We want a good disnlay of all kinds of supplies and fixtures. We have a room on purpose for exhibits, and any goods sent to the Secretary in care of the "Na-tional Hotel," Rochester, N. Y., will be placed on exhibition, and either sold or re-turned to the exhibitor, as directed. Re-dneed rates at the hotels have been secured, also rates on some of the railroads. All will have to pay full fare one way—retarth ticket at 1-3 fare by presenting certificate from the Secretary, who will furnish them on apulication. We want an active vice from the Secretary, who will furnish them on application. We wabt an active vice-president in every county in State. Please name one or send the name of some one, for your county.

F. C. BENEDICT, SEC.

#### Honey as Food and Medicine.

128 To create Honey Markets in every village, town and eity, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 eents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. " Honey as Food and Medicine " are sold at the following prices :

Single copy, 5 ets.; per doz., 40 ets.; per hundred, \$2.50. Five hundred will be sent pestpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the beekeeper who scatters them).

'To give a way a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview by sending the names to this office, or we will send them all to the agent.

### Local Convention Directory.

1886 Time and place of Meeting. Feb. 11.-Rhode Island, at Providence, R. I. Geo. A. Stockwell, Sec., Providence, R. I. Feb. 16-18.—New York State, at Rochester, N. Y. F. C. Benedict, Sec., Perry Centre, N. Y. Feb. 17, 18.—Cedar Valley, at Laporte City, Iowa. H. E. Hubbard, See., Laporte City, Iowa. Feb. 17, 18.-E. Iowa & W. Ills., at Davenport, Iowa. Wm. Goos, See., Davenport, Iowa. Feb. 20.-Marshall Co., at Marsballtown, Iowa. J. W. Sanders, See., LeGrand, Iowa. Feb. 24.—Oneida County, at Rome, N. Y. O. J. Evans, Sec., Camroden, N. Y. Mar. 10.-N. Jersey & Eastern, at N. Y. City, N. Y. W. B. Treadwell, Sec., 16 Thomas St., New York.

Apr. 27.—Des Molnes County, at Burlington, Iowa. Jno. Nau, Sec., Middletown, Iowa. Oct. 19, 20.–11linois Central, at Mt. Sterling, 11ls. J. M. Hambaugh, Sec., Spriog, 11ls.

10 order to have this table complete. Secretaries are requested to forward full narticulars of time and place of future meetings.-ED.

Good Results.-A. P. Lawrence, Hickory Corners, 9 Mich., on Jan. 26, 1886, writes :

In the fall of 1884 I placed 91 colonies in the cellar, 4 of them starved, 12 were lost by "spring dwindling," sold 2, and started in 1885 with 73 good colonies of bees from which I cleared \$300. The first part of the season was all that I could ask for, but after the last of July there was but very little honey gathered. We have to depend mostly upon white clover, and there is but little basswood in this vicinity. I increased my apiary to 114 strong colonies. I took 3,500 fbs. of honey, 700 fbs. being extracted. I moved my apiary 1 mile on November 26, and placed them in the cellar, and now they are all in good condition.

Bees Wintering Finely.-C. H. Pntnam, Galesburg, +0 Ill., on Jan. 28, 1886, writes :

My bees thus far are wintering finely. 1 have just examined them, and I find that there has been no accumulation of moisture in the hives, and no signs of disease; they also appear very contented, and remain quiet on the approach of the light. I am wintering them in two bee-houses, into which I placed 113 colonies on Dec. 6 and 7, 1885. I keep the tem-perature as near 45° above zero as possible. Last season was a very poor one for honey in this locality. All of my bees have natural stores, which I consider the proper food for them.

Actions of Bees in Winter.-J. A. Procter, Union City, o+ Ind., on Jan. 30, 1886, says:

and there is so much difference in the different colonies that 1 begin to conclude that the bees of no two colonies act alike under the same conditions. One of these colonies was out at the front of the hive, and all over it when the mercury was  $10^{\circ}$  below zero, and the bees of the hives next to it were perfectly quiet. There is another colony that at any time since they were put in, the bees can be seen in the entrance of the hive humming merrily; and the next one to it is perfectly quiet. If some of our experts in apiculture will explain the reason for the different actions of the different colonies side by side, I will be very grateful.

Reports of the Honey-Crop.-L. Highbarger, Adeline, 5 Ill., on Jan. 28, 1886, writes:

I was well pleased with Dr. C. C. Miller's report, page 44, as far as it goes, but I do not think that it covers all the ground. It is entirely wrong, not only to ourselves but to the honey market, when bee-keepers report only when they obtain large crops of honey, and not when they have small crops. The Doctor's ideas have the right jingle, but do not jingle enough; there is one great point left out-how much sugar syrup have we fed in order to carry our bees through the winter? Now, Doctor, how much sugar syrup have you fed to carry those 340 colo-nies through the winter? I move an amendment, Mr. Editor, to the Doctor's suggestions, and will sauction it by giving my report:

No.	colonies,	Fall 1884	70
6.6	66	Spring 1885	40
64	66	Fall 1885	60
		ey " "	
	" Sugar S	yrup fed, 1885	400

Surplus..... I attribute my winter losses to the so-called honey-dew-not to pollen.

P.S.-My object is to show to the consumer that our honey crop is not all dollars and cents. We have been showing the bright side too much, and the dark one not enough.

Dampness in Hives, etc.-Allen H. Thorne, Fountain City, o+ Ind., on Jan. 21, 1886, writes:

It is too early in the season to make a report for this winter, but I can report up to Jan. 18, 1886. In the fall of 1884, I placed 23 colonies in winter quarters packed in sawdust. All were weak, and all died but one, caused, I think, from dampness collecting on the under side of the oilcloth and dripping down on the bees, thus causing them to become diseased, and what did not die with disease froze during the cold nights of last winter. One-half of the colony that I saved froze to death. They clus-tered on both sides of a comb near the comb near the centre of the hive, and all on one side froze in a cluster, leaving those

leaving about 30 pounds in each hive,. part of it being extracted and part comb honey. I purchased 3 colonies and emptied 8 hives of all their contents for one of my neighbors, that he was culculating to kill for their honey. I put them into hives on 7 combs, and fed 26½ pounds of syrup made of coffee A sugar to each colony in September, and then packed them for winter the same as I did last fall, with the exception that I took the enameled cloth off and put burlap covers in their place, giving them 3/3-inch space over the top of the frames for a bee-space. I left the top off of the hive and put 8 inches of dry saw-dust over all and 18 inches of dry flaxtow on top of the sawdust, well packed down; the object being to keep the dampness out of the hives. They are wintering well so far without any sign of disease. I also gave them from 1 inch to 5 inches at the entrance of the hives as an experiment, and I now see no difference, for all are wintering well. We have had some pretty cold weather-20° below zero.

My Experience in Bee-Keeping.-N. W. Afflerbaugh, of Cameron, Nebr., on Jan. 25, 1886, writes :

Two years ago last August I ob-tained 2 colonies of bees, the hives being then full of brood, but without honey. They worked on the heart's-ease, and in 2 weeks they filled the hives with honey. Heart's-ease is one of our best honey-plants. I in-creased them to 17 colonies by division. creased them to 17 colonies by division. I am wintering them on the summer stands packed in straw, and to-day they had a flight. They came out dry, healthy and strong. I am wintering them on their natural food—honey— which was made for both them and man. The hive I use is one of my own construction, being a double-walled chaff hive. It opens on the side so I peed not lift out the frames. side, so I need not lift out the frames, as they are taken out on the side; a bee-feeder in the back end of the hive, put in when the hive is made, and is intended to remain there. It does not interfere with anything about the hive, and I can feed both in summer and in winter with no danger of rob-bing. The beauty of it is in handling the frames by taking them out at the side, thus causing scarcely any dis-turbance of the bees. I am well pleased with it.

No Trouble in Wintering.-L. F. Guice, Winterville,+o Miss., on Jan. 26, 1886, writes :

I am now shipping the last honey from the crop of 1885. I started with 43 colonies for producing extracted honey, and 13 for increase, and during the season I took 5,500 pounds of honey, some of which I sold at home for good prices, and shipped the balance to different markets, realizing about 4 cents per pound for it. I closed the season with 108 colonies in I have 11 colonies of bees in a bee-house made purposely for them, with sawdust filling. Then the hives are packed in sawdust 3 or 4 inches deep, as it does not pay to ship honey. We of the South do not have any trouble about wintering our bees—leave them plenty of honey in the fall and they will be all right the next spring. There is only a month or two here that bees do not bring in some pollen, and I think it is as necessary for them as bread is for people. I hope that we may have a prosperous season this year.

Bee-Keeping in Southern Ohio.-E. Henkle, of Washington C. H., Q O., on Feb, 2, 1886, says:

I was very unsuccessful with my bees last season, having lost 18 colonies with diarrhea last spring, which left me 34. I had only one swarm during the summer, and obtained only about 40 pounds of comb honey, and no extracted honey. I have about 300 section-boxes nearly full, but the drouth set in so soon and cut the white clover bloom off so short that the bees could not finish them. We had no fall honey. I have 35 colonies packed with chaff and leaf cushions on the summer stands. I cannot say how they are wintering at present, as they have had no flight since Jan. 1. My bees never were strong enough during the summer to swarm naturally or bear dividing. I have concluded that the southern part of Ohio Is a poor place for an apiary. When I read the reports of other bee-keep-ers getting 300, 400 or 500 pounds of honey from one colony, and when I have never been able to get over from 40 to 50 pounds per colony, it looks to me as being very doubtful.

Knowing Pure Honey.-W. Mason, Fillmore,+o Ind., on Jan. 30, 1886, savs:

While attending the recent meeting of the Indiana State Bee-Keepers' Association, I was frequently asked Association, I was frequently asked how we are to know when we are getting pure honey. My first answer was, "Buy of only honest dealers or producers." Every consumer who buys honey of a dishonest honey-pro-ducer or dealer, and is satisfied of this fact, should publish such parties as a fraud, and thus warn the people. It should be one of the essential It should be one of the essential points that our associations should watch and stamp out all such frauds. in the honey-markets, and see that no one has a place in our meetings who is guilty of selling adulterated honey. The time will soon come when the consumer will know of whom to buy his honey, for it is fast becoming one of the staples of table sweets, and we will soon know pure honey almost by sight, if not by faste.

**Prospects** in California. -J. D. Enas, Napa,+o Calif., on Jan. 1, 1886, writes:

We are having a wet season and warm rains so far, with prospect of a fair honey season for 1886. As considerable seed did not sprout last perature of my cellar has varied be-season, and the birds and wild game tween 44- and 48° above zero. The must have cleaned up pretty well winter was very mild up to Jan. 1,

what seed did mature, bees are gen-erally in poor condition. It will take most of the early crop to get them built up. Bloom is starting, but it is sparse, though should we have warm spring, there may be a good late-season, as the ground is per-fectly saturated with water. Farmers are buoyant as a general thing, grain is up several inches in height, and the hills are green with feed for farm-stock. Weeds will be plentiful. Stock can get their living now in the hills where there is shelter. The ditches and rivers are all full of water. In my article on page 776 of the AMERICAN BEE JOURNAL for 1885, it reads thus: "It appears to them that bees can hore or puncture fruit," instead of reading, "It appears to them that bees cannot," etc.

The Lewis Exhibit.-Dr. A. B. Mason, Wagon Works, vo O., on Jan. 22, 1886, as chairman of the committee on exhibits at the Detroit Convention, writes as follows :

MR. EDITOR: The report of the committee on exhibits at the recent convention at Detroit. did not include the exhibit of G. B. Lewis & Co., of Watertown, Wis. In a letter to Mr. G. M. Doolittle, a member of the committee, they call attention to the omission. Their letter was forwarded to me, and I wrote them, asking what they exhibited and where. In reply they say: "Our sections were dis-played in the sample room of the Newhall House, and also they were brought down to the office." This accounts for the omission in the report, for the committee supposed that all the exhibits were made at the Antisdel House. They state: "We exhibited only 4¼x4¼, open-top, very white basswood sections, and some English section-folders." Please insert the above in the BEE JOURNAL.

[If the "exhibit" mentioned was not made at the place designated for such by the Society, that, of course, accounts for the omission in the report of the committee. We are also cited to the fact that the names of neither of the members of the firm are enumerated in the published list of members of the Society. On that, we know nothing more than we find in the report as published.-ED.]

Bees in Splendid Condition.-Wilson Sherman, Chester Centre, O Iowa, on Jan. 22, 1886, says:

My bees were placed in the cellar on Dec. 5, 1885. They had a chance for flight every day up to Dec. 4, if they wished to do so. They have now been in the cellar over a month and a half, and they are all quiet and in splendid condition. I do not think that they have consumed on an average over 3 or 4 lbs. each, so far. The tem-

but since that time the weather has been very cold, and bees that were left out-doors are suffering considerably.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a.m., Feb. 8, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

CHICAGO. HONEY.-There is an easier tone to the comb honey market, and prices are fully one cent per pound less that at quotations, 15c. being the price for white comb honey in 1-lb. sections, and lots coming lato different commission houses, and all being easier to sell, the yunderbid regular honey bouses in order to do so Extracted honey brings 6@\*c. per ib. BEESWAX.-24@26c. K. A. BURNETT, 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY.—The market for hocey continues dull, and prices are ruling lower; however, if the cold weather continues, it may improve the trade in a short time. We quote as follows : Fancy white comb in 1-lb, glassed or ucglassed sections, 13@14c, the same in 2-lb, glassed sections, 13@14c, the sections, glassed, 9c; in 1-lb, sections, glassed or unglassed, 10@11c. Extracted—white clover el%@Rc. buckwheat, 5%@R4c. BEESW AX.—Prime yellow, 25@28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

### ST. LOUIS.

HONEY.—The market is quiet and the demand light just now. We quote prices as follows :— Choice comb honey, 10@12c. Extracted, lo bar-rels, 44@5c. Extra facey of bright color and in No. 1 packares, ½ advance on above prices. BEESWAX.—Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEY.—'The demand is extremely slow for ex-tracted honey. Manufacturers seem to have taken a rest. There is only a fair demand for honey in glass jars, and for comb honey. Prices are un-changed and nominal, with occasional arrivals and a large stock on the market. We quote extracted honey at 463c, and choice comb honey at 12@14c, is a inhibur way.

Dety at 40%, and choice could have a react of a jobbing way. BEESWAX.—There is a good home demand for We pay 25c, per 1b, for choice yellow. C. F. MUTH & Son, Freeman & Ceotral Ave. it.

#### CLEVELAND.

HONEY.-The market is not quite as active as it has been, owing, no doubt, to many attractions of the Holiday Season. Best white, 1-lb. asections aeliat 150, and 2-lbs. for 130-ltc, but there is not ao much sale for the latter. Second grade honey is duil at 126-13c. Old white, 106-12c. Extracted, 7acsc. per lb. BEESWAX.-Very scarce at 22@25c. A. C. KENDEL, 115 Ontario Street.

#### KANSAS CITY.

HONEY.-Sales are extremely light and prices are very low. Choice comb honey in 1-lb. sectiona brings 14@15c.; 2-lba. 12@13c. Dark fall honey 1 to 2 cents less. Extracted honey is very dull and of slow sale. We had to unload a lot of very fine ex-tracted honey his week at 5c., and stocks continue to accumulate. BEESW AX.-Scarce and higher-22@25c. CLEMONS, CLOON & Co., cor. 4th & Walnut.

#### BOSTON.

HONEV.--It is selling very well but prices are very low, and we are often obliged to shade our prices in order to make rates. We quote comb honcy in 1-1b. sections at 14@16c, and 2-lb. sec-tions at 12@14c. Extracted, 6@8c. BEESWAX.--30 cits. per ib. BLAKE & RIPLEY, 57 Cbatham Street.

#### SAN FRANCISCO.

HONEY.-Choice comb honey is in light supply and is bringing firm figures. There is a fair move-ment in best qualities of extracted at steadyrates. We quote as follows: White to extra white comb, 106124c.; amber, 76%c. Extracted, white hiquid, 54654c; light amber colored, 44644fc; amber and candied, 4%c; dark and candied, 4464fc; BEESWAX.-Quntable at 23625c, wholesale. O. B. SMITH & Co., 423 Front Street.

#### DETROIT.

HONEY.-It is dull and lower. Best white in 1-pound sections, 15c. There are no sales of dark honey. Light extracted brings 10 cts, in 25 and 50 pound the-rans. BEESWAX.-25@27c. M. H. HUNT.

THOMAS G. NEWMAN & SON. PROPRIETORS. 923 & 925 WEST MADISON ST., CHICAGO, ILL.

At One Dollar a Year.

ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

To Correspondents. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

" Don't Stop "-that is what many write to us about their papers, when their time is nearly out. One subscriber says: "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It runs out with this month ; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

When renewing subscriptions please send an extra name or two with your own and secure a premium. We have some colored Posters, which we will send FREE, to put up in conspicuous places. We will with pleasure send sample copies to any one who will try to get up a club.

----

Preserve your papers for reference. If you have no BINDER we will mail you one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

2 Our rates for two or more eopies of the book, "Bees and Honey," may be found on the Book List on the seeond page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

Beeswax Wanted .- We are now paying 24 cents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be put on every package to prevent mistakes.

### System and Success.

All who intend to be systematic in their work in the aplary, should get a copy of the Apiary Register and commence to use it. The prices are as follows :

The larger ones can be used for a few colonies, give room for an increase of numbers and still keep the record all together in one book, and are therefore the most desirable.

To any One sending us one new subseriber with their own renewal (with \$2.00), we will present a copy of the new "Convention History of America."

The Time for Reading has now come. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books and ean fill all orders on the day they are received.

Any person not a subscriber, receiving a copy of this paper, will please consider it an invitation to become a subscriber to it.

Cash in Advance is the rule, but no longer than six months of grace ean be allowed on the small sum of \$1.00. Subscriptions may commence at any time, and discontinuances may be ordered at any time, when arrearages are paid up.

Agents can sell the Guide and Hand-Book like "bot-eakes." Send us an order for five copies (with \$2,50) and we will send you the Weekly BEE JOURNAL free for a year. This is a rare opportunity to get the Weekly BEE JOURNAL without cost []

Perforated-Zinc .-- We have laid in a stock of perforated zine, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces ent to fit the Langstroth hive-19%x14½-Price 25 cents each.

All the Numbers from the beginning of the year are sent to new subscribers, unless otherwise ordered.

Extracted Honey. - Any one having white extracted honey for sale, are invited to correspond with us. We are paying 7 eents per lb. for it, delivered here.

Write to F. J. Crowley, Batavia, N. Y., for Price List (1886) of Apiarian Supplies, Bees, Queens, Foundation, etc.

'To Fill the egg basket, keep the poultry supplied with bones, shells and offals of bones with meat on, ground to a suitable size. To do this get one of Wilson's Hand Mills.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

NOTICE.-For \$3.00 I will mail direct, Frank Cheshire's great scientific work now publishing in parts, "Bees and Bee-Keeping,"-Arthur Todd,-Dadant Foundation Depot-Germantown, Pa. 6A4t

WANTED.-Two young men to work with bees. Three hundred colonies-27 years' ex-perience. Address, S. I. FREEBORN. ITHACA, W18. AAtf

BEES, bee-hives, imported queeos-first-class-cheap. OTIS N. BALDWIN, Clarksville, Mo. 4AIV

1869. UP WITH THE TIMES. 1886 Armstrong's Perfection

The brood-frames, honey-rack, and section-boxes are all **Reversible**. At the St. Joseph and St. Lonis, Mo., Expositions in 1885, it took the first premium over several of the most prominent bee-bives now in use.

Illustrated Catalogue sent free. Address, 5D13t E. ARMSTRONG, Jerseyville, Ills.

A WARDED First Premium at Michigan State-A Fair in 1884; and and again in 1885 at the Inter-State Fair beld at St. Joseph, Mo. Pricea greatly reduced. SPECIAL RATES on large lots. Address as above for price list of Apiarian Supples and Berry Packages. 6A3t

# The NEW Heddon

We have made arrangements with inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail ; nailed and also in the flat.

The engraving gives a good idea of the hive. The brood-chamber is in two sections; also the surplus arrangement, which may be interchaoged or inverted at will. The cap, bottom-board, and top and bottom of each sectional case has one-half of a regular be-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this bive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

ALL be bored for wires. A SAMPLE HIVE includes the bottom-board and stand; a slatted honey-board, and cap; two 6-inch brood-chambers, each containing 8 frames; two sorplus arrangements, each containing 28 one-pound sections, one with wide frames and separa-tors, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete. The same ready to nail, \$2.75. For further particulars send for onr new Illustrated Catalogue for 1886.

### FOR SALE CHEAP!

96 ACRES, bill-land, 1/2 well-stocked with apples, 96 ACRES, bill-land, ½ well-stocked with apples, 96 peaches, peira, plums, quinces, grapes, and small fruit, to fine bearing conoition. The remain-der is in pastore, grass, grain, etc. A plary coordains 140 ITALIAN COLONES in Longstroth hives. Bee-bouse and all modern appliances for applicative, in as good location for bees and honey as can be found. Good 10-room house, beautifully located, commanding a view of the city, river and aurrounding country. New barn and out-buildings, cistern, never-failing springs, etc. Reasons for selling-age and ill-health.

1Atf S. A. STILLMAN, LOUISIANA, MO.

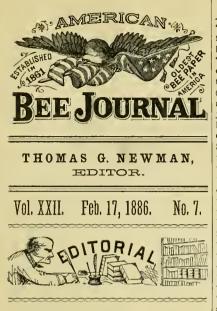

Queen-rearing is a fascinating pursuit. Every bec-keeper should rear a few queens for amusement and experiment. The best method for rearing queens may be found in the third editor of **The Bee-Keepers' Haudy-Book**, a work of 300 pages and 100 illustrations. Of this treatise on bec-culture, Mr. Langstroth says: "It certainly is the best authority on this important branch of bee-keeping. You have done more, in my opinion, than any one clse to facilitate the breeding of choice queens, and to simplify the process by which those who breed such queens either on a large or small scale, can make the most of all time they devote to this important branch of bee-culture." The hook is bandsomely and substantially bound in cloth, and sent by mail for \$1.50 per copy.

per copy.

Prospectus and price-list of queens and supplies sent free. Address,

4Etf HENRY ALLEY & CO., Wenham, Mass.

The Bees are Glad!—The fine and spring-like weather of the past week has been very general, and the bees have been enjoying a nice flight. The mild weather has extended from the Atlantic to the Pacific coasts. Bee-keepers generally are rejoicing and are nearly as hilarious as the bees. There is a good prospect now for a bonntiful erop of honey during the present year, for the clover has been protected by the snow, and it looks very healthy.

**Dr. C. E. Rulison,** of Flnshing, Mich., drove 30 miles on Wednesday morning, Feb. 3, to attend the Bee-Convention at East Saginaw, Mieh., and returned in the same manner in the evening of that day. A journey of 60 miles to attend a "bee-talk" shows that the Doetor is an enthusiast.

Florida has suffered very much this winter from "the cold wave." The mangroves have been killed, and this source of honey destroyed. The orange trees have suffered, and the oranges are frozen. One redeeming feature may be mentioned, which we find in a Sonthern paper, viz: "that Northern capitalists propose to utilize the frozen Florida oranges by making wine of them, for which purpose the frost has not injured them."

Fertilizers.-Where the materials eome from; where to get them in the cheapest form; how to compound formulas, etc., by J. J. H. Gregory, A. M., is the title of n pamphlet of 116 pages, just issued from the press of Rand, Avery & Co., Boston, Mass. It contains much practical information, given in language that farmers ean understand. It has been heartily endorsed by such men as Dr. Sturtevant, of the New York Experimental Station. Price, 30 cents,

------

The Indiana State Fair will be held at Indianapolis, Ind., commencing Monday, Sept. 27, 1886, and hold for a week.

The Rev. Robert West, editor of the Advance, appears to be too busy with "revival work" to even notice our demand for a retraction of his falschoods about comb honey being mannfactured, filling and "capping the so-called honey-cells by machinery," etc. We have always supposed that religion should make men honest (especially those "who minister at the altar"), but Mr. West's example indicates just the opposite !! He stands convicted, by the facts, of having broken the Ninth Commandment, which was thundered from Sinai in these words : "Then shalt not bear false witness against thy neighbor." and when it is pointed out to him, instead of making an honest confession that he was deceived by that lie of Prof. Wiley, (which the latter says he wrote as "a scientific pleasantry," and not as a sober fact,) Mr. West dodges the issue, says that he "surmises," has "reason to believe," etc., but wilfully withholds the retraction, meanwhile allowing the falschoods to be eopied by hundreds of papers all over the country, which naturally believe them to be true, because they were positively stated as facts by a "minister," and sanctioned by their appearance in a "religions paper !" During all this time an honest industry is suffering on account of his unjust accusation, and subsequent nnhallowed silence! Is not a profession of "religion" which permits such base characteristics, a mockery? Does not the actions of such "priests" do more harm to public morals than all the good their preaching could do in a life-time? "True religion " bleeds at every pore, being stabbed by its professed friends and hired-laborers. Solomon, the wisest of men, remarked : "He that nttereth slander is a fool."-Prov. x, 18. This is as true to day as it was 3,000 years ago, when it was written.

New Price-Lists have been received from the following persons :

E. Kretchmer, Coburg, Iowa.—30 pages— Bee-Keepers' Supplies, Apiarian Implements, Italian Bees, etc.

B. Walker & Co., Capae, Mich.—4 pages— Apiarian Supplies.

Monroe County Nnrseries, Rochester, N. Y.-10 pages-Trees, Shrubs, Plants and Vines.

Elwanger & Barry, Rochester, N. Y.-48 pages-Fruits Cultivated at Mount Hope Nurseries.

F. N. Lang, Baraboo, Wis.—48 pages—Tree, Flower, Vegetable and Field Seeds.

J.W. Bittenbender, Knoxville, Iowa.-12 pages-Bee-Keepers' Supplies.

F. J. Crowley, Batavia, N. Y.-12 pages-Apiarian Supplies, Bees, Queens, etc.

R. H. Allen, 191 Water St., New York.-92 pages-Seeds, Roots, Plants, and Garden Requisites.

Edward Gillett, Southwick, Mass. - 16 pages-Plants.

D. B. Ulery, New Carlisle. O.-16 pages-Bees, Queens and Apiarjan Supplies.

John Nehel & Sen, High Hill, Mo.—6 pages –Bees, Queens and Bee-Keepers' Supplies.

Emil J. Baxter, Nauvoo, Ills.-2 pages-

Any one desiring a copy of either of them, ean obtain it by sending a postal eard to the address as given above. Food Adulteration.—The Cedar Rapids, Iowa, Standard says: The following is a copy of the bill introduced into the House of Representatives by Congressman Frederick. It has been read twice, referred to the committee on the judiciary and ordered to be printed. It is an Important measure, and should be adopted :

A Bill to prevent the adulteration or lmitation of food :

Be it enacted by the House of Representatives of the United States of America In Congress assembled, that it shall be nnlawful for any individual, company, or corporation to manufacture or sell, any adulterations or imitations of fnod whatever, nuless they be branded or stamped, plainly giving the ingredients contained therein, and the relative proportion of each ingredient contained therein.

SEC.2. That any person who manufactures, sells, or offers for sale any adulterations or imitations of food of whatsoever kind, unless the same be plainly branded or stamped as heretofore provided, shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be punished by fine or imprisonment, the fine to be not less than \$200, and the imprisonment not less than six months, or both fine and imprisonment, at the discretion of the court.

SEC. 3. That any person or persons filing information, under oath, that leads to conviction of above, shall be, and is hereby, entitled to one-half of the fine imposed for such violation.

In the South the present winter has been very severe, and nearly all the disasters to bees so far recorded are from that section. The Rev. L. Johnson's letter in this week's JOURNAL is a sample of the wide-sprend desolation among bees. Let us hope that the frost may be of some value in other ways. The Chicago Times says:

The recent freeze at the South was not an unmixed evil. The frost penetrated the earth to the depth of a foot, and soil that had been impacted for several years was loosened and made ready for unusnal productiveness, while numerous pests of the worm and hug order were probably destroyed by the cold.

**Opinious** expressed concerning the pamphlet on Convention History and Reports of the National Society from its commencement, are as follows :

The "Convention Pamphlet" is a souvenir of apieultural intelligence, and worth many times its price to any bee-keeper.—James Heddon, Dowagiac, Mieh.

It cannot fail to awaken renewed interest In future Conventions, to publish the Reports in pamphilet form. - J. H. Andre, Loekwood, N. Y.

The publication of the History of the North American Bee-Keepers' Society in pamphlet form is a grand thing, and you deserve the thanks of the whole bee-keeping fraternity. J appreciate it.—J. B. Mason, Mechanic Falls, Maine.

It contains a great deal of valuable information for bee-keepers.—F. L. Dougherty, Indianapolis, Ind.

It is certainly very valuable to those who have but a limited knowledge of conventions, and none can afford to do withont it. -Frank A. Eaton, Bluffton, O.

The Convention Report Pamphlet is reeeived. The whole work is a credit to your office, from the subject-matter to the cover. —T. L. Von Dorn, Omaha, Nebr.

-T. L. Von Dern, Omana, Nebr. It is standard authority on the doings of the Society, and no library of bee-literature will be complete withont it. I think that every member and all others particularly interested in the fascinating pursuit of apiculture, will extend a vote of thanks for compiling a work so valuable and useful to the bee-keepers of North America.-C. R. Isham, Peoria, N. Y.

**REPLIES by Prominent Apiarists.** 

### Using Old Comb Foundation.

Query, No. 197.—Last spring I filled brood-frames for about 20 hives with comb foundation, and also starters in surplus boxes. Can I use them next spring as they boxes. Can I use them next spring as they are, or will cold weather or age injure them? If so, what shall I do about it?-P. W., New Vork.

Use them.-JAMES HEDDON.

I should use them as they are.-G. M. DOOLITTLE.

I should use them as they are.-C. C. MILLER.

You can use them. If warmed up so as to soften the wax, they will be as good as ever.—A. J. COOK.

Place the brood-frames in the sun, do not allow them to get too warm, put them into hives having good, strong colonies, and they will be all right.-H. D. CUTTING.

It is possible that the foundation may not be drawn so quickly, but it can be used. If it is not readily drawn, dip it into water heated to  $120^\circ$ ; if this does no good, melt it and have it made over.—W. Z. HUTCHINSON.

If they are kept where dust will not settle upon them, they can be used another year as they are. If the fonndation becomes partially detached from the frames, as it sometimes does, it may be re-waxed just before using.—G. L. TINKER.

Neither age nor cold will injure them. Look out for mice in winter, and moths in summer. Keep them dry .-- DADANT & SON.

If you manage them rightly you will have no trouble. If you hive swarms on them, give the swarms no more combs at a time than they can completely cover. The only difference between old and new foundation is that the former being dry and hard requires a higher temperature in the hive when it is being worked into combs.-G. W. DEMAREE.

I have used foundation 4 and even 5 years old, and found no trouble in its being accepted and drawn out. If found too dark for surplus it will be fully as good as any for use in the brood-chamber. It will be well to dip old foundation into warm water to soften it a little before giving it to the bees, if it is found to be very hard .-J. E.POND, JR.

### Keeping Bees Near the Railroad.

Query, No. 198.—1 have 120 colonies of bees that I expect to movo in the spring within 50 yards of the railroad where there is a very heavy grade. The trains sometimes shake the windows in my house. Will the noise or jar eaused by the trains molest or prove fatal to the bees ?—P. B. F., Mo.

No. The bees will get used to it .-DADANT & SON.

I have always considered near a railroad an unfavorable location for an apiary.—II, R. BOARDMAN.

I would prefer to move them away from the track if possible.—H. D. CUTTING.

The cars will do no harm at all, I ink. The smoke will be more to be think. The smoke will be more to be feared than any jar or noise.—A. J. COOK.

I knew of one instance of the kind, and I doubt if any harm resulted.— C. C. MILLER.

I should have no fears about the railroad injuring the bees. My apiary is situated near a railroad over which not less than ten regular trains pass daily.—G. W. DEMAREE.

I have kept bees for 15 years within 30 yards of a railroad, where heavy trains are passing every hour. I have never seen any ill-effects therefrom. The trains sometimes jar my whole house. From my experience I should apprehend no difficulty .- J. E. POND, JR.

I think not in the summer, but if they are placed in a cellar for winter-ing, the bees will be agitated by every passing train.—G. M. DOOLITTLE.

I think not. Colonies in trees are often jarred or swung about by the This disturbance is of a somewind. what different character, but I do not think either would be detrimental .-W. Z. Hutchinson.

It will have no effect upon them if other conditions are right. It is like bee-bread, it does not injure bees if not eaten out of season; and it will not be eaten if conditions are right.--JAMES HEDDON.

I have known bees to be located near a railroad track, but they did as well and wintered as well as other bees. They probably get accustomed to the jarring noise. From the ex-perience of a Canadian bee-keeper who kicked the hive containing his Carniolans, with diminished effect every time, this particular strain of bees would do nicely located near your "heavy grade."—G. L. TINKER.

### Aniary Near a Railroad Track.

Query, No, 199.—Will an apiary located 10 rods from the railroad track be affected by the jar of the trains so that they will not winter as well? Will the bees eat more, or will it have a bad effect on them in any way? E. E. S., Mich.

I think not.-W. Z. HUTCHINSON.

No harm will result, I think. See Query, No. 198.-A. J. Cook.

The railroad will do your bees no harm at that distance from it.-G. W. DEMAREE.

I would prefer them at a much greater distance.—II. D. CUTTING.

I should prefer not to locate an apiary near a railroad if I had my choice. I should consider the smoke in summer from the engine more objectionable than the noise or jarring-II. R. BOARDMAN.

wintering, I see no trouble; some colonies eat more and some less, in any case. I have lost only 2 full colonies in 20 years of wintering on the summer stands, and both of those starved last winter when I was sick and could give them no attention.— LE POND LE J. E. POND, JR.

S.E. FOND, JR. See Query, No. 198. Also: Last winter I selected one of my colonies-wintering so nicely upon all sugar-syrup stores, and jarred it, and aroused it every day for weeks, and when put out, the bees, like others wintered on the same food, voided nothing whatever.—JAMES HEDDON.

While at a friend's once, who had his bees in a cave within 5 rods of the railroad track over which was run 6 to S trains daily, he requested me to go into the cave with him about traintime. Soon we began to feel the jar from the train, and as it became more distinct the bees began to roar, and by the time the train had passed the quiet of the cave was transformed to a noisy place. My friend's success in wintering bees was not good, and he believed that the cars was the cause of it.—G. M. DOOLITTLE.

### Bees Swarming Out.

Query, No. 200.—What is the cause of bees swarming-ont in early spring when they have plenty of honey and brood ?—E. C.

It may be because the bees are weak in numbers; and have more brood than they can care for.-W.Z. HUTCHINSON.

Perhaps because the bees have died off till there are not enough to cover the brood.—C. C. MILLER.

Lack of pollen or of water, or a remnant of bad feeling from winter confinement.—DADANT & SON.

A cold brood-nest. The remedy is, to carry all weak colonies into a warm, dark room or cellar on the approach of cool nights, and return them to their places when the weather is suitable for bees to fly out. They must be carried back and forth until they become strong enough to protect the brood.—G. L. TINKER.

Want of room is supposed to be the the prime cause of swarming. It is their nature, also, and the way they multiply. The cause for swarming abnormally in early spring is not fully known, but many theories are given therefor. See any work on apiculture for the ordinarily accepted reasons.— J. E. POND, JR.

Something obnoxious about the hive, I think. I have never had such a case, but have often heard of it. We should look to it that all hives are thoroughly cleaned in the spring. Dead bees in the hive are very offensive.—A. J. Cook.

In the early spring there are but few young bees in the bive to stay with the queen when the bees take a general flight, and when she finds herself nearly alone in the hive, she may become alarmed and take wing to join the bees, and when once out I think not. See my answer to to join the bees, and when once out Query, No. 198, for reasons. As to with their queen the bees are as likely

to do one thing as another. I once discovered a colony in a starving condition, and upon supplying their wants, giving them liquid tood, so many of the workers took wing that the queen became excited and left the hive to join the bees in the air. That was a case of "swarming out." However. I have seen cases that I could not discover the cause that induced desertion.—G. W. DEMAREE.

Dissatisfaction, always. I think that it usually results from a diseased condition of the bees, caused by imperfect wintering, caused by too low a temperature, or bad food, or both.— JAMES HEDDON.

### Strengthening Weak Colonies.

Query, No. 201. — What is the best method of strengthening weak colonies in early spring, when one has strong colonies to draw from ?—C. E.

Keep them well contracted, and assist them with frames of brood.— II. D. CUTTING.

By adding capped brood, but not so rapidly as to result in the chilling and loss of bees.—A. J. Cook.

Give them hatching brood and young bees—especially young bees just hatching.—DADANT & SON.

Change places with the strong and the weak colonies; do it when the bees are not flying.—W. Z. HUTCH-INSON.

By giving frames of capped brood as soon as they are strong enough to protect it. The mistake is often made of giving a frame of brood that the weak colony cannot cover.—G. L. TINKER.

I use the wire-box plan as given by myself for forming nuclei, in back numbers of the BEE JOURNAL.—G. M. DOOLITTLE.

I would not do it until I could safely transfer combs of hatching brood (bees), and then I would do it in that way.—JAMES HEDDON.

Draw from the strong colonies and give to the weak, being careful to give only as much brood as the weak colonies can care for.—J. E. POND, JR.

Feed the strong colonies to stimulate brood-rearing, and draw from them to strengthen the weak colonies, either brood or young bees, or both, as circumstances may dictate.—H. R. BOARDMAN.

Give them a frame of hatching brood from a strong colony, and then another after they are strong enough to take care of it. I rarely ever draw on my strong colonies to belp up the weaker ones. One good, strong colony, when the early honey harvest begins, is worth more than two weak ones.—G. W. DEMAREE.

I do not believe that it will pay to draw from strong colonies in early spring. Cuddle up the weak ones as warm as you can, and if they die, the strong ones can spare material for new ones later, at less expense than they could help the weak ones early. Helping "dwindlers" is a discouraging business.—C. C. MILLER.

## Number of Colonies in One Place.

Query, No. 202.—Taking the average of years, what number of colonics, in your location, kept in one apiary, do you think would yield the largest total of snrplns honey?—S. J. M.

I wish that I knew. Perhaps 125.-C. C. MILLER.

I have never kept more than 100 colonies; but I am satisfied that more could be kept with prolit.—W. Z. HUTCHINSON.

I have no opinion on the subject. We need light on this very question.— A. J. Coox,

This cannot be answered—some locations will take 200 colonies, others 50 or less. We do not like more than 100 in one place. Some seasons there is no end to the honey; in other seasons the flowers are scarce.—DADANT & SON.

There are in my location—say a diameter of 3 miles—about 250 colonies. My bees do as well now as they did when there was not 25 colonies in the bounds. I have reasons to believe, however, that about 200 colonies in a place is enough, taking all things into consideration.—G. W. DEMAREE.

About 100 colonies. But we have some seasons that white clover is so abundant that 1,000 colonies could not overstock the location.—G.L.TINKER.

It would depend so largely upon the locality, that no one could be a guide for another. Try and see for yourself.—J. E. POND, JR.

Of course the answer to this would be only guess-work. I have never kept more than 200 to 300 colonies in one apiary, and I have never felt quite sure that this number diminished the average yield of honey. This subject of overstocking is a very interesting one to me, and I would like to know more about it. — H. R. BOARDMAN.

About 175 colonies will secure the product of my field so as to give the most profit to the apiarist. If those about me keep 100, I can keep but 75, unless we all suffer loss.—G. M. DOO-LITTLE.

That is a most important question to us who have several hundred colonies, and I should like to be able to give an answer that I could consider somewhere near correct. — JAMES HEDDON.

### Distance between Apiaries.

Query, No. 203.—If you had a brether about to establish an apiary, and you wanted him located as near you as possible without materially interfering with your honey crop, how far would you want his apiary from yours ?—S. J. M.

Ten miles.—G. M. DOOLITTLE.

Not nearer than 4 miles.—W. Z. HUTCHINSON.

Four miles in a bee-line.—DADANT & SON.

It would depend upon the location. Moses Quinby, of New York ; two of If the location was a good one, one's interest would not suffer if his brother ean apiculture, and usher in a new era.

were to locate within a mile of him.— G. W. DEMAREE.

That would depend upon the size of the brother's proposed apiary. If a hundred colonies or more, I should say about 2 miles.—G. L. TINKER.

It depends much upon the size of the two apiaries proposed. If large, 4 or 5 miles; if small, very near.—H. R. BOARDMAN.

I should say about 5 miles. This is simply opinion, and may be worth very little.—A, J. Cook.

Perhaps 5 or 6 miles.-C.C.MILLER.

If the ground is level and quite open, not less than 6 miles. In some locations where broad forests and hills intervene, a less distance would thus be warrantable. I speak from careful observations taken about my own locations.—JAMES HEDDON.

So much would depend upon the size of my own apiary, the size of my brother's, and the yield of honey in the locality, that it is impossible to give an answer of any value. I do not consider the question one of any practical value, in any case; to answer fully would open up the whole matter of how many colonies will overstock a given locality. A few would do this in a poor season; how many would in a good season, no one can tell.—J. E. POND, JR.

### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

A Brief History of the North American Bee-Keepers' Society, with a digest of its 15 Annual Conventions, and a full Report of the Proceedings of the 16th Annual Convention held at Detroit, Mich., on Dec. S to 10, 1885. This is the title of a new pamphlet of 64 pages just issued at this office. Price, 25 cents.

This pamphlet also contains engravings of the principal honey-plants, and portraits of the Rev. L. L. Langstroth, of Ohio, and Moses Quinby, of New York; two of the pioneers who helped to revolutionize Ameriean apiculture, and usher in a new era.

## King Winter.

FRANK D. HARROUN.

King Winter reigns right loyally ; Behold his sparkling crest l When wakes the golden eye of morn He gleams from east to west, And laughs to see with fiendish glee All chill at his behest.

He hies him o'er the lap of Earth-Nor shows her mercy now. But blows his breath, replete with death,

Full on her faded brow ; The shrub, the bireh, the lordly oak,

In meek submission bow.

Where are the royal robes of green That Earth was wont to wear? The bright plnmed birds with liquid notes

That filled the seented air?

Will these ne'er come again to thrill " Her bosom, cold and bare ?

Aye ! Lurking there 'neath heaps of snow Sweet hidden beauties lie.

That but await the magic glance From Summer's glorious eye, E'er springing into life, and call

The bird from foreign sky.

Sweep on, bold, roving Winter King, Make merry while you may !

For soon in joyous notes shall ring The songster's roundelay,

Rejoicing with the buds and flowers That you at last decay.

Clinton, Iowa, Feb. 4, 1886.

Explanatory.-The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is beated near the centre of the State named: 5 north of the centre; 9 south; 0+ east; •O west; and this of northeast; `O northwest; Southeast; and 9 southwest of the centre of the State mentioned.

For the American Bee Journal. Making History---New Bee-Hives.

### G. W. DEMAREE.

Rev. W. F. Clarke, one of our most fluent writers on bee-culture, and the Editor of the AMERICAN BEE JOUR-NAL, widely known as an able and NAL, where where we way as an ane and prudent journalist, have both given their cordial opinion of Mr. Heddon's "new" patent hive. The first char-acterizes it as a "revolutionizing" invention, and the latter says it is "new and original." With these things before way on the pages of the things before me, on the pages of the I take it that the discussion is open and free to all contributors. We are "making history," and surely all the facts should go to record.

As to the utility of a hive made in horizontal sectional parts, I am not I have experiwithout experience. mented in that direction for the past six years, and I now have bees wintering in a hive made of cross sectional parts only 5% inches in depth. When When the bees were prepared for winter in September, they were shut down in a single sectional part of the hive, the frames being only 5½x173% inches, outside measure. I have experimented quite extensively with the sectional shallow-frame cases, using them for brood-rearing, tiering them up to suit the size of the colony, and for queen-rearing, using a single sec-tional-case; and I have employed them largely for taking extracted honey on the tiering-up plan. Those persons who have read my articles in the American Bee-Keeper, New England Apiarian, Kansas Bee-Keeper, and the American Apiculturist, know that I mentioned my shallow-frame system time and again; and in the discussion between my distinguished friend. Dr. Southwick, and myself, published in the AMERICAN BEE JOURNAL, Vol. 19, pages 370 and 371, I mentioned my shallow-trame system, using it as an argument in favor of shallow frames.

With these scraps of history already gone to record, it is impossible that any hive made in horizontal sectional parts could be "new and original" at this late date. In fact the *idea* was not *new* when I commenced my experiments six years ago. The practice of tiering one "story" of a hive on another, is common to all bee-keepers —"common property." When we hive a swarm in the lower "story," or brood-department of a hive, we speak of it as a "hive;" and when we add another story to it to give the bees more room, we still call it a "hive," because it is a hive in sectional parts. Now the mere difference in the depth of the sectional parts can never change an old idea into a new one.

Having shown that the "new" patent hive is not new in conception or idea, I now propose to show that in its mechanical construction there is not a single new feature about it, that is of intrinsic value.

The case to hold the frames is simply a shallow box, the chief features of which are shallow rabbets at the bottom as well as at the top, and some tin strips nailed in the rabbets to support the frames. The frames have wide end-bars, and are dovetailed at their corners. When finished, the frame is the same as the old "close end-bar frame.<sup>5</sup>

As to its manner of adjustment in the ease, it is a "standing frame," *i. e.*, it rests on strips of tin at the bottom of the case, instead of being suspended in the case. The frames are made as long as the inside of the ease, and hence it closely to its front and rear walls (a most objectionable feature in a warm climate); and lastly, the frames are clamped together by means of a set-screw at each end of the case.

It is proper to say that the frames

will work with either side down, or up. Comment is unnecessary.

Every well-posted apiarist will recognize every feature described as an "old acquaintance."

The application of a set-screw to a bee-live may be new as to the appli-cation, but "thumb-screws" have been in use for years to clamp hives, etc. No device is more commonly used than a " set-serew."

Now, I might safely defy anybody to point out a single new feature con-nected with the "new " patent hive, but my purpose is simply to give the facts. There are but few independent apicultural writers, and these must "hew to the line, let the chips fall where they may." It is far more pleasant to write a "puff" that pleases, than to write words of truth that may burt.

Christiansburg, & Ky.

### For the American Bee Journal.

### Honey-Interests of Florida.

### JNO. Y. DETWILER.

Since writing my letter on page 60, I have made a trip down the river, and in my estimation the mangroves have been entirely destroyed by the recent cold wave. As a consequence, the honey-interests of the coast country are greatly damaged, and, in my opinion, will be no better than the interior of the State for years to offered for sale preparatory to leaving for more inviting fields. The tendency of property owners who have lands for sale, is to consider the damage to the honey interests as of but of one or two years' duration ; but when it is taken into consideration that the mangrove is of slow growth (the average size of the trees being about 5 inches, the result of the growth since 1835, the date of the previous frost), it becomes more serious. The dead trees of 6,8 and 10 inches are numerous in the more isolated swamps or islands.

The damage to the bearing orange groves of the coast is considered as but slight, though some of the young wood and much of the nursery stock has been damaged, as well as the ungathered crop of oranges. I have been informed that the coccanut plantations, as well as the pine-apple tracts of Southern Florida, have been sadly damaged, if not entirely destroyed.

The groves of the interior have suffered much more than is admitted, as it has a tendency to direct emigration to other localities near salt water protection. Take away the honey and orange interests of Florida and there is but little left for humanity to subsist upon, except the food resources of the coast and the genial elimate, which in many instances prolongs life where disease has taken a firm hold upon the system.

Another cold wave may not visit are adjusted in the case so as to leave Florida again for many years, and as a shallow bee-space both at the top I have found by actual experience and bottom of them, and the case that it does not pay to lose heart and become discouraged by reverses. I expect to remain where I am—let the damage to the honey-interests of Florida be little or great. I consider it best to state plain tacts, as personal examination has warranted me in doing lot it initiate where it doing, let it injure whom it may.

New Smyrna, O Fla., Jan. 25, 1886.

### Indiana State Convention.

The seventh annual meeting of the Indiana State Bee-Keepers' Society was called to order promptly at 1:30 p.m., on Jan. 20, 1886. President Jonas Scholl in the chair, with about 70 members in attendance. The work of the Society was commenced with the payment of dues and the enroll-ment of new members. The reports of the officers followed, showing the Society to be in a processing with Society to be in a prosperous condi-tion. The regular dues of the memtion. bers was reduced from S1, to 50 cents. A special committee, appointed at the last meeting of the Society, for the purpose of revising the constitu-tion, reported in favor of changing from a delegate body, allowing all to become active members on the payment of dues as prescribed in the bylaws.

Mrs. C. Robbins was given a vote of thanks for the beautiful badges which she provided for the members of the Society.

President Scholl, in his annual address, after giving a kind greeting to those present, remarked as follows :

The past winter was a remarkable one, a winter of unusual severity, and caused a fearful destruction of bees in some parts of the State. While the spring and summer were in the main favorable for an increase of colonies, but little surplus was obtained, and that only in favored localities. The statistics for 1885 show a large reduction in the number of colonies and pounds of honey. With our home markets almost bare of honey, we have good reason to expect better prices for what can be produced next season. The progressive bee-keeper, however, will not concern himself so much about an increase of price for his crop, as how to produce honey at less cost, so that he can well afford to take current prices; and with the facilities and improvements now at our command, at a fair profit, even if compelled to take lower prices than were obtained the last two years.

We all admit the superior quality of honey that is allowed to remain in the hive to the close of the honey season, when it is all capped, and thor-oughly ripened by 'the heat of the bees. But we know also that this diminishes the yield very much. If, therefore, the same object can be accomplished by the concentrated beat of the sun, I would say, all honor to the man who will perfect an to the man who will perfect an arrangement for ripening honey by solar heat.

We all rejoice to learn that the next

city, and now let us take the necessary steps to give a hearty welome to the National Society, which, after an absence of 13 years, returns once more to Indianapolis. Here it was organized in 1870, and met here in 1872. I would recommend that a committee be appointed to make such preparations as will insure our brother beekeepers from abroad a hearty and welcome reception. The parent So-ciety has been, and is yet, a power for good in the interests of bee-keeping.

#### EVENING SESSION.

The discussion in the evening was opened by Mr. Davis, on the subject of "Planting for Honey." He did not believe that it would pay small farmers to devote any tillable ground exclusively to honey-producing plants. He had great faith in Alsike clover, both as a honey-producer and a forage-plant, and said that bee-keepers would be helping themselves and their neighbors by inducing all farmers to plant it. His opinions were endorsed by all present who knew anything about this comparatively new clover.

Mr. C. F. Muth read an essay on "The Effects of Pollen in the Hive for Winter." He did not believe that pollen was injurious to the bees ex-cept in aggravated cases. The subject of this paper was considered in all its bearings, showing it to be a subject to which bee-keepers have given con-siderable thought. Mr. Muth also spoke of his trip through the South. He talked at considerable length on the possibilities of bee-keeping in Florida, and said that he thought it might be the Eldorado of the bee-keeper who worked for extracted honey, but that a peculiarity of the climate in the mangrove country-dampness-made the producing of comb honey impracticable. This led to the subject of what kind of honey, comb or ex-tracted, was in greatest demand, and the most profitable to the producer. The facts on this subject would indicate that there was a very great difference in the kind of honey demanded, depending upon locality. The decision of the convention was that extracted honey could be produced at less than half the cost of comb honey, but that bee-keepers should produce both kinds, being governed by the demand in their own markets, as to which kind they should produce the most of. The subject was continued to the hour of adjournment.

#### SECOND DAY-MORNING SESSION.

The meeting was called to order at 9 a.m., President Scholl in the chair. After disposing of the usual prelimi-naries of the Society, Mr. Reynolds read an essay on "Early Spring Management;" calling particular attention to several causes by which coloring which coloring were likely to be diminished during early spring. Bees leaving the hive in search of water he thought was one of the most frequent causes, and advocated putting water into the hives to prevent the necessity of their having to leave the hives in search of it. Mr. Muth had tried the meeting of the North American Bee-Keepers' Society will be held in this colonies to which he gave water

suffered losses equally with those not having the water attachment. Mr. Learning said that Father Langstroth mentioned this subject at consider-able length in his book, and believed the plan of much benefit. Mr. Bull did not believe that it was of much advantage. Bees use considerable water during early spring, but he said that the rearing of brood stimulated the bees to extra exertions, and they left the hives in search of new honey as well as for water. The Sec-retary had noticed that if the bees during a pleasant day got a taste of honey from the soft maple or willow, that the day following they would leave the hives in great numbers though the weather be very cold.

Mr. Cotton called attention to the fact that the next meeting of the North American Bee-Keepers' Society would be held in this city next year, and moved that a committee of five (two of which should be ladies), should be appointed by the President to confer with the Executive Committee of the National Society, and give all assistance possible in the way of making the meeting a success. Messrs. I. N. Cotton, Sylvester John-son, F. L. Dougherty, Mrs. Robbins, and Mrs. Landers were appointed as the committee, the members of the Society pledging their hearty support to the undertaking.

Mr. Knowlton moved that a committee of three be appointed to pre-pare a new premium list for the Apiarian Department, and asked its adoption by the State Board of Agri-culture for the next State Fair. Messrs. Knowlton, Cox and Lane were named as such committee.

The Society then proceeded to the election of officers, resulting as fol-lows: President, I. N. Cotton, Trad-ers' Point, Ind.; Vice-President, E. J. Howland, Indianapolis; Secretary, Frank L. Dougherty, Indianapolis; Treasurer, Mrs. E. Stout. Miss Eva Scholl read an essay on

"Winter Protection of Bees," which was well received, and showed the writer's familiarity with the subject in hand. A very large majority of the members coincided with the main features of the article, offering evi-dence of experience that much had been gained in the way of successful wintering.

Mr. Mason read an essay on "The Most Desirable Quality of Bees," giving the preference to Italians. Mr. Knowlton said that there was but one true race of the yellow bees, the others being offshoots from the Ital-ians. The Secretary said that there was sufficient evidence in favor of the Italians, as all of the most practical bee-keepers in the country reared them and did all in their power to keep them pure from any stain of the native black bees.

Several valuable essays were fol-lowed with appropriate discussions full of valuable information to brekeepers, after which the convention adjourned. F. L. DOUGHERTY, Sec.

Any person not a subscriber, receiving a copy of this paper, will please consider it an invitation to become a subscriber to it.

Read at the Maine Convention.

### Bee-Keeping in Maine,

### SECRETARY'S REPORT.

It again becomes my duty,as Secretary of the "Maine State Bee-Keep-ers' Association." to present the annual report. We number, at the present time, 111 members—92 gentle-men and 19 ladies—showing a gain of 16 members during the year. At the last regular meeting, the manner of gathering statistics, relating to the bee and honey industry of the State, was left with the President and Secretary, who, after due consideration of the matter, thought it better to gather the statistics by towns, rather than from individual bee-keepers, as had been the custom heretofore. Accordingly eards of inquiry were sent to nearly every city, town and plantation in the State. While the returns have not been so full and satisfactory as we would have liked, still enough have been returned to the bee-keeping industry in the State than we have had heretofore.

From the reports received, I have From the reports received, I have made up the following estimates: Number of persons engaged in bee-keeping in the State, 2,360; number of colonies of bees in the spring of 1885, 13,393; number in the fall of 1885, 22,597; number of pounds of honey taken during the season of 1885, 384,503, or 1924 tons; number of pounds of wax taken, 3,304; value of bees in the State at the present time. bees in the State at the present time, including hives and flxtures, \$225,970; value of the honey erop of 1885, at 15 cents per pound, \$57,675.45; value of wax at 30 cents per pound, \$991.20; making the total value of the product of the busy bee in the State, during the past year, \$58,666.65.

I also gather the following items of interest, from the reports received : There are about 200 towns in the State in which no bees are kept; there are 25 persons engaged in beekeeping in the town of Dexter, 17 in Oxford, and 13 in Bluehill. There are 500 colonies of bees in the town of Caribou, 200 in Poland, 162 in Clinton, and 160 in Columbia. There were 10,000 pounds of honey gathered in the town of Caribou; 5,250 in Clinton, and 3,000 pounds in Poland, the past season.

The early part of the season of 1885 was very unfavorable for bees. Many colonies that had succeeded in getting through the winter, died, or were greatly reduced in numbers in the months of April and May. The month of June was more favorable, considerable surplus honey having been taken from the frnit and raspherry blos-soms. In many sections of the State clover was winter-killed badly, and the weather being unusually wet dur-ing its period of bloom, therefore the crop of clover honey was light. A very large crop of honey was gathered from basswood, and in the wet part of the State, a large crop was gath-ered from fall flowers. The season, upon the whole, was favorable for the

production of honey and increase of

bees. The State Agricultural Society offered quite liberal premiums for a display of bees, honey and apiarian implements, at their annual Fair at Lewiston. Although the numbers of exhibitors were not so large as could have been wished, there was a very creditable display, being the largest, by far, ever shown in the State.

The interest in bee-keeping is increasing with each succeeding year; also the facilities for gaining a prac-tical knowledge of the business. There are six flourishing bee-keepers' associations in the State, one having been formed at Brunswick during the the past year, Kuyan Apicultural Society." WM. HOYT, Sec. the past year, known as the "Maine

For the American Bee Journal.

### The Season of 1885.

### F. R. MANNING.

My bees came through the past honey season in good condition, giving me an average of 67 pounds of honey per colony, spring count, in one plenty of honey in the brood-cham-bers for them to winter on. On Dec. 28, I carried them into the cellar, and prepared them for winter as follows: I laid ½-inch square strips crosswise of the brood-frames, then spread a burlap cloth over that, and covered the cloth with about 2 inches of oat-chaff. I placed the hives one on top of the other, with a 4-inch block be-tween them, to give an air-space. I have them piled 5 hives high. That is the way I wintered my bees last winter, and they all came out in good condition. I am wintering 33 colonies, 29.of which are in good condition, and strong with bees, and 4 are weak in bees, but have plenty of honey.

Four years ago I started in the beebusiness with what I considered good Italian bees, but now they are crossed so much with the German and black bees, that there are very few Italians among them. As all my neighbors have bees, the past season I allowed mine to increase by natural swarming. I have about decided to dispose of my present stock of bees and half-filled sections, and start in anew in the spring with a pure strain of bees, as I will then move my apiary where there will be no other bees within 3 miles of mine.

I disposed of my honey crop in my home market, getting 15 and 20 cents per pound for it, and 1 could have sold 1,000 pounds more if I had had it. I do not say that my honey is better than anybody else's, but those who bought honey of me said that they could never eat honey until they had tried mine.

The mercury was 24° below zero the past 2 mornings, and I fear that the bees that are on the summer stands will suffer if they are not thoroughly packed.

Reynolds. vo Ills., Jan. 25, 1886.

For the American Bee Journal.

### Nebraska State Convention.

The Nebraska State Bee-Keepers' Association met at Lincoln, Nebr., on Jan. 13, 1886, with all the officers present and a goodly working number of old members in attendance. The eonvention was called to order by President Von Dorn.

Owing to the late snow-storm, the regular order of business was deferred until the next day, so as to give members, that might be delayed, an opportunity to have a voice in the special proceedings.

The remainder of the day was spent in discussing a hive that was pre-sented by James Jardine, of Ashland, after which the subject of wax-rendering and other minor points of the industry were discussed.

The meeting then adjourned until

Thursday morning. On Jan. 14, at 9 a.m., the President called the convention to order, which proceeded to act upon the deferred business. The minutes of the last meeting were read and approved.

The committee appointed at the last annual meeting to secure the passage of a law to prevent the spreading of foul brood, and if possible extinguish it from the State, reported. By request the law as passed, was read, and thought not to be adequate. Immediately followed a lively discussion on foul brood, after which the convention adjourned until the afternoon.

At 1 p.m. the convention was called to order, and the subject of bees puncturing grapes was discussed.

Other subjects of less interest were also discussed during the afternoon. when the convention adjourned until 7:30 p.m.

At the appointed time the evening Messrs. R. E. Leach, of York, James Jardine, of Ashland, and E. W. Whit-comb, of Friend, were appointed as a committee on arranging a suitable premium list on bees and honey to be presented to the State Agricultural Society.

Mr. E. W. Whitcomb was recom-mended to the Agricultural Society of the State of Nebraska, as a suitable person to superintend the Apiarian Department at the next annual State exhibit.

The election of officers for the next term resulted as follows: President, W. F. Wright, of Johnson county; Vice-President, T. G. Hodges, of Saline county; Secretary, H. N. Pat-terson, of Richardson county; and Treasurer, R. E. Leach, of York county.

Immediately after the election of officers, the thanks of the Association were voted to the retiring officers for past services. The remainder of the evening was spent in discussing the subject of wintering bees, after which the convention adjourned to meet at 9 a.m. the next day.

On Jan. 15, at 9 a.m., the convention was called to order by President Wright. T. G. Hodges, E. W. Whit-comb and R. E. Leach were appointed

to investigate the probability of foul brood existing along the line of Filmore and York counties; where-upon the following resolution was unanimously adopted: *Resolved*, That this Association request the Governor to notify the inspectors that have been quantity

inspectors that have been appointed under the foul-brood law, that they must report the inspection of all colomust report the inspection of all colo-nies in the infected districts under their supervision, by the 10th day of May next, in default of which their commission will be cancelled and others appointed in their places. The remainder of the session was

spent on miscellaneous subjects, and the convention then adjourned to meet in Lincoln for their next annual meeting. H. N. PATTERSON, Sec.

For the American Bee Journal.

Discouraging Brood-Rearing.

8-J. A. GREEN, (85-100).

I fully agree with Mr. Dadant, in his communication on page 60. In my locality, the bee-keeper who would discourage brood-rearing in his hives 15 or 20 days before the beginning of the honey crop, would be very apt to be unspressed be unsuccessful.

Here, sweet clover often yields a great deal of honey after white clover and basswood have ceased blooming. There is also considerable uncertainty as to the time of blooming of both white clover and basswood. Moreover, white clover and basswood. Moreover, any one of these plants is liable to fail to yield honey while the others pro-duce it freely. Ordinarily only a small part of my honey crop comes from basswood, the other sources of supply being white clover, sweet clover, and in the fall, heart's-ease. Last year almost all of my honey was obtained from basswood, and this bloomed unusually late. If I had stopped brood-rearing 15 or 20 days stopped brood-rearing 15 or 20 days before the usual time that white clover blooms, it would take very few figures to represent my honey crop of

last year; (not so very many, as it is.) Still worse off would have been a bee-keeper only 12 miles from my apiary, who got no white clover or basswood honey, but had a good yield from sweet clover after my honey was all gathered, although there is plenty of sweet clover within reach of my bees. This illustrates well what a difference there is in localities. Again, if I expect to get any fall honey-and sometimes our heaviest yield is in the fall-there must be no diminution of brood-rearing during the earlier yields, else there will not be enough bees to gather this crop.

Let no one be led into the system of disconraging brood-rearing until he has by long experience made him-self familiar with all the sources of honey-supply in his locality. While a careful man might carry it out successfully where there is but one short honey-flow, I have never seen the time from the first of June to the last of September when I considered that my hives were too full of either brood or bees.

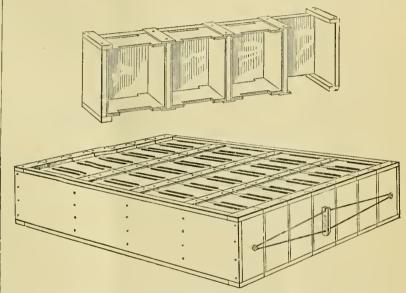

Dayton, & Ills.

### For the American Ree Journal. A New Surplus-Case.

J. M. SHUCK.

The engravings show a new surplus honey-case devised and used by me during the last season. It is sec-tional.permanently separatored, and is invertible. There are no top or bottom bars in the way to hinder, when sections are to be removed. The sections have the false tops and bottoms, peculiar to all my cases, to protect them from the travel of the bees; in

me that the queen might be found where the bees had been poured out the morning before—about 24 hours previous-and there to my amazement was a cone-shaped cluster of bees as large as a tea-cup, and in the centre of it was the queen, cold and stiff. Upon taking her to a fire, in a few minutes she was restored to activity, and on lifting the cushion over the bees and presenting her, the first thing, even before she left the fingers, a bee "gave her to eat," and there-upon, almost instantly, a joyful hum passed through the hive; and quicker than it can be told, dead bees were

fact, the bees can touch the sections carried out, and defensive warfare nowhere, except on the inside. I think that no other method of separatoring in use is equal to this. New inventions are plentiful, but practical bee-keepers will criticise closely, in order to be able to choose the best.

Des Moines,⊙ Iowa.

### For the American Bee Journal.

### Queen-Introduction---An Incident.

### REV. WEISEL BEALE.

Mr. John Hewitt's article on the introduction of queens, page 54, re-minds me of the following touching incident of filial fidelity in the bee; which also confirms his system of introducing queens:

Last fall, while putting my colonies in order for wintering, they were carried, one by one, a few yards from the summer stands, and the frames removed, boxes cleaned, etc.; the bees adhering to one hive were poured on the ground with the scrapings from the hive, and the queen with them. Shortly after the colony had them. Shortly after the colony had been replaced upon its stand, robbing began, thus indicating something wrong with the queen. Her bive was closed until sundown, and visited early the next morning—a light frost having fallen—when it occurred to

against robbers began.

The fidelity exhibited in protecting their mother on that frosty night, and the joy manifested on her safe return home, are worthy of our imitation. New Madrid, ~ Mo.

### For the American Bee Journal

### Introducing Queens, etc.

### FRED BECHLY.

Mr. Hewitt, on page 54, says: "I may be pardoned for saying that this system of mine is infallible." Some years ago I had a colony of bees that had been queenless for a month or more, and had become weak in bees, with no brood or eggs, and no sign of laying workers, and at a time when honey was scarce and robbers were plentiful. I took a nice, large hybrid queen and let her run in at the hiveentrance, and the bees balled her at once. A few minutes later I looked to see what they were doing, and found several bees dragging her out,

### LAYING WORKERS.

These are generally considered a great pest, but I think that a laying worker is not regarded as a queen by other bees, nor are they themselves unwilling to accept a queen, but it looks rather as though a few eggs and a little brood leads them to believe that they are not queenless. If I should find any the coming season, I shall try Mr. Doolittle's plan, by depriving them of their comb, caging a queen with them, and placing them in the cellar over night. Let others who may have laying workers in their apiaries try the plan and report their experience in the BEE JOURNAL.

Searsboro,⊙ Iowa.

#### **Convention Notices.**

The Union Bee-Keepers' Association of Western Iowa will meet in Dexter, Iowa, on April 10, 1886, at 10 a.m. M. E. DAABY, Sec.

10, 1886, at 10 a.m. M. E. DARBY, Sec. 10, 1886, at 10 a.m. M. E. DARBY, Sec. 10, 1886, at 10 a.m. M. E. DARBY, Sec. 10, 1886, at 10 a.m. M. Hold their ninth semi-annual convention at Cooper Union (Room 22) in New York City, on Wednesday, March 10, 1886, at 9:30 a.m. All who are interested in bee-culture or honey are re-spectfully invited to attend. We expect a large delegation from the Philadelphia Association to meet with us, and it promises to be one of the most interesting as well as instructive conventions that this Associa-tion has ever held. A special invitation is extended to ladies, well knowing that they are by no means a small factor in our in-dustry. Beginners, it is well known, will learn more by attending one good conven-tion than a year of practical experiments will teach them. All are requested to bring something to exhibit, and if you cannot come, send ns an essay to read on some live subject. W. B. TREADWELL, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. M. HAMBAUGH, Sec.

inelemency of Owing to the the weather, the meeting of the Marshall County Bee-Keepers' Association was postponed from Jan. 16, 1886 to Feb. 20, 1886; at which time the same programme will be carried out as was intended for Jan. 10. J. W. SANDERS, Sec.

### Honey as Food and Medicine.

128 To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine " are sold at the following prices :

Single copy, 5 ets.; per doz., 40 ets.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bec-kceper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantlty of it.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview by sending the names to this office, or we will send them all to the agent.

### Local Convention Directory.

1886 Time and place of Meeting.

Feb. 16-18.—New York State, at Rochester, N.Y. F. C. Benedict, Sec., Perry Centre, N. Y.

Feb. 20.—Marshall Co., at Marshalltown, Iowa. J. W. Sanders, Sec., LeGrand, Iowa.

Feb. 24.—Oneida County, at Rome, N. Y. O. J. Evans, Sec., Camroden, N. Y.

Mar. 10.-N. Jersey & Eastern, at N. Y. City, N. Y. W. B. Treadwell, Scc., 16 Thomas St., New York.

Apr. 10.-Union, at Dexter, Iowa. M. E. Darby, Sec., Dexter, Iowa.

Apr. 27.—Des Molnes County, at Barlington, Iowa. Jno. Nau, Sec., Middletown, Iowa.

Oct. 19, 20.—Illinois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

17 In order to bave this table complete, Secretarles are requested to forward full particulars of time and place of future meetings.-ED.

Bees Wintering Nicely.-Frank A. Eaton, Bluffton, o O., on Feb. 4, 1886, says:

The bees are wintering nicely so far. although the weather is continu-ously cold; but if it continues much longer those colonies on the summer stands will be in great danger.

Another Cold Week.-G. M. Doolittle, Borodino,⊙N. Y., on Feb. 6, 1886, savs :

We are having another cold week here, the mercury ranging from 10<sup>o</sup> to 20<sup>o</sup> below zero, with a searching wind. If Prof. C. C. Blake's promised warm weather does not come soon, there will be a fearful loss of bees here, from those wintered on the summer stands. In fact some have already died in apiaries near here, and many more are besmearing heir hives. I have lost one colony, and 4 or 5 are getting uneasy. Those in cellars are nice.

[Prof. Blake's promised warm weather arrived in Chicago on time on the 7th, and the bees bave been flying several days, giving them an enjoyable and health-giving time.-ED.]

Condition of Bees in Kentucky.-Rev. L. Johnson, Walton, & Ky., on Feb. 9, 1886, writes :

Dead, dead, dead-such is the sad record I am making all through my apiary. Bees had not a day in which they could leave the hive from Jan. 2 until Feb. 8, much of the time the mercury being below zero, and twice as low as 14° below. Out of 67 coloand the end not yet. I think that fully one-half of all the bees in this

part of the State will be lost before spring. Of every colony lost, so far as I have examined, there still rewithin one inch of the bees. The cold was so intense that they would not leave the cluster, and when all was consumed that they covered, starvation ensued. Some of the combs are badly smeared, and many of the bees distended to bursting. Yesterbees distended to bursting. Yester-day and to-day, Feb. 8 and 9, the weather has been bright and warm. The bees have had a grand time, and we may hope that the worst is over. The Cyprians have all yielded to the frost, and I am at last rid of them. I hear considerable complaint among farmers who have kept a few colonies of black bees, which indicates that they have fared badly. So, after all, these disastrous winters we are having may have a beneficial effect in driving out shoddy bee-keeping, and demonstrating the "survival of the fittest.

Very Cold Weather.-J. W. Sanders, Le Grand. O Iowa, on Feb. 4, 1886. writes :

We have had very cold weather and lots of snow. It was 32° below zero this morning, but it was some warmer through the day. The mercury has dropped down again this evening to 10° below zero. The bees that were left out-doors will stand a poor show where unprotected. The temperature in my cellar is about  $40^{\circ}$  above zero; I would like to say  $45^{\circ}$ , but I hope that all will be well. My cellar is dry.

Bees in Good Condition.-W. J. Cullinan, Mt. Sterling,+o Ills., on Feb. 7, 1886, says :

We have just passed through as steady a month of solid Old Winter as I ever remember to have experi-enced; but to-day it is thawing sharply with the mercury at 50° Fahr. My bees had a fine flight to-day—the first in two months-and they are in good condition, so far as I could ascertain. I placed them against the yard fence on Dec. 1, and packed in straw. I think that I shall try cellarwintering another year.

Space Between Brood-Combs, etc.-A. J. F., of Columbiana County, & O,, asks the following questions :

1. Where box-hives are used with stationary bars  $\frac{7}{8}$  of an inch wide, would not  $\frac{3}{6}$  of an inch space between the combs for breeding purposes be just as good or better than  $\frac{1}{2}$  inch or more? In a hive 14 inches wide, instead of holding 10 combs with  $\frac{1}{2}$ inch space between them, it would hold 11 with 3% of an inch space be-tween, thereby making less lurkingspace for the bees in the brood-cham-ber in the honey harvest. 2. Would there not be considerable gain in the force of bees in the surplus boxes? 3. Would there not be sufficient room in <sup>3</sup>/<sub>8</sub>-inch space between the combs for a sufficient amount of bees to collect in a cool spell of weather to protect the brood? 4. Would there not be a less liability of building brace-combs between the top-bars and honey-boxes in <sup>3</sup>/<sub>8</sub>-inch space with <sup>7</sup>/<sub>8</sub>-inch combs, than in a wider space? 5. Would not the queen be more liable to breed to the top of the top-bars in such combs than che would in bars in such combs, than she would in thicker ones? 6. Would an entrance  $\frac{3}{8}$ x14 inches be large enough for yentilation in the warmest weather for a strong colony of bees in a hive of the above style, of about 3,000 cubic inches? If not, how large should it be?

[1. They have been so used without serious harm resulting. In some respects they are better, and in some worse than when placed farther apart.

2. Undoubtedly it would have that tendency.

3. Analogous to the above, the widespaced combs would have the advantage in this direction.

4. I think there would, but, after all, the difference would depend mainly upon other causes.

5. No doubt slightly so, but to no such degree of advantage as we gain by reversing or interchanging.

6. If the hive was kept shaded (as all should be), such an entrance does very well. I use and prefer 1%-inch space for each comb to occupy, adding allowance for the extra outside space. -JAMES REDDON. ]

The Detroit Convention.-Mr. L. C. Root, of Mohawk, 5 N. Y., on Feb. 6, 1886, writes as follows :

MR. EDITOR :- I have received a American Bee-Keepers' Society in pamphlet form. The thanks of every member of the Society are due you for the very full and accurate report you have given. At the price you offer it, you should be able to place it in the hands of every bee-keeper in North America. One thing may truly be said, and that is, that much of the spirit of that meeting cannot be communicated. I shall ever be grateful that I was permitted to be present.

Infallible Queen-Introduction.-O. N. Baldwin, Clarksville. & Mo., writes:

I have read Mr. Hewitt's article on this subject, on page 54, and it is good; yet I think that I have a simpler way, and with me it has never failed. I be-lieve that it is as Mr. H. says, "infallible "- not only for laying queens but also for virgin queens. I would like to hear reports from others after they have used it. It is as follows: The hive of the colony to which I wish to introduce the queen is removed from its stand, closed up, and another hive is put in its stead on the stand. In this hive I put some empty combs or

day when the most of the old bees are in the field, and when they return they will stay with the hive and cluster on the combs. I leave them in this con-dition for 24 hours, then let the queen run in at the entrance and she will be accepted. If a virgin queen is being introduced, leave them alone for 24 hours more, till the old bees get used to her, then take out the old queen and move the hive back where it was; then in a couple of hours all can be safely put into one hive. If a laying queen is being introduced, as soon as she is put in, without waiting 24 hours, take out the old queen, and as soon as the bees miss her, in 1 or 2 hours, put them all together. I have lost only 3 queens in all my experience, and I have introduced a great many, but I have never lost one by the above plan.

Report for 1885.-Marshall Swain, Edwards, & N. Y., on Feb. 7, 1886, says:

I began in the spring of 1885 with 3 colonies of Italian bees, which I increased to 12 colonies during the season, by natural swarming, and ob-tained 40 pounds of comb honey, that I sold for 20 cents per pound. I worked my bees entirely for increase. I have only 12 colonies, and they would be of little use to me without the American Bee Journal.

Bees Having Good Flights.-II. M. Seeley, Harford, & Pa., on Feb. 9, 1886, says :

Bees are wintering finely. They had a good flight on Jan. 2, and they are also out to-day in large numbers, and spot the snow a little.

Sugar Syrup for Winter Stores.-Dr. C. C. Miller, (179-340), Marengo, 5 Ills., on Feb. 10, 1886, says :

Mr. Highbarger's inquiry on page 91, is to the point. I fed my bees about 1,700 pounds of granulated sugar for winter, or just as many pounds as the surplus they gave me. I did not mean to misrepresent, but withholding the above certainly does not give the whole truth.

Bees Wintering Well.-2-Jno. E. Heard, (36-54), Pikeville, o+ Tenn., on Feb. 8, 1886, writes:

As we have had such cold weather I thought that my bees would all be killed, but I find them all right. My hives are all two-story with Gallup frames; some of them are only 12 inches wide, others 12x13<sup>1</sup>/<sub>2</sub>, and others 12x18, clear, inside. I have them put on flat rocks without any bottomboards, and the bees can go in and out at many places around the hives, as the rocks are not smooth. I have nothing over or around them except enameled cloth on the frames. The mercury was 10° below zero many The days together, only last week it was 2° below, but now it is 74° above zero, and the bees are out as if they were foundation, and a little honey. All swarming. I have to cover some this must be done in the middle of the hives, as the bees began to rob one

another. As the snow began to thaw yesterday, myself and daughter cleaned out the dead bees from every hive, I tipping back the hives and she sweeping out the dead bees. I noticed that many colonies wintered in the upper story, while others stopped below. We did not get as much as a tea-cupful of dead bees at any one hive, and neither can I see any signs of disease among them.

Experience in Bee-Keeping.-J. L. Anderson, Lawrence, & Ills., on Feb. 4, 1886, writes:

I wonder whether there is any other side to bee-keeping except the bright side. Are there any, except Dr. Mil-ler, that get less than a small fortune from every colony of bees that they keep? If there are, let them hold up their hands. As I do not see any except my own hand, I will give my re-port. Two years ago I put 82 colonies into my cellar, and the next spring took out 45, the balance having died with the diarrhea. The 45 were in-creased to 70, which I put into the cel-lar one year ago last Nov., and in the spring of 1885 I took out 36 colonies, which i increased to 68, by both nat-ural swarming and division, and se-cured 1,000 lbs. of honey. Comment is unnecessary. The present prospect for honey the coming season is not very flattering. The mercury was 25° below zero this morning, and has been below that point for several days; also, the snow is from 24 to 30 inches deep.

Bees Flying .- F. A. Gemmill, Stratford, Ont., on Feb. 9, 1886, says :

The weather being fine to-day, the bees in this vicinity have had a fine flight, the first since their winter continement of 3 months. No doubt it gladdened the hearts of all beekeepers here, as all those wintered in chaff hives gave no signs of disease, and, in fact, spotted the snow (on which there was a fine crust) little if any. Three of my weakest colonies, which are in the cellar as an experiment, I did not disturb, as they seem to be in such good condition that I concluded to test the cellar thoroughly, in order to ascertain whether I can utilize it for next year's wintering.

Wintering Finely, etc.-T. C. Davies, Pittsburgh, Pa., on Feb. 9, 1886. writes:

Bees are wintering finely, with me, so far. Yesterday was a fine, sunny day, but to-day it is warm and beau-tiful, and the bees are having a fine-flight. In all of my 40 colonies packed in chaff on the summer stands, they look strong and healthy. The two during the last cold spell, are as bright as gold. Last season was a poor one here on account of the failure of white clover, but every thing looks very encouraging for next season. It seems that I must get some of the new reversible hives. That hive-fever is catching. I am convinced that some plan different from

the two-story wide-frame plan, to hold the sections, is needed in this locality. I have used cases, but I never have liked them for many reasons. I have been dreaming for the last 3 years about a one-story, wide reversible frame, but I have never seen anything that came near to it until I was in the apiary of Mr. D. R. Jones, of Iowa, a year ago last Au-gust. He had something very near it, but having them set in a case, a la Ileddon, it seems to me exactly fills the bill. I shall be very happy to try them next season.

The Air Alive with Bees.-E. F. Smith, Smyrna, ON. Y., on Feb. 11, 1886, writes joyfully as follows:

After so much very cold weather we have just had three of the finest days for bees to fly that I ever knew at this time of the year. About 40 colonies had a flight on the 8th, but on the 9th and 10th they all (76) came out and carried everything by storm : the air was alive with bees, and the roar could be heard several rods. also took 25 colonies from the cellar on the 9th, and they had a cleansing flight. These latter were returned to the cellar at night. No bees got chilled by falling on the snow. Beekeepers are rejoicing.

Misrepresentation, etc.-17-J. M. Valentine, (165), Carlinville. Ills., on Feb. 3, 1886, writes :

My bees appear to be doing well so far this winter. They were in good condition when stored away in my bee-house. I was in the bee-house last evening for the first time this winter, and there was only the sound as of rippling waters. As a member of the Bee-Keepers' Union, I would say, put the Rev. Mr. West through, unless he retracts and publishes an apology for his bogus honey articles, or proves them true, if there is suf-ficient ground for an action. It is high time that the publication of such falsehoods were stopped. I do not think that the funds of the Union could be used for a better purpose.

Recipes for Honey-Cakes, etc.-Dr. A. B. Mason, of Wagon Works, vo O.. on Jan. 28, 1886, writes:

My bees are in splendid condition, all quiet and happy. They are con-suming but little honey this winter, so far. I examined a few colonies a few days ago, and found that they had not eaten a pound of honey. The following are recipes for making honey-cakes, that have taken premiums at our Tristate Fair: To3 eggs well beaten, add 1½ cupfuls of ex-tracted honey, 1 cupful of sour cream or rich butter-milk, 1/2-tea-spoonful of soda, and 3 cupfuls of flour, to which of baking powder. Bake it in jell pans, and put it together with the following lemon paste : In the juice of one lemon dissolve 1 table-spoonful of

1 table-spoonful of sugar. Another: 1½ cupfuls of extracted honey, ¾ cupful of butter, ½ cupful of sweet-milk, 3 eggs well beaten, 3 cupfuls of flour, 2 tea-spoonfuls of baking powder, 2 cupfuls of raisins, and 1 tea spoonful or a cupful of a cupful or a spoonful of a cupful of a tea-spoonful each of cinnamon and cloves.

Adopting New Hives, etc.-O. P. Miner, Taylor Centre. N. Y., on Feb. 6, 1886, writes:

I am puzzled to know whether to adopt the reversible frame or the reversible bive, or to continue using the standard Langstroth hive. In the spring of 1884 I purchased one colony of Italian bees; the season was a poor one for honey in this locality, and in consequence I received no surplus, but increased my number of colonies to 3. In the fall of 1885 these colonies were in chaff hives, the two new colo-nies having their hives hardly half filled. I fed them a little in the fall, and they wintered nicely. The past season they increased to 6 colonies, and produced 120 pounds of comb honey; but one absconded. At the present writing they are alive, and so far as I know they are doing well. We are having another cold spell now, the mercury being 20° below zero.

[We must caution all to be very slow in changing hives or fixtures. The Langstroth (or any good hive) will answer, and beginners especially should carefully avoid needless expense. When new hives are necessary for increase, to indulge in a trial of a new kind would be admissible, but do not throw away a good hive or fixture for a new kind, simply because it is *new*. It is too expensive a luxury. Be cautious and careful, if you would succeed !-ED.]

Bees all Right.-Christian Schrier, Peotone, & Ills., on Feb. 12, 1886, says :

My bees thus far are wintering rely. They had a good flight on finely. Feb. 10, after 70 days of confinement to the hives. They are on the sum-mer stands packed in straw, with boards for a roof to keep the hives dry. 1 leaned boards up against the fronts of the hives to protect the entrances from snow and wind. I found very few dead bees on the bottom-boards.

### System and Success.

I All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are as follows :

The larger ones can be used for a few colonies, give room for an increase of numbers corn-starch, pour on  $\frac{1}{2}$  cupful of and still keep the record all together in one boiling water.  $\frac{1}{2}$  cupful of honey, and and still keep the record all together in one

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Feb. 15, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.-There is an easier tone to the comb honey market, and prices are fully one cect per pound less than at last quotations. I.Sc. being the price for white comb honey in 1-lb. sections, and some extra nice brings 16c. This is owing to small lots coming into different commission houses, and all being eager to sell, they underbid regular honey houses in order to do so Extracted honey brings (exc per lb. PENEWLY - 016000 asc per lb. BEESWAX.-24@26c.

R. A. BURNETT, 161 South Water St.

#### NEW YORK.

HONEY. - We dote an improvement of sales of honey the past week, but prices continue to rule low. We quote as follows: Fancy white comb in 1-b, paper carbons, 136/46, and fair to good in 2-b, glassed sections, 126/136, the same in 2-b, glassed sections, 166/46, and fair to good in glassed 2-b5., %69c. Fancy buckwheat honey in 1-b, unglassed sections, 10c, the same in 2-b, sections, Rissed,%69c. Extracted,white,6%67%c; buckwheat, 5%66. BEESWAX.-27@2%c.

MCCAUL & HILDRETH BROS., 34 Hudson St.

#### ST. LOUIS.

HONEY.—The market is quiet and the demand light just now. We quote prices as follows:— Choice come honey, 10@12c. Extracted, in bar-rels, 4½@5c. Extra faucy of bright color and in No. 1 prickares, 14 advance on above prices. BEESWAX.—Firm at 22½c. for prime.

D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEY.-The demand is extremely slow for ex-tracted honey. Manufacturers seem to have taken a rest. There is only a fair demand for honey in glass jars, and for comb honey. Prices are un-changed and nominal, with occasional arrivals and a large stock on the market. We quote extracted honey at 42%c. and choice comb honey at 12%14c., in a tobhing way.

honey at 1997 at 1997

### CLEVELAND.

HONEY.—The market is not quite as active as It has been, owing, no doubt, to many attractions of the Holiday Season. Best white, 1-1b. sections sell at 15c, and 2-1bs. for 13@14c, but there is not so much sale for the latter. Second grade honey is dull at 12@13c. Old white, 10@12c. Extracted, *Twose*, pre Ib.

BELSWAX.-Very scarce at 22@25c.

A. C. KENDEL, 115 Ontario Street.

#### KANSAS CITY.

HANSAS CITT. HONEY.—The market continues about unchang-ed, except that stocks are somewhat reduced, and possibly a little firmer feeling on extracted houey. The demand, however, is not heavy for this time of the year, and we cannot expect any better pri-ces, as no one seems indluced to hold, and conces-sions are made in the buyer's favor. Choice 1-lb. sections of comb houey, 15%16c; 2-10s, 12%14c. Extracted, 5%7c, according to quality. BEESWAX.—It is in very light supply, and it would bring 22%25c, for good average grades. CERVONS CLOON & CO. core 4th & Walnut

CLEMONS, CLOON & CO., cor. 4th & Walnut.

#### BOSTON.

HONEY .- The sale for honey for the past month 

#### SAN FRANCISCO.

HONEY.-Choice comb honey is in light supply and is bringing firm figures. There is a fair move-meet in best qualities of extracted at steady rates. We quote as follows: While to extra white comb, 10(a)2×c, amber, 788c. Extracted, white liquid, 54(a)5×c, light amber colored, 4×a+4/c, amber aud candied, 4×c, i dark and candied, 4×4/c. BEESWAX.-Quotable at 23(a)52c, wholesale.

O. B. SMITH & Co., 423 Front Street.

### DETROIT.

110NEY.—The market is well supplied with comb honey and prices have declined. Best white in 1-lb. sections, 14c.; honey in larger sections can be bought for less. BEESWAX.-23 §25c. M. H. HUNT., Bell Branch, Micha

THOMAS G. NEWMAN & SON. PROPRIETORS. 923 & 925 WEST MADISON ST., CHICAGO, ILL.

At One Dollar a Year.

ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

To Correspondents, -- It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, he sure to give the address we have on our list.

Frank Cheshire's new book on Bees and Bee-Keeping, can be had at this office in parts. Price, \$3.00.

Cash in Advance is the rule, but no longer than six months of grace can be allowed on the small sum of \$1.00. Snbscriptions may commence at any time, and discontinuances may be ordered at any time, when arrearages are paid up.

Wire Nalts have advanced in price, as will be seen by quotations on page 111, last column.

Preserve your papers for reference. If you have no HINDER we will mail you one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

I Onr rates for two or more copies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

All the Numbers from the beginning of the year are sent to new subscribers, unless otherwise ordered.

Heeswax Wanted .- We are now paying 2.1 cents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be put on every package to prevent mistakes.

" Don't Stop "-that is what many write to us about their papers, when their time is nearly out. One subscriber says : "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It runs out with this month ; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

To any One sending us one new subscriber with their own renewal (with \$2.00), we will present a copy of the new " Convention History of America."

Perforated-Zinc .- We have laid in a stock of perforated zine, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive-19%x14½-Price 25 cents each.

When renewing subscriptions please send an extra name or two with your own and secure a preminin. We have some colored Posters, which we will send FREE, to put up in conspicnous places. We will with pleasure send sample copies to any one who will try to get up a club.

Extracted Honey. - Any one having white extracted honey for sale, are invited to correspond with us. We are paying 7 cents per lh. for it, delivered here.

WANTED.-Two young men to work with perionec, Address, S. I. FREEBORN, 4Atf ITHACA, WIS.

# The NEW Heddon Hive.

We have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

The engraving gives a good idea of the hive. The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cap, bottom-board, and top and bottom of each sectional case has one-half of a regular bee-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the hitter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

A SAMPLE HIVE includes the bottom-board and shand; a slatted honey-board, and cap; two di-inch broad-chambers, each containing as frames; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separa-tors, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for inmediate use. Price, \$4.00, complete. The same ready to mail, \$2.75. For further particulars send for our new Illustrated Catalogue for 1886.

THOS. G. NEWMAN & SON.

NEW PHILADELPHIA, OHIO.

923 & 925 West Madison Street, CHICAGO, ILL.

1Atf S. A. STILLMAN, LOUISIANA, MO.

A Clergyman, who is also a bee-keeper, sends us a rhyme, which reads like this : Please give no rest To itev. R. West, 'Till he with zest Grants your request. To which we add : Let him do his best-Counteract the jest-Or he'll be non est, When comes the law test. Since the above was put in type, and just as this paper is ready for the press, we have

received a letter from the Rev. Robert West, in which he intimates that the next issue of the Advance will contain something that will set the matter right. He adds: " I sincerely regret if I have misrepresented any honest industry." We shall look with interest for his next week's paper, and hope that those newspapers which have copied the slanders on the industry of bee-keeping. will also eopy the retraction-if such is made in the Advance. We have no ill-will towards Mr. West, and only ask simple justice for our pursuit.

Frame Plyers, for taking frames out of hives, or moving them. This is the latest tool received at our Museum. They are gotten up by John M. Jones, Palmyra, N. Y. The tool is made of galvanized iron, and can be utilized in many ways. It has a long claw for loosening frames, a book, which may he used for carrying other frames besides the one held by the plyers, and it is supplied at a very moderate cost-by mail, for 40 cents.

Frank Leslie's Popular Monthly for February is all that its patrons can desire. The articles vary in character and treatment, are all interesting and timely, and all well illustrated. Mr. Croffut's article on the late William H. Vanderbilt gives a striking picture of the career and life of the createst American millionaire and the greatest American millionaire, and the reader can judge for himself of the man, his palace, his gallery, his stables and his tomb.

To any One sending us one new subscriber with their own renewal (with \$2.00), we will present a copy of the new "Convention History of America."

The Rural Canadian for February is brimful of good things. In the department of "Bees and Honey," we find among other things of interest, the following item concerning Father Langstroth at the Detroit Convention -

What a benignant face it was that smiled What a benkmant face it was that smiled upon us from the platform, showing how "the grand old man" enjoyed himself, to see the boys enjoying themeelves! The poet Ossian says: "Old age is dark and unlovely." No; not always. We have seen an example of it bright, cheery and beauti-ful, and it will often re-appear io memory when the vision itself has disappeared from earth. May the day be yet far distant on which that catastrophe shall happen! "Touch him gently, Father Time."

Concerning Heddon's new book and management, it remarks thus :

Hardly has the new year dawned when out comes Mr. Heddon, like a Jack-In-the-box, with a new hive and a new hook. Not since the discovery of the movable-frame has there been such a turn in the wheel of progress. We have been fiddling and fumbwith a new hive and a new book. Not since the discovery of the movable-frame has there-been such a turn in the wheel of progress. We have been fiddling and furmb-ling with single frames, and have meddled and meddled with our bees until " confusion worse confounded " has been the condition of affairs in many an aplary. Now, lo and behold, the simple principle of handling hives instead of frames has been che condition of affairs in many an aplary. Now, lo and behold, the simple principle of handling hives instead of frames has been che condition of affairs in many an aplary. Now, lo and behold, the simple principle of handling hives instead of frames has been che unclated, and it will revolutionize chaos 1. There is hardly a needful manipulation in the aplary but can be done in a twinkling on the new Heddon system. It is original and unique. Instead of one cumbrous hive, we have two halves, each complete in itself. Instead of one clumsy frame, we have two little shallow ones, which can be loosened as quickly as you can say "Jack Robinson," when neces-sary, which it seldom will be. Do I want to reverse frames? I have only to tip over a half-hive. Do I want to make an artifielai swarm? I remove a full half-hive and replace it with an empty one. Do I want to get rid of queen-cells, and prevent swarm-ing? I upset the half-hive. Queens cannot be reared standing on their heads I if i wish to make assurance doubly sure, I can cut out queen-cells with my pocket-knife, inside of a few seconds. Do I want to contract the brood-chamber? I shake the bees out of a half-hive. Is it desired to force the bees into section-boxes? Remove half-hive, shake the bees out of it in front of the other half, and put on a case of empty sections. Do I want to enlarge the brood-nest? I take the top half-hive, in which is the surplus honey, dubling the brood-nest. Do I want to form nuclei, rear queeos, or make a home for an overplus of bees? The half-hive ke top one, put on a section-boxet, set he little squat receptacle over my hopper-stan squat receptacle over my hopper-stand, pack chaff around and over it, and leave them to bibernate, have a flight, rear brood, eat pollen, or anything clse at "their own sweet will," until the advent of spring. Or I earry the half-hive into the cellar, regulate the temperature, and "leave it be."

□Geo. W. Meade & Co., of San Francisco, Calif., have issued their annual Review of the Crop of Honey, from which we extract the following :

The honcy product of 1885 was: Ex-tracted, 1,500,000 pounds; comb, 750,000 pounds; becswax, 60,000 pounds; raisins, 470,000 20-lb boxes.

pages-Early Southern Queens.
pages-Early Southern Queens.
Hutchinson & Taylor (W. Z. Hutchinson.
Rogersville, Mich., and R. L. Taylor, Lapeer, Mich.)-4 pages-Bees, Queens, Comb Foundation, etc.
Frank A. Eaton. Bluffton, O.-2 pages-Italian Bees and Queens.
Like extracted, and for the same reasons, the product of comb honey of 1885, is considerably less than that of 1884, but unlike demand on Eastern account for our comb honey has already been marketed, and at prices all the way from 25 to 100 per cent.

over the figures obtained in 1884. While the output, therefore, in pounds, fell short from the year previous, in actual dollars and cents, a large portion of this shortage has been covered. To still further increase and extend the solve of California court heaver we argue

To still further increase and extend the sale of California comb honey, we again repeat our former suggestions, that a one-pound section be adopted instead of the two-pound now so generally used, and that at least one-half of the cases be made to hold but 30 pounds instead of making them all 60 pounds, or thereabouts, as is now the custom. custom.

California honey, both comb and extracted. California honey, both comb and extracted, is now recognized everywhere as the finest produced in the world; and while bad seasons and low prices will be met from time to time, on the whole the bee-industry of this State, one year with another, promises as fair returns for the labor and capital invested, as any other growing industry of the Golden State.

Hunt's Adulterations received much attention in the BEE JOURNAL for 1884, on pages 475, 724, 787 and 812. Mr. T. L. Von Dorn, President of the Nebraska Bee-Keepers' Society, had the so-called honey tested, and the result was published. Mr. Hunt depied the adulteration, and the Marshail county, Iowa, Society proposed to have it re-tested, and we agreed to publish the result of that test, but so far no such matter has been offered us for publication-though it is over a year since. Now Mr. Von Dorn has sent us a "statement" of the proprietor of the Townley House, at Llocoln, Nebr., and its clerk, Mr. Adams, who says that Mr. flunt inquired of him where he could purchase glucose which he desired to mix with honey he had for sale ; that he did procure it and sold the Towniey House 5 gallons of the mixture, claiming that it was just as good as the pure article, and that hut few could discover the difference. Doubtiess Mr. Von Dorn has acted for the interests of bee-keepers in the matter, but it must be said, however, that the Townley House proprietor bought the mixture (not as pure honey, but an adulteration), knowing its true character. This statement we make in justice to all concerned, and now the subject is dismissed from our columns.

**REPLIES by Prominent Apiarists.** 

### **Reversible Frames.**

Query, No. 204.—Do you consider the reversible frame a good thing? If so, what is the best and cheapest way to make them? Would it pay to change the frames of 60 colonies?—J. C., Iud.

Go slow in adopting radical changes in bee-keeping, is my advice, especially to beginners. Let the old, experienced bee-keepers thoroughly test these novelties first.—H. R. BOARDMAN.

It may be in the hands of the experienced comb-honey producer. Change the frames of a very few colonies, and try them, and if you approve of the change, then do it; but go slow until you can prove by practical ex-perience whether you want to use reversible frames.—11. D. CUTTINO.

No. Reversing will do for people who want all the boney in the supers, and wish to feed their bees after the crop. We want our bees to have enough honey left in the brood chamber to live on, and breed without feeding. Reversing has been prac-ticed in Europe for scores of years, and is generally abandoned. — DA-DANT & SON.

Yes, but I consider a reversible hive of far greater value, As to which style of frame is the best, if a reversible hive is not used, I am not posted. I shall change more than 60 hives next season, and would not do so unless I thought it would "pay." W. Z. HUTCHINSON.

No, I do not. I do not deny that an advantage is gained in reversing by bringing the brood up close to the sections (if it is not already up close, as it generally is in the shallow frame at the proper time); but the advan-tage is not so great as to warrant the time and trouble required to do it. There are many annoyances as from uneven combs, propolis, etc., that make the whole operation disagree-able, besides disturbing the colony in their mode. I fourthes acougilat that their work. I further consider that there are solid reasons against inverting hives. I connot conceive of a circumstance in which I should want to either reverse brood-combs or invert hives. The necessity for it certainly cannot exist with a shallowframe hive.-G. L. TINKER.

For myself I should not make the change inquired about. I can succeed in gaining all that is claimed by the advocates of reversible frames in an easier way. Invertible hives and reversing frames will both have their day and then play out, in my opinion. -J. E. POND, JR.

I am not prepared so say that I do. I have trames, and sectional parts of hives in my apiary that can be readily inverted, but 1 can see no rational reason why it should be done, except for the one short job of having the duce uniform markings. -G. combs securely fastened in the frames. TINKER,

In fact. I have seen but two arguments in favor of inverting frames, or hives, that are worthy of serious thought, and the exception I have named above is one of them. My answers to your concluding questions will be found on another page.—G. W. DEMAREE.

1. So far I have had no use for re-versible frames. 2. Try 1 or 2 of the 60 with reversible frames, and then if you like them and think it will pay, you can change the other 58. Remember that practical experience is the best teacher in all of these things.— G. M. DOOLITTLE.

I have not decided to use any such frames yet, because I think that I can have the principal advantages with-out reversing. I should, however, be not greatly surprised if, five years from now, all my frames were revers-ible; and still less surprised if others gave up their use. Reversible hives have some advantages that reversible frames do not possess, and if I ever go into the reversing business it will likely be in that direction.—C. C. MILLER.

Of all the suspended reversible frames that I know anything about, I prefer the one described on page 9 of the American BEE JOURNAL for 1885. If I did not prefer that one I should use the one I did prefer. After using thousands of them for two seasons, I never expect to use frames that will not reverse .- JAMES HED-DON.

1. I do decidedly. 2. I think so, but you had better try a few first and see if you think so. I tried them for one year, then changed part, and at the end of the second year I resolved to change all. Now comes the reversible hive, which will make me wait till I try it.-A. J. COOK.

### Carniolans vs. Italians.

Query, No.205.—Is the Carniolan race of bees any better than the Italian bees?—F.W.

Those which I had were not as good.-G. M. DOOLITTLE.

My experience with them has been too limited to enable me to say that they are better.—W. Z. IIUTCHINSON.

The reputation of the Carniolans for swarming is a serious objection.-C. C. MILLER.

That is a question on which authories differ. Time will tell.-A. J. ties differ. COOK.

I never have tried them. They belong to the dark or black race of bees, and all black bees are inferior to the yellow bees.—G. W. DEMAREE.

We do not think so. We tried them in 1876, and discarded them. They are black bees, rather large, and quite prolific.-DADANT & SON.

If they are a better race of bees than the Italians, they have not yet proved themselves so to be. They are essentially hybrid bees that the in-breeding of a thousand or more years of natural selection has failed to pro-L.

I do not know just how the races that you mention compare, because they are different in so many characteristics. But when the Carniolans are compared with the best Italians or German bees, I believe that the Germans will prove to be the best.-JAMES HEDDON.

They are said to be far more gentle, and equally as good honey-gatherers; the queens fully as prolific, and the workers very hardy indeed. The only drawback (if it is such) is said to be that they have a strong inclination to throw out swarms during the honey season. This last, I think, is owing to their nature not being well under-stood.—J. E. POND, JR.

### Dark Capping of Honey.

Query, No. 206.-Why is my honey cap-ped over so as to appear so dark? It seems to be of good color and nice flavor, but it is capped over so very darkly as to be un-salable. I practice both side and top storing. -H. J., Mass.

I should like to know more of the particulars before deciding. There may be something in the strain or variety of bees.—W. Z. HUTCHINSON.

Because the cells are full and the honey touches the cappings. Whereever the honey does not touch the cappings, it looks lighter.-DADANT & SON.

If the combs look watery it is because the honey is filled too close to the cappings, and if not caused by dampness, but comes so from the hive, you had better change your strain of bees. If the cappings them-selves are dark, like old comb, it may be the surplus is too near the broodcombs, and the bees carry some of the dark wax from the latter to the surplus.-C. C. MILLER.

Probably it is fall honey. Perhaps it remained in the hive too long and was soiled by the bees. It hardly if ever pays to sell honey in the comb that is capped in the fall. It is better to extract it and use the combs for light honey the next season.—A. J. Cook.

It is impossible without a sample of the honey to do more than guess. It may be darkened by being travelstrained, or the honey may be swelled against the cappings; or, if old dark combs were in the surplus depart-ment it might be mixed with the cappings .- H. R. BOARDMAN.

Perhaps the bees used wax taken from dark brood-combs to seal the surplus honey with. I have seen newly built brood-combs that were near to old black combs show dark capping as though the bees had drawn on the old combs for wax to cap them with. If you had taken the trouble to uncap a section and extract the honey, you could have seen whether or not only the capping was of dark color.—G. W. DEMAREE.

When I used side-storing hives I had the same trouble. I have never been able to get white capped honey at the side of a hive, or at any point in the hive where the field workers

 $\overline{}$ 

collect for the night after their day's work is done.-G. L. TINKER.

Probably because the honey was left on the hive for some time after the capping is done. Fall honey, as a rule, is capped darker than earlier yields. The warmer the weather and the sooner the honey is removed after being capped, the lighter the cappings will be found.—J. E. POND, JR.

There might be several reasons, the most common one being that the cells were filled too full. This is not likely the trouble in your case, if your bees are Germans, or have a dash of German blood in them.-JAMES HEDDON.

Certain strains of bees do this, and I found last summer that even the brown bees did such work when get-ting honey from Alsike clover. 1 never saw such work when honey was coming in from basswood or teasel, no matter what kind of bees were kept.-G. M. DOOLITTLE.

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is bouted near the centre of the State named: b north of the centre; \$ south; \$\$\$\$ east; •• west; and this & northeast; • northwest; • southeast; and 9 southwest of the centre of the State mentioned

For the American Bee Journal.

### The Origin of Honey, etc. DR. J. P. H. BROWN,

Query, No. 189, involves so much of the occult in vegetable chemistry and physiology, that answers can only be based on analogical reasoning. It cannot for a moment be presumed that the honey is in the ground ready to be pumped up into the flower. Prof. Johnson, in his work on "How Crops Grow," says :

"The sap in all cases consists chiefly of water. This liquid, as it is absorbed, brings in from the soil a small proportion of certain saline mattersthe phosphates, sulphates, nitrates, etc., of the alkalies and alkali-earths. ingredients. These may be derived from matters stored in reserve during a previous year, as in the spring, sap of trees; or may be newly formed, as in summer growth.

"The sugar of maple-sap, in spring, is undoubtedly produced by the transformation of starch which is found According to Hartig (Jour, fur Prakt. ch., 5, p. 217, 1835), all deciduous trees contain starch in their wood and yield a sweet spring sap, while evergreens contain little or no starch."

This is, no doubt, the reason why the flowers of evergreens yield comparatively little honey. The Evonymus, a beautiful evergreen that hedges the walks of many a southern yard, often blooms profusely, but its flowers are rarely visited by honey-bees. Its nectaries secrete a resinous matter that emits a disagreeable odor, and are visited by flies and other insects, but by no bees. The deficiency of but by no bees. The deficiency of starch in this plant would preclude the formation of honey.

That the constituent elements, as well as the proximate elements of a plant, vary in proportion by the char-acter of the soil and the moisture and condition of the atmosphere, is a fact fully demonstrated. Fruits are sweeter and better flavored in seasons when there is not too much rain, but just enough to sustain the fruit to tull size and maturity. Melons grown on low, moist lands, or in wet seasons, contain less sugar than when grown on uplands with not too much rain. The same applies to the sweet-potato. Sugar-cane always yields more sugar and makes better syrup when the season is not too wet.

"The soil, or the supplies of food, manures included," observes Prof. Johnson, "have the greatest influence in varying the proportions of the ash-ingredients of a plant." Sweet-potatoes grown on sandy uplands contain more sugar and starch than those grown on flat, moist lands. My experience has been the same with the Irish potato—those on uplands being more mealy. The flavor of the grape is very much influenced by the fertilizers used. Melons fertilized by Peruvian guano are not as sweet nor as fine in flavor as those grown with stable manure.

Therefore, if the production of sugar in fruits and plants is so greatly influenced by wet, moisture, atmos-pheric conditions, and soil, we can safely infer that the organs of the flower that secrete the honey are affected by the same causes. True, the rationale is not well understood; but scientific investigation is destined to make plain many operations in nature that now seem to us inexplicable.

### Convention at Meadville, Pa.

The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers Association met at Meadville. Pa., at 11 a.m., on Jan. 20, President Mason in the chair.

The reports of the Secretary and Treasurer were read and approved; the annual dues were by vote reduced to 25 cents for the present year; and the name changed to "Northeastern Ohio, Northern Pennsylvania, and Western New York Bee-Keepers' Association," and the Constitution amended accordingly. In the afternoon President Mason

delivered the annual address, which was replete with good ideas; D. H. Lefever delivered an address of his colonies came through the winter

welcome, which was replied to by D. Videto, in a happy manner. The election of officers resulted as

follows: President, C. II. Coon, New Lyme, O.; Secretary, J. II. Wood-worth, West Williamstield, O.; Treasurer, Geo. Spitler, Mosiertown, Pa.; 1st Vice-President, C. H. Wright, Conneautville. The President was instructed to appoint two vice-presidents from each county represented. Andover, O., was chosen as the

next place of meeting.

The first topic discussed was "Spring Management of bees, pre-vious to the honey-flow." U. E. Dodge said that it was an important subject, for upon the way we manage at this time depends the whole ques-tion, as to profit. It is hard to tell what to do, and how to manage, as each colony differs from others, hence the impossibility of laying down any set rules. He winters his bees in a cellar, and is a firm believer in a warm temperature; he keeps the room in which his bees are wintered at a temperature of from  $55^{\circ}$  to  $60^{\circ}$ ; and tries to keep his bees in the cellar until soft maples blossom. If it gets too warm he uses ice to keep down the temperature ; he does not like to set his bees out until warm weather; he uses absorbents on the top of the bees (chaff and sawdust, mostly the latter). When he puts his bees out, if all right, he lets them alone; if weak, he feeds them and takes brood from such colonies as can spare it, to

build up the weak ones. By request, Mr. Dodge gave a de-scription of his cellar, which was, in brief, as follows: A common cellar under the house in which he lives; has a room partitioned off in one corner, directly under the sitting corner, directly under the sitting room : has sub-earth ventilation, but has the pipe but 3 feet under ground, because the cellar was already built; if he had to do it again, would put the pipe near the bottom. He has a pipe connected with the pipe in the ground, which he has run some distance in the air, and in which he has a valve with which to regulate the temperature of the cellar; he also has a ventilating pipe extending from the room in the cellar to the stove-pipe. He has a large stove in his sittingroom, directly over the bees, in which there is a good fire continually; has never had the temperature fall below 42° in the coldest weather. He winters S5 colonies in this room; too many, he thinks; almost all his colo-nies have brood before he sets them out in the spring. He winters some out-doors, because he does not like to risk all in one place. His losses in the cellar have never exceeded 11 or the cellar have never exceeded 11 or 12 per cent., often none; while out-doors they were at times 20 to 25 per cent. He does not get as much honey as he would if he hired some help in the busy seasons, but it being almost impossible to get the right kind of help, he prefers to do with less honey.

D. Videto said that no person should expect 100 pounds of comb honey unless all queens are prolific. Drone combs must be removed; you want but few drones. Very few of

strong. He had 120 colonies in the fall of 1884, and only one came through strong, had 24 weak ones, the remainder were dead. Some filled but two spaces, and some had no queens. They did not commence swarming until July 12. He bought 8 colonies. He had many combs of sour honey from those colonies that died which he fed gradually to the bees. Would never sell it, as people who bought such stuff once, would never want to eat honey again. His yield was between 2,900 and 3,000 pounds of comb honey, besides abund-ance of frames saved for winter and spring feeding, and 200 pounds of extracted honey. If bees are weak, he contracts the brood-nest to from 3

"Production of comb honev" was the next topic discussed.

D. Videto-How to manage to get the greatest amount of comb honey is an important question. •Successful bee-keeping is the securing of the greatest amount of honey out of each hive. To secure this swarming must be prevented. As it is almost impossible to prevent swarming, he lets them swarm, places the hive with the swarm where the old colony stood, placing the old hive just back of the new one. Lets them remain for 24 hours, then takes a frame of uncapped brood from the old hive and puts into day until all the brood is in the new hive, the old colony being thus destroyed, swarming fever is destroyed. In 21 days all the brood is hatched, and a large force of workers are ready to gather honey. This is the way to do if you do not want increase. If increase is wanted, different method must be pursued.

U. E. Dodge lets them swarm nat-urally, and with the old colony and the increase, can get more honey than with one colony after Mr. Videto's plan.

Evening Session.—Topic: "Is it advisable to attempt to prevent swarming, when running for comb honey ?'

M. E. Mason-It is not advisable.

Mr. Shepard—To prevent swarming bees want plenty of room. Some seasons he got large increase of colo-nies and little honey, while other seasons he got much honey and little or no increase.

Some discussion was then had on Italianizing, foul brood, cellar wintering, tiering-up, cleaning combs, breeding queens, etc.

### SECOND DAY.

President Coon in the chair.

Mr. Videto said many claimed the cause of the depressed state of the honey market was owing to overproduction, which he was sure was not the case. He lays it at the door of the general business depression, In order to sell we must put our etc. goods in better shape, and not sell too soon.

Mr. McLean—Some seem eager to sell, and take off honey when but about two-thirds capped. He always sells by sample, and sells honey on its merits.

Mr. McGonnell could always sell his honey; he tries to have it in good condition.

Pres. Coon said that 2 years ago he had some honey very early, which he thought he could sell for a good price, but to his surprise others were ahead of him, but with an inferior article, not ripened and capped, which they were selling at 12½ cents per pound. He got disgusted and took his honey back home and realized 16 cents per pound for it. He cannot see why people act so with honey; they do not with other tarm products.

Mr. Masou-The same laws govern the sale of honey as other products. If only a first-class article was offered for sale, a good price could be realized. He detailed his experience in building up a trade for honey, in Pittsburgh, where he shipped over six tons last season. When he went there he found the markets glutted, not with good honey, but with stuff which had once been good honey, but had been ruined in a cool, damp cellar. A person who buys a good article will buy again. Always sell honey for what it is. Never mix first and second-class honey in the same case, if you wish to keep up your reputation.

The question box was opened and a variety of questions answered.

Afternoon Session. — On motion, Art. III of the Constitution was amended so as to require only two vice-presidents from each county instead of four.

Wintering bees was the first topic discussed, and one of the most important, from the fact that nothing in apiculture is so uncertain as is the wintering of bees.

Mr. Sterrett does not see much difference between chaff and sawdust for winter packing. Has had equally good results with either.

Mr. See prefers buckwheat chaff. Mr. Lefever had wintered bees without packing, but lost largely.

Mr. Herman uses chaff hives with 3 inches space. Uses buckwheat chaff for packing, and has lost but one

colony in three years. Mr. Videto thinks it is not all in packing, but in other conditions. Locality has much to do with it, as well as stores. Has packed, and in twelve years has three times lost all his bees. Has some in the cellar now. All should try both methods. and adopt that which is best suited to the locality.

Mr. McLean related an instance where bees were covered thickly with snow. Some were uncovered and some left in the snow; those that snow. were uncovered died, the others came through all right.

J. H. Wright-In putting in comb for winter, put in alternately one heavy and one light, and out of 60 last winter lost one. Thinks his honey was better than some others, as he had no honey-dew.

After discussing several other topics the convention adjourned.

127 The Union Bee-Keepers' Association of Western lows will meet in Dexter, lows, on April 10, 1886, at 10 a.m. M. E. DARBY, Sec.

For the American Bee Journal.

### The Reversible-Hive System.

DWIGHT FURNESS.

On page 71, Mr. G. M. Alves (after penning some well-worded sentences which show his high literary ability, and, if meant literally, his non-progressive tendencies), asks four ques-tions in regard to the new Heddon hive. After a careful study of that hive, and some experience with the method of management to which it is especially adapted, I am fully con-vinced of its superiority, and I am now making 100 of the new hives for next season's use. 1 would answer those questions from my experience briefly, as follows:

1. No. The hive is quite simple. This question was probably inspired by the thumb-screws. These screws are just the thing for clamping together wide frames in any style of Super. The fixedness of the different parts makes it, with its peculiar system of management, at once the simplest, speediest and best. 2. The new hive requires well sea-

soned lumber, carefully and accu-rately cut. It is all plain, straight work, however, and can be done on any first-class circular-saw table. Like all of Mr. Heddon's inventions, it possesses practicality in an eminent degree.

3. Yes, when by so doing they can diminish labor one-half; or, in other words, care for two colonies with the same labor now required by one. I believe that the new hive will enable us to do this. The cheaper the honey When made in large quantities, the new hives will cost not to exceed onethird more than the ordinary Langstroth hives. In retailing hives there is much expense besides the cost of making

4. I think it is true, that Mr. Heddon's new method of horizontal interchanging of brood-combs will secure to us most of the advantages that we know by experience are realized by reversing. This is one of the brightest thoughts of the day, but as stated in his book, especially advantageous when used in connection with reversing. I do not know why Mr. Alves, or any one else should wish to transfer this principle to the Langstroth hive, when it is so much better carried out in the new hive as constructed by Mr. Heddon. Without connecting it with inversion, perfectly filled frames of combs are wanting, and we have nothing to take the place of inter-changing, when contracting to one case-a system that I have thoroughly tested and prize highly. By this com-bination of the two systems we may be able to practically control swarming, for the first time in the history

The inventor claims that in the construction of the new hive he combines nearly all the advantages of both closed-end and suspended frames, and embraces but few of their peculiar disadvantages. To echo the words of Dr. C. C. Miller, it seems to me these

are such self-evident truths that it needs no experiment to know them.

I will not mention the many other improvements in manipulation, for which the new hive is especially adapted, and which cannot be carried out with suspended frames, or any others unless arranged substantially as Mr. 11. has them.

In the grand march of progress, Mr. Heddon has taken a long stride in advance of us all, and, like all others who get "ahead of the crowd," he will be the target for a volley of criticism, sarcasm and ridicule from the elbowing mass in the rear.

Furnessville, ~ Ind.

### Maine State Convention.

The Maine State Bee-Keepers' Association met in convention at Skowhegan, Me., at 1 p.m., on Jan. 19, 1886, President J. B. Mason in the chair, who gave his annual address.

An essay was read by Isaac Hutchins, upon the "Coming Bee." Mr. Hutchins advocated a cross between the German and Italian races, for the "coming bee."

F. O. Additon read an essay entitled, "Of what practical benefit are the improvements in bee-keeping, and to what extent may bee-keeping be carried ?"

An essay was read by L. F. Abbott, of the Lewiston *Journal*, entitled "Pure Honey."

Are drones of any use, other than for fertilizing queens?

Various opinions were expressed some thinking that they may help in evaporating and scaling the honey; also in keeping up the warmth of the hive. Others thought that they were of no use other than for fertilizing queens.

Is stimulative feeding in the spring desirable ?

All favored it. It was decided that feeding should begin as soon as pollen comes in freely, and to feed inside the hive.

Are the yellow bees an improvement over the blacks ?

It was decided that they were.

How can we best develop a home market for our honey?

Many related their experience in developing a home market; the essential points being to carefully grade the honey, and for the beekeeper to place his name upon every package sold; to educate the people to eating honey, and if necessary to introduce it; that is to say, take it from house to house.

In what way can swarming be best controlled ?

Each bee-keeper seemed to have a method of his own to control swarming; but it was the general opinion that all after-swarming should be checked.

To what extent should comb foundation be used ?

It was decided best to use full sheets in the brood-chamber, and that all frames should be wired.

It was resolved that bee-keepers this, but should sow Alsike clover for its honev ing one :

and forage, and recommend it to farmers for hay.

Mr. Cornforth said he could produce extracted honey for 15 cents per pound, easier than he could produce comb honey for 25 cents; and that he could sell ten pounds of extracted honey when he could sell one of comb honey, at their relative prices.

The following officers were elected for the ensuing year: President, James B. Mason; Secretary, Isaac Hutchins; Treasurer, W. H. Norton.

Jonathan Pike, John Reynolds, and F. F. Graves were to make arrangements with the State Agricultural Society for an exhibit of bees, honey, and apiarian implements at the next State Fair.

J. B. Mason, Isaac Hutchins and L. F. Abbott were to arrange for the next meeting at Mechanic Falls, in January, 1887.

F. O. Additon, W. H. Norton and F. F. Graves were to use and decide upon the merits of the different reversible frame attachments.

WM. HOYT, Sec.

### For the American Bee Journal.

Prospects for the Coming Season, etc.

### E. J. BAXTER.

We had very cold weather again week before last and last week—from  $24^{\circ}$  to  $27^{\circ}$  below zero. The first 3 days of this week were very warm, comparatively— $65^{\circ}$  in the shade at noon. My bees had a splendid flight, and I find that not one of my 230 colonies has perished—possibly because they all had pollen in great abundance last fall when they were put into winter quarters. White clover is abundant, and looks vigorous; it has been growing some under the snow. If nothing happens to kill it out between now and the opening of spring, the possibility is that we will have a crop of white clover honey.

I am making preparations to greatly increase my aplaries the coming summer. I work nearly all of my aplaries for extracted honey, as I find that it pays me best. I will run only one aplary, this year, for comb honey. The great bulk of the increase of my aplaries is made by division. Last year I had only 12 natural swarms, and I made 90 by division, all being good and strong. I invariably use full sheets of foundation in the broodframes, and if we have an average honey season this year, I expect to use at least 200 pounds of heavy foundation. I now use full sheets of foundation in all of my sections, and surplus frames, also, and I find, after repeated experiments, that it pays well.

I have tried hives with *deep* frames, and hives with *shallow* ones; *large* hives and *small* hives—8-frame Langstroth, and my experiments and observations have taught me that *large* hives with *deep* frames are the best and the most profitable every time. I could mention several facts to prove this, but I will give only the following one:

Last year we had a very poor honey season in this part of Illinois, as every one fully knows. Last spring I determined to work 30 colonies of my home apiary for extracted honey, and all the others for increase. I began to work early with the bees, so as to get them as strong as possible for white clover bloom. By the middle of May the most of the 30 colonies worked for extracted honey had their 10 frames (18 inches long and 10½ deep) almost covered with worker brood; and by the middle of July I had extracted 2,475 pounds of as fine white clover honey as was ever gathered—or an average of 82½ pounds per colony; while my neighboring bee-keepers, with 8-frame Langstroth hives, had scarcely anything — not enough, in fact, to make it worth the trouble to take it from the hives.

Nauvoo,+o Ills., Feb. 12, 1886.

### The Wisconsin State Convention.

The Wisconsin State Bee-Keepers' Association met in Madison, Wis., on Feb. 4, 1886. President C. A. Hatch delivered his annual address. which brought ont a discussion on "Wintering Bees."

Why is clover honey better for wintering bees than fall honey ?

Mr. Elver—In the fall bees sometimes gather impure sweets from grape-vines, cider-mills, etc., while in clover time they find plenty of pure honey, and that only.

Frank McNay—I have found by experience that fall honey is as good as any in my locality.

F. Wilcox—Impnre honey is not good at any time or in any condition. Fall honey is as good if not better, because it is thicker than clover honey, unless taken out and stored in a damp cellar, when it would absorb moisture and spoil.

moisture and spoil. Is clover better than basswood honey? Bees leave clover for basswood.

F. McNay-They go to the basswood because they get honey faster.

Mr. Elver—Basswood is as good as clover. I think it a mistake to feed sugar; pure honey is good enough.

Mr. France—I winter my bees on basswood honey. I fed 600 pounds of it on Aug. 1. I have 510 colonies, and extract once a week when the yield is good.

Mr. McNay read an essay on "Managing bees for producing comb honey."

F. Wilcox practices the tiering-up plan. Ile does not remove the sections as soon as finished, as he thinks that it ripens better and is not much soiled if full cases are kept on top.

Mr. Wilcox reported that the State Board of Agriculture had agreed to leave it with this Association to revise the premium list of the aplarian department, and add 25 per cent. to the amount allowed last year. The President and Secretary were authorized to revise the list.

Mr. France warned the members against shipping honey to G. W. House, of New York, as he was irresponsible.

#### AFTERNOON SESSION.

The following officers were elected : President, C. A. Hatch; 1st Vice-President, Dr. J. W. Vance; 2d Vice-President, E. France; Secretary, F. Wilcox; and Treasurer, F. Minnick.

Mr. Daniher exhibited a bee-feeder which resembled a brood-frame without a top-bar, with a thin board on each side, the cracks and joints being waxed. He recommended candied honey as food, softening it with warm water when necessary.

Mr. Spangenberg exhibited a new implement for uncapping honey. It was like a small paddle three inches wide, with small steel wires onefourth of an inch-apart, driven in the end. The projecting wire was sharp, and curved like a cat's claw, to scratch open the cappings.

The following resolutions were then passed unanimously:

*Resolved*. That the bee-keepers of this State endeavor as far as possible to create a home market for their honey, so that there will be no need of seeking city markets in which to dispose of our surplus products.

Resolved, That we thank Mr. T. G. Newman, of Chicago, for his efforts in securing re-duced rates of transportation on honey, and congratulate him upon his success.

Resolved, That we desire to express to Mr. Newman our sincere appreciation of his labor and zeal in fighting the glucose adul-terators, and bringing to light their nefarious schemes against the interests of bee-keepers.

Resolved, That the bee-keepers of the State are urged to make more creditable exhibits at the next State Fair.

Dr. Vance read a well prepared essay on "Foul Brood," reciting the fact that he had since our last convention lost all of his bees by that dis-ease. He related the experiments of ease. He related the experiments of Mr. Cheshire, of England, in treating the disease with phenol, and spoke very hopeful of the result of his researches.

Has there ever been any assessment of bees in the United States ?

F. Wilcox-I am taxed on them.

Mr. Waller-In Richland county they are never taxed. Mr. Elver—They pay a premium for

keeping them in some parts of Enrope.

Mr. Sanford-I think that bees ought not to be taxed.

F. McNay thought that bees ought to be taxed.

STATISTICS .- Twelve of the members present reported 78t colonies in the spring; 1,230 in the fall; 10,075 pounds of comb honey; 46,050 pounds of extracted honey.

From the census report for Wisconsin, taken June, 1885, we get the fol-lowing: Number of colonies in the State, 51,917; pounds of wax produced the year preceding, 44,281; value of bees, \$247,481; pounds of honey, 1.432,766; value of the same, \$160,076.

Mr. Hatch—I can say of my own knowledge that the statistics of bees and honey was not complete.

The convention then adjouned. F. WILCOX, Sec.

197 The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednesday, Oct. 19 and 20, 1886.

J. M. HAMBAUGH, Sec.

### For the American Bee Journal. Do Bees Hear ?

### A. W. OSBURN.

There seems to me to be no doubt that bees hear; not only do I think they hear, but I have been placed in circumstances when I was fully convinced that they could hear, and hear quickly, too. While keeping bees in California, several times I have seen bees attack horses, dogs, etc., and from the time that the first bee attacked these animals, it would not be half a minute before there would be 10,000 to take part in the battle. Those that have never seen bees attack an animal in earnest, can form no idea how short a time it is before the object of their wrath is completely covered with the little stingers. Now if bees cannot hear, how do they communicate so quickly? The numbers and numbers of evidences that I see while handling bees constantly leads me to think that they can hear. At that particular time when they have decided to sting something to death, I would say do not attempt to liberate whatever they are wreaking their vengeance upon, for at that time they show no respect of persons. I tried it once, and I shall never try it again. Although I had a veil on, I was so badly stung that I had to go to bedthe only time in my life that they got the best of me to such an extent. Were it my own horse, dog or cow, and it could not get away itself, I would not take the chances for the price of a good many such animals. Talk about boiled down and concentrated wrath-the words do not express what one sees, when a large apiary of bees has fully decided to kill somebody !

Cuba, W. I., Jan. 25, 1886.

### For the American Bee Journal,

### Lamp Nursery for Queen-Rearing.

### W. Z. HUTCHINSON.

As most bee-keepers are probably aware, the lamp nursery is simply a tin hive with double-walls, the space between the walls being filled with water, which is kept at a proper temperature by means of a lamp under-The one that I have was made neath. by our village tinner at a cost of \$2.00. It is placed in the top of a box 4 feet high, the space between the outside of the nursery and the inside of the box being about one inch. Blocks of wood nailed in the corners of the box afford a support for the nursery. Strips of wood are fitted in between the upper edges of the nursery and box. The warm air not only strikes the hottom of the nursery, but has access to its sides. There is a wooden cover to the nursery with strips of cloth tacked to it to prevent the escape of heat at the joints. A ther-mometer is attached to the cover upon the inside, and a hole covered with

a large tin lamp that will hold one gallon of oil.

The nursery is kept in a closed room on the north side of the shop, and there is no trouble in keeping the temperature so that it will not vary more than 5°. Incubators for hatching chickens have an arrangement for controlling the temperature, keeping it at exactly the same degree. Such an attachment could be used in connection with a lamp nursery, but I hardly think it necessary, as the tem-perature in a colony of bees varies more than 5°. I believe Mr. Heddon keeps his queen-nursery in the cellar, and succeeds in keeping the temperature so that it varies only 1°. I try to keep the temperature between  $90^{\circ}$ and  $95^{\circ}$ . If it goes above  $100^{\circ}$  the queens are usually destroyed. I have never known them to be injured by a low temperature; and I have some-times had it run down to  $70^\circ$ , when the light had gone out because the oil was all used sooner than I expected it would be. In fact, I once acci-dentally left a cell out-of-doors upon the north side of a hive, for two days, and when I discovered it the queen was just cutting her way out.

The nursery should be of such a size that several of the regular combs can be placed inside. When queens are reared by giving a comb of eggs to a queenless and broodless colony, there is usually a large number of cells upon the comb, and the queens will hatch before the workers, and it is advisable to brush the bees from the comb instead of cutting out the cells, and place the comb, cells and all in the nursery. When the cells are taken from a colony that has swarmed, for the reasons that the cells are usually scattered about, only two or three upon a comb, and the eggs in the center by the scattered about, and the eggs in the combs having been laid at different times, bees would be hatching out in large numbers in the nursery. I have been told that virgin queens would not kill one another unless they had first found and eaten food. Even if this were true, which I do not know, it would be difficult to take advantage of it, as, when whole combs are placed in the nursery there is certainty an abundance of food, while, if all cells were cut out they must first be cleaned up by allowing the bees to have access to them after they are cut out; otherwise there would be plenty of food available at the freshly cut

edges. The best way that I have found to avoid losses from young queens killing one another, is to examine the nursery often, as often, at least, as once in two hours, and cage or remove the hatched queens. By listening carefully, any queens that may be guawing out can be heard. A window in the room can be readily shaded with a curtain; a hole in the curtain admits a ray of light; by holding a queencell before the ray of light entering a darkened room, the inmate can be easily seen; especially is this the case if the comb upon which the cell is built is new comb. The last thing in glass is made in the cover, thus allow-ing a view of the instrument. I have of a lamp, all of the cells. By holding

the cells in different positions between the light and the eye, the queens can usually be seen. Any queen that shows signs of hatching is put in an apartment by itself. To furnish these separate apartments, a "wide frame," the same size as an ordinary brood-frame, is divided by partitions into little "pigeon-holes." One side of this frame of little apartments is covered with a thin board, the other side with glass doors, one door for each apartment. Each door is "hung" with a cloth hinge pasted on, and is fastened shut with a catch made by driving a common pin partly in, then bending it over. To release the door the eatch is turned in an opposite direction.

When I first began using the nursery, I took queen-cells from the bees as soon as they were sealed, or soon after; but this disturbing of the cells when the queens were so immature, resulted in so many maimed and crippled queens, that I soon abandcells until they begin to show a brownish color, which indicates that the queens are nearly mature. When the bees are given eggs that are just beginning to hatch, I remove the cells about the ninth day, and the queens hatch in two or three days.

The great object in using a lamp us to examine the cells at *any* time, which would be impracticable if the cells were with a colony of bees. If a young queen hatches out in a colony of bees, unless they have the swarming impulse, the remaining queens are destroyed, and it is quite a task to find the queen. If the cells are allowed to remain with the bees until they "turn color," I think that queens hatched in a lamp nursery are as good as any.

Rogersville, & Mich.

Read at the New York State Convention. Does Bee-Keeping Pay ?

### WM. F. CLARKE.

At the recent Detroit Convention, an essay by Dr. C. C. Miller in dis-cussion of the above question, was read. It only professed to open the discussion, which it did so effectually that a your live is the terms of the second second second that a second second second second second second second that a your live is the second sec that a very lively debate sprung up, which was only closed by a resolution to lay the subject on the table, which, on motion, was carried. This action is usually taken by Legislative bodies. when a discussion is unfinished, or there seems no likelihood of arriving at a decision. The question is one of those concerning which much may be said on both sides without arriving at a satisfactory conclusion. After the amplest discussion, one can only look at the pros and cons, and judge for himself, so that the question really is,

"Does bee-keeping pay ME?" It will simplify the matter very much if we start with a definition of the word "pay." Dr. Miller sets out to discuss the question solely from a pecuniary stand-point, but he decides it, so far as he does decide it, on totally different grounds. He states the

question at the outset in these terms : Can I make as much money, in a series of years, at bee-keeping as I can at any other business?" He can at any other business?" He decides this question for himself in the negative. He says: "I am obliged to confess that I could make more money to give up bees entirely." In reply to the query, why he continues at the business, he replies, in effect, that it pays him otherwise than in dollars and cents. He says: "I like it. It keeps me out-doors, and is good for my health. It allows me to be with my framily more than any other calling at which I could make as much, and for the privilege of these enjoyments, I am willing to I would make at a more lucrative calling. Whether the price may not become too large for me to afford to pay, is an open question.

Now it is only in this broad and comprehensive light that we can fairly consider whether anything pays in this world. We are all the time investing more than money in our occupations. We call money the capi-tal which we invest, but it is not all, nor indeed the most valuable investment that we put into our business. We embark ourselves as well as our money in whatever calling we undertake, and the most important question in regard to the calling we pursue, is its influence upon ourselves. Does it make us happy or miserable, better or worse, richer or poorer in those qualities that go to form a desirable character? At the conclusion of the auction sale of the fixtures of his saloon. "The Ship." in New York, Paul Boynton said: "Gentlemen, I thank you for helping me to leave a business I have felt to be a curse upon me ever since I entered it. I would rather cultivate bricks than touch the gin-trade again." It paid him in dollars and cents most likely, but it was a dead loss in its influence upon himself. A bright day will dawn on the world when the profits of all businesses are gauged by their intellectual and moral, as well as their pecuniary results.

Undoubtedly there are some occuapart from the motive under which they are followed, to make people selfish, grasping, narrow, ill-tempered, stolid, coarse, low, and grovelling. There are others that tend to uplift, ennoble, and improve the minds and characters of those engaged in them. Is it not patent to all the world that Wall Street stock jobbery tends to make the men who pursue it wild beasts of prey, and that the haunts of this kind of business are made hideous by the yells and howls of the predatory bipeds that prowl about in them, seeking whom they may devour? That kind of business may and often does pay in dollars and cents, but the more successful it proves in that line. the more serious and impoverishing is the loss of moral character involved in it.

A business pays in the broad sense of the term if, in addition to yielding a fair profit in money, it is conducive my neighbor. It may pay him, but to health, cheerfulness, mental cul- not me to prosecute it. But for this

ture, growth in virtue, and home comfort. Without making invidious comparisons between it and other occupations, it may be safely affirmed that bee keeping stands these varied tests well. It pays fairly, if properly carried on, as a money investment. Being pursued mostly in the open air during the pleasantest weather, it cannot but be promotive of health, and the cases are not rare in which invalids have been completely cured of former ailments by adopting this avocation. It is pre-eminently a calling that demands study, thought, investigation. It presupposes a high grade of intelligence. There is very little of mere routine about it. Con-stant observation of natural phe-nomena is essential to its prosecution. No business oftener brings one face to face with the why and the wherefore of things. An unreasoning bee-keeper must prove a failure, for suc-cess depends mainly upon judicious linking of cause and effect. So there is a constant exercise of thought going on, which is eminently favorable to mental improvement. A business, to be enjoyed, must be capable of awakening interest and entursiasm in those who prosecute it, and there is no more fascinating occupation under heaven than this, to those who have a taste, as most people have. for observing the wise ways and wondrous habits of the animated tribes that people the earth. A bee-live is a world of wonders in itself, and one never tires of watching the marvellous processes that are constantly going on before his eyes in the development of insect life and activity.

Bee-keeping demands, in a high degree, those moral qualities which are essential to excellence of character, self-command, patience, gentle-ness, industry, vigilance, attention to minute details, unswerving rectitude, kindness of heart, and evenness of temper. This is a galaxy of noble qualities, and that bee-keeping tends directly to their cultivation is a fact which "nobody can deny." Finally, this is peculiarly a home calling, prosecuted close to one's own threshold, away from the ten thousand temptations that haunt the shop, the factory, the street, the market. To pursue it, one is not obliged to forsake the loved ones at home, and live half or two-thirds of the time among strangers; he can have regular meals, and time to eat them; he can carry out the good old rule, "early to bed and early to rise;" and pursue the even tenor of his way without those breaks and interruptions which are fatal to family order, peace, and good government.

These hints may aid those who are debating the question whether to go There is still the point of special personal adaptation to be considered.

"Every man can't be a poet, No more than every sheep a go-at."

 $\Lambda$  business may be a good and paying one, but I may be entirely unsuited for carrying it on. If so, the part of wisdom is to pass it on to

variety of adaptation, everybody would be crowding into the same line of things, and that division of labor which is necessary to the world's work being well and faithfully done, would not take place. There is no honest business that pays so much better than any and every other as to justify a universal rush into it. The lot of man is wisely equalized in this world, and when in harmony with the eternal litness of things a person finds a place that suits him, and to which he is suited, he had better consider himself the right man in the right place, and stay there. But if there is a mislit, a square peg in a round hole, or vice versa, it is well to seek a change for the better, and there can be little doubt that many would find it in bee-keeping. That this business pays, in the broad and high sense which has been explained, is a fact, which is respectfully submitted to all those who are looking for a suitable vocation.

"The world is all before them where to choose

And Providence their guide."

Should they make choice of bee-keeping, let us hope they will not get out of their latitude, or find it an uncongenial sphere, but that it may prove, in their case, "the way to be bealthy, and wealthy, and wise " above all, the way to be good, happy, and useful.

Guelph, Ont.

### For the American Bee Journal. Making Reversible Frames.

### G. W. DEMAREE.

In Query, No. 204, J. C. asks for the "best and cheapest" way to make a frame that can be inverted. He also frames in 60 hives. The answer to the last question is short and will be given first. It certainly will not pay you. Try a half dozen hives first, and find out for yourself that it will make "fuss" on your hands without corresponding returns.

To make a frame that can be in-verted at will, make the end-bars 35x135 inches, and as long as you want your trames deep. "Inset" them on their edges like the one-piece section, and cut gains in their ends the right size to receive the ends of the long bars. Make the long bars (top and bottom bars) % of an inch wide, and of a thickness to be in accord with depth or weight of the comb. The two long bars are of the same length. When the frame is nailed together it has no projecting top-har. Now nail a block seant 3% of an inch thick, 7% of an inch wide, and exactly 1 inch long, to the outside of each end-bar, exactly in their centre.

If the work is accurately done, the bearings of the blocks will be just 1/2 inch from the centre of the frame, up and down. Now nail a thin strip of wood on the inside, to the front and rear ends of the hive or case. You will see that when the frames are dropped into place, the end blocks

will rest on the strips, and the frames will work one side up as well as the other; and when the case is filled with these frames and "keyed up" tightly, there is no reason why the case might not be turned upside down if one should see any cause to do so.

The above plan of adjusting frames gives the bees perfect control of the interior of the hive, the bee-spaces being perfect all around the frames, a feature that can never be dispensed with where movable frames are used —especially in a warm climate. The central block device for supporting frames, originated with myself so far as I know, or care. At any rate it works splendidly in my shallow-frame cases, or sectional parts of hives.

Christiansburg, & Ky.

For the American Bee Journal.

My System of Using Shallow Frames.

### T. F. BINGHAM.

In response to the following which was sent to me from the BEE Jour-NAL office for reply, I would offer the following remarks. Here is the query:

"EDITOR BEE JOURNAL :-- I wish you would persuade T. F. Bingham to detail his management of his shallow frames—how he tiers them up, what he puts between the tiers, what he uses for an outer covering, etc.-TURNER BUSWELL, Solon, Me.

While Mr. Buswell's queries are in order, and like many that have been sent to me from all parts of the country, I must, just now, be excused from a lengthy answer to them.

The fastening which I use is an oblong link or loop made of small, soft iron-wire the length of the width of the hive used. Each end of each of the two movable sides of the hive contains one 10-penny nail, the head of which is left out about 14-inch; over these nails the wire link passes loosely. When the frames and sides are to be fastened togther, a short piece of soft wood, square at each end, is put between the two sides of the link, and turned so as to hold them apart. The power is simply immense. Frames and sides thus bound together may be handled like a shallow box.

The division-board used between the sets of frames when tiered up any number above another. I call a "strip bottom-board." It is like the bottomboard that I use, except that it is made of strips  $\frac{1}{2}$  of an inch thick, having  $\frac{1}{2}$ -inch bee-passages between them. The outside cover is a box open at the bottom, the end pieces of which are wider than the sides and reach below the bottom-board when only one set of frames is used. The sides of the box rest on the top of the sides of the hive on a cleat, while the ends of the box pass loosely down by the ends of the frames and bottomboard, which protects the frames, etc., from storms, etc. The spare honey chamber, of course, is one of the objects of this box or cover, and is 6 in. high and of the size of the hive. Abronia, 9 Mich.

### For the American Bee Journal. Ventilating Hives in Winter.

### R. F. HOLTERMANN.

It appears to me that the proper way to ventilate hives may largely depend upon the place our colonies are in. If the colonies are in cellars or reposiciently high, as Messrs. Barber, Hall, etc., have them, there is no necessity for upward ventilation, as the heat either drives off the moisture, or on account of the high temperature the atmosphere is able to hold more moisture. Should the temperature tall, the moisture would condense. Whilst now it may be perfect wis-

dom to permit of no upward ventilation (or practically so) under these circumstances, it might be, and is, in my estimation, a great mistake to give bees wintered outside or in cold repositories, no upward ventilation, for the moisture condenses upon the interior and contents of the hive. have frequently, even late in the fall, found moisture condensed in great drops upon the under side of enameled cloth of a propolis-covered quilt, and I never permit them to remain upon the hive after cool weather comes on.

But whilst I would under the above circumstances strongly condemn anything that would prevent a passage of moisture, I would as strongly advo-cate putting upon the top of the hive flannel, chaff, etc., to binder the pas-sage of the heated air as much as possible. True, if the moisture passes upward and out, the hot air must to a degree, but we have above the bees a substance which is practically known as an absorbent of moisture and a repeller (or confiner) of air. In our Canadian climate, from experience and observation, I would say, for outdoor wintering a clamp appears to me to be the best way to winter bees above ground. Chaff hives are expensive, unwieldy, inconvenient for manipulation, manipulation, besides possessing many other disadvantages which more than cover the advantages. Brantford, Ont.

The New Jersey and Eastern Bee-Keepers' Association will hold their ninth semi-annual convention at Cooper Union (Room 22) in New York City, on Wednesday, March 10, 1886, at 9:30 a.m. All who are interested in bee-culture or honey are re-spectfully invited to attend. We expect a large delogation from the Philadelphia Association to meet with us, and it promises to be one of the most interesting as well as instructive conventions that this Associa-tion has ever held. A special invitation is extended to ladies, well knowing that they are by no means a small factor in our in-dustry. Beginners, it is well known, will learn more by attending one good conven-tion than a year of practical experiments will teach them. All ner equested to bring something to exhibit, and if you cannot come, send us an essay to read on some live subject. W. B. TREADWELL, Sec.

Are you Entitled to a pension? You may be and may not know it. If you examine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

### Local Convention Directory.

Time and place of Meeting. 1886. Mar. 10.-N. Jersey & Eastern, at N. Y. City, N. Y. W. B. Treadwell, Sec., 16 Thomas St., New York. Apr. 10.-Union, at Dexter, Iowa. M. E. Darby, Sec., Dexter, Iowa.

Apr. 27.—Des Moines County, at Burlington, lowa. Jno. Nau, Sec., Middletown, lowa.

Oct. 19, 20.-Illinois Central, at Mt. Sterling, Ills. J. M. Hambangh, Sec., Spring, 1lls.

17 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.-ED.

Bees Quiet in the Cellar.-T. F. Kinsel, Shiloh, & O., writes :

My bees are in the cellar. The temperature is never higher than 44° Fahr., and never as low as 32°. They are very quiet yet; with my ear against the hives I can always hear them—day or night. Are they hiber-nating? Do bees snore in their sleep?

[We give it up. Ask us something easier, next time.-ED.]

Pleasant Weather Again.-G. M. Doolittle, Borodino, ON. Y., on Feb. 9, 1886, says :

The cold weather has ended, and to-day the bees had a fine flight, with the mercury at 51° in the shade. All of my bees had a flight except one colony that died about Feb. 1, with the diarrhea, contracted about the middle of October. There is some-thing about this disease that none of us understand yet.

Varnish Barrels for Honey.-T. J. C., Cincinnati, O., asks the following question :

Would barrels that had copal varnish in them, be good to keep honey in, if they were cleaned out and then waxed ?

[By no means. The honey would be spoiled.-ED.]

Bee-Keeping in Texas.-C. Beal, Columbia, Texas, on Feb. 7, 1886, writes:

I have received a vast amount of useful knowledge in bee-culture from the perusal of the AMERICAN BEE JOURNAL. Cook's Manual is worth its weight in gold to any man, though he has but a few colonies of bees. Honey is so plentiful here that we let the bees live on their natural stores. The 10-frame Langstroth hive is good enough for me. Myself and Mr. Jesse Parks formed a partnership in the bee-business last spring, he furnishing the bees and the hives in flat, and I doing all the work. The honey was

equally divided. I extracted about 275 gallons. I commenced last spring with 70 colonies, increased them to 130, lost 7 by the combs melting down and by the moth. All my old colonies were in box-hives, and my young colonies are in Langstroth and Gallup hives. My apiary is on the banks of the Brazos river. We had 5 overflows during spring and summer, which was a big drawback to bees gathering honey. My bees, for the last 10 days, have been carrying in pollen. They have been carrying in pollen. They are all blacks, and become very cross sometimes, but with a Bingham smoker I can soon quiet them. Last October I introduced 4 Italian queens successfully, and now the young Ital-ians are working nicely.

Feeding Bees for Winter, etc.-J. H. Andre, Lockwood, Q N. Y., on Feb. 10, 1886, writes :

On page 59 I spoke of putting 3 colonies into winter quarters which had been fed late in the fall, and cold weather shut the young bees in without their having a flight. It is conceded that such colonies will not stand the winter well on account of stand the winter well on account or pollen eating, but it is nearly 3 months since they have had a flight, and I carried them out for a flight to-day, and so far as I could see they were all right, and spot the snow but very little. One of them was fed for a week or more, probably 8 or 10 pounds of syrup. I do not see how Mr. Dadant could have told any more plain facts in the same amount of space than he did on page 75. It is my opinion that good honey is the most natural food for bees, and I cannot see where the profit comes in by extracting all the honey and then feeding all winter. noticed on a neighbor's farm a willow tree that did not blossom until after fruit-blossoms were gone. It is the only one I ever saw in this vicinity. The bees were working upon the blossoms in a perfect swarm. It would be a valuable acquisition to our bee-pasturage here, as it blossoms between fruits and white clover. would like to hear its name through the BEE JOURNAL, and whether it is planted in any place purposely for its honey-producing qualities.

Good Prospect for Clover.-John Nebel & Son, High Hill, or Mo., on Feb. 10, 1886, write :

Our bees seem to have stood the winter pretty well so far. They had a good cleansing flight on Feb. 7 and 8, the mercury being as high as 50° above zero, and the 6 inches of snow which has been on the ground since Jan. 8, has all melted. The snow has proven a blessing in protecting the proven a blessing in protecting the clover this winter, as it is alive and looks as if there would be a good crop this season. We never have much of a clover crop when the earth is bare and the weather extremely cold, as it has been the past month, the mercury being as low as  $20^{\circ}$  below zero, and for five days  $11^{\circ}$  and  $12^{\circ}$  below. We notice that the bees have wintered better during the past cold spell than the quilt carefully and look among ever before. As they had no flight the bees on top of the frames. If you

for 6 weeks we thought some of them would be in poor condition, but we find that very few dead bees have been carried out, and they have not spotted the snow as much as they usually do when being confined so long. They are wintering on the summer stands packed in chaff. Those in celtars are resting quietly. Al-though it is not over yet, we teel safe now in getting our bees through the winter.

Strengthening Weak Colonies.-H. R. Boardman, East Townsend, & O., on Feb. 18, 1886, writes :

I protest against the plan men-tioned hy W. Z. Hutchinson, in his reply to Query, No. 201. It certainly will result in disaster to change places with 2 colonies of bees in early spring when honey is not coming in. I have had queens killed and large numbers of bees destroyed by making such changes when I considered it very fair honey weather. My advice to beginners would be, to be a little cautious about changing places with colonies except in the heighth of the honey gathering.

An Original Invention.-Wm. A. Stolley, Grand Island, ONebr., wishes to give this testimony:

I have read Mr. Demaree's article on page 102, and I feel it my duty to testify that I was employed by Mr. Heddon during the year 1884, and I am personally acquainted with the development of his latest invention, for many of his experiments were placed in my charge. I know that the idea of a brood-camber in two parts originated with him, and I remember just when, where and how. I further know that the idea of thumb-screws for clamping frames was original with him, though we found it had been previously used in bee-hives, but not as (nor for the purpose) he uses it. Simple justice compels me to say that I never saw any one more careful and conscientious about copying the work of another. I think he would as soon steal wood, as the results of another's mental labor. His students know, and will testify to the truth of these statements.

Finding Queens.-Warren Pierce, Garrettsville, & O., writes :

Although the answers given to Query, No. 195, are sufficient for the expert, and will work especially well with Italian bees, yet for a crowded colony of blacks or cross hybrids, and an inexperienced band, I think I can suggest a better plan, as follows: A short time before you wish to remove the queen, examine the hive and see that the honey-board, quilt or enameled-cloth which covers the brood-chamber, is not propolized down, but can be removed without delay. Then after they have become wict give them a fow good wiffs of quiet, give them a few good puffs of smoke, and in a few seconds remove the quilt carefully and look among

A "Sweet Hum."-John Rey, East Saginaw, O Mich., Feb. 18, 1886, says :

My bees had a fine time last week; they were flying for 4 days, and cleaning house in general, and preparing for another cold spell. I think that the bees that are wintered on the summer stands, in this section, will fare better than they did last winter. They are in good condition so far.

Very Much the Best.-D. Videto, of North East, ~ Pa., writes thus :

I have always read with great interest all the writings of Mr. G. M. Doolittle, because he gave us instruc-tions which I thought were new and valuable, until I read what he said on page 83, viz.: "I do not know but there could be a better Bee Journal gotten up than the one you publish, but so far there never has been." Now I think that Mr. Doolittle was positively conscious that everybody that reads bee-papers at all knows this to be a fact; only he should have stated that it is VERY MUCH the best.

Bees Doing Well.-14-J. V. Caldwell, (125-165), Cambridge, ~ Ills., on Feb. 9, 1886, says:

In the fall of 1884 I had 156 colonies of bees; in the spring of 1885, 125 colonies, those lost having dwindled. I increased the 125 colonies to 165, during the season, and obtained 2,800 pounds of comb honey, or about 221/2 pounds per colony, spring count. The pounds per colony, spring count. The average price per pound that I re-ceived for my honey was 13 cents. Our honey season was cut short by dry weather in July, and we had no fall crop. My bees are all in a bee-cave and cellar, and are doing well, so far as I can judge, as they are packed in closely.

Bee-Keepers are Jubilant.-Smith & Smith, Kenton,+0 O., on Feb. 15, 1886. write :

Bees have had a fine flight the past week, and are in good condition. On the morning of Feb. 8 the sun rose brightly, with a south breeze soft and balmy; by 12 m. the mercury went up balmy; by 12 m. the mercury went up to  $50^{\circ}$  in the shade, and the bees had a good flight. On Feb. 9, 10 and 11 the weather was clear and warm, and the bees have cleaned out there hives, etc. Very few dead bees were brought out. The bees look clean, bright and bealthy. We have talked with quite a number of bee-keepers, and they all report well. We have not heard of a single colony being lost so far. Bee-men all feel jubilant. We have almost all our bees in a cellar, and they are very quiet, and seem to be in splendid condition.

Bees had a Splendid Flight.-T. F. Bingham, Abronia, 9 Mich., on Feb. 15, 1886, writes :

My bees on the summer stands had a splendid flight last week, and have wintered finely so far. They cared very little about flying, though they had no flight for 3 months. In the cellar as well as out-doors, there were bardly any dead bees, and it was as still as a summer eve, though 3 months in the cellar on 5-inch frames. It would please any one to see them cluster below the combs in the open space allowed them for the purpose.

Gathering Pollen.-7-Z. A. Clark, (85-157), Arkadelphia, & Ark., Feb. 16, 1886, writes as follows:

My bees brought in the first pollen on Feb. 13 and 14—about the same time for the past two years. I have lost about 5 per cent. of my bees up to this time, but from now until honey comes in it will require careful attention. Alder is now in bloom; elm and maple are nearly open, and if we have pleasant weather we do not anticipate much trouble. My bees are now beginning to build up. I take out the outside combs that are empty, and replace them with frames having foundation starters in the centre of the brood-nest a little later, and have nice frames of worker combs built. While the colonies are weak they will build worker comb.

Bees Wintering Nicely, etc.-J. H. Tait, Endicott, Nebr. on Feb. 11.1886. writes :

My bees are thus far wintering nicely, with the exception of 3 colonies that have been very restless for a week or more. I use the Langs-troth hive with the portico, and on putting them into the cellar I con-fined them by wire-screens over the entire fronts of the hives. The 3 coloring referred to filled the fronts and colonies referred to filled the fronts and kept beating against the wire until a large number of the bees had perished. I removed the wire, second-story and sheet, scraped out the dead bees and left them for a half hour, and upon returning I found them quiet and apparently happy and contented; there no indication of disease among them. The remaining 20 colonies are perfectly quiet. The average tem-perature of my cellar is from  $40^{\circ}$  to  $45^{\circ}$ . All my bees have natural stores. Will any of the prominent apiarists please state the cause of the disturbance with these 3 colonies ?

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one ean afford to do without it. We will present a Binder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few honrs, to get subscribers.

The Southern Wis. Bee-Kcepers' Association will hold its 3rd, annual meeting at the court-house in Janesville, Wis., on March 9, 1886, at 10 a.m. All interested are invited. Jonn C. LYNCH, Sec.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Feb. 22, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.-Sales have been quite good this month for best grades of comb honey, some bringing 16c. per pound when in perfect order. There is a light supply here, and now is a fayorable time to for-ward shipments. Extracted honey brings 6@8c. BEESWAX.-25@3ce, per lb. R. A. BUANETT, 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY.-We note an improvement of sales of honey the past week, but prices continue to rule low. We quote as follows: Fancy white comb in 1-lb. pare cartons, 13@14c; the same in 1-b, glassed or unglassed sections, 12@413c; the same in 2-b, Rissed sections, 14@413c, the same in 2-b, sections, glassed sections, 10@.the same in 2-b, sections, glassed, Sectors, 10@.the same in 2-b, sections, glassed, Sectors, 10@.the same in 2-b, sections, glassed, Sectors, 10@.the same in 2-b, sectors, glassed, Sectors, 10@.the same in 2-b, sectors, glassed, Sectors, 10@.the same in 2-b, sectors, glassed, Sectors, 10@.the same in 2-b, BEEESWAX.-27@28c. MCCAUL& HILDRETH BROS., 34 Indson St.

#### ST. LOUIS.

HONEY.—The market is quiet and the demand light just now. We quote prices as follows:— Choice comb honey, 10@12c. Extracted, in bar-rels, 44@5c. Extra fancy of bright color and in No. 1 p. ckages, 14 advance on above prices, BEESWAX.—Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

CINCINNAT. HONEY.--The demand is extremely slow for ex-tracted honey. Manufacturers seem to have taken a rest. There is only a fair demand for boney in glass jars, and for comb honey. Prices are un-changed and nominal, with occasional arrivals and a large stock on the market. We quote extracted boney at 4@Rc. and choice comb honey at 12@14c. in a jobling way. BEESWAX.-There is a good home demand for it. We pay 25c. per b, for choice yellow. C. F. MUTH & SON, Freeman & Central Ave.

### CLEVELAND.

CLEWPLAND. HONEY.—The market is not quite as active as it has been, owing, no doubt, to many attractions of the Holiday Season. Best white, 1-1b. sections sell at 15c, and 2-1bs. for 130-14c, but there is not so much sale for the lutter. Second grade honey is dull at 120-13c, 01d white, 100-12c. Extracted, 700-9c. per lb. BEESWAX.—Very scarce at 22025c. A. C. KENDEL, 115 Ontario Street.

#### KANSAS CITY.

KANSAS CITY, HONEY.-The market continues about unchang-ed, except that stocks are somewhat reduced, and possibly a little druer feeling on extracted honey. The demand, however, is not beavy for this time of the year, and we cannot expect any better pri-ces, as no one seems inclined to hold, and conces-sions are made in the buyer's favor. Choice 1-b, sections of comb honey, 15@16e; 2-bs. 12@14e. Extracted, 5@7c. according to quality. BEESWAX.-It is in very light supply, and it would bring 22@25c. for good average grades. CLEMONS, CLOON & Co., cor. 4th & Walnut.

### BOSTON.

HONEY.—The sale for honey for the past month has been as light as we have ever known it, and prices are weak. Ooe-pound, white clover, 13@13c; 2-pound sections, 11@13c. Extracted, 6@8c. BEESWAX.—30 cits, per b. BLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

HONEY.—The market is very dull. We quote as follows: White and extra white comb, 115,013c.; dark comb, 64,08c. White extracted, 54,053/c.; amber, 404%c.; dark and candied, 3%,04c. BEESWAX.—Quotable at 23,025c., wholesale. O. B. SMITH & Co., 423 Froot Street.

### DETROIT.

HONEY.—The market is well supplied with comh honey and prices have declined. Best white in 1-h. sections, 14c.; honey in larger sections can be bought for less, BEESWAX.—23225c.

-23@25c. M. H. HUNT., Bell Branch, Mich.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of nseful information ever put together in such a cheap form. The printing, paper, and binding arc excellent, and the book is well worth a dollar. To any or excellent, because head for any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

Issued every Wednesday by THOMAS G. NEWMAN & SON. PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

> ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

To Correspondents. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, he sure to give the address we have on our list.

Golden Rules for successful advertising, are these : 1. Attractive display, 2. Salient points clearly stated. 3. Repetition. Don't spend all your money in one insertion. 4. Choice of the Paper which reaches the people you want to reach. These rules never fail.

Wire Nails have advanced in price, as will be seen by quotations on page 127, last eelumn.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, ou a Postal Card for it.

Beeswax Wanted .- We are now paying 24 cents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be put on every package to prevent mistakes.

Perforated-Zine.-We have laid in a stock of perforated zine, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive-19%x14½-Price 25 eents each.

Extracted Honey. - Any one having white extracted honey for sale, are invited to correspond with us. We are paying 7 cents per lh. for it, delivered here.

When renewing subscriptions please send an extra name or two with your own and secure a premium. We have some colored Posters, which we will send FREE, to put up in conspicuous places. We will with pleasure send sample copies to any one who will try to get up a elub.

# Advertisements.

### The NEW Heddon Hive.

inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

The engraving gives a good idea of the hive. The brood-chamber is in two sectious; also the surplus arrangement, which may be interchaoged or inverted at will. The cover, bottom-board, and top and hottom of each sectional case has one-half of a regular be-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

ALL be bored for wires. A SAMPLE HIVE includes the bottom-board and stand; a slatted honey-board, and cover; two 6-inch brood-chambers, each containing 8 frames; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separa-tors, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

\$1.00, complete. 111 VES READY TO NAIL.—10 filling orders for these hives, in the flat, we make 6 different com-bipations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kieds will be known by the following numbers :

knows will be known by the following numbers:
No. 1 consists of the stand, bottom-board, cover, two 6-loch brood-chambers, 16 frames, and the statted honey board. Price, \$1.55 each.
No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators-ioterchangeable, but not reversible.
Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus sto-ries as therein described. Price, \$2.50 each.

ries as therein described. Price, **32.50** each. **No. 4** is the same as No.1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-combers. Price, **\$2,30** each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample called hive. Price, \$2.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deduc-tions from the above prices: Stand, 14 cents; honey-board, S cents; and the 25 or 56 sections, as the case may he, at \$\$ cent each, respectively,

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives, 5 per cent. discount; for 25 or more hives, 7 1-2 per cent.; for 50 or more, 10 per cent.

It is absolutely essential to order one natied hive as a pattern for putting those in the flat together correctly.

### THOS. G. NEWMAN & SON,

923 & 925 West Madison St., CHICAGO, ILL.

In order to more fully supply the wants of his cus-tomers, has entered into partnership with his neigh-bor, R. L. Taylor, and will offer for sale, hees (tull colonies, or by the pound), queeus, Given founda-tioo, white poplar sections, hives, cases, feediers, empty combs, etc., etc. Also hens' eggs, for liatch-ing, of three varieties. For circular and price-list, address W. Z. HUTCH INSON. SEtt ROGERSVILLE, Genesee Co., MICH.

40 **COLONIES OF ITALIAN BEES for** and utensils. I intend to move away in the spring. Terms given upon application. L. **ADANS**. 8E3t MAYFAIR, Cook Co., ILLS.

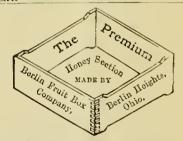

### SEND FOR IT.

We have just issued a new Circular that will interest any heckeeper. Send your name on a postal eard for it. Cash paid for Beeswax.

### FOR SALE or RENT

45 COLONIES of Bees, with ample faelilities Increase and Surplus. Preparations mostly for extracted honey, though either or both may be worked for to advantage. Safe and convenient wintering repository, good pasture and location,— 7 miles north of Omaha. N. FEARSON, 8A11 (Concord Apiary), FLORENCE, NEBR.

We Regret to learn that Mr. E. C. Jordan, one of the principal bee-keepers of Virginia, is unwell—having been dangerously ill in Washington. Hc is convalescing new.

Our Correspondents have rushed in so many communications that we are unable to give one-tenth of them space at present. We have more on hand new than we can use in three months. Please exercise a little patience, and not conclude hastily that communications are refused or gone to the waste-basket.

As a Legitimate Result of the persistent assertions by ministers and others, who know nothing about it, that comb honey is being manufactured by machinery, etc., a turbulent fellow gathered a crowd around him near our office, asserting very vehemently that he knew it to be true that comb was made and filled and eapped by machinery, etc.-that he had a relative in California whe was engaged in the business, and had made and sold lots of it in New York. We produced a letter from the bee-keeper in question, and an article over his signature, on making comb foundation, and his advertisement of it for sale. This he pooh-poohed -said it was only a "blind," etc. He would rather believe the statements of the religious and secular press, than all the evidence to the contrary in the world. Truly, "Where ignerance is bliss, 'tis folly to be wise."

The Christian at Home, a valuable paper published at Asbury, N. Y., reviews our book cntitled "Bees and Honey" thus :

It is an exceedingly valuable book for any person who desires to study the babits of bees or the improved methods of manipulating them and their productions. Nor does the value of the information which the hook contains exceed the interest of it. There is nothing in natural history more interesting or mere astonishing than a thorough knowledge of the mancers and customs of the little creatures who furnish us so much of the sweetness. A vast amount of information has been gathered and stored away in the 191 pages of this book, while the many illustrations help to give clear conceptions of the auther's descriptions.

The Hev. Robert West, editor of the Advance in this eity, two months ago announced editorially that so-called comb was being "manufactured and filled and eapped by machinery;" that a "grocer in this eity, who had recently purchased from Ohio 1,000 pounds of what he honestly supposed real honey," was convinced by him in five minutes that it was "made of syrups deftly secured in the comb;" that he was "familiar" with the place where bogus comb honey was manufactured in this eity, etc.

We publiely pressed him for the proof, as our readers are aware, and labored with him by private letters. Mr. A. I. Root also wrote him that he would "willingly spend \$1,000 in hunting up the establishment where such an article is made, if it be made anywhere " —adding that "no such thing as manufactured comb hency has ever yet appeared" in "any market in the world." Mrs. L. Harrison also gave Mr. West a severe criticism in the *Prairie Farmer*.

Last week we noted the fact that we had received a letter from him, saying, "I sincerely regret if I have misrepresented an honest industry," and promising a retraction in the next issue of the Advance. It has come to hand, and this is what he says:

"Wc are very glad to be corrected in statements made in these columns to the effect that honey-comb had been manufactured by machinery. We were misled by what seemed to be good authority."

This acknowledgement is all right so far, and sets the matter at rest, but how few of the papers which have copied it, will notice the retraction? The mischief is done, and it will take more than a life-time to counteract the damage incurred by such unqualified and positively false statements as were made by Mr. West. He should have further stated that he did not know what be was speaking of—was not "familiar" with the place where it was manufactured in this eity or elsewhere, and that the whole statement was unwarranted—unjust to the beekeeping interests, and wholly untrue !

We are thus particular to note the points, not to stir up ill-feelings, but to warn ethers from making statements that they eannet prove, which may damage an industry and ruin a large trade.

A Surprise Party consisting of three sleigh-loads (says the Valparaiso Vidette), a few days ago, visited the residence of Mr. T. S. Bull, near that city. They were shown the apiary, workshop, tools and implements used in modern bee-culture, and expressed much wonder over the habits and instincts of the bees, and were interested in Mr. Bull's explanations, etc. After enjoying a splendid supper, they returned to their homes having had a nice time.

The Anti-Adulteration Journal is the name of a new monthly published at Philadelphia, Pa., at \$1.00 a year, by the "Society for the prevention of adulteration of food, drngs, medicines," etc., at 142 Sixth Street. The adulteration of food of all kinds (including honey) is so general that all honest persons will wish that Society suceess. A stringent law against adulteration of food is demanded, and we hope such will be enacted by Congress, and be rigidly enforced.

We have a Host of Queries waiting their turn to appear in the BEE JOURNAL. This fact will explain to some why we cannot comply with their request to have their queries answered "next week." Even if there were but few ahead, it takes about a month to get the querics put in type, sent to those who answer them, and have them returned and appear in proper order. We will cheerfully accommedate all, hut must have sufficient time to "do the fair thing ' by all those who seek instruction in this valuable department. In order to try to "entch up" we have divided our Query Corps into two companies, and sent a different lot of Queries to each, just as a trial, and to gain space and time,

As Manager of the National Bee-Keepers' Union, we had engaged a lawyer to bring suit against Rev. R. West, and so informed him—thinking we had given him all the time necessary for a retraction. This is the second time that the Union has served the interests of bee-keepers in defending their rights.

Next month eemes the trial of the raisin growers of California against Mr. Behn, and the Union has taken a hand in the preparation of the appealed case, by contributing over \$100 to hiro au able attorney, affidavits, etc., etc. The National Bee-Keepers' Union is a "power in the land," and is working energetically for the defense of the rights of our chosen pursuit. If the reader of this has not yet joined the Union, he should do se at once.

Hay and Straw, pressed in a strong hay press, are to be used for making hives. We have a medel in our Museum from Orr, Rotramel & Ce., of Carlisle, Ind. Such walls are non-conductors of heat and celd, and de not gather dampness. They are trimmed by a knife and plastered eutside with cement. Hay is alse used for building dwellings, conservatories, etc., and it is said that the tenderest plants bloom within such walls during the severest Northern winters.

New Price-Lists bave been received from the fellowing persons :

J. P. Meore, Morgan, Ky.-4 pages-Italian Queens and Bees.

North Carolina Tar-Heel Apiaries-1 page -Bees, Queens, Cemb Foundation, etc.

Reynolds Bros., Willinmsburg, Ind.-16 pages-Bee-Keepers' Supplies, Bees, Queens, etc.

Sumner & Prime, Bristol, Vt.-20 pages-Bee-Keepers' Supplies.

E. M. Yeomans, Andover, Conn.-3 pages-Italian Queens, Bees and Nuclei.

Will J. Stratton & Bro., Atwater, 0.-16 pages-Vegetable Seeds.

Ellwanger & Barry, Rochester, N. Y.-142 pages-Ornamental Trees, Shruhs, Plants, etc. Lewis Roesch, Fredonia, N. Y.-22 pages-Grape-Vines, Plants, etc.

John S. Collins, Moorestewn, N. J.-30 pages-Snall Fruit Plants.

Any ene desiring a copy of either of them, ean obtain it by sending a postal card to the address as given above.

One of the Prettiest Marches published this season is the G. A. R. Grand March, by Wiegand, price 40 eents, Ign. Fischer, publisher, Toledo, O.

**REPLIES by Prominent Apiarists.** 

## Wild Plum-Trees and Melilot Clover.

Query, No. 207.-1. Do wild plum-trees yield honey when in bloom ?

2. Will sweet or melilot clover do well among trees where it will be shaded to a considerable extent?-C. M.

1. I think so.-G. M. DOOLITTLE.

1. Yes.-W. Z. HUTCHINSON.

1. Yes, they do here; I think they do in most localities.—JAMES HED-DON.

1. Yes. 2. Yes, but it will do better on waste ground, and will produce more honey.—DADANT & SON.

1. I have seen bees work on them, and I think they get honey from them. 2. Yes.—C. C. MILLER.

1. Yes. 2. Not so well as when unshaded.—A. J. Cook.

Wild plums yield honey nicely here. Melilot clover succeeds poorly here in the most favored spots. Low, moist places give the best results.—G. W. DEMAREE.

Large or Small Hives---Which ?

Query, No. 208.—I am so situated that I can keep but a limited number of colonies, and those will he in 2-story chaff-hives. The top story will hold 10 wide-frames. Would it he hest to make the brood-chambers wide enough to hold 13 Langstroth brood-frames, and use a division-board when needed? or make it only wide enough for 8 frames?— Cashier, Nebr.

In this location I should make them the capacity of hut 8 frames.—JAMES HEDDON.

I should prefer the 13-frame hive and use division-boards or dummies for contraction.—G. M. DOOLITTLE.

I should prefer chaff hives to hold 13 brood-frames, and contract with division-boards for winter. — G. L. TINKER.

Under the circumstances I would use a division-board.—W. Z. HUTCHIN-SON.

In my locality 10 Langstroth frames, or their equivalent in space, is about right. If you use division-boards you can govern the size best suited to the needs of your bees, even though you choose to make room for 13 frames.—G. W. DEMAREE.

Make the brood-chambers for 12 or 13 frames, by all means. If you make them large enough, you will not have a chance to regret their small size. A large hive can always be adjusted to the size of the colony; a small hive cannot. The difference in cost is insignificant, considering the advantages.—DADANT & SON. It depends upon so many things that it is hard to give a categorical answer. If size and weight are no objection, perhaps you had better have the wider hive.—C. C. MILLER.

Why make chaff hives ? I prefer single-walled hives and cellar wintering. Chaff hives are awkward, heavy and expensive. I should make the brood-chamher for 8 frames.—A. J. Cook.

No, sir; a 10-frame, full size Langstroth is just the right size, in my opinion, for a brood-chamber. It will hold frames enough for the best season, and give room for winter packing. I am aware that a *few* differ from me, but a trial will convince any unprejudiced person that I am correct.—J. E. POND, JR.

### Surplus Arrangemeuts.

Query, No. 209.-What kind of erates, wide frames or other arrangements are the best for producing surplus house?-W. T.

The kind with which you succed the best.—H. D. CUTTING.

I like the Heddon crate or case very much. This, however, does not permit the use of separators.—A. J. COOK.

Wide frames holding sections, I think, is the best arrangement for surplus comb honey yet invented.—H. R. BOARDMAN.

Wide frames containing but a single tier of sections.—G. M. DOOLITTLE.

If separators are not needed, I prefer the Heddon case; if they are, then the wide frames one tier of sections high.—W. Z. HUTCHINSON.

In my opinion plain cases just beespace deeper than the section used, and of the same size of the brood department of the hive, made so that they will tier one on the other, are the simplest, cheapest and hest things out. The fewer "gim-cracks" about the surplus case the better it is.—G. W. DEMAREE.

The kind I use, of course. At present I use one of which I do not know the name, a little like the old Heddon, but with **T** tin rests. What I will use in five years from now, goodness knows !—C. C. MILLER.

I prefer to have the sections massed together in a case without separators. Then if the sections have side-passages the supers will be to the bees as if there were no partitions and the combs all one. The secret in getting nice combs in sections without separators, is having a narrow case to hold only 4 or 5 sections wide. I am not surprised that some bee-keepers who have used a case one foot wide without separators, should at last decide in favor of separators. I also have failed to get nice, straight combs in wide cases. Wide frames are always stuck up so much with propolis that I have discarded them.—G. L. TINKER.

Explanatory.—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark  $\bigcirc$  indicates that the apiarist is located near the centre of the State named:  $\eth$  north of the centre;  $\blacklozenge$  south;  $\circlearrowright$  east;  $\circlearrowright$  west; and this  $\circlearrowright$  northeast;  $\circlearrowright$  northwest;  $\circlearrowright$  southeast; and  $\blacklozenge$  southwest of the centre of the State mentioned.

# Apicultural Discussions, etc.

### DR. C. C. MILLER, (179-340).

As I think over the bitter personalities that were so common years ago in the columns that bee-keepers like so well to read, there is a great feeling of satisfaction that that trouble is all in the past, although I know it took some editorial back-bone to make it willing to stay in the past. I so much enjoy the peace and quiet of later years that I deprecate anything that squints, in the least, in the direction of a return to the past. Possibly I am unnecessarily alarmed, but it seems to me just a speck of a cloud begins to threaten, as I read what points to a controversy over the Heddon hive. Not that I think controversy should be repressed—perhaps we cannot have too much of it so long as it is conducted in the right spirit. The Dadant-Hutchinson battles over the size of hives were of that character that both combatants won renown. Although perhaps the question in dispute may not be fully settled, good points have been brought out, and it made pleasant reading all through, because neither contestant appeared to lose his temper and indulge in personal flings.

appeared biose has tended and the dulge in personal flings. But with reference to the Heddon hive, W. F.Clarke starts with a "come on," as who should say, "You just dare to say a word against the Heddon hive!" and even W. Z. Hutchinson loses his usual equilibrium and puts a chip on his shoulder, talking about the great blow of opposition before any blow began; then another begins to talk on the other side, using something else than square argument —hrethren, please don't! Do you not see how easy it will be for this thing to run into just the kind of discussion that we do not want? Bro. Newman, if we get back to one of the old sort of personal quarrels, please leave it all out of the copy of the BEE JOUR-NAL that you send to me, and print instead quotations from the old poets."

When any man puts before the public a new thing, especially if it be patented, that public has the right to discuss it. It is entirely proper for A to say that no other hive but the Heddon should be used, giving reasons for such belief; and it is just as

proper for B to say the hive is worthless, giving reasons for such belief. For my part I shall be glad to see plainly shown every advantage that the hive may possess, and every objection that may be brought against it. Aside from any interest in the hive itself, this may incidentally bring out points of interest to those who have never seen, and who never care to see the hive.

There are some principles of the bive that I should like exceedingly to The ability to have a contracted use. brood-chamber, and at the same time have brood under each and every part of the surplus chamber, is something I have dreamed over not a little. This accomplishes it to perfection. On the other hand, without having tried it, it hardly seems that I could reconcile myself to fastening and unfastening with thumb-screws. Like many with thumb-screws. Like many another thing, however, familiarity with it might take away all objection, but at present it seems "fussy." Will not the space between theorem. not the space between the upper and lower half of the brood-chamber be filled with comb and honey? Perhaps, however, I ought to stand this, as Mr. Heddon has helped me to get rid of this difficulty under the sections, where it is still more objectionable. The greatest objection, perhaps I ought rather to say the most serious question I have, is as to wintering. Is that open space between the two sets of shallow frames a thing the bees will like in winter? One tier of the shallow frames will give capacity enough for wintering, and if they will winter well on such shallow frames, this will be a very nice arrangement. Indeed, I should like it very much, for it would make nice, light handling, and occupy much less space in the cellar. We shall probably have some reports on this point in the spring, from those who are making the trial.

To those who adopt his bive, Heddon's book is indispensable, and in-teresting to all. The valuable, prac-tical hints which it contains make it a real accession to the somewhat limited number of books on apiarian subjects.

Speaking of books, I notice that Frank Cheshire's book is advertised in parts, at \$3. As that is a pretty and price to pay for a book unless we know something about it, can we not have some information on the subject? In what shape is it? In two or three volumes, bound in cloth, or does it come in monthly numbers, and are all the parts on hand now, or part unpublished? Please let us know something about it.†

#### BEES SWARMING OUT IN SPRING.

I want to say a word anent Prof. Cook's reply to Query, No. 200. 1 had, perhaps for the first time, last spring, considerable experience with bees swarming out, leaving plenty of honey and brood in the hive. I do not be-lieve. Professor, that it could have been from anything "obnoxious about the hive." In nearly every case, if not every case, the colonies had been previously put into fresh, clean hives. The only thing that I could discover

unusual was the very large quantity of brood in proportion to the number of bees. Whether this may be the true reason I cannot say. Several of the replies seem to favor it. It could hardly be, as Messrs. Dadant & Son suggested—"lack of pollen or of water," in the case of my bees. If the lack of bees enough to cover the brood should be the cause of the difficulty, Dr. Tinker's suggestion to carry the bees into a warm place for a time, might work. A more radical plan would be to take away one or more frames of brood containing the least amount of sealed brood, and giving them to a strong colony. Even if the brood taken away should be destroy-ed, it would be better than the destruction of the colony.

Marengo, 5 Ills.

\*Bro, Miller is right; but there will be no war among the correspondents of the American'BEE JOURNAL. Some writers use very vigorous language, but they are harmless as doves. Should the discussion show indications of anger, we shall promptly shut down on the whole subject until all parties are willing to discuss it in a friendly way-as brothers. Criticisms made in any other spirit will be useless. There will be no war, Brother Miller; rest assured of this.

†Mr. Cheshire's book is now being published in parts. When complete, it will be offered in a bound volume. About 6 parts are now issued. There will be 19 in all.-ED.]

### The New York State Convention.

The New York State Bee-Keepers' Association commenced its annual meeting in the Court House, at Roch-ester, N. Y., on Feb. 16, and in the absence of President Root, the chair was taken by Vice-President C. G. Dickinson, of Oxford, N. Y.

The minutes of the last meeting were read and confirmed.

The Treasurer reported \$15 paid to Mr. Potter, and the balance of \$8.93 paid to the janitor.

### EVENING SESSION.

Pres. Root called the meeting to order at 7:15, regretting that he was not present at the opening session, and expressing the hope that the same spirit might prevail as at Detroit. The meeting then proceeded to dis-

cuss the prevention of after-swarms. F. L. Smith said it could be done by removing all cells after six days,

except one. R. B. Rians practiced the moving the old hive, cutting out the cells, and had but little trouble.

L. C. Root thought it a good plan to have a good laying queen to introduce immediately, so that the colony may not be queenless a day.

A. Strauss cuts out the cells on the first and second day, also on the 7th.

F. L. Smith-The queen introduced must be a young queen ; an old queen will get up a swarm in about two weeks.

Mr. Whiteneck—The great trouble about introducing a young queen is that the bees are liable to swarm out and leave the hive when she takes

her bridal tour. The question, "Does it pay to raise Alsike clover for honey," was then discussed -

Mr. Davis found it hard work to persuade his neighbors to sow it, but it was an excellent honey plant. The it was an excellent honey plant. red clover is failing, and Alsike is coming in to take its place.

Mr. Aspinwall said that Alsike would grow in rough places, and was excellent for honey

Mr. White said that it would pay to sow it for honey alone.

Mr. Rians said that for two years the bees had gathered largely from the basswood, but this year the flow was thin.

W. E. Clark thought the yield of Alsike varied considerably in differ-On valuable land it ent localities. would not pay to grow it for honey alone, but on clay land it yields bountifully. For the last two years he obtained more from Alsike than from basswood.

Mr. Knickerbocker said it makes the best of hay, and yields honey when it is so dry that white clover does not secrete any.

L. C. Root mentioned the case of a bee-keeper who got 100 pounds of honey per colony from Alsike clover.

Mr. Dickinson was prepared to affirm that bees do gather from red Mr. Vandervort said that the key

to the whole thing was in the fact that we do not all live at the same The altitude makes a great altitude. difference in the secretion of honey. He had noticed that the honey in red clover is secreted on the side of the tube at times, so that it does not need long-tongued bees to gather it. When the Italians first came to this country with the reputation of being red clover bees, he proved this; fifty colonies gathered 50 pounds per colony from red clover, and the blacks none.

The sale of honey was next discussed. Mr. Davis had labored for 20 years to establish a market.

Mr. Vandervort was of the opinion that if we could produce honey a little cheaper, it would sell more readily.

Mr. Aspinwall urged the education of the masses in the consumption of honey

Mr. Davis said that for 20 years the the tendency of the price of honey had been downward, and he thought it had now touched bottom.

Mr. Vandervort said that in lessening the cost of honey production he had secured as much profit as when the price was better.

The question of the desirability of instructing our neighbor in the art of bee-keeping was then discussed. Mr. Ashley said: If in the supply business, yes; if not, no. Mr. Murdock—The supply business

is the tender spot.

Mr. Schofield-If our neighbor is rightly instructed, it will not help the supply dealers.

Mr. Dick-It is a different thing instructing your neighbor and instructing those who come to conventions.

W. E. Clark thought we should do to others as we would that others should do to us.

L. C. Root was of the opinion that we are not doing our neighbors a favor to instruct them in bee-keeping, while honey is at its present price.

### WEDNESDAY MORNING.

Pres. Root called the meeting to order at 9 a.m.

After the appointment of some com-After the appointment of some com-mittees, an address was delivered by P. H. Ellwood, of Starkville, N. Y., on "Apiculture as a pursuit." In connection therewith, a paper by Arthur Todd on the "Marketing of our products," was read. The two topics were discussed conjointly. The edultarization of house, was as usual adulteration of honey was, as to an pointed out as a great hindrance to the development of bee-keeping, and the development of bee-keeping. Cultivation of a home market, employment of middlemen, services of drummers, peddling honey, and va-rious other side issues were adverted to.

W. F. Clarke said it was of no use W. F. Clarke said it was of house to fight the laws of trade. One of them was that cheapness increased consumption. The history of penny postage, and of all cheap things proved this. The cheapest railroad on this continent was the most trav-eled, and he believed it was the only one that had a quadruple track. Much one that had a quadruple track. Much was said about keeping up the price of honey. We would be better em-ployed in bringing it down. Mer-chants who try to do a big business sell cheap, and sometimes run off goods below cost to win custom. Mr. Todd was right in taking the ground that the best way to increase the con-sumption of honey was to reduce the cost, so that it would be as cheap as cost, so that it would be a cheap as sugar. Then it would be a necessary of life, and would sell itself. We do not advertise honey enough. Some one has said he who does business without advertising is like a man who winks at a vietty give in the dark winks at a pretty girl in the dark. He may know what he is doing, but no one else does. People do not need to be educated to eat honey any more than to drink milk. Let them see the tempting thing, and the appetite will spring up for it soon enough. Show the public the value of honev as food and medicine, and it will be consumed largely without fear. Patent medion all vacant fences, make the rocks vocal, the result is people buy and use the articles thus conspicuously advertised. "Let your light" shine, and people will avail themselves of it, never fear.

### AFTERNOON SESSION.

The President's address and a paper by Rev. W. F. Clarke on the question, "Does bee-keeping pay?" (See page

length.

Mr. Davis, of Vermont, was asked the cost of producing a pound of honey, and replied that there was nothing in it at less than 18 or 20 cents a pound. He was in favor of producing a choice article, and keeping up the price.

The best surplus arrangement was next discussed, and the discussion glided into size of sections, with the usual preference for the one-pound section, as more easily marketable.

The election of officers resulted as follows: President, W. E. Clark, Oriskany; Vice-President, C. G. Dickinson, Oxford ; Secretary, George H. Knickerbocker, Pine Plains ; Treasurer, J. II. Scofield, Chenango Bridge.

Representatives were elected, on nomination, for every county in the

State. The committee on resolutions reported as follows :

That this Association would record That this Association would record its grateful appreciation of the action of the United States Department of Agriculture in establishing an api-cultural station at Aurora, Ills., in charge of Mr. N. W. McLain, from whose experiments much benefit is expected by the bee-keepers of the band land.

Resolved, That in token of said appreciation, this Association will henceforth adopt as its distinctive badge, the national colors-red, white and blue.

Resolved, That this Association has Resolved, That this Association has read with pleasure the public an-nouncement made by Thurber, Why-land & Co., that they will hereafter put up no more comb honey in glass jars, with glucose around it, which they have heretofore done to the detriment of the honey industry, and which here subjected them to scorer which has subjected them to severe criticism by this Association, and the bee-keepers at large.

A paper was read from J. M. Shuck, of Des Moines, Iowa, on "Reversing hives, frames and sections;" also one entitled "Midnight musings of a New York bee-keeper." The two were made the basis of a long discussion on the principle of reversing, in the course of which the Heddon hive received a large share of attention.

#### THURSDAY MORNING.

The amount of increase preferable in connection with the production of comb honey was the first order of the day. It was agreed that the answer to the question depended much on location.

An address by L. S. Newman, of Peoria, N. Y., followed, on the "Production of comb honey with and without separators in wide and narrow sections.'

On motion, it was decided to take a Association, by a rising vote, ex-pressed its preference for separators.

The committee on resolutions presented the following:

WHEREAS, The best interests of our calling require more thorough work in creating a market for our products; and

121) were discussed conjointly at some honey for medicinal, manufacturing,

and general table purposes may and should be greatly increased; and WHEREAS, We believe that these results can be best accomplished through the efforts of those who are thoroughly conversant with the best interests of bee-keeping in all of its branches, and who are also acquainted with and command the confidence of bee-keepers generally by their un-questioned honesty. Therefore, be it

Resolved, That we, the bee-keepers of the State of New York, in convention assembled at the city of Roches-ter, this 17th day of February, 1886, do appoint L. C. Root as a person fully qualified to work for our interest as above expressed, and that we hereby instruct him to take such action and make such investigations as in his judgment will result in our greatest good.

Resolved, That we invite each mem-ber of the Association, as well as beekeepers generally throughout the country, to aid him in his efforts, the results of which he shall present to this Association at its next annual meeting to be held in Albany on Jan. 18-20, 1887.

The resolutions were adopted, and a committee of three appointed by the President to co-operate with the commissioner.

On motion, it was agreed that the necessary expenses connected with the effort to improve the honey market be raised by an assessment per capita on the members of the Association.

#### QUESTIONS AND ANSWERS.

Is it advisable to rear drones in more than one hive ? Yes.

Would it be beneficial to distribute the pamphlet on "Honey as Food and Medicine" more widely? Yes.

Do bees polish off the cappings with , their " tother end ?" Yes.

Why does some honey granulate quicker than others? No answer. Which is the best hive for general

use? Your own. Which pays best, comb or extracted honey? No answer.

Is it advisable to use full sheets of comb or strips in the brood-chamber? Full sheets.

Is it a good plan to clip the queen's wing ? One member responded "yes."

Is it advisable to have a bee-space between each tier of sections? A general response in the affirmative

Is it desirable to have plenty of brood in hives when they are taken out of winter quarters? Yes.

In wintering on the summer stands is it desirable to pack under the bot-tom of the hive? Yes.

Is there any good reason for setting hives close to the ground ? No.

For a double-walled hive, is a quarter inch dead-air space enough ? No. Which man seems to know the most

about bee-keeping, the expert or the beginner? The beginner, every time.

Are not tin separators on the whole the best? Several novices, "no."

The committee to consult with Mr. L. C. Root and co-operate with him in WHEREAS, We feel certain that, improving the honey market was with proper effort, the demand for nominated by the President as follows: Messrs. Aspinwall, Benedict, and Ira Scotield.

The committee on exhibits reported a list of articles displayed for the use of hee keepers. Beport adopted

of bee-keepers. Report adopted. On motion, thanks were voted to the proprietors of the National Hotel, for reduced rates; to the Monroe county officials for the free use of the Court Room, and to the reporters of the city papers for their attendance and reports of the proceedings.

The Association then adjourned sine die.

For the American Bee Jonrnal.

Revolution in Bee-Keeping---Criticisms.

### WM. F. CLARKE.

Mr. Alves comes with a jaunty air, and with apparently hostile intent, but lo! it is on the same side! He has, however, some questions to propose. The first relates to the machinery used in the new reversible hive. First, is there not too much? This may be answered by another: How could there be less? Simplicity of action is the great thing in any machine. Most certainly we have simplicity here. There is not a complex feature about the hive.

2. The demand for mechanical nicety and accuracy is an excellence rather than a defect. For the minimum of friction, there must of necessity be precision.

3. Can a \$4 hive be afforded? Yes, a \$10 one if necessary. The interest on \$4 is hardly 25 cents a year.

4. No, the interchange of two shallow hanging-frame hives will not answer all the practical purposes of inversion. It will not shake the bees and queen from the hive, nor expose queen-cells, nor secure their easy removal without disturbing a frame. These are important practical purposes, and they are secured in a twinkling.

twinkling. It must be highly gratifying to Mr. Heddon that his hive and book have met with so prompt an endorsement by practical bee-keepers. Opposition to them comes only from a Kentuckian who has never had to face the more serious difficulties of bee-keeping, and whose personal antagouism to Mr. Heddon largely discounts in advance his criticisms on the new departure. He tells us that there is not a single new feature about the system that is of intrinsic value. Of course, then, he will not adopt that which is worthless. To do so would be to contradict the position he has taken. But is it not a valuable feature that we can now manipulate hives instead of frames, and so perform the work with half the time and labor formerly required? Is it not an idea of intrinsic value to have controllable brood-nests? The mechanical means by which this is done is of the very greatest intrinsic value

Mr. Demaree is making history. What is the history of every new invention? Is it not the linking of old ideas to valuable uses? Franklin caught the lightning on his kite-

string, but a Morse was needed to yoke it to the electric cable, and give it intrinsic value. The uses of steam have long been known. It has lifted the historic tea-kettle lid from time immemorial, but only became of intrinsic value when it was made to fill the boiler and drive the piston-rod. Steam as an agent has been known for ages, but the man who harnessed it to the locomotive made it of intrinsic value. Sectional hives are not new, but their use in practical bee-keeping has only now come to the front and assumed intrinsic value. Mr. Demaree threatens to burst the whole thing. He can only do it by infringing the patent. There is a moral barrier in the way of his doing this, and if there were not, the penalty for infringement blocks the way effectually.

We have all used the tiering-up method for taking surplus honey, but tiering down is a new and original idea for which we are indebted to Mr. Heddon. Mr. Demaree says there are few independent writers on apiculture. Of course he is one of the few. He will "hew to the line" regardless where the chips may fall. They are few and scattering as yet, but perhaps will fly thicker as the axe gains in power. That a new revolution is upon us, becomes daily more evident. No power can check it, and the sooner we fall into line, the less we shall have to unlearn.

Mr. Demaree is ahead of me in having read the patent. If e will have to read it again when re-issued, and made to cover the ground more fully. But, after studying the hive, and learning its many uses. I still consider it new and orignal, and predict for it wide and general adoption. This will not necessitate hasty change. Those who are using other hives, can readily adapt them to the new order of things, and avail themselves of such features as are of intrinsic value. That the new hive will gradually supersede all others, and bécome the "standard of excellence" is one of the inevitables to which Mr. Demaree will have to bow, with the best grace he can command. Opposition will but hasten the ultimate issue.

Mr. Demaree says that he is simply amazed at my article. He will be still more amazed when he finds himself adopting the hive, and joining me in commendation of it. I shall use no other in my future dabblings in bee-keeping. This is what I want, and all I want. It is "long-lookedfor, come at last." I have dreamed of a hive like this, and the reality surpasses the dream. It will henceforth be a luxury to keep bees. The hard, slavish work is all taken out of the business, and what remains is mostly pastime. The danger now is that bees and bee-keeping will become too common. Everybody will want to rush into a business so inviting. But little honey will "waste its sweetness on the desert air" in the "good time coming." With the winter problem solved, and this simple principle of handling hives instead of frames-brought into use, there is no good reason wby honey should not become as cheap as sugar. Then it

will rank among the necessaries of life, and be in universal demand. The market for it will be practically unlimited, and it will come into use in a thousand forms unknown before. It only now needs that the improvement of the bee itself shall keep pace with the improvement of the hive, and all the possibilities of bee-keeping will be realized.

Guelph, Ont.

For the American Bee Journal.

The Northeastern Michigan Convention.

The Northeastern Michigan Bee-Keepers' Association held its fourth annual meeting on Feb. 3, 1886, at East Saginaw, Mich. The following subjects were discussed :

#### USING COMB FOUNDATION.

Dr. Whiting — The two or three years that I used comb foundation without wires I spent much time cutting out the stretched portions of the comb and fitting worker comb in its place.

James Ure—I use foundation 6 feet to the pound, and have little trouble with its sagging. If it does sag it is always at the top where it will be filled with honey.

with honey. W. Z. Hutchinson—This stretched part would be at the bottom if the frames were reversed.

James Ure—I would no sooner invert a bee-hive than I would turn a house upside down. The most of my comb foundation is drawn in the spring. I do not hive swarms upon foundation.

### WINTERING BEES.

. Dr. Whiting—Previous to this winter my hives have been packed upon only three sides; I now think that a hive packed on only three sides is not much better than one that is not packed at all.

w.E. Harris—I have always packed my hives on all sides, still I have lost many bees in the spring. In the Saginaw valley we cannot have cellars, and I should like to know something about houses above ground.

Dr. Whiting—I have known of beekeepers who were very successful for several years in wintering their bees in houses above ground, but sooner or later there always came a winter when they lost their bees.

Dr. C. E. Rulison—I believe that the only sure way of wintering bees is to give them good stores and put them into a warm cellar.

J. E. Wellington—I have noticed that when bees are uneasy in the fall they seldom winter well. They should be prepared for winter early. I think they will winter upon clover honey.

Dr. Rulison—The clover honey is all right, but we want that to sell; sugar is cheaper and just as good for winter stores.

J. E. Wellington-I admit it. I was not advocating using clover honey for winter stores, in preference to sugar; I only wished to say that I thought clover honey as safe food for winter.

O. J. Hetherington-At Lansing, last winter, our President, R. L. Tay-lor, said that he had prepared nearly all of his 200 colonies for winter by selecting combs that were practically free from bee-bread, feeding the bees sugar, and wintered them in a cellar. should like to know how they wintered.

Pres. Taylor—I never had bees win-ter better. They seemed to be stronger in the spring. I do not mean stronger in numbers, but healthier, as though they had wintered perfectly. They seemed unusually bright, clean, strong and active and there was no dwind and active, and there was no dwind-

W. E. Harris—The feeding of sugar puts more honey upon the market, it causes the public to look with suspicion upon our honey, while sugar is not much cheaper than the darker grades of honey which are almost impossible to sell.

R. L. Taylor-It is true that fall honey sells slowly, and at a low price, but the question is, is it not better to take out this fall honey and sell it for what it will bring, and then feed sugar, than to leave it in and lose the bees?

W. E. Harris-Yes, if you are sure that the sugar will save them. I should fear that late feeding would start breeding. How long does it take

to feed a colony ? R. L. Taylor—The feeding is done so quickly, never requiring more than 3 or 4 days, that brood-rearing is not started at this season of the year.

W. F. Card-When should bees be taken from the cellar?

R. L. Taylor-Leave them in until there is something for them to do.

W. F. Card-1s it advisable to take them out for a flight, and then return them ?

W. Z. Hutchinson-I have tried this. Those that were in a healthy condition remained so; those that were diseased, it did not save.

#### DIFFERENT RACES OF BEES.

W. Z. Hutchinson-Were my apiary devoted exclusively to the production of comb honey, I think I should choose pure blacks.

Dr. Rulison-I ain surprised to see a man stand up in a convention and make such an avowal. I prefer Cyp-rians, Syrians or Italians. The Cyp-When I have plenty of time I can handle Cyprians without a veil or gloves; when in a hurry I want both. Dr. Whiting-In a poor season the

Italians will gather more honey than the blacks. Of course blacks make whiter, straighter combs, and are less inclined to fill the brood-nest with

honey. W.Z. Hutchinson—I agree to all this, and will add that when the great honey harvests come, from which we get our surplus, the blacks will store just as much.

Dr. Whiting-I think there is a great difference in different strains of the same variety of bees. I was much annoyed by some colonies that

and giving them others, I finally succeeded in nearly eradicating this trouble from my apiary. I think much can be done by selection.

#### TOP-STORING VS. SIDE-STORING.

Dr. Rulison-With me the bees work more readily in the side boxes, but they put in too much pollen, and I have abandoned it.

Dr. Whiting-Bees are inclined to put their pollen in the combs nearest the entrance. If the combs are used crosswise to the entrance, and the sections put in the back end of the hive, there will be no pollen placed in them.

### QUEEN-REARING.

W. E. Harris-I have found it quite an advantage to cut into strips the comb containing the eggs from which I wish to rear queens, and put these strips, with the cells, in a vertical position, between the upper edges of the combs, holding them in position by pressing the combstogether against the strips. The colony must of course have no other eggs or unsealed brood. By destroying some of the eggs, a la Alley, the cells can be secured in the places wanted. When the cells are inished they can be easily removed by simply moving the combs apart.

### HIVING SWARMS WITH WING-CLIPPED QUEENS.

R. L. Taylor-I clip my queens' wings, and do not see how I could get along without so doing. When several swarms issue at nearly the same time, I simply cage the queens. If the swarms cluster together it does not trouble me. I just take enough from the cluster to make a swarm, hive them and give them a queen, and continue to do this as long as the supply of bees and queens holds out.

The officers are as follows: Presi-dent, R. L. Taylor, Lapeer, Mich.; Vice President, W. E. Harris, South Bay City; Secretary, W. Z. Hutchin-son, Rogersville; Treasurer, Dr. L. C. Whiting. East Saginaw.

The convention adjourned to meet in Bay City, Mich., on the first Wednesday in February. 1887. W. Z. HUTCHINSON, Sec.

## For the American Bee Journal.

### Wintering Bees in the Cellar.

#### EUGENE SECOR.

January was a cold month; February, so far, has been quite mild. On some days bees could have flown. My 32 colonies, put into the cellar during the forepart of November, have not seen daylight since, and I hope that they will not until the middle of April. They appear to be wintering linely—showing but few dead bees and small consumption of honey. A thermometer, hanging in the room all the time, has shown extremes of  $37^{\circ}$  to  $48^{\circ}$ , the mercury generally standing at or near  $44^{\circ}$ . Part of the hives are raised one inch had a strange propensity to build from the bottom-boards, and the brace-combs in every conceivable honey-boards lie evenly on top. They place. By destroying their queens, appear to be dryer and sweeter than from the bottom-boards, and the

those resting down on the bottom-boards. The cellar is quite dry. A soft-coal furnace is in constant use in an adjoining room, which overcomes the natural dampness in the whole cellar.

I am satisfied that a great many who winter bees in cellars do not keep them warm enough. If the bees are uneasy, some people think it is because they are too warm, when the contrary is the fact. To illustrate : A neighbor has had a colony in the north side of his house for a number of years. They are next to his bed-room. He tells me that when the weather is severe he can hear the bees roar. He then leaves the sittingroom door open, and as soon as the room gets warm next to the bees, they quiet down immediately. My neighbors who have lost their bees in trying to winter them in cellars, have allowed the rooms to become too cold. If very damp, cold is fatal to bees, so I believe, and so I teach; and the fact that I have had the best success in wintering bees of any one in this part of the State, is evidence, to me, of the soundness of the doctrine.

Forest City. & Iowa, Feb. 22, 1886.

### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of hoth. All postage prepaid.

### Convention Notice.

The New Jersey and Eastern Bee-Keepers' Association will hold their minth semi-annual convention at Cooper Union (Room 22) in New York City, on Wednesday, March 10, 1886, at 9:30 a.m. All who are interested in bee-enluire or honey are re-spectfully invited to attend. We expect a large delegation from the Philadelphia Association to meet with us, and it promises to be one of the most interesting as well as instructive conventions that this Associa-tion has ever held. A special invitation is extended to hadies, well knowing that they are by no means a small factor in our in-dustry. Beginuers, it is well known, will learn more by attending one good conven-tion than a year of practical experiments will teach them. All are requested to bring something to exhibit, and if you cannot come, send us an essay to read on some live subject. W. B. TREADWELL, Sec.

### Local Convention Directory.

1886. Time and place of Meeting. Mar. 10.-N. Jersey & Eastern, at N. Y. City, N. Y. W. B. Treadwell, Sec., 16 Thomas St., New York. Mar. 20.-Patsalaga, at Arcadia, Ala. M. G. Rushton, Sec., Raif Branch, Ala. Apr. 10.—Union, at Dexter, lowa. M. E. Darby, Sec., Dexter, lowa.

Apr. 27.—Des Molnes County, at Burlington, Iowa. Jno. Nau. Sec., Middletown, Iowa. Oct. 19, 20.-Illinois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

17 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.-ED.

Bees all Right Now.-J. Q. Wells, Boone Grove, > Ind., on Feb, 24, 1886, says:

I use the American hive, or, in other words, a hive composed of 9 frames 12 inches square inside, making the hive 13 inches square inside. From 31 colonies, last year, I ex-tracted 16 barrels of honey, 32 gallons to the barrel, and increased my apiary to 52 colonies. There are no bees of any consequence within 5 miles of mine. Bees are wintering finely so far, but the worst time is yet to come. I winter my bees in the cellar.

Uniting Queenless Colonies.-V. Heinemann, of Valparaiso, vo Ind., practices the following plan :

My method of uniting queenless colonies with colonies that contain queens is as follows: Take the bot-tom-board off the hive of the queen-less colony, and place it on the hive which contains the queen, leaving the honey-board with communications on the lower hives, close the outerpace in the lower hive; close the entrance in the top hive, and give a little smoke to each colony. This must be done in the evening, after the bees quit flying. The queenless colony should be left on from 24 to 48 hours. If the detect on from 24 to 48 notrs. If the queenless colony has not united with the lower colony at the expiration of the time mentioned, they should be brushed down. This plan I have practiced for a number of years, and I have never lost a queen or bees by its use its use.

Disinfecting Foul-Broody Hives. etc.-G. J. Pease, Ann Arbor, Mich., writes :

In the spring of 1884 I had 8 colonies of bees, 6 of them gave me 500 pounds of comb honey, and 300 pounds of extracted honey; one colony stored 230 pounds of it. My bees had the foul brood, but I did not know it until the spring of 1885. I then commenced smoking them with thyme, as per the BEE JOURNAL, only more thoroughly, giving coch him from 95 to 75 miles giving each hive from 25 to 75 puffs from the smoker each morning before

working hours. I think it may have done some good, as 6 colonies stored over 600 pounds of honey in the season of 1885, and 3 colonies sent out swarms, but they soon returned to their old home. I gave them plenty of room, tiering-up several stories in height. They all seemed to be full of hees, and putting in full time. Foul brood increased as the honey-flow ended, and in the fall of 1885 I submitted a sample of comb to one of our best and most scientific apiarists for advice. He advised me to destroy the bees. I did it with sulphur. I have 10 hives, 8 supers, bottoms and covers, frames and sections, boxes in all conditions, some empty, some filled with comb, and some partly filled; some very nice and white, and some dark; some filled with honey. some partly filled, some with foundation starters : the honey candied—all a confused mass, and mostly stacked up in my honey-room. My apiary was on tin and iron roofs over buildings. From accounts of the foul brood malady all the work my the mark of the four the roofs must be more or less infected. I am desirous to re-stock my apiary, if I can do so with a good prospect of success. I wish to have advice, first, as to how to disinfect adjoining roofs; second, will a coat of paint make my apiary roof all right ? third. for disinfecting hives, will will painting them with some solution, or boiling, be the cheapest and most effective? and fourth, how can I best utilize candied honey in the comb, there being dark comb and some foul brood in a few frames?

[Will some one having had experience with foul brood please reply to the above.-ED.]

Honey-Comb.-W.J.C., Brown Co., Ills., asks the following :

Is honey-comb digestible?

[No.-ED.]

Producing and Selling Honey.-3 -R. Grinsell, (19-43), Baden, or Mo., on Jan. 22, 1886, writes:

In the fall of 1884 I had 50 colonies of bees, 10 were rather weak, and the balance were in good condition. I wintered them on the summer stands, wintered them on the summer stands, having lost very heavily the year previous by cellar-wintering. In the spring of 1885 I had 17 good colonies and 2 weak ones to start with, and about 400 empty combs. I worked 13 colonies for extracted honey, and secured 1,000 pounds of honey, one-half clover and the balance light-colored fall honey. I considered that colored fall honey. I considered that doing well for a farmer bee-keeper. I worked these colonies a la Dadant; had only 3 swarms, and those I hived in 10-frame Simplicity hives, 3 deep, with empty frames in each. In working for comb honey I use the Heddon plan-an S-frame hive with cases of sections 1½ inches wide with no sep-arators. I think that Dadaut & Son have the secret of producing extracted Dagget." I had a conversation with honey, but what I am looking for is Mr. Dagget, and he said that the the secret of selling it. I sold all of increase was all obtained by natural my clover honey at a good price, but swarming, and he used only 2½ pounds

I sold a 500-pound barrel of fall honey for 5½ cents per pound. How does that compare with the cost of production? In St. Louis to-day I can buy 10 tons of extracted honey at 5 cents per pound. If bee-keepers do not learn to sell their extracted honey at home, their days are numbered. I put 43 colonies into the cellar last fall. The temperature in the cellar is from 38° to 45°. They are doing well.

Bees in Splendid Condition.--Henry W. Haag, Pettit,+0 Ind., on Feb. 18, ISS6, says:

My bees are in splendid condition. To day I took them from the cellar for a flight after 77 days' confinement. I examined one of the weakest colo-nies, and to my surprise I found brood in all stages of development. I have 12 colonies, and one 3-frame nucleus, which is also in fine condition. I have been wintering my bees in a cellar where the mercury was between  $40^{\circ}$ and almost at freezing point.

Large Hives, etc.-8-Fayette Lee, (64-124), Cokato, O Minn., on Feb. 23, 1886, writes :

The best hive for any bee-keeper who does not want to feed his bees in the fall, is a 10-frame Langstroth hive, the first story for extracting, or 2 cases for comb honey. Mr. Chas. Dadant is right in regard to large hives, for in them we always get enough honey in the brood-chamber to winter the bees on if we manage rightly, and every comb is filled. Capped honey is the cheapest food for winter. Any hive that will not hold honey enough (say 20 pounds) besides what combs the brood covers, is a poor hive for beginners. Bees will store just as much honey in the upper story if there is 30 pounds in the brood-chamber after the 30 pounds is put there. I think that some one said that bees would not eat pollen if the temperature was right in the cellar. The temperature of my cellar has been from  $40^{\circ}$  to  $45^{\circ}$  all winter, and the bees do eat pollen. I still think that dampness is the cause of bee diarrhea. and I am not alone in this belief. My bees are all right yet, with only two pailfuls of dead bees on the cellar floor.

Good Results.-Joseph Beath, Corning, 9 Iowa, on Feb. 16, 1886, writes thus:

I have always supposed that we had hardly an average country here for bees, but the following dated Feb. 1, 1886, appeared in a local paper of Feb. 4: "I started last spring with 20 colonies of bees, and I increased them to 89, obtained over 2,000 pounds then to 89, obtained over 2,000 pounds of comb honey, and sold \$365 worth of bees and honey. I have 50 colonies in the cellar, and they have from 30 to 80 pounds of honey each.—S. T. Dagget." I had a conversation with Mr. Dagget, and he said that the

of foundation for both the brood-nest and sections of each hive. If we take the whole 89 colonies and suppose them to equal the 50 (and Mr. D. said that his last swarm gathered 35 pounds, which was the lightest of any after allowing 6 pounds for the bees), we have 34134 pounds of comb honey for each colony, spring count, and 39-20 swarms. What I would like to know is this: Have we the "boss" beepasturage in the world, or the "boss" bee-bee-keeper? or what? If the above is true, it must have been all gath-ered in 1885, for his bees were starving in the spring, and he had to feed them. I should like to know the nearest to this that has ever been reported and well authenticated. After the honey harvest his hives contained from 35 to 104 pounds each. My own report is this: Eleven colonies in the spring of 1885, 23 in the fall, and 1,500 pounds of extracted honey, with a fair supply left for the bees to winter on; also 4 swarms that absconded. I wish that some of the prominent correspondents of the BEE JOURNAL would tell me the best way to fasten the wire into foundation without a press. I wire my frames and then press the wire into the foundation by running a small wooden wheel over it, but last fall I had considerable to fall down when the honey was coming in fast.

Bees and Fixtures Burned.—James Nipe, Spring Prairie, Wis., on Feb. 20, 1886, writes :

My house took fire on the afternoon of Feb. 16, and was burned with a large portion of its contents, including 163 colonies of bees that were in the cellar with about \$100 worth of bee-fixtures.

A Diseased Colony.—S. J. Youngman, Cato,⊙ Mich., writes :

Having examined my bees to-day. I find them very quiet, only one colony showing any signs of diarrhea. They have been confined 55 days. The cellar is dug in heavy clay ground. I was obliged to drain it about 200 feet, and about 4 feet in depth; the water has been constantly flowing in the drain. The walls of the cellar are 18 inches thick, built of stone; then one corner of the cellar was partitioned off, filing in all around with 6 inches of dry planer shavings, except overhead which is celled with 1-inch boards. When there is a fire above, the temperature is 50° above zero; without the fire, 48° above. There is no upward ventilation in it. Some of the hives have nothing whatever over the frames; on those that have cushions the bees cluster on the outside to some extent, which seems quite refreshing when the temperature is 18° below zero, outside of the cellar. The colony that shows signs of disease occupies a two-story hive, which rests nearer to the ground than any of the others. It has no cover over the frames; the bees can be seen crawling over the frames, and can be reached handily. I would like to have some of the experienced bee-

keepers tell me if anything can be done for this colony; for without help they will surely perish before there is any chance of their having a cleansing flight. They could be fed any kind of medicated syrup without any trouble. The bees that get out of the hives fall into the water with which the cellar bottom is covered, and that causes a mildew or mold to form on the bottom, which results in an unpleasant edor. Should this mold and dead bees be removed ? It will disturb the bees to some extent.

Feeding Bees Rye Meal.—W. R. F. asks the following questions:

I desire some information on feeding rye meal to bees in the spring, for pollen. Should it be fed dry or mixed with honey? How will the bees find it?

[It should be put on a dish or board in the sun a few rods from the hives where the bees will generally find it; if they do not, a small piece of honey placed were the bees will find it, and then taken to the meal and placed on it, will soon cause large numbers of bees to work on it and the meal too.—ED.]

Bee-Keeping in Utah.—John Dunn, Toole, +0 Utah, on Feb. 16, 1886, says:

This has been an open winter here ; bees have been out a great deal, and if the weather continues long as it has been since Jan. 1, there will be some brood in the hives, and perhaps some of the colonies are breeding now. Last year we had a good flow of honey, although I had not the time to take it all out last fall; but I find that there will not be any lost, as the present winter has been such that the bees required more honey. I have just left my bees on the summer stands, and have not put any extra covering over them, and I think they will come out just as well as those that have housed them. We sometimes have a line winter until March, and then sometimes we have bad weather until to May, and it is then that our loss is great; for the bees are nearly all breeding before that time, and I have seen the brood frozen in the combs; but it is to be hoped that it will not be so this year.

Illinois State Convention.—Mrs. L. Harrison, Peoria. 118., on Feb. 15, 1886, writes thus:

In compliance with the suggestion of Mr. Cutting, President of the North American Bee-Keepers' Society, and acting in the capacity of Vice-President for Illinois, I wrote to Charles F. Mills, Secretary of the State Board of Agriculture. I would like to have the opinion of bee-keepers of this State, as to the propriety of calling a convention at Springfield next winter, as suggested by Mr. Mills. Here is his letter:

"There will be little, if any change think. I have had bees for 25 or 30 in the premiums for bees, honey, etc., years, and one of my chief hobbles

this year. If you wish to make any suggestions as to a new classification in this Department another year, the Board will be pleased to receive them, and aid the bee-keepers of the State in any way in their power. So little interest has been manifested at the Fairs, that the Board has had no encouragement to offer more than they do. It is very desirable that an Illinois Bee-Keepers' Association should be organized, and if you will call a meeting of those engaged in that industry, the meeting to take place in Springfield, the writer will do all in his power to assist you in its organization."

Sharp Hits and Truth.—Franklin P. Stiles, Haverhill, & Mass., on Feb. 22, 1886, says:

Sharp hits and naked truths are enjoyed by all, and the "chips" from such "hewing" should have unobstructed right of way; but does "history making" require that chip dirt shall be thrown in the face of the entire fraternity? What think you?

[Cheerfully we reply that "dirtthrowing" in controversies always indicates a lack of argument, but we discover no "dirt" in the article evidently referred to. Our correspondents must take dne notice that whenever we discover any but *kind* criticisms (which are always valuable) we shall let the subject rest until all are content to be good-natured in the controversy.—ED.]

Bees Wintering Finely.--Wm. H. Miller, Berrien Springs, 9 Mich., on Feb. 20, 1896, writes:

I lost 67 colonies last winter, being all but one that I had the fall previous, and the one left was very weak. In the spring I bought 2 colonies and worked them for increase, but only by natural swarming. I lost one good colony, and I now have 16, which I think are wintering finely, as they were all right last week. I hope that the coming season will be as good as the last.

Report for 1885, etc.—F. A. Gibson, Racine, Wis., on Feb. 23, 1886, writes:

My bees did very well the past season. 1 obtained 2,000 pounds of comb honey, and 2,000 pounds of extracted honey, and have sold all of it in the tome market, the comb honey from 16 to 20 cents, and the extracted from 12 to 15 cents per pound; and the bees have had plenty to winter on. I have 89 colonies packed in my bee-cellar, that I put in on Nov. 20, 1885. They have been very quiet all winter. The temperature has been 40°. My hives are reversible. I keep no bottomboards on them through the winter, but put them on the top—the only true way to winter bees safely, I think. I have had bees for 25 or 30 years, and one of my chief hobbles has been to winter bees safely, and I feel satisfied that I have finally succeeded in finding the true way. My cellar has no ventilation, only when I visit my bees, and that is every day. I look at them with a light, and it does not disturb them at all. They have consumed only 2 pounds per colony, and only a few dead bees can be found on the cellar bottom. They have had no flight since I put them in. I prevented them from swarming last season.

Cleansing Foul-Broody Hives and Combs.—N. II. Ward, Winchester,↔ Ind., on Feb. 22, 1886, says :

For cleansing foul-broody hives and combs I use lye made from wood ashes; close the entrance of the hive, put in the lye, and with a stiff broom give it a good scouring. If you wish to see how nicely the hive will be cleansed, try it. To clean foul-broody combs, take a sharp knife with a rough edge, and shave off the cappings, have a vessel of lye large enough to take in a frame and dip it in until all the cells are filled; then throw the lye out of the cells, and pour cold water upon the combs until they are well washed. You can then place them in the hive, and the bees will accept them and go to work on them.

**Good Increase, etc.**—Moses Bailey, Winterset, Q Iowa, on Feb. 18, 1886, writes:

On May 1, 1885, I had 4 colonies of bees left—1 good colony, 1 of medium strength, and 2 quite weak, the 4 making not more than one strong enough for surplus honey gathering. The strongest one had the most beebread, probably as much as the other 3, if not more; they also had one frame of very good honey close to them, which they used from liberally. I increased them to 47 colonies, and about 35 of them had plenty of stores to supply them until May 1. The balance were quite short of stores, and several of them may starve. I took about 200 pounds of honey, threefourths of it being extracted. Two starved colonies came to my apiary in the latter part of June, which were fixed up, and they went to work finely.

My Experience with Bees.-H.J. Smith, Burlington, Wis., on Feb. 16, says:

On Nov. 16, 1884, I put 100 colonies of bees into the cellar. Twelve of them were lost in the cellar, 3 starved, 9 died with diarrhea, and a great many more were affected with the disease, so that when I put them out in the spring of 1885, they dwindled badly. The spring was so cold and wet that when they left the hives they chilled before they could return again; that weakened them so that I had to keep on doubling them up until the honey season came, when I had only 60 colonies left, and weak ones at that, to commence the season

with. These I increased to 94 colonies, and obtained 2,000 pounds of honey, 300 pounds of it being comb honey, and the balance extracted. We had hardly any fall honey, and so the bees were left rather light in stores, thus causing much feeding. Last fall I put 94 colonies into the cellar on Dec. 16 and 17, and they are doing tinely so far. There is no disease to be seen yet. I read Mr. J. M. Goodrich's article on page 57, about upward ventilation in wintering, and I think that he is correct. I tried it last winter, and got enough of no upward ventilation. Had I given my bees upward ventilation as I always had done, my loss would not have been nearly as large as it was.

Bees Doing Well.-Wm. Anderson, Sherman, O+ Mo., on Feb. 23, 1886, writes :

After such a hard winter so far my bees are doing very well, except that we had some weather that was moderate enough to cause an uproar in the hives, and not warm enough to allow them to get out; so they voided as best they could, and smeared the hives and combs very much. A great many of the bees are frozen in this locality, as so many bee-men were not expecting a very cold winter, and so failed to put their bees in condition to stand very much cold. My loss will be very little, unless something happens in the future.

### How I Winter my Bees.—O. F. Beal, of Mineral Point, • Mo., writes:

We have had 3 very cold winters, and it has thinned out the bees considerably here. Last season was a poor one for honey; during white clover season the weather was cold and wet, and in the fall, when we had a little flow of honey, it rained for 5 or 6 days, thereby leaving the bees short for winter stores. I have had so many bees to freeze, that I finally constructed a house that holds 8 colonies (4 below and 4 above). The house is double-walled, with two thicknesses of lumber, and also two thicknesses of building paper-forming a dead-air space of half an inch all about it. The doors are made double also. I had 7 colonies in one house and 6 in the other. Three colonies were very small, not over a quart or two of bees in each, and they froze. These bees were in apartments 15 inches square by 20 inches in depth. I took out the honey-boxes in the top-tier and hung the brood-combs in their place. Had the other 3 colonies been a little larger I think that they would not have frozen. I make a hive after the same pattern for only one colony, but it makes an expensive hive. I believe if we would make better hives we would not lose so many bees. We have had a temperature of 10°, 15° We and 20° below zero, at different times this winter. I examined my bees (opened the door to see how they were getting along) when the thermometer was at zero, and there was but very little frost near the door.

Wiring Brood-Frames.—M. P. C., of Newport, 5 Vt., asks the following question:

In wiring brood-frames for the purpose of putting in comb foundation, what would be the objection to having the wire run horizontally instead of perpendicularly, the usual way, thus lessening the labor of wiring ?

[Foundation warps from two causes —expansion and gravity. Vertical wires avoid the latter cause, and in any case the closer together the wires are placed, the less liability to warping from expansion. Many have tried both ways, and a large majority prefer vertical wiring—"the usual way," as you say.—JAMES HEDDON.]

Condition of Bees in Kentucky, etc. -G. W. Demaree, Christiansburg. & Ky., on Feb. 20, 1886, writes :

I was very much surprised, as well as very sorry, to see the discouraging report of my good friend, Rev. L. Johnson. His location is less than 50 miles north of mine, and my losses are not serious at this date. Two or three good colonies, and some weak nuclei perished, being unable to reach their stores on account of continued low temperature. My apiary is in better condition now than it was last winter at this time. I have not heard from all the bees around here, but I am satisfied that the losses will be less than that of last winter, and less than that of 1881. Allow me to say that the old AMERICAN BEE JOUR-NAL leads all bee-periodicals, in my estimation. I admire it the more because it treats bee-culture solely as a business industry. Success to it.

The Honey Trade.—Jerome Twichell, Kansas City,+0 Mo., writes :

Having sold my interest in the firm of Clemons, Cloon & Co., it is with regret that I announce my retirement from the honey business for the present. It is now five years since I commenced handling honey in this city, and from a few thousand pounds sold only during the fall and winter season, I have seen the trade grow to nearly a quarter of a million poundsyearly, and sold during every month from January to December. But my alliterative hobby, "Honey, health and happiness," has made me an enthusiast on this subject, and I presume it will be impossible for me long to remain out of the business. I must acknowledge my heartfelt gratitude for the many courtesies received from bee-keepers, and my continued interest in their welfare and success, and should I again become associated with them in a business way, I hope to meat the same cheerful co-operation that I have had in the past.

Preserve your papers for reference. If you have no **BINDER** we will mail your one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

Issned every Wednesday by THOMAS G. NEWMAN & SON. PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

> ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

Golden Rules for successful advertising, are these : 1. Attractive display. 2. Salient points clearly stated. 3. Repetition. Don't spend all your money in one insertion, 4. Choice of the Paper which reaches the people you want to reach. These rules never fail.

To Correspondents. — It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if yon live near one post-office and get your mail at another, be sure to give the address we have on our list.

**Perforated-Zine.**—We have laid in a stock of perforated zinc, for excluding drones and queeus, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive—19½x14½—Price 25 cents each cents each.

A Good B ecord.—In the Seed Catalogue of Jas. J. H. Gregory, of Marblehcad, Mass., page 10, is found the following extract from a letter of D. S. Lyon, Solsville, N. Y.: "This makes twenty-one years we have used your seed and always to our complete satisfac-tion." In our advertising columns Mr. Gregory offers to send his catalogue of such seed as this, free to all mankind.

Beeswax Wanted .- We are now paying 24 cents per pound for good, average, yellow Beeswax, delivered here. Cash on arrival. Shippents are solicited. The name of the shipper should be put on every package to prevent mistakes.

We have received a copy of Green's New Catalogue and Fruit Guide. It contains more in-formation on fruit culture thao any other pub-lished. It is a complete guide for growing all kinds of fruits. Send for it and for a sample copy of that aprightly paper, GREEN'S FRUIT GROWER, Illus-trated, edited by Chas. A. Green, Send your ad-dress an a postal curd for Catalogue and paper, both free. Address, GREEN'S NURSERY CO., Box 592, Rochester, N. Y.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it.

. . .

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Mar. 1, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

IIONEX.—Sales have been quite good this month for best grades of comb boney, some bringlog 16e. per pound when in perfect order. There is a light supply bere, aod now is a favorable time to for-ward shipments. Extracted hooey brings 6@8c. BEESWAX.—25@3cc, per b. R. A. BURNETT, 161 South Water St.

### NEW YORK.

NEW YORK. HONEY.-We note an improvement of sales of honey the past week, but prices continue to rule low. We quote as follows: Fancy white comb in 1-b. paper cartons, 13@14c; the same in 1-b. glassed or unghassed sections, 12@13c; the same in 2-b, fassed sections, 9@104/cc, and fall to good In glassed 2-lbs., 8@9c. Fancy buckwheat honey in 1-b. unglassed sections, 10c; the same in 2-b. sections, glassed, 3@9c. Extracted, while, 03/@74/cc; buckwheat, 5@6c. BEEESWAX.-27@28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

### ST. LOUIS.

HONEY.-The market is quiet and the demand light just now. We quote prices as follows:-Choice comb honey, 10@12c. Extracted, in bar-rels, 44@5c. Extra fancey of bright color and in No. 1 prekages, 14 advance on above prices. BEESWAX.-Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

CINCINNATI. HONEY.—There is no speculation whatever in the market, and the demand is slow for extracted boney from manifacturers, while it is fair for boney in glass jars, for table use. Demand for comb honey is slow and the market is well supplied with all kinds. Extracted boney brings 488c, and choice comb honey brings 12@15c. In a jobhing way. BEESWAX.—The home demand is good, while arrivals are slow. We pay 25@27c. for good yellow to choice.

C. F. MUTH & SON, Freeman & Central Ave.

#### CLEVELAND.

HONEY.—The market is not quite as notive as it has been, owing, no doubt, to many attractions of the Holiday Season. Best white, I-ib. sections sell at 15c, and 2-ibs. for 130-14c, but there is not so much sale for the latter. Second grade honey is duil at 120-33c, Old white, 106-12c. Extracted, 7@8c. per ib. BEESWAX.—Very scarce at 22@25c. A. C. KENDEL, 115 Ontarlo Street.

#### KANSAS CITY.

HONEY.—Sales are improving and we have a good trade in comb, although prices are not as itrm, owing to good prespects the Califoroia for a large crop having reduced their prices about 2 ets. We quote as follows: Choice comb io 1-b. sections, 16c.; fair to dark, 12@14c.; in 2-th sectios, 12@14 cents. Extracted is dull and slow. Dark brings 3 1-2 to 4c; white, 6@7c. BEESWAX.—23C. CLEMONS, CLOON & Co., cor. 4th & Walnut.

BOSTON.

HONEY.—The sale for honey for the past month has been as light as we have ever known it, and prices are weak. One-point, white elover, 13@15c; 2-nound sections, 11@13c. Extracted, 6@8c. BEESWAX.—30 cits, per lb. BLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

110NEY.—The market is very dull. We quote as follows: White and extra white comb, 11%013c; dark comb, 54%05c. White extracted, 54%054c; mber, 404%c; dark and eaodied, 3%04c. BEESWAX.—Quotable at 23%25c, wholesale. O, B. SMITH & Co., 423 Front Street.

#### DETROIT.

HONEY.—The market is very dull. Best white in 1-b, sections, 14c. There is ecosiderable in commission houses and prices are liable to be lower. BEESWAX.—It is in good demand at 23@25c. M. H. HUNT., Bell Branch, Mich.

The Great Marblehead Seedsman. The Great Marblehead Seedsman.— For 30 years Jas, J. H. Gregory, of Marblehead, Mass., has been distributing his Seed all over the United States until his name has become a house-hold word in the house of nearly every farmer, and his Seeds have established for themselves an international reputation. The value of a crop of aoy kiod is always determind by the value of the Seeds that are sown. Gregory's Seeds never fail, therefore the 30 years of successful husiness. Look up his advertisement in our columns of this week.

### Convention Notices.

The Union Bee-Keepers' Association of Western lowa will meet to Dexter, lowa, on April 10, 1886, at 10 a.m. M. E. DARBY, Sec.

The Southern Wis. Bee-Keepers' Association will hold its 3rd, agnual meeting at the court-house in Janesville, Wis., on March 9, 1886, nt 10 a.m. All interested are lovited. JOHN C. LYNCH, Sec.

277 The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. M. HAMBAUGH, Sec.

127 The next meeting of the Patsalaga Bee-Keepers' Association will be held at Arcadia, Ala., on March 20, 1886. M. G. RUSUTON, Sec.

Wire Nails have advanced in price, as will be seen by quotations on page 143, last column.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

# The NEW Heddon Hive.

We have made arrangements with the inventor by which we shall make and soll the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

It is absolutely essential to order one nailed hive as a pattern for putting those in the flut together correctly.

THOS. G. NEWMAN & SON,

923 & 925 West Madison St., CHICAGO, ILL.

WE have a large stock of choice yellow hees-tion for brood-comb, cut to any size for 42c, per lb, Extra thin Vandervort foundation, 4%, per lb, We guaraotee onr foundation to be made from pure beeswax, and not to sag. Will work up wax for 10e per lb, and 20 ets, per lb, for sections.

F. W. HOLMES, COOPERSVILLE, Ottawa Co,, MICH. 9Dtf

### 1886, ITALIAN OUEENS, 1886, FROM APRIL UNTIL OCTOBER.

UNTESTED, \$1.00, per Dozen \$8.00. Reared from Imported Mothers. Money refunded if not furnished promptly. Address, WALTER PICWILLIAMS,

9D6t

GRIFFIN, GEORGIA.

### FOR SALE.

A PIARY 120 ft long, 50 colonies arraoged for comb hooey-simplicity style. Dwelling-house new, harn, poultry-houses, 30 acres arable land, hourd and wire fence, and 50 acres woodland; on the hills 1 mile from centre of Yazoo City, Miss. There are 2 acres of strawheries and about 600 young fruit trees (200 bearing), springs of running water, &c. Good fruit and bee country Farm and Apiary at the low price of \$2,500-one-half cash, balance in 1 year. If you want a bargain, at once aiddress, "WIEDWOOD PLACE," 9A2t YAZOO CITY, MISS.

MY 650 Colonies of bees are more than 1 ery 106 full colonies, \$5,00 each for hybrids and \$6,00 for pure Italians. Discount on larger num-bers. I will also sell a few colonies of Crucasian bees, which breed I imported from the Caucasus Mountains, Asia, in 1880, and have proved to me of great value. Address,

JULIUS HOFFMAN, CANAJOHARIE, Montg, Co., N. Y. Formerly Fort Plain, N. Y. 9A3t

### THE AMERICAN BEE JOURNAL.

2C6t A. J. NORRIS, Cedar Falls, Iowa.

EDITORIAL militim AMAN 

The Australian Bee-Keepers' Journal is the name of a new bee-paper edited by R. L. J. Ellery and J. H. Kitchen, Melbourne, Australia. No. 1 is on our desk ; it contains 16 pages, and presents a neat appearance.

"Flowers that Bloom in the Spring." -A bouquet of blooming flowers from Mr. J. W. Winder, of Louisiana, is on our desk. Among them white clover with stems 12 inches long; several blossoms from Cuba, gathered there on Jan. 26; and several others from Louisiana, gathered on the 1st inst. While everything is frozen up solid here at the North, it is refreshing to think that our Sonthern brethren are enjoying "the flowers that bloom in the spring." Truly, this is a vast country.

The American Bee Journal is regularly sent to almost every eivilized country in the world. It has regular subscribers in England, Ireland, Seotland, Wales, France, Italy, Austria, Germany, Sweden, Norway, Russia, Asia, Africa, Australia, New Zealand, South America, Mexico, Cuba, and all the Provinces of the Dominion of Canada, as well as in every State and Territory of the United States. Advertisers should note this fact when reaching out for business. The AMERICAN BEE JOURNAL offers them inducements which cannot be obtained elsewhere.

Wm. Dyer, of Hastings, Minn., has sent a reversible-frame attachment to our Museum. It consists of a piece of wire of the length of the side-bar of a frame, with each end twisted into a ring, but in opposite directions from each other. The wire is fastened to the centre of the side-bar by little staples, and when the frame is reversed the ring that was under the bottom-bar turns out to form the projection to hang the frame; the one motion turning the projecting end out earries the other under the bottom-bar. It can be made for and attached to any frame in use, by simply eutting off the end-bar, and without disturking the comb.

Schacht & Lemeke, of San Franelseo, Calif., have issued their annual market review of the honey and beeswax husiness of California, from which we extract this:

The honey erop of 1885, like that of the year before, was not a remunerative one for the producer on this Coast. The reason that the expected inprovement in prices did not take place, was partly in the general depres-sion of trade, in the low sugar prices, and in the decrease of the foreign and Eastern demand for our boney, in consequence of a full supply there ; but particularly we may attribute the low prices ruling since August, 1884, to the circumstance that a large por-tion of the erop of 1884 was held over by the producer for a raise in ease of a short erop in 1885, or a better demand for the article from any canse. Consequently, the quantity put on the market during 1885 was not small, but larger than could be handled without a larger foreign or Eastern demand.

To Europe very little honey has been evabout 2,000 eases), for the reason that supplies on hand there were full too, and in supplies on hand there were full too, and in consequence of a new tariff in Germany, raising the duty on honey from 3 to 30 marks per 100 kilos, since July 1, 1885. Sales to Germany, therefore, stopped entirely since that date, and supplies increased in England, in consequence of the heavy arrivals in the first six months of the past year, and end of 1884. The low prices result-ing from these canses have, however, increased a good deal the cousumption of this article, both here and abroad.

The supply on the market and in the hands of producers now is not large, par-ticularly of the better grades of liquid honey and comb honey, which are getting scarce; for which reason prices for choice extracted honey and comb honey, the crop of which was especially short in 1885, are a good deal higher than at this time of the previous year.

The estimated quantity in first hands is about 5,500 eases of extracted honey, and 1,200 eases of comb honey; against about 15,000 eases of extracted honey, and 5,000 eases of comb honey, at the close of 1884.

10,000 cases of extracted being, and processes of comb honey, at the elose of 1884. During the last six years, the quantity of honey arriving in this city has been reported as follows: In 1880-3,000,000 lbs. In 1881-1,200,000 lbs. In 1882-1,500,000 lbs. In 1883-4,3600,000 lbs. In 1885-2,000,000 lbs. In 1885-4,000 lbs. In 1885-2,000,000 pounds of honey, and sinee then the balance of about 800,000 pounds ; showing that most of the honey received during the past year was honey of the erop of 1885. Even among the 800,000 pounds received since July 1, 1885, was a good deal of old honey, and we may therefore safely say that if all, or nearly all, the honey of 1884 would have been consumed, sold or exported before the new crop of 1885 came into the markets, we should have been consumed, sold or caported before the new crop of 1885 came into the markets, we should have been consumed, sold or caported before the new crop of 1885 came into the markets, we should have been consumed, sold or caported before the new crop of 1885 came into the markets, we should have been consumed, sold or caported before the new crop of 1885 came into the markets, we should have been consumed, sold or caported before the new crop of 1885 came into the markets, we should have been consumed. Sold or caported before the new crop of 1885 came into the markets, we should have been consumed. Sold or caported before the new crop of 1885 came into the markets, we should have been consumed. Sold or caported before the new crop of 1885 came into the markets, we should have been consumed. Sold or caported before the new crop of 1885 came into the markets, we should have been consumed. Sold or caported before the new crop of 1885 came into the markets, we and no doubt much better prices during the last season. We estimate the erop of Cali-fornia for 1885 at about 1,250,000 pounds, against nearly 8 times that amount in 1884.

The whole honey erop in the United States or the past year is estimated at about The whole noncy erop in the United states for the past year is estimated at about 26,000,000 pounds of honey, and the States of New York, Tennessee, Ohio, North Caro-lina, Pennsylvania, Kentucky, Illinois and Iowa were the leaders in the honey-produe-ing States—producing, each of them, more than California in 1855; for which reason, prices in the Atlantic States did not encour-age shimments from here age shipments from here. Comb honey has improved a good deal in

Comb honey has improved a good deal in prices, in consequence of the small yield; and we may mention that a much greater demand in the East, with better prices, could be obtained, if our apiarists would use one-pound sections instead of the two-pound sections. In the East the prices are about two cents higher for comb honey in one-pound sections, and the demand is better for these packages than for California honey in two-pound sections honey in two pound sections.

The prospects for better prices are not The prospects for better prices are not very bright for the next season, especially as it now promises to be a good erop for 1886; but values are now so low for ex-tracted honey that they can hardly go lower; and we even may expect higher prices, should we have a good Eastern and foreign demand, and a general improvement in the trade, which we trust will be the ease.

To Double the Postage on fourth-class matter (which includes bees and all kinds of bec-keepers' supplies), the Hon. James F. Wilson, of Iowa, has introduced a bill in Congress. We have written to our Congressman to use his influence to defeat the measnre, and he has replied assuring us of his willingness to do so. Prof. Cook says :

"The postage on fourth-elass matter is "The postage on fourth-class matter is now 16 cents per pound; before 1872 it was only 8 cents per pound; in Canada it is 4 cents now, 1 think. A Canadian bee-keeper can send a pound of queens or bees to any place in Canada or the United States for 4 cents, while we now pay 16 cents, and possibly may have to pay 32 cents. This matter deserves the immediate attention of all bee-keepers. I have written to our Con-gressmen, and would urge all others do the the same. Few, except the seed-men, would feel this oppression more than bee-kcepers.

The proposed increase would make the rate the same as letter postage, and would benefit only the express companies. The Postoffice Department would lose the buslness, and hence would not be benefited. Every one buying or selling bee-keepers' supplies should immediately write to Congressmen to use their influence to defeat the measure. If any change is made, it should be decreased instead of increased !

Hints concerning Bee-Keeping for March. – The experience of many bee-keepers, not all novices, is that while they can get their bees through the winter well, the early spring is the most trying time. The life of the worker-bee is short at best, and the great proportion of those that go into winter quarters die before the season is half over. New brood must be reared to maintain the strength of the colonies. It is often fatal to success to start colonies at work rearing brood too soon, which is done when they are placed too early upon the stands before the weather remains continu-ously propitious. It is better to wait. Colo-nies coming through the winter very strong may be trusted out earlier than weakly ones. Warm weather will excite the bees to activity; if this occurs unusually early, the colonies thould be tent cs out a goegeible. Hints concerning Bee-Keeping for and y be transfer out earlier than weakly ones. Warm weather will excite the bees to activity; if this occurs unusually early, the ecolonies should be kept as quiet as possible. When the red buds of the soft maple put forth, the bees, as a rule, may be safely released from their imprisonment. Queen-are liable to disease and death, and it happens that sometimes a colony is without a queen. In such a case it may well ie united with a weak one that has a queen if both, after close examination, prove healt iy. If honey is exhausted, feed : and it is well to place fine, unbolted rye flour where it is accessible to the bees. They will use it in place of pollen, if few flowers are open or the weather rough.—American Agriculturist for March. for March.

New Price-Lists have been received from the following persons :

J. D. Goodrich, East Hardwick, Vt.-2 pages-Bee-Keepers' Supplies.

Iowa Seed Company, Des Moines, Iowa .pages-Seeds.

Andrew Banks, Reisterstown, Md.-pages-Chatsworth Herd of Jersey Cattle. Md.-48

T. L. Von Dorn, Omaha, Nebr.-6 pages-Apiarian Supplies.

Joseph E. Shaver, North River, Va.-1 page -Bee-Kcepers' Supplies. [By an oversight this address was given as Pa. instead of Va., in a recent issue.-ED.]

J. A. Everitt & Co., Watsontown, Pa.-50 pages-Seeds.

Oliver Foster, Mt.Vernon, Iowa-7 pages-Italian Bees and Queens.

J. W. Clark, Clarksburg, Mo.- 16 pages-Apiarian Supplies and Bee-Keepers' Diary.

Any one desiring a copy of either of them, ean obtain it by sending a postal eard to the address as given above.

### **REPLIES by Prominent Apiarists.**

Getting Ready for the Honey-Flow.

Query, No. 210.-In my locality, bees begin to work with the advent of tag-alder and skunk-cabbage, and we have almost every species of honey-producing plants, shrubs and trees indigenous to the temper-ate zone, especially black and red raspber-ries, white clover, basswood, willow-herb, buckwheat, goldenrod, and a profusion of fall boncy bloom. Our climate is cold and changeable tor the latitude, and more or less of the above fail each year to secrete honey. I want to know when we should have our bees ready to receive the honey-flow, and what particular management in-cluding brood-space of the hive will produce the hest results, taking the season through. What would likely be the best shape to take the surplus honey in, for profit, comb or extracted ?-A. G., Pa.

I think that the safest guide is for every bee-keeper to be the judge of his own locality .- H. R. BOARDMAN.

1. The way you describe it yours is a paradise for bees, so far as a profusion of flowers is concerned. Get the bees strong as soon as possible, and give the queens all the room for breeding that they can utilize. 2. It Prowill depend on your market. Pro-duce both kinds, but be sure and push extracted honey on your home market. It will pay you best by-and-by.-G. W. DEMAREE.

In order to be fully successful, one must know the flora of his locality: must know the flora of his locality; when it begins to yield honey, and the duration of yield—then have the bees ready at all times to take care of it. This is the only rule that can be given, as the time will vary in different localities, and sometimes in different seasons in the same locality different seasons in the same locality. "Eternal vigilance is the price of a big crop of honey."-J. E.POND, JR.

From the description I should judge there is no time when there may not be a honey-flow, consequently the bees can hardly be ready any too soon. If there is a continuous yield, the bees will probably get themselves ready; but if there should be any considerable interim, it may be well to feed. The other questions would take a large space to answer, and have been gone overpretty thoroughly in bee-books and papers. - C. C. MILLER.

I have arranged surplusage for both comb and extracted honey, on each and all of my bives, for 1 find it most profitable to take my light honey in combs, and darker (autumn) grades in liquid form. It pays me to go to this extra expense. After you deterthis extra expense. After you deter-mine the probable time when fieldworkers are needed, give plenty of room to breed up a large number of bees to be ready to work at that time; after that, when breeding would not result in bees that would be just the right age at the right time, contract the brood apartment, stopping exces-sive breeding, and crowd the bees into the surplus department in large numbers.-JAMES HEDDON.

### Suppressing Second Swarms.

Query, No. 211.—Having made a swarm from a colony, what is the best method to suppress a second swarm from issuing naturally?—Arthur.

Leave but one queen-cell and give room as needed.—H. D. CUTTING. Heddon's method of prevention of after-swarms, if carried on carefully and not overdone, is the best.-DA-DANT & SON.

By occasionally removing a frame of brood and inserting in its place a frame of empty comb or foundation. The remedy is also assisted by using the extractor.—J. P. H. BROWN.

Extract the honey, ventilate the hive well and keep it shaded. Extracting is almost sure. Adding space by giving crates of sections is also an aid, especially if we reverse the combs. The honey is then removed from the frames, which gives the queen room, and swarming is deferred.—A.J.Cook.

If a colony is divided, as soon as it is strong enough, it will probably "swarm." One division does not prevent the bees having their " turn." I should prefer to let the bees swarm once, then prevent after-swarming by the Heddon method .- W. Z. HUTCH-INSON.

### Influence of Pollen on Honey.

Query, No. 212.-We have cells of honey uncapped for extracting-does the pollen floating in that honey influence its taste or color in any way ?-T.

I think it would.-C. C. MILLER.

It never does anything of the kind here. There is not enough pollen in 10 pounds of white clover honey to load ten bees, or one bee to the pound. Honey gathered from large, open flowers, such as pumpkins, melons, etc., may contain pollen more or less, sufficient to give a distinctive flavor, but there is little of such honey gathered here.-G. W. DEMAREE.

Floating pollen in honey frequently affects its taste. Apple-bloom honey nearly always contains pollen in large quantities, not only injuring the flavor, but it also acts like yeast, fermenting and souring the honey .-II. R. BOARDMAN.

Yes. I have said considerable about diarrhea being caused by the bees was floating in their honey. It may be that the principal way it gets into the honey is by soaking up and mix-ing with it in cells where both are stored together.-JAMES HEDDON.

It will depend wholly upon the quantity. Pollen is found to a greater or less extent in nearly all honey. As a rule, not enough is found to injure the flavor, and when so found it should be saved for early stimulative feeding, as the pollen contained therein will urge on brood-rearing at a time when little if any is found in the field. A very small amount of float-ing pollen might injure the color, when it could not be detected by taste.—J. E. POND, JR.

### Stimulative Feeding.

Query, No. 213.—My bees are in the cellar; the temperature is 48° Fahr. When and how shall I feed them to stimulate breeding ?—Lucas Co., O.

I do not care to have them "breed " until taken from the cellar.-G. M. DOOLITTLE

When it is warm enough for them to fly every day. You can feed them in the open air if there are no bees near you.—W. Z. HUTCHINSON.

If you *must* stimulate them, slightly break the capped honey nearest the cluster. If in deep frames, break the cells on top. If stores are short, feed liquid food.—H. D. CUTTING.

I have found that they do better when they do not breed, and so I would not stimulate them. I think that a warm cellar and plenty of pollen would be the best stimulants, if one wished for breeding .- A. J. COOK.

We would advise you to leave them alone till you take them out. They will breed a little anyhow, but the stimulation of breeding in confine-ment will lead to disaster. Feed them after removal from the cellar, and only in mild weather.-DADANT & SON.

### Introducing Virgin Queens.

Query, No. 214.—Please give the best method of introducing virgin queens to full colonies of bees. Why are they more diffi-cult to introduce than fertile queens ?—Ioa.

If the virgin queens are "just hatched," they can be introduced by just letting them toddle in among the bees. After they are a few hours old, I cage them in a provisioned cage, and introduce them in the same way that I do fertile queens, watching them until the bees are willing to accept them. Bees have a well grounded prejudice, instinctively of course, against virgin queens of 2 or 3 days old, because they seem to be aware of the fact that a laying queen has a very slim chance for her life when engaged in mortal combat with the keen, active virgin queen. For this reason they keep a jealous eye on her till such time as they despair of relief from queenlessuess from any other source.—G. W. DEMAREE.

1. The colony should have been queenless about 24 hours. Run the virgin queen in at the entrance, or any other part of the hive, following her with a light whiff of smoke. Do this as soon as she is hatched. 2. They are not, unless too old; and when the bees would recognize either as a stranger, they seem to favor the best finished job.—JAMES HEDDON.

Any answer to the above, especially the second part, will be largely theoretical. I never introduce virgin queens except as a matter of experiment. prefer to use ripe cells. In a large apiary this might not be quite convenient, but answers my purpose well. A hopelessly queenless colony will usually accept any queen, if the queen conducts herself as she ought, i.e., calmly and coolly .- J.E. POND, JR.

Explanatory .- The figures BEFORE the names indicate the number of years that the persen has kept bees. Those AFTER, show the number of eolonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is located near the centre of the State named:  $\delta$  north of the centre;  $\varphi$  south;  $\circ$  east; •• west; and this 6 northeast; • northwest; • southeast; and 9 southwest of the centre of the State mentioned.

For the American Bee Journal.

## Wide Frames with Separators.

### 16-G. M. DOOLITTLE, (40-95).

For several years there has been quite a cry against wide frames with separators, some even going so far as to predict that they would soon be "things of the past;" but after trying most of the various arrangements which are used to secure honey in sections without them, I am satisfied that there is one at least who will continue to use wide frames and separators, a few years longer at least; for I believe them to be of real value in securing a crop of comb honey in the most marketable shape. While speaking regarding this subject perhaps it might be interesting to some to know something of the past, and how wide frames and separators came into general use.

Years ago, when I first commenced keeping bees, I knew of no box for surplus honey smaller than the 6-pound box as then used on the Langstroth hive. I next saw the Alley or 3-pound box, and afterward the Harbison section, none of which pleased me. I then made a box to hold 21% pounds, and prepared a hive so these could be placed all around the brood-nest, and at the top, but as I must of necessity glass them before the bees filled them, in order to keep the bees from bulging the combs one into the other, it was rather slow progress which I made. In the winter of 1871-72 I visited Mr. N. N. Betsinger, of Marcellus Station, (a place 11 miles from me), and while there he showed me (as I believe) the first wide frames with tin separators that were ever known, which he had invented a short time previous. As soon as I saw them I said that this was just what I had been looking after for some time, and at once adopted them, the use of which gave me the best of satisfaction.

These wide frames were so arat the side of the hive or on top, or both, at the pleasure of the operator. Mr. B. never used them on the tier-ing-up plan that I know of, yet he might have done so without my knowledge of it. In 1874 I made and used several sets on the tiering-up knowledge of it. In 1874 I made and (the first year or so) a hand vise so used several sets on the tiering-up arranged that I could pry over one plan, by making the top and bottom end of the wide frame, thus drawing

piece alike and using a part directly on top of the frames and each other, *a la* Tinker, and a part with beespace between, a la Heddon. After a few years' trial I became satisfied that I could not obtain so much honey by this tiering-up plan as I could by using a single tier on top, in connec-tion with side-boxing as I had first planned, before I ever saw a wide frame; so I threw away all of my open-top wide frames and worked entirely on the plan I have given so many times in the BEE JOURNAL.

Prior to 1876 wide frames had only been used containing a single tier of sections, as both Mr. B. and myself used two wide frames with a bee-space between when we wished them two tiers high at the sides of the hive, neither he nor I ever using a two-story hive at that time. In March, 1876, at the request of Mr. A. I. Root, I sent him a set of wide frames as I used them on the standard Gallup hive. Upon receiving it he wrote as follows: "Yours is the nicest box and case I have ever seen, and is the most complete arrangement for comb honey I have any knowledge of. If the plan of the whole is of your own invention, I would suggest that you get them patented." I wrote him that the wide frames (or cases as we then called them) were the invention of N. N. Betsinger, who had not seen fit to patent them. Soon after this Mr. Root came out with his "broad frames" to be used in a two-story hive, and from these sprang the wide frames as they are generally used at the present time.

This using of two tiers of sections in one wide frame is what has caused while if only one tier had been used in a frame and these tiered up, those liking the tiering-up plan would not have tried to substitute any other arrangement for wide frames, it seems to me; for I find them better adapted to the securing of surplus honey than anything else, all things considered, especially as they can be made for any size of sections, and used on any size of hive.

Now about making and using wide frames: Get all the pieces out true and square, after which nail them over a true square form. If you wish to use them on the tiering-up plan, make both top and bottom 5-16 of an inch narrower than the ends; if to be used only one tier high, then have the top the thickness of the tin wider than the sides or ends, for the sep-arator is to be nailed on the ends. After using several kinds of material for separators, I prefer tin to anything else. The nailing on of this tin has much to do with our liking or disliking wide frames, for if nailed on loosely, so it can kink and bulge, the operator will become disgusted with them. Mr. Betsinger used to nail on one end of the separator in its proper place, when by means of a weight and pully attached to the other end of the tin it was drawn tightly when being nailed. Instead of the weight, I used

the tin tight when nailing. While thus working, one day, I noticed that in drawing the tin I often sprung the top and bottom of the frame out or in, as the case might be, and from this I soon had a perfect way of put-ting on tin tightly every time.

I made a form a trifle shorter than the frame was long, ontside measure, this form being perfectly true and square, which gave advantage over the vise method, for with that the frame was sometimes drawn out of true. Was sometimes drawn out of rue. Next I made a block the size of the inside of the case (except a little shorter), and of the same thickness as the ends to the frame, which was tacked to the form. To use it, I sprung or bent the top and bottom bar of the frame a little, thus shortening it, until it went into the form, when 1 laid on the tin separator, placing a straight edge on top of the tin and a weight on this. I now had the tin just where I wished it with all bulging taken out of it, when it was nailed fast to the wide frame. Upon removing it from the form, the top and bottom sprung back into place again, thus drawing the separa-tor as tight as a drum-head. I have put on separators in this way for the past 10 years, and like it very much.

I have tried all ways of keying these wide frames together, using them in a clamp, e.c., all of which I did not like, as I wished a plan that would allow of my using as few or as many wide frames on a hive as I pleased, from 3 up to 12, according to the strength of the colony, for often with the old plans we are obliged to with. At last (about 4 years ago) I accomplished what I was after by procuring some rubber bands about 34 of an inch wide. These I cut into pieces 3 inches long. To one end I attached a stout string (by means of a slip knot) about 5 inches long, and to the other end one about 18 inches long. The short strings was firmly tied to a nail driven into the end of the board that comes against the outside of the outside wide frame, another being attached to the opposite end of this board in the same way. In each end of the hoard which goes on the outside of the opposite outside wide frame, is driven a large-headed, steel-wire carpet-tack. This tack is driven in within about 1-32 of an inch of its large head, so that when a string is wound around it a little more than once, it is clamped as securely as if tied. The wide frames are then placed on the hive, 2, 3, 5, 8, or 12, as the colony requires, putting on the outside boards to close all, draw the rubber till a strong tension is made, and wind the string around the tack. In this way the wide frames are held as in a vise, yet they give all the lateral movement required, and can be taken off as one case or separately, tiered-up. inverted, etc. Borodino,⊙ N. Y.

To give away a cepy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

### Cedar Valley, Iowa, Convention.

The Cedar Valley Bee-Keepers' Association met at La Porte City, Iowa, on Feb. 17, 1886, and was called to order by the President, C. P. Hunt, of Waterloo.

President Hunt read a selection from the State Horticultural report. which was very interesting.

The Secretary then read a very in-teresting letter from Dr. Jesse Oren, who is now in Florida, concerning the boney-production of that State. The honey-production of that State. The minutes were then read and approved, after which questions were asked and answered as follows:

Do bees freeze? Mr. J. K. Oren thinks that they do not hibernate, and therefore will freeze. Othershad different opinions.

Which is most profitable, comb or extracted honey, all things consid-ered? All would rather produce ex-tracted honey if they could get a ready market for it.

What is the best sized shippingcase for one-pound sections? It was thought that 48-pound cases were the best; some preferred glass fronts, and some without.

What is the best material to use in smokers? Some preferred rotten wood, and some used burlap.

Is it best to use whole sheets of foundation in sections? Mr. L. L. Triem thought it best to use whole sheets, while others thought it best to use only a starter.

The evening session was called to order by the President at 7 p.m.

Which is the best to use in the end of section-case next to sections, glass or wood? It was generally thought that wood was best. How do bees communicate to each

other? By sound and scent.

When is the best time, and how is it best to stimulate in the spring? Feed a syrup after fruit-bloom.

Is it better to feed in the hive or out-of-doors for stimulating in the spring? It is best to feed out-of-doors if not too many neighboring bees near by.

Do bees have a place selected to go to before swarming? They do. What is the best method to intro-duce virgin queens? Mr. A. J. Nor-ris drops them in front of the hive and lets them run in at the entrance. L. L. Triem and H. E. Hubbard think it best to introduce in a queen cage.

The Thursday morning session was called to order by the President at 9 a.m.

What is the best method to stop robbing? Mr. Hubbard practices covering the front of the hive with hay or grass, and then sprinkles with water. Some others exchange places with the colony that is doing the robbing.

How many bees ought to be taken out of the cellar at one time? Mr. C. out all at once. J. K. Oren and II. E. Hubbard practice taking out ½ or

a difference of opinion was expressed, but a board laid on top of the hive was thought sufficient.

The afternoon session was called to order by the President at 1 p.m. It was decided that the President

appoint a time as soon as convenient before the State convention meets, for the annual meeting of this Association.

What race of bees is best, all things considered, for general use? Mr. J. K. Oren thinks that the Holy-Land bees are the best, and also thinks that the leather-colored Ital-ians are superior to the light-colored Italians as honey-gatherers; but does not like the "business-end" of light hybrids at all; thinks it most too much business.

The Secretary's report was then read and approved.

How far apart should apiaries te? It was generally thought that four or five miles was sufficiently far apart.

How far should the feeder be from the bee-yard to prevent robbing? Twelve or fifteen rods.

How near to each other should beehives be placed in the apiary with success? Not closer than 6 feet.

Is it best to move a swarm to its stand as soon as hived, or let it remain where hived ? Move it as soon as hived.

It was decided that it is detrimental to the interests of bee-keepers to use whole sheets of foundation in sections.

The President, Vice-President and Secretary were appointed a committee on programme for the next meet-

ing. The convention then adjourned. H. E. HUBBARD, Sec.

# For the American Bee Journal.

### Bee-Keeping in Iowa, etc.

### B. F. LITTLE.

The season of 1885 was not as profitable with me in the production of honey as other years. I lost three-fifths of my colonies during the winter and spring of 1884 and 1885, leaving 50 colonies. The white clover flow was very limited, basswood yielded nothing comparatively, and there was no fall flow of honey. I obtained in all about 1,400 pounds of honey, and increased my aplary to 84 colonies by letting them swarm all they would. It is possible that the grasshopper crop may have had something to do with it. The last 3 years the grasshoppers have been on the increase; the honey flow on the decrease. In 1883 my white clover surplus was about 2,200 pounds; in 1884 less than 1,500; and in 1885 less than 1,000.

I am afraid there is some truth in the assertion made by an Iowa beekeeper, that the winter problem in this northern Iowa climate is the one most of all that needs a solution. Talk about a winter flight! From Dec. 1 to March 25 there has not been 1/2 at one time, and at about 3 p.m. on a nice, warm day. Is it best to shade hives, and if so what is the best shade? Quite a

a thaw on the sunny side of a building. My bee-cellar is 7 feet deep, double-walled from half way down up to the top, lathed and plastered sides and overhead, and a building over it 16x26 feet, which is also lathed and plastered, sheeted and sided. It has double cellar doors, and yet the temperature will go down to 34° above zero ordinarily, and as low as 28° when very cold, unless kept up by artificial heat, which I am using this winter.

I am quite sure that the Bee-Keepers' Union can effect much good in the direction of spending some of its money for the purpose of bringing those to justice who are constantly giving publicity to the notorious falsehoods about manufactured and adulterated comb honey.

The marketing of our honey is another of the unsolved problems— one that is of vital importance. I see no excuse for the present low price of honey as reported from the leading cities, only through the imprudence of crowding the honey into the large cities, and leaving country towns without any, thus bringing the whole crop to the price of gorged markets. Brush Creek, & Iowa.

For the American Bee Journas.

My Experiments in Wintering Bees.

### JAMES HEDDON.

I had thought that I would not write again upon this subject until next May, but in consideration of the facts that I am experimenting quite extensively, and the subject is a momentous one—one so very inti-mately connected with our success or failure its intermediate discussion failure, its intermediate discussion and report will not be uninteresting.

My Glenwood Apiary, of 150 colohives, were all worked for extracted honey during the past season. Owing to the unprecedentedly cold August, our late surplus crop was very nearly a failure, consequently these colonies managed for extracted honey, nearly all lacked sufficient stores for winter.

Believing that cane-sugar is a better having no trouble in disposing of my honey at 7 to 8 cents per pound, and being able to manufacture pure canesugar syrup at a little less than those figures, I ted nearly every colony from 5 to 15 pounds of the syrup, which they added to the stores which they already possessed.

I had no fears of any bee-bread that the combs might contain, as long as the temperature was kept above that point which forces the bees to exertion, in order to be comfortable; and that temperature I determined to maintain.

I had no bee-ccllar there, but a house-apiary 12x48 feet, and 7 feet high; the ceiling covered with saw-dust, and the walls filled with the come I this build bui

also a filled wall containing tightfitting doors.

As I live 6 miles from Glenwood I doubted my ability of controlling the temperature of the bee-house. I will describe how I have done it so far. The walls are rather thin, and having no heat to depend upon except that produced by the bees (which is slight when a quiet, healthful condition is maintained), I decided to test the ventilation guestion, and depend upon tightly-closing the room for the maintenance of a temperature no less than 45° during our coldest weather. That temperature has been main-tained during the protracted cold, and although at one time this room was for over three weeks closed as tightly as good carpenter-work and packing could make it, yet (notwithstanding the large number of bees for the size of the room) no uneasiness nor signs of disease have resulted. The bees always have been very quiet.

Although we have had some severe weather, there has been several protracted warm periods during the present winter, and notwithstanding this room has been tightly closed, the temperature has not been above 50°. and the bees have not been uneasy. The entrances to the hives are wide open, but the tops are tightly sealed. I doubt if this same regularity in temperature and quietude would have existed had there been no sugar syrup in the hives (all other conditions being the same.) with natural stores in its place. Bees seem to maintain greater quietude when their stores are of sugar syrup

I have 300 colonies here in two cellars, and during all the cold periods these cellars have been "hermetically sealed," as it were, and the same apparently healthy condition exists. The few colonies that I have examined are in the much desired "quiescent" state, which Mr. Clarke has chosen to call "hibernation."

Here my experiments are conducted differently. I have quite a number of colonies all wintering upon canesugar syrup with no honey or bee-bread in the hives; many more are on all natural stores; besides other experiments that I am making.

While I believe that all my colonies will winter well, past experience compels the belief that those consuming nothing but sugar syrup will void nothing on their first flight, while those consuming honey will void a thin, yellow excrement which the microscope will show to be composed of pollen-grains and water. As I have previously stated, I believe that bees never touch bee-bread when the temperature is kept above that point which induces exertion ; but that they do of necessity consume pollen if such pollen is floating in the honey which they eat. This much I know: Bees may pass a 5 months' confinement on sugar stores only, and accumulate no fecal matter. I have never seen my bees fly, even after two months confinement, upon natural stores, without discharging more or less of these accumulations, the solid substance of which I believe always to be composed of pollen-grains.

Whether or not all our minor conclusions are correct, I am confident that all may now unitedly say that "our great enemy is conquered, and the wintering problem is practically solved." No doubt we have yet more to learn regarding some of the less important laws—a knowledge of which will aid us in accomplishing our purpose in the simplest and cheapest manner—but [ no longer doubt that provided for the simplest and doubt that practical success in wintering bees depends upon proper food and temperature.

Dowagiac, 9 Mich., Feb. 15, 1886.

## Oneida County, N. Y., Convention.

A meeting of the Oneida County, N. Y., Bee-Keepers' Association was held at Rome, N. Y., on Feb. 24, 1886. The attendance was large. Secretary O. J. Evans being absent, W. E. Cherk of Origherry was any W. E. Clark, of Oriskany, was appointed Secretary protem.

Chairman Bacon said that bee-culture was quite a business. It had become an element in the business interests of the country. He said that he had intended preparing a paper on marketing honey, but as that ques-tion was made prominent before the late State Convention at Rochester, and as the chairman of that conven-tion was present, he could present the matter much better. He then called on W. E. Clark, of Oriskany.

Mr. Clark said that the subject of marketing honey was the most promi-nent before the convention. It had been decided to send a committee-man to Thurber's, in New York, where the resources for selling honey are five times as large as any other place in the United States, and see if they would not put a practical boneyman at the head of their department. Honey must be produced so as to be sold cheaper in order that it may compete with other sweets. It should compete with cane-sugar, that it may be more extensively used for table There seems to be an impurposes. pression that old women, broken down men, and those who have been unsuccessful in almost every other business can conduct a bee-business. This is all wrong. It is hard work to do it properly, and requires strong men. There are too many middle-men between the producer and the consumer. He had known honey to be bought at 11 cents and sold as high as 30 cents per pound. We must get rid of these middle parties, then honey will be cheaper and more generally used.

At this point Secretary Evans arrived and read the proceedings of the last meeting.

Mr. Bacon said that when he stated at the last meeting that his bees only consumed from 5 to 10 pounds of honey in wintering, it was only for the time that they were shut in about 120 days.

M. D. Parkhurst, of Boonville, said that he kept his bees in the cellar with the temperature at about 35°. and that they consumed from 18 to 24 The committee appointed at the pounds of honey. If it was warmer last meeting to confer with the and that they consumed from 18 to 24

they would be livelier and consume more.

Mr. Clark continued: It is a good idea to dispose of honey at home, by peddling it around. When people come to your place try and sell them some honey. Why, some time ago the tax-gatherer came to my house, and before he went away I had a 10pound pail of honey sold to him. Honey is at present a drug in the market, on account of hard times. In selling it at home you get accustomed to using it. There is one thing that is injuring the business, and particularly prices, and that is the custom of farmers who produce a little honey, coming in and exchanging it for gro-ceries. They do not get what it is worth, but they establish a price and then it is hard for us to sell our article for its value.

Mr. Smith, of Chittenango, urged the producers to stand by each other and keep prices where they belong.

At the afternoon session the question of frames was taken up. Mr. Smith said that no one could tell what frame was the best to use. Incality is a question to be considered in this connection. He uses a 9x14-inch frame. The question is a broad one, and will bear much study.

Secretary Evans said that the size of the frame for extracting should be in accordance with the size of the sections. We should avoid extremes in the matter of frames.

W. E. Clark said he did not believe that they could agree upon any one size of frame.

The question of comb foundation was brought up and discussed.

Secretary Jones said that too heavy foundation should not be used, as the bees cannot draw it out properly.

Mr. Clark said that sometimes foundation is put in too early. If the foundation is heavy it will not be drawn out. He recommended the

Markin Goundation. Mr. Warriner said that he had found that the thinner he could use the foundation and retain the sidewalls the better.

Mr. Smith said that a yellow foundation could be bleached white in the sun, but it became hardened at the same time.

Mr. Clark said that wax bleached was hard and not satisfactory. Use yellow wax in preference to bleached.

Mr. Smith read an interesting essay on the production of comb honey.

President Bacon suggested that one day was too short a time in which to transact the necessary business, subsequent meetings be held for two days.

It was decided that meetings be held semi-annually for two days each, and that the next meeting be held in Utica, N. Y.; all subsequent meet-ings alternately in Rome and Utica.

A committee of three was appointed to answer such questions at the next meeting that may be sub-mitted in the meantime. The com-mittee is Messrs. Clark, of Oriskany, Evans, of Camroden, and Smith, of Chittenago.

Oneida County Agricultural Society in reference to making exhibits of honey at the County Fair, asked for an extension of time, which was granted.

For the American Bee Journal.

## Feeding Sngar---Reversible Hives.

### W. Z. HUTCHINSON.

First allow me to thank Mr. Dadant for his frankness as shown on page 75; next, please allow me to explain that those who force the honey into the surplus receptacles by " contracting, reversing, or by using small hives," have no intention of feeding back again to the bees the honey that has been forced into the surplus receptacles, but expect to replace it with the cheaper and safer food, canesugar; or, if they find that some par-ticular kind of honey is safe for winter stores, the "contracting, re-versing, and small hive" method will enable them to choose this par-ticular kind of stores for winter. This method does not compel us to feed, but enables us to do so if we wish without first extracting the honey from the brood-combs.

Considerable is now being said against the use of sugar for winter stores. The low price of honey has been attributed to this practice. Some have accused it of being the founda-tion upon which has been built the sensational stories in regard to adulteration; and those who have prac-ticed it have been accused of building up the sugar trade at the expense of the honey market. When our commission merchants quote low prices, I believe they never mention this as a reason-it is always "owing to several carload lots from California." " or something of this kind that is given as a reason for low prices. If no as a reason for low prices. If no more sugar should be used for winter stores, or fed for any purpose, for 20 years, these same stories would live and be repeated. The truth of the matter is, that when small broodnests are used and the bees given but little more honey than enough to last them until honey can be gathered in the spring, there will be practically none of it left by the time of the com-mencement of the white clover harvest, which is about the first from which we secure a surplus.

The talk about "building up the sugar market," even if there were any objection to so doing, is all "bosh." The sugar fed to bees is not even a drop in the bucket so far as the sugar market is concerned. That the practice puts more honey upon the market is a more reasonable idea, but it falls upon a deaf ear when told to the man who would have no honey to sell at any price unless he winters his bees; and can only succeed in so doing by feeding them sugar for winter stores. We may argue as long as we please, and bring forth the best of arguments, yet our arguments will be useless, if the bee-keepers who now lose their bees during winter learn that they can winter them success-fully by substituting sugar for natural or did not use a two-story brood-when such men as Wm. F. Clarke

stores; and when they come to this decision they will welcome the hive and system that will enable them to bring out the bees in the fall in nearly a starvation condition, and it will only be necessary to put on the feed-ers and feed, the work being done in a few hours.

THE NEW REVERSIBLE HIVE.

I would like to say a few words in reply to Mr. Alves' questions concern-ing the new reversible hive, on page 72:

1. There is no more machinery about the Heddon hive than about an ordinary one, except the thumb-screws, and these are fast and seldom nsed.

2. Yes, it does require exact work in manufacturing, but this is made up many, many times when we once get them right and begin manipulating them.

3. Four dollars is only the price of a single sample hive; they can, of course, be made much cheaper in large quantities. If a high priced implement enables us to dispense with labor to a sufficient extent, it is profitable.

4. Mr. Heddon's principle can be used with two shallow Langstroth hives, and the advantage of interchangeableness will be secured, but the advantage of reversing each section is lost; as well as some of the advantages of manipulating hives instead of frames.

Criticisms from Mr. Alves are always valuable, because he appears fair, and willing to accept the truth. Mr. Demaree, in his article on page 102, claims to have used sectional

brood-chambers for some time past; and as proof, refers to his articles in several defunct bee-papers, and also in the AMERICAN BEE JOURNAL. With the exception of the AMERICAN BEE JOURNAL he mentions no pages. Will Mr. D. please state the pages and volumes where he has mentioned using a hive the brood-nest of which is, or can he, divided into sections longitudinally; or, better still, quote some of the passages bearing upon the subject, as many of us may not have files of the papers mentioned. The article on pages 370 and 371 of the AMERICAN BEE JOURNAL, Vol. XIX, shows conclusively that Mr. Demaree used the ordinary Lang-stroth frame in the brood-chamber. and that the shallow combs were used in the supers only for securing ex-tracted honey. Mr. Heddon does not claim to have originated the idea of "tiering-up" hives, but of "tiering-up". here and although the security of the se up" brood-chambers; and although he has no patent upon this, he does claim that, whether "prior" as an inventor of this process of not, he was original in its discovery and use, and the first to make it public, clothed in practical shape, and presented as a system of management, after testing and tinding it good. Mr. D. may have accidentally gotten his queen and brood into one of these shallow supers, or he may have put them there purposely, and is now wintering them there, but it amounts to nothing; as everybody knows that whoever used

chamber, Mr. Heddon was the first to Tt. place the idea before the public. is now a year since I knew of Mr. Heddon's new hive, and I have used them one season; all this time I have watched closely to see if the same idea was advanced by any one else. I

Mea was advanced by any one else. I have watched in vain. Mr. D. says: "When we hive a swarm in the lower story or brood-department (?) (italics are mine) of a hive, we call it a 'hive;' when we add another story to it to give the hees more room, we still call it a hive, because it is a bive in sectional parts because it is a hive in sectional parts. Now the mere difference in the depth of the sectional parts can never change an old idea into a new one." Why does Mr. D. apply the term brood-chamber to the lower story? Because it is the brood-chamber, and the upper story is not added for brood but for surplus; and the idea of making this brood-chamber in longitudinally sectional parts that can be interchanged at will, is original with Mr. Heddon, and was first published by him.

Mr. Demaree attempts to defame the hive by saying the case is simply a shallow box, etc. In so doing he inadvertently praises it. Its "sim-plicity" is really wonderful, consid-ering how much can be done with it. Mr. Alves is respectfully referred, for an answer to his first query to para-graph 5 of Mr. Demaree's article.

Mr. Demaree further says : "It is proper to say that the frames are adjusted in the case, so as to leave a shallow bee-space both at the top and bottom of them, and the case will work either side up or down ;" and he dismisses this grandest of all the grand features of the hive with, "comment is unnecessary." Perhaps he meant that it would be unwise, for there can be no imaginary question as to the newness of thus arranging trames so as to have the bee-space on either side, or divided between both at will.

When reading the paragraph in reand to the use of thumb-screws, which ends with, "No device is more commonly used than a 'set-screw," I could not help exclaiming, "Why didn't he say, Mr. Heddon's hive is made of wood, and no material is more common out of which to make hives ?"

Please allow me to relate an incident: Last week, at Adrian, Mich., I had the unexpected pleasure of meeting Dr. A. B. Mason, of Toledo, O. Not having read "Success in Bee-Culture," he did not exactly understand how Mr. 1leddon's hive was made, and questioned me concerning it. As one feature after another was explained, his genial face lighted up explained, his gemal face lighted up as a face will only when its owner is bearing pleasant news; and his tongue belied not his face when it said: "Is that so?" "That's it, that's it." "Well, well !" or similar expressions. It was new to the Doc-tor. Now, when a man like Dr. Mason, who reads the bee-papers, attends conventions and fairs, and is a special well-paced bee-keeper a practical, well-posted bee-keeper, learns of the features of this hive

pronounce it as "revolutionizing," Thos. G. Newman as " new and original;" and when A. I. Root and D. A. Jones consider it patentable, it ill becomes an "independent" writer to apply such terms as "old idea," "common property," "old acquaint-

ance,"etc. Father Langstroth gave us the movable frame, and Mr. Heddon now gives us the movable hive, i. e., by means of his hive and system of management, we can run our apiaries almost entirely by manipulating hives instead of frames; it is a grand step, and its progress over the land will not be stayed by a few unproven assertions.

Rogersville, & Mich.

### For the American Bee Journal. Selling Extracted Honey.

### M. M. BALDRIDGE.

The editor, knowing me to have had considerable experience for a term of years in handling extracted honey as a specialty, and successfully, desires me to answer the following queries :

"Will some one having experience please answer the following questions through the AMERICAN BEE JOUR-MAL? 1. Do those who practice sell-ing extracted honey in small cans still find a growing demand for it in erly sold it? 2. What size packages do they use?—North Freedom, Wis."

1. My experience in selling extracted honey is directly to consumers, and not, under any circumstances, to retailers. When I supply a town, village or city, I visit every family in it with a true sample of the honey that I propose to deliver, for the purpose of securing orders for the quantity desired. In no case do I the quantity desired. In no case do 1 take an order for less than 5 poinds, nor more than 20 pounds. No family is omitted—no matter how poor nor how rich, nor whether they be white or black—and the price to all is the same under all circumstances. When the orders are secured I then deliver the honey and collect the pay-unless I agree, when the order is taken, to wait for it until a specified date.

As a rule, the first time a town is properly canvassed more honey will be taken than at any one time after-ward, for the simple reasons that many will buy who are not lovers of honey, but wish to have some in the house for sickness, or for the novelty of it, or perhaps because their neighgood the quality of your honey may be, there is in every town plenty of people who do not relish the article, and never will. After supplying a town the second time, the sale of honey from year to year will be quite uniform, provided the same is "gilt-edged." I have now in mind one city that I have supplied regularly for the past twelve years, and my sales the past year have been as good and as satisfactory as during any one of those years. The great secret of my success

perhaps is that I never sell a poor quality of honey.

2. I use only one size of package, and that is a common 2-quart tin-pail with a loose cover, which holds 5 pounds of thick liquid honey, net weight. When 1 deliver the honey the consumer can keep the pail or empty it as may be desired. If the pails are emptied and returned to me at the time of delivery, I deduct 10 cents for each pail. I find that most of my customers prefer to empty the pails and keep the honey in glass fruit-jars.

St. Charles, & Ills.

### For the American Bee Journal

### Bees as Fertilizers of Flowers.

### J. F. LATHAM.

On page 6, Mr. G. M. Doolittle quotes two paragraphs from a paper which he "chanced to pick up," and makes the ideas embodied therein the subjects for the comments contained in his article.

As Mr. D's quotations are too cramped to be illustrative of the whole of the article from which the quota-tions were made, it seems not im-proper, for the "first author" quoted. to direct his attention to pages 260 and 261 of Vol. XIX of the AMERICAN BEE JOURNAL, where he will find the subject more broadly treated. If I rightly construe the gist of Mr. D's critique, a fair digest of the whole of the article from which his quota-tion was copied, would illuminate any doubt, pro or con, having direct reference to the actual agencies which aid the fegundation of the melliferous flora, or flowers which are not nectar-producing; and thus relieve an apparent misapprehension. The second quotation in Mr. D's article (for which I have no further use), was quoted "second hand." the explana-tory purport of which I, like Mr. Doo-little or was inclined to have little, am not inclined to endorse. That the flowers of many species of the vegetable world do not require insect aid in the process of fecundation is evident; and that any species of the melliferous flora is absolutely dependent upon the insect tribes for their fecundation, I am not prepared to accept as an axiom from which deductions may be drawn, that harmonize with the principles of sympathetic reproduction as nnfolded in cosmogony.

At the commencement of the first paragraph on page 7. Mr. Doolittle records another slight mistake in asserting "that he (myself) represents that both the breeze and the bees may that both the breeze and the bees may be needed to fertilize the same and all plants." Such is not the sense of the quotation. The pbrase, "may be needed." is not in the sentence quoted, neither does it embody the idea that all or even any flower actually demands the aid of the breeze or insects to complete the de-signs of pature in its generative signs of nature in its cosmic capacity, so to speak. If my authority, and my deducements therefrom are corglobe many epochs prior to the devel- valuable. Here I wish to say that no

opment of an animal organism capable of winging its way from "flower to flower," and accelerating the in-crease of vegetation by insect "ferti-lization."

According to Dr. Hitchcock's ar-rangement of the different animal and vegetable species, in the order of their development, geologically, flowering plants existed on the land dur-ing the latter part of the Salurian and Cambrian periods, when no ani-mal life except that inhabiting the water existed (or, in fact, could ex-ist); while the sub-order, hymenop-tera, to which the honey-bee belongs, did not make their appearance until the latter part of the Tertiary period. Such being the premises, it is evident that the luxurious growth of flowerdecayed during the limitless evolu-tionary epochs intervening the two periods mentioned, especially during the Carboniferous period, must have depended upon other agencies than those of the honey-bee, or other nectar-feeding insects, for their "fer-tilization;" as the earlier insects seem to have been allied to the Aphis family.

That the flowering plants, which evolved ther organism contemporary with that of the nectar-subsisting insects are dependent upon those insects, to a greater or less degree, through sympathetic sources, for their perfect fecundation, does not appear improbable; in fact, the influences pertaining to the development of cosmic matter in all its organic forms, tend to support such a theory, and confirm the idea of nature's "prime method" of distributing the fecundating element.

As Mr. Doolittle says in his con-cluding paragraph, "Let us have the scientific" part, from those qualified to impart it.

Cumberland, 9 Maine.

### For the American Bee Journal

Sectional Brood-Chamber Hives.

### DR. G. L. TINKER.

The extensive discussion during the past year in the bee-papers, on the methods and the advantages of reversing brood-combs, as well as the result of the trials, has proved that there is no profit in reversing single combs, because of the great labor required, and that there is no advantage to be gained from the practice. Like many discussions on other subjects, the truth is made to appear, although, as in this case, the truth that we had sought—the germ of wheat sifted from all the chaff—is quite unlike what we

had been seeking or had anticipated. It is no new idea, by any means, that the getting of the brood close up to the sections in working for comb honey is a measure of great value. As the outcome of all the invention and discussion we have discovered perhaps all of the measures by which brood can be brought near the sec-tions, so that we can now point out

one man is entitled to all the credit of the discoveries made, because all or nearly all bee-keepers have had a part in making them, and have prepared the fraternity at large for an innovation in our methods, that withmind would have been impossible. The credit, I am bold to assert, is due rather to the great fraternity of beekeepers who, through their united labors, bave not only made discovery labors, bave not only made discovery possible, but now make the introduc-tion of the new appliances and methods certain. As the matter stands, one bee-keeper is as much entitled to the benefits as another, and I trust and believe that all will bed when it is this light and besitate look upon it in this light, and hesitate not by virtue of a just right to adopt the improved methods as soon as convenience will warrant, and the revotion in the construction of broodchambers and in our methods of management will demand.

But first, what is the most practical and advantageous method of disposing the brood near the sections, at will? Beyond question it is the proper management of the shallow sectional brood-chamber! Has it any disadvantages? I assert fear-lessly that it has not, neither in wintering, the laying of the queen, or in the manipulation of hives or combs!

Until about 5 years ago, a hive, the brood-chamber of which was in three brood-chamber of which was in three shallow sections, each  $5\frac{1}{4}$  inches deep by  $12\times16$  inches inside, has been in this town and contained bees uninter-ruptedly for 30 years. The colony in its thin walls of walnut had resisted the cold and the buffeting of storms for 20 winters and it of heat one for 30 winters, and it at last suc-cumbed to the depredation of robber rotten corners. It had always done well, was generally on hand with a rousing swarm in season, and besides stored a liberal surplus for its owner. When Father Langstroth, a few years since, recommended a thin walled hive for ont-door wintering, I was quickly reminded of this old hive. (The pannels in the sides of each of the cases were not over 14-inch thick.) That it had not been manipulated on the modern plan of tiering-up the cases and the placing of the brood next to the super, was no fault of the bive. The combs were attached to top-bars in each case on the Dzierzon plan.

### REVERSING HIVES.

In a shallow sectional brood-chamber I believe that there is no advantage whatever to be derived from reversing its sectional parts. The plac-ing of the brood next the super, and any honey that may be in the upper case below the brood, will accomplish all that can be done. I shall therefore have no use for a reversible hive. Again.as we shall not have occasion to handle the frames very much, but the sectional parts instead, it will not be greatly to our advantage to have the frames as readily movable as are Langstroth frames. On this account a very simple case is all that is necessary to hold the frames-a case without ornamentation, clamps, screens, or anything of the kind. Neither do

we want a complicated bottom-board. but all the parts of a practical bive of this nature should be, and will be made only of a few parts, and all very plain and easy of construction. The frames can be supported in the sectional case on strips of sheet-iron cut 5-16 of an incluide and as long as the case is wide inside, the strips to be inserted in thin saw-cuts made 5-16 of an inch from the inside lower edges of the ends of the case and to enter the wood only 3-16 of an inch. This construction will give a proper bee-space under the frames which should extend to the top of the case. The width of the end-pieces of the frames should be  $1\frac{3}{6}$  inches, and the thick-ness  $\frac{1}{4}$  of an inch, making a closedend frame to rest on the sheet-iron strips. The width of the top and bottom bars should be the same, and may be 34x14 inch in thickness.

Here let me call the attention of bee-keepers to the comparative cheapness of these frames, if dovetailed at the corners, to those in common use. They need no nails, and a set of 14 for one hive can be put together in a few minutes; and as they can easily made with great accuracy, they will always fit nicely in the cases. The always fit nicely in the cases. length of the frame might well correspond with the 41/4 x41/4 sections now so popular. The outside would there-fore be 17 inches long, and if made just 5 inches deep, it will just take one-half of a sheet of foundation cut the regular size for the Langstroth frame. The frames can be taken out of the cases very readily, since, being very shallow, the cases can be set on end and the frames pushed through, one or more at a time. Hence, the worthlessness of all clamps to hold the frames will be apparent.

Again, if we are to handle hives rather than frames, I can see no advantage in having so many frames in each sectional case. I think that we will find 7 enough, though many may prefer S or 9 frames to the case. It will be then very light to handle, but to further lighten it I would make the sides only % of an inch thick and the euds 5%, and make the usual handholes in the ends or nail cleats across the ends a little above the middle

line to handle them by. The bottom-board I would make out of  $\frac{1}{2}$ -inch stuff, with a cleat of 6inch stuff across each end, the rear piece to be 2 inches wide and the tront piece 5 inches; the board to be cut  $1\frac{1}{6}$  inches shorter than the hive is long, and the wide cleat nailed across 2 inches from the end. This would give an entrance of ½ inch across the front. If blocks are nailed on each side to go under the front corners of the hive, ordinary entrance blocks can then be used.

Sectional hives containing only 7 or 8 frames in each section will be so light that we will find it an easy task to carry them back and forth from cellars in wintering, where the bees can be placed under our full control and wintered in a scientific manner, which we shall never be able to do in outdoor wintering where we cannot regulate the temperature at will. Only direct to this office. It will pay any o one of the sectional cases, well filled, devote a few hours, to get subscribers.

will be necessary for each colony for the winter.

To operate a sectional hive of shallow frames successfully, we shall need a honey-board with strips of per-forated-zinc set in thin saw-cuts made in the edges of the slats composing the board. This construction and use of perforated-zinc is my invention, but it is free to all to use. As any kind of a sectional-case or super can be adjusted to this hive every bee-keeper will be expected to use his favorite.

The capacity of two of the sectional brood-chambers will about equal the 8-frame Langstroth hive, but many would prefer to use three of the parts in building up colonies for the honey harvest. The frames alone are made to reverse, but we will need to reverse them but once, and that simply to get the frames filled out with comb plump to the sides all around. Ordinary 6-inch boards can be split and dressed to % of an inch for the sides of the cases, and we shall have no trouble to get whole boards wide enough for the bottoms and covers and yet there will be ample room for top-storing on the hive. For a very cheap hive We will never get a cheaper, and a better hive for large results may not be possible. It will hardly be necessary to add in conclusion that this hive is not patented or patentable except in one or two features, which are my inventions, and are hereby freely given to the public.

New Philadelphia, o+ O., Feb. 7,1886.

### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

### Local Convention Directory.

1886. Time and place of Meeting. Mar. 20.—Patsalaga, at Arcadia, Ala. M. G. Rushto, Sec., Raif Branch, Ala.

Apr. 10.—Union, at Dexter, lowa. M. E. Darby, Sec., Dexter. lowa.

Apr. 27.—Des Moines County, at Burlington, Iowa. Jno. Nau, Sec., Middletown, Iowa.

Apr. 29, 30.-Western, at Kausas City, Mo. P. Baldwin, Sec., Independence, Mo.

May 5, 6.—Texas State, at McKinney, Tex. B. F. Carroll, Sec., Dresden, Tex.

Oct. 19, 20.—Illinois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

177 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

**Good Prospect for Honey**.—8—Jno. C. Gilliland, (7-16), Bloomfield, 9 Ind., on Feb. 24, 1886, says :

My bees have wintered well, only one colony lost. To-day they carried in pollen lively. There has been very little loss of bees in this county this winter, and the prospect is good for the honey yield next season.

Bees Doing Well.-L. Highbarger, Adeline, & Ills., on March 2, 1886, writes:

Bees are doing much better than they did at this time last year. So far 1 have been unable to discover any signs of diarrhea; but at this time last year they were badly diseased. The reason for this is that they have a better quality of honey to winter on. Whenever our bees have honey-dew for winter stores we can expect to meet with losses.

Feeding Sugar Syrup.-W. J. Dawson, Dickson's X Roads, & La., asks this question :

Why do bee-keepers use sugar for feeding when honey is quoted at  $3\frac{1}{2}$  to 4 cents per pound ?

[The only reason which can be given, is that some prefer it for winter use, even if it is dearer.—ED.]

Bees Wintering Well.-27-F. A. Snell, (70-100), Milledgeville,  $\infty$  Ills., on Feb. 25, 1886, says:

1 commenced on June 1, 1885, with 70 colonies of Italian bees; during June 1 sold 5 colonies. 1 secured 4,000 pounds of surplus honey. On Nov. 18, 1885, I put 100 colonies into winter quarters in good condition. Late in May, 1885, I reported 105 colonies, but by June 1 I had disposed of the 35 colonies, thus leaving me 70 with which to begin the season for surplus. About one-tenth of my bees were worked for queen-rearing. My bees are wintering well so far. **Bees Working on the Elms.**—B. F. Carroll, Dresden, & Texas, on Feb. 25, 1886, writes :

The bees began work on the elm. bloom on Feb. 8, and 10 days since they have gathered anice lot of pollen and honey. The weather is very fine for bees and farmers, and both are busy. Corn planting is going on briskly. Bees have wintered well after our first zero weather ever felt here. I hope this may he a prosperous year to all apiarists.

How Larval Bees Eat. – B. J. Bailie, Sarnia, Canada, savs :

I understand that Mr. J. Rutherford, of Scranton, Pa., claims to have discovered that larval bees live by *absorption* (osmotic action), and that they are not fed as our bee-books would have us to understand. I wish to know who was the first to discover this fact.

[This is a well known fact. It is not confined to larval bees, but is also true of many maggots, and nearly all entozoa. The tape-worms have no mouth, nor alimentary canal, and so of course they have no other way to secure nourishment. When insects or worms are bathed in liquid aliment, this is the common or usual method of securing the nutritious material. Some of our worst insect pests live wholly by imbibition, or by receiving food through osmosis. The Hessian-fly maggot is an example. It is impossible to say who was the first to discover this fact.-A. J. COOK.]

Bees in the Cellar.—Noah Field, Spencer, Q N. Y., on March 1, 1886, says:

We are having a cold spell now. My bees are in the cellar, and they appear to be doing well at present. I have one most excellent colony that has not had a dozen dead bees in its hive this winter, and I think that it has over 100 pounds of honey in the hive. I suppose if some bee-men had it they would make 4 or 5 colonies out of it. I think that the BEE JOURNAL contains so many good articles. I can hardly wait for each number to reach me.

Wintering Bees-Old Foundation. -J. M. A. Miller, Galva, o Ills., on Feb. 25, 1886, writes :

I have just examined my 28 colonies of bees that are in the cellar, and I find them seemingly to be in a state of quietude that indicates comfort. They were put into the cellar about Nov. 25, the hives being placed on 2x4 inch scantling set edgewise upon blocks 8 inches thick, with the entrances all open, and no extra preparation of chaff, quilts, or blocks, etc., but they are simply in a dry cellar with some cloths over them that were on during the summer, and the covers

are on the same as in summer. think that I never have seen bees in better condition, not a pint of dead bees being on the cellar bottom. Why is it that if bees do so much better on the summer stands in chaff hives, we so often see this expression, or a sim-ilar one? "My bees are on the sum-mer stands in chaff hives, except a few week ones that I put in the cellar." If the chaff hive is so nice, and so much better than the cellar, why not put the few weak ones on the summer stands, and the strong ones in the cellar? I sell all of my honey in my home market, and I have no trouble in selling it. My trouble has been for two years past to produce enough to supply the demand. About 80 per cent. of all the bees in this vicinity died last spring during the cold. May storms. I lost 35 colonies. There was no brood in the hives, and the old bees died. I have a quantity of foundation that is two years old. Will it pay to have it worked over? or will it do to use it as it is? It seems to it do to use it as it is? me that the bees would take to it better if it was fresh.

[You can freshen the foundation by dipping it in warm water just before using it.—ED.]

No Signs of Disease. — Gotlieb Hoffman, Symerton, & Ills., on Feb. 27, 1886, says :

My bees are thus far wintering nicely, both those in the cellar and those on the summer stands packed with chaff. They had a fine flight a few days ago, and there is no sign of disease.

**Reversible Frames**,—B. Losee, Cobourg, Ont., on Feb. 22, 1886, says :

Mr. T. C. Davies, on page 107, says that he is interested in a reversibleframe bee-hive. I have used mine during the last 15 years, being hollow walled, formed by wide standingframes, half-inch rods, top and bottom reversible, with perforated metal divisions for producing honey in sections, arranged to be moved without disturbing the sections in the crates above.

Bees Packed in Sawdust.-J. R. Nichols, Danville,⊙ Ind., on March 2, 1886, says :

My 56 colonies of bees are wintering nicely, one-half of them being in the cellar, and the balance packed in sawdust on the summer stands. It looks now as though they would get through the winter without the loss of a single colony.

Bees in Good Condition.—F. M. Taintor, Coleraine,+o Mass., on March 1, 1886, says :

Bees in this locality appear to be wintering finely. Mine were never in better condition than at present. I placed them in the cellar on Nov. 16, 1885, and since then they have been very quiet, with the thermometer at 45°. The weather this winter has been very favorable for bees out-of-doors. We have had only 2 weeks of extreme cold weather this winter. I look forward with pleasure to the time I place them on the summer stands. I look forward with pleasure to Friday when I always get the AMERICAN BEE JOURNAL. Of the several bee-papers printed, the old "American" stands pre-eminently at the head in my oninion and now as the head, in my opinion, and now as the price has been reduced to one dollar a year, no bee-keeper can afford to do without it.

Managing Prime Swarms.-O. P. Miner, Taylor Centre, ON. Y., on Feb. 27, 1886, asks the following :

Would the following be a good way to manage a prime swarm in a Langstroth hive, for comb honey? Hive them on 7 brood-frames and 2 wide frames filled with sections—one on each side of the brood-nest; when sections are nearly filled, place them on top of the brood with others and replace them with brood-frames. In replacing should they be placed in the spaces made vacant by the wide frames, or spread the frames and place them in the centre of the brood ?

[Yes; that plan will work nicely. Place an empty brood-frame between two full ones; but it would be very advantageous to fill the empty frames with comb foundation.-ED.]

Feeding Bees in the Cellar.-A. B. Howe, Council Bluffs, 9 Iowa, on Feb. 26, 1886, writes:

Bees are wintering exceedingly well about 20 colonies nicely put away in the cellar, and about as many more on the summer stands in chaff hives. I examined all of them a day or two ago, and found all in very fine condi-I have commenced feeding tion. those in the cellar to get early brood. I feed about two spoonfuls of ex-tracted honey or sugar syrup at the flated none overy evening. In a very few days the bees can be trained to come down to the entrance and take the honey. We have had very fine weather for bees this week; they could have a flight almost every day. I look for a good honey crop in this locality this year.

### Convention Notices.

The Upion Bee-Keepers' Association of Western Iowa will meet to Dexter, Iowa, on April 10, 1886, at 10 a.m. M. E. DARNY, Sec.

The semi-annual meeting of the Western Bee-Keepers' Association will be held in Kansas City, Mo., on Apr. 29 and 30, 1886. It is desired that this meeting shall be better than any of its predecessors. Essays will be read on the leading subjects io bee-culture, which will be announced as soon as arrangements are completed. Let all who have bees, queens, fatures, etc., bring them if possible. Due notice will be given in regard to a hall. P. BALDWIN, Sec.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Mar. S, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.—Sales have been quite good this month for best grades of comb honey, some bringing 16c. per pound when in pertect order. There is a light supply here, and now is a favorable time to for-ward abipments. Extracted honey brings 6@8c. BEESWAX.—250/26c, per lb. R. A. BURNETT, 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY. - We note an improvement of sales of honey the past week, but prices continue to rule ow, we quote as follows: Fancy white comb in 1-lb, paper cartons, 13@14c,; the same in 1-lb, glassed or nuglassed sections, 12@18c, the same in glassed sections, 9@10½c, and fair to good in glassed 3e-lbs, 8@0. Fancy bickwheat honey io 1-lb, unglassed sections, 10c.; the same in 2-lb, sections, unsased, 8@0. Extracted, white,6%@7%c; buckwheat, 5@6c. BEFEW AX.-27@28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

#### ST. LOUIS.

HONEY.-The market is quiet and the demand light just now. We quote prices as follows:-Choice comb honey, 10@12c. Extracted, in bar-rels, 44%5c. Extra fancy of bright color and in No. 1 prekages, 14 advance on above prices. BEESWAX.--Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEX.- There is no speculation whatever in the market, and the demand is slow for extracted honey from manufacturers, while it is fair for honey in glass jars, for table use. Demand for comb honey is slow and the market is well supplied with all kinds. Extracted honey brings 4 ke.c., and choice comb honey brings 12@15c. in a jobbing way. BEESWAX.- The home demand is good, while arrivals are slow. We pay 25@27c. for good yellow to choice.

C. F. MUTH & SON, Freeman & Central Ave.

#### CLEVELAND.

HONEY.—There is a great improvement in the demand of hest 1-b. sections since our lest report, and all receipts are finding ready sale at 14 centa, with occasional sale of single crates at 15 cents. Two-iba. are neglected, very little wanted at 13 cta. Old honey, 10@11 cts. and slow. Extracted, 7@8c. BEESWAX.—Scarce at 25c. A. C. KENDEL, 115 Ontario Street.

#### KANSAS CITY.

HONEY.—Sales are improving and we have a good trade in comb, although prices are not as frm, owing to good prospects in California for a large crop having reduced their prices about 2 cts. We quote as follows: Choice combin 1-b. sections, 16c; fair to dark, 12@14c; in 2-th. sections, 12@14 ceots. Extracted is duil and alow. Dark brings 3 1-2 to 4c; white, 6@7c. BEESWAX.—23c. CLEMONS, CLOON & Co., cor, 4th & Walbut.

### BOSTON.

HONEY.—The sale for honey for the past month has been as light as we have ever known it, and prices are weak. One-pound, white clover, 13@15c; 2-pound sections, 11@13c. Extracted, 6@8c. BEESWAX.—30 cls, per lb. BLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

HONEY.—The market is very dull. We quote as follows: White and extra white comb, 11%@13c.; dark comb, 85%@6c. White extracted, 54@55c.; amber, 464%c.; dark and candied, 33%e4c. BEESWAX.—Quotable at 23@25c., wholesale. O. B. SMITH & Co., 423 Front Street.

#### DETROIT.

HONEY.—The market is very dull. Best white in 1-ib. sections, 14c. There is considerable in commission houses and prices are liable to be lower.

wer. BEESWAX.—It is in good demand at 25@28c. M. H. HUNT., Bell Branch, Mich.

### -----Convention Notice.

287 The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886.

### J. M. HAMBAUGH, Sec.

Keepers' Association will be held at Arcadia, Ala., on March 20, 1886. M. G. RUSHTON, Sec.

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

> ALFRED H. NEWMAN. BUSINESS MANAGER.

# Special Notices.

To Correspondents. – It would save ns much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office. County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Perforated-Zinc.-We have laid in a stock of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x5 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth bive-194x1442-Price 25 cents each.

Beeswax Wanted .- We are now paying Beeswax Wanted.-we are now paying 24 cents per ponnd for good, average, yellow Beeswax, delivered here. Cash on arrival. Shipments are solicited. The name of the shipper should be put on every package to prevent mistakes.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it.

Wire Nails have advanced in price, as will be seen by quotations on page 159, last column.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

To any One sending us one new sub-scriber with their own renewal (with \$2.00), we will present a copy of the new "Con-vention History of America."

Are you Entitled to a pension? You may be and may not know it. If you ex-amine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOUNNAL for 1886 and the Guide Book will both be sent for \$1.30.

**Preserve your papers** for reference. If you have no **BINDER** we will mail you one for 75 cents, or you can have one FREE if you will send not 4 new yearly subscrip-tions for the BEE JOURNAL.

Golden Hules for successful advertis-ing, are these : I. Attractive display. 2. Sal-ient points clearly stated. 3. Repetition. Den't spend all your money in one insertion, 4. Choice of the Paper which reaches the people you want to reach. These rules never fail.

The Guide and Hand-Book, is a book The Guide and Hand-Book, is a book of ready reference and an encyclopardia of everything desirable to know. As a guide to the home-seeker, it is invaluable. Its con-tents are partially given on page 160, and will convince any one of its value. We do not think any of our readers can afford to do without it. As a book of ready reference we find it of great value in our library. We will send the Weekly BEE JOURNAL for a year and the Guide for \$1.30

**CFT** Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to in-terview by sending the names to this office, or we will send them all to the agent.

# Advertisements.

FOR SALE.

A PIARY 120 ft. long, 50 colonies arranged for comb honey-simplicity style. Dwelling-house new, harn, poultry-houses, 30 acres wooldand; on the hills 1 mile from centre of Yazoo City, Miss. There are 2 acres of strawberrics and about 600 young fruit trees (200 bearing), springs of running water, &c. Gool fruit and beecountry Farm and Apiary at the low price of \$2,500- one-half cash, balance in 1 year. If you want a hargain, at once address, "WIEDWOID PLACE." 9A2t YAZOO CITY, MISS.

# COMB FOUNDATION.

BROOD FOUNDATION 38 cents per pound. Thin foundation 48 cents per pound. Other Supplies cheap. Send for our Price-List at once.

KENNEDY & LEAHY, 10AIt HIGGINSVILLE, Lafayette Co., Mo.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

Also S. hives of Southern yellow pine, and Bee-Keepers' Supplies in general. Price

J. M. JENKINS, Wetumpka, Ala. List Free. 8A4t

## SEND FOR IT.

We have just issued a new Circular that will interest any bee-keeper. Send your name on a postal card for it. Cash paid for Beeswax.

A. B. HOWE, COUNCIL BLUFFS, IOWA, 8A4t

Dadant'sFoundation Factory, wholesale and retail. See Advertisement in another column.

## BEESWAX.

We pay 24c. per lb., dellvered hera, for yellow Beaswax. To avoid mistakes, the shipper's name should always be on each package.

THOS. G. NEWMAN & SON, 923 & 925 West Madison Street, CHICAGO, ILL.

Italian Bees in Iowa. 60 CENTS to \$1 per Ib.; QUEENS, 30 cents to \$2.50. NUCLE1 and COLONIES. Order from my new Circular. OLIVER FOSTER, MT. VERNON, Linu Co., 10WA. 10Atf

The NEW Heddon We have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; railed and also in the flat.

The engraving gives a good idea of the hive. The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cover, bottom-board, and top and bottom of each sectional case has one-half of a regular bec-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

ALL be bored for wires. A SAMPLE IIIVE includes the bottom-board and stand : a slatted honey-board, and cover; two e-inch brood-chambers, each containing 8 trames ; two surplus arrangements, each containing 8 trames; pound sections, one with while frames and Separa-tors, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate usc. Price, \$4.00, complete.

It is absolutely essential to order one nalled hive as a pattern for putting those in the flat together correctly.

HIVES READY TO NAIL-In tilling orders for these hives, in the flat, we make 6 different com-binations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers :

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 trames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition one surplus story containing 28 sections without separators-interchangeable, but not reversible,-Price, \$2.00 each.

Price, \$2.00 each.
No. 3 is the same as No. 2, with two surplus storles as therein described. Price, \$2.50 each.
No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections m wide frames with separators, which can be reversed, inverted, and interchanced, the same as the brood-cnambers. Price, \$2.30 each.
No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each. Those desiring the hives without the stand, honey-

There describes the relevant the stand, honey-board or sections, may make the following deduc-tions from the above prices : Stand, 14 cents ; honey-board, 8 cents ; and the 28 or 56 sections, as the case may be, at  $\frac{1}{16}$  cent each, respectively,

We will also make the following deductions on quantities ordered all at one time: For 10 or more bives, 5 per cent. discount; for 25 or more hives, 7 1-2 per cent.; for 50 or more, 10 per cent.

### THOMAS G. NEWMAN & SON 923 & 925 West Madison-St., CHICAGO, ILL.

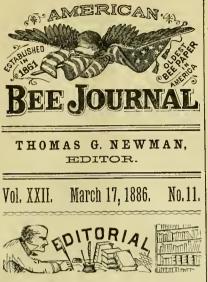

CLARK'S BEE-KEEPERS' DIARY. THREE cents only. Price-List of Supplies, Bees, Italian and Carniolan Queens, free. Send for them nov. J. W. CLARK, (box 34), 10A1t CLARKSBURG, Moniteau Co., Mo.

MY 650 Coloneles of hees are more than 1 My 650 Coloneles of hees are more than 1 serve to the full colonies, \$5.00 each, for hybrids and \$5.00 for pure Italians. Discount on larger num-bers. I will also sell a few colonies of Cauncaian hees, which breed 1 imported from the Caucaian bees, which breed 1 imported from the Caucaian bees, which breed 1 imported from the Caucaian ters, which breed 1 imported from the Caucaian bees, which breed 1 importe

The British Bee Journal, alluding to the new bee-discase, states that, in its opinion, supported by actual experiment, the new bee-discase of America is noue other than the Baceillus delphilis (auet Gaytoni) of Mr. Cheshire, and it further states that "a colony treated carefully with phenol has been entirely freed from all traces of the disease."

The Postage on Merchandise, sought to be doubled by Senator Wilson, as mentioned last week, has had a "set-back." The House Committee, last Wednesday, decided to report adversely to it. The measure is not only uncalled for and unjust, but is against the policy of the Government, and has caused a perfect storm by "protesting merchants" all over the country. The measure, if carried, would be a detriment to the Postoffice Department as well as an injustice to the general public; and we do not believe that Congress will commit such an error. Senator Wilson still insists that he will get his bill through the Senate, if possible-but it is highly improbable that it will pass the House of Congress.

Beginners in bee-culture, during the first year, generally know it all; after that they find out by degrees that they know much less about the pursuit. Mr. F. L. Dougherty, in the *Indiana Farmer*, puts it thus:

It has always seemed somewhat strange to us why beginners in bee-culture were not satisfied to accept the teachings of practical heckeepers and follow them, until they gained sufficient knowledge of their own to save them from falling into the theoretical pittalls of hearsay bee-keepers. Bees are not taught, but simply guided in a line with their instinct. They may be led in this direction to perform certain things that to the novice seem incredible. Success depends on a knowledge of the laws by which they are governed, and the advantage we are able to take of it for our own good.

J. E. Pond, Jr., and M. P. Beckett have formed a partnership in the practice of law at North Attleboro, Mass. The BEE JOUR-NAL wishes the new firm prosperity.

Bees Not Well-Marked in Italy.-When the Editor of the AMERICAN BEE JOURNAL was in Italy, seven years ago, he visited many largo apiaries, and upon his rcturn, remarked that he there saw many colonics of bees-the markings of the bees being either very indistinct or the golden bands entirely lacking. Some doubted this, and a discussion concerning "Black Bees in Italy" followed. At that time we had much corroborative testimony, but now comes further proof from our friends and colaborers, Mr. Ed. Bertraud, editor of the Bulletin D'Apiculteur, in Switzerland, and Mr. T. W. Cowau, editor of the British Bee Journal, of London, England. These gentlemen went to Italy, lately, together, and visited several of the "noted queen-breeders," and Mr. Bertrand, in his paper, makes the following remarks on this subject :

"It is well known that all the bees of the Italian race have not got the three yellow bands of the abdomen equally distinctly marked. This I have substantiated on several different journeys. At Ornavasso, at Golasecca, and at Milan there are colonies only showing two bands. In 1881, at Milan, at the Sartori establishment, I saw droues as destitute of any yellow bands as any drones bred by our black bees. But abroad, three bright yellow bands arc considered an indispensable sign of purity, hence the reason why Italian breeders, while attaching no real value in work to the color of the rings, endearor to have no bees in their apiaries that will not show 3 bright bands."

Mr. Bertrand visited the Sartori queenrearing cstablishment at Milan, Italy, two years after we were there, and in the above extract, he uses this very positive language: ' I saw drones as destitute of any yellow bands as any drones bred by our black hees." This coincides with our experience exactly. We saw precisely the same thing at that very place. With us, at that time, were Count Barbo, the distinguished President of the Italian Bee-Keepers' Association. and Signor Alfonzo Visconti de Saliceto, editor of the Italian bee-paper, L'Apicolore, published at Milan. We talked the matter over, and all agreed that the bees looked much inferior to our fine American Italians. for we took with us some samples of drones well-marked and well-developed, that were reared in the apiary of the AMERICAN BEE JOURNAL, in this city. These American Italians were admired by prominent aplarists, to whom we exhibited them in England, Scotland, France, Switzerland, Italy, Austria, and Germany. The only reason that we can give for the difference in the Italian bees bred in their home in Italy and those reared in America, is the extra care exercised here in breeding from the best colonies and for superior traits of character.

We are glad to notice by the above extract that the breeders of Italy are getting more particular and systematic in their work, and that in the future they intend to "have no bees in their apiaries that will not show three bright bands." To elevate the industry by breeding with carc is surely worth all the labor it costs, and should be encouraged everywhere.

The American Apleulturist for March is on our desk. By it we notice that Mr. Silas M. Locke has sold his entire interest in the business to his late partner, Mr. Philip H. Morant, who will hereafter conduct the business. We wish the "Api" success under the new management.

## Blow, March Wind, Blow !

### F. D. SHERMAN.

Blow, wind of March, and sing

Your songs unto the timld buds and grass: Unclasp the fetters of the woodland spring Hushed in its house of glass.

Blow, wind of March, and thrill

The languid pulses of the barren trees, Until the empty hands with blossoms fill And tempt the honey-bees.

Blow, wind of March, and wake

The sleeping violets with gentle words : Spread your green canopy of leaves and make

A shelter for the blrds.

Blow, wind of March, aye, blow,

Until the orchards heed your volce, and bloom;

Then whisper softly where the wild flowers grow

About the winter's tomb.

Lippincott's Monthly.

A German scientific journal says that "bees are good storm-signals." The auddenness with which a bee ratses a storm depends upon what portion of the anatomy the insect alights. If on the bare neck, "thunder and lightning !"—if not a stronger expletive—will follow immediately.—Norristown Journal.

A Bearing Orange Grove in Chicago. -One of the greatest novelties of the age will he presented to the people of the Northwest, at the Exposition Building in Chlcago, during the latter part of March, in the shape of a grove of bcaring orange trees. This exhibit will be made in connection with an exhibit of Citrus fruits, such as oranges and lemons from the now famous orange section of the Pacific Coast, under the auspices of the Immigration Association of Southern California. The transcontinental railroads have generously offered to bring this exhibit to Chicago free of freight. It will fill twenty cars, and twelve men will accompany it. This will be a novel exhibit for the people of Chicago and the Northwest; and will attract crowds of peoplo.

New Price-Lists have been received from the following persons :

James W. Tcfft, Collamer, N. Y.-4 pages-Queen City Hive.

O. H. Townsend, Alamo, Mich.-2 pages-Queens, Bees, and Comb Foundation.

Henry G. Pyle, Dn Quoln, Ill.-2 pages-Poultry and Eggs.

Thos. Jackson, Portland, Maine.-10 pages -Forest City Nurserics.

Isaac F. Tillinghast, La Plume, Pa.-60 pages-Field, Flower, and Vegetable Seeds. B. J. Miller & Co., Nappanee, Iud.-16 pages-Bee-Keepera' Supplica.

Aaron Low, Essex, Mass.-100 pages-Vegetable, Flower, and Garden Seeds.

Any one desiring a copy of either of them, can obtain it by sending a postal card to the address as given above.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

**REPLIES** by Prominent Apiarists.

### Cellar-Wintering of Bees.

Query, No. 215.-1. About what time should bees be put into the cellar for wiuter? 2. What should the temperature of the cellar be? 3. Should the hives be open at the top, or should they be covered? 4. Abont what time should they be put out in the spring ?-- C. S.

1. When there are no prospects of weather flights: before freezing weather if possible. 2. 45°. 3. The hives should be covered. 4. When there is something for them to gather. -W. Z. HUTCHINSON.

1. From Nov. 1 to Nov. 20, according to the latitude. 2. From  $42^{\circ}$  to 47°. 3. The hives should be covered lightly. 4. About the time elm and soft maple bloom.-G. M. DOOLITTLE.

1. Before severely cold weather comes. 2. As nearly 45° Fahr. as is possible. 3. I prefer no upward ven-tilation; though in a good cellar it is not a serious question. 4. With us, about April 10—when pollen can be secured.—A. J. COOK.

1. The first very cold weather after a warm day, say the last of November or early in December in this latitude. 2. 45°. Try that which will keep them the most quiet, and do not guess at it as some do, but have a ther-mometer right there. 3. A little upward ventilation suits us, unless there is a large lower ventilation. 4. The first warm day of spring, not too early-March 1. to? March 15 in this latitude.-DADANT & SON.

### Feeding Bees in the Spring.

Query,'No. 216.-At what time is it best to begin feeding bees in the spring to promote breeding? Should I begin before or after they commence carrying in pollen ?-W. J. C., Ills.

When I do feed bees to stimulate breeding, I commence as soon as the bees can fly out nearly every day. But when my bees have plenty of honey it does not pay me to feed them.—G. W. DEMAREE.

Perhaps if they have an abundance of stores and plenty of spring pasture you need not meddle with them. If they do not do so of their own accord, try to have them breed fast about live weeks before you expect a harvest .-C. C. MILLER.

I do not advise stimulative feeding in early spring indiscriminately. If advisable at all it should be done early enough so that the young bees would emerge from the cells in time to allow 

and the time it begins to secrete nectar must be known and kept in mind. It takes 21 days from the egg to pro-duce the worker, and 3 or 4 days more to make it serviceable.-J. E. POND. JR.

I will not attempt to advise you, but in this locality I would advise never to feed bees to stimulate breeding. If our hives and bees are what they should be, feeding could do no good. Brood development will go on as fast as other conditions will admit, without any feeding.-JAMES HED-DON.

I would not begin at all if they have plenty of stores. In any case I should not feed unless short of stores, before the bees can get pollen. The grand secret in building up strong colonies in the spring is to have plenty of healthy bees to begin the work. If they have ample stores they will then need no attention. If they have lost half of their numbers in wintering, and are diseased, they will require the brood-nest contracted, and protection on frosty nights. Then feed moderately on warm syrup.-G. L. TINKER.

### Granulation of Honey.

Query, No. 217 .- When extracted honey is to be sold in glass and in tin, it is desirable that the honey in glass should not granulate, and that in tin should granulate. By what means can granulation be retarded in one ease and hasteued in the other ?- Me.

The granulation of honey is retarded by keeping it in a warm place and sealed from the air. -G. L. TINKER.

The granulation of honey can be hastened by storing it in a cold place, or retarded by storing it in a warm place.—H. R. BOARDMAN.

Keep the glass warm and the tin cold. After all, it may be a matter beyond your control.—C. C. MILLER.

A high temperature will retard granulation in honey, but when it is subjected to a low temperature it subjected to a low temperature it seems to granulate the sooner on that account. I would not advise tinker-ing with honey in any way. Keep it in the best place that you have, and rely on its purity and good quality to sell it.—G. W. DEMAREE.

Who can tell? Some kinds of honey granulate sconer than others. Heat will retard granulation and cold The rule, accelerates it, as a rule. however, can only be applied gener-ally on account of the difference in various honeys. I will pay a hand-some sum for a correct answer to this plete answer; I fear, though, that I shall not have a chance to do so for a long time yet.-J. E. POND, JR.

In my experience clear liquid honey out-sells that which is candied in any receptacle, the only object in candy. ask those who adulterate honey. say, educate the people to liquify honey at will; buy it candied and use it either or both ways .- JAMES HED. DON.

### Giving Bees Winter Flights.

Query, No.218.-What is the best method of giving bees that are in a cellar a winter flight? What precautions should be taken as to weather, sunshine, temperature, etc.? What is the lowest safe (temperature measured by a thermometer in the shade ?-Me.

I do not approve of taking bees from the cellar for a winter flight. have a warm, still day, with the tem-perature not lower than 50° in the shade.—W. Z. HUTCHINSON.

If they are quiet, do not give them any. A winter flight incites them to breed, and they may be restless after that. If they are taken out at all, the mercury should not be under  $50^{\circ}$  in the shade, and the sun must shine; without wind or clouds .- DADANT & SON.

I never, of late years, give mine such a flight, believing it worse than useless. Bees can safely fly with the mercury at 45° in the shade, providing the sun shines and it is still.—G. M. DOOLITTLE.

The cheapest method is to have the cellar all right, then no winter flight is necessary. Unless the tempera-ture is above 60°, Fahr., in the shade, bees ought not to fly. Of course sunshine is desirable, and heavy winds very objectionable.-A. J. COOK.

### Rearing Drones.

Query, No. 219.-Most apienitural writers advise the prevention of drone-rearing and excluding them if reared when working for surplus honey. On the other hand, a few think that colonies to do their best should have their proportion of drones; that their office is to generate heat and keep up the temperature of the hives, as well as to fertilize queens ; that their large bodies and stomachs are better fitted for this purpose than workers; and they are allowed in the hive as long as brood or queens are to be reared, and then destroyed. Is it not possible that we are on the wrong track in entirely excluding drones? What are your ideas on this subject ?- Pawtucket, R. I.

I think that the prevention of dronerearing is a little over-done, and time will show in what respect.—H. D. CUTTING.

From my own experience in the production of honey, I find that a few square inches of drone-comb is no disadvantage. It is more than probable that they do assist not only in evap-orating the honey, but also in main-taining the heat for the brood.—J. P. II. BROWN.

I have carefully watched this matter, and wish no drones, except enough for use in mating, and these only from best colonies. Of course these should be sufficiently abundant that the queen need not be out long .-A. J. Cook.

It is possible, but not probable, that we err in curtailing the production of drones. They are never reared unless needed for the fertilization of queens. Five days before swarming bees will rear drones; after swarming, neither colony will rear them, unless the old queen is quite old and likely to be superseded.—W. Z. HUTCHINSON.

No, we are not on the wrong track. We can rear 3 workers where 2 drones are reared, and the 3 workers staying at home during the first 10 days of their life, will generate as much heat as 2 drones. Besides, drones are reared in warm weather, when the hive is sometimes already too warm, and the bees have to ventilate it at great labor. The necessity of drones, as of "setting-hens," is imaginary.— DADANT & SON.

### Cutting Out Queen-Cells.

Query, No. 220 .- Is it necessary to cut ont all the queen-cells hefore introducing a queen, especially when introducing one into a hive whose colony has cast a swarm a few days before ?-D. J. A.

It is safer to cut out all the queencells.-H. R. BOARDMAN.

It is safest to do so. If the hive has been moved a day or two before to a new location, so as to lose nearly all its flying force, it is hardly ever nec-essary.—C. C. MILLER.

According to my experience it is essentially necessary as long as the swarming impulse is likely to be pres-ent, and the safest way at all times, and under all circumstances.-G. W. DEMAREE.

In swarming time it is not, and especially in the case indicated; but introducing queens to colonies having queen-cells is always risky. never saw a colony that acted as if really queenless until deprived of all unsealed brood. Then there is the smallest risk.—G. L. TINKER.

I have introduced queens successfully where queen-cells were not all cut out; and I have lost them also in the same way. I advise the cutting out of all as a precautionary measure, for no one can foretell what the re-sult will be. I think, as a rule, that colonies having queen-cells will not accept a queen as readily as those that are hopelessly queenless; that is, that have no queen and no brood from which to rear one.—J. E. POND, JR.

Not always, if the cells are nearly ready to hatch. Many a time have I successfully introduced virgin queens into colonies with many queen-cells almost ready to hatch. I supposed that the bees thought that one cell had given up its inmate and then vanished.-JAMES HEDDON.

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is This mark  $\bigcirc$  indicates that the apparist is located near the centre of the State named:  $\Diamond$  north of the centre;  $\Diamond$  south;  $\circlearrowright$  east;  $\circlearrowright$  west; and this  $\Diamond$  northeast;  $\circlearrowright$  northwest;  $\circlearrowright$  southeast; and  $\Diamond$  southwest of the centre of the State mentioned.

## Apicultural Discussions.

### JAMES HEDDON.

I have read Dr. Miller's article on page 132, and can say that he is right. While I know that he is not pointing his finger at me, unless in prospec-tive, I will assure him that I, for one, will try to avoid the spirit which he and many so much dislike. If I have not done so as much as I should in the past, I am sorry for it; and now, while so many of our leading bee-keepers are cheering my late efforts to make our pursuit a little easier and more prolitable, and according to me all the merit and honor I ask or deserve, it is hardly possible for me to harbor any ill-feeling toward any one.

I do not think that Dr. Miller un-derstands Mr. Clarke in coming forward in his jolly manner. I take it, that "Come on, MacDuff," has reference only to a good-natured, logical, and well-meant controversy.

When we see such statements as are made by Dr. Tinker, on page 154, wherein he describes my hive with some of its valuable features omitted, and makes an effort to persuade beekeepers that I have no right of in-vention, and finally claims the invention for himself, and tries to give my hive to the public, we see that which is apt to cause ill-feeling in the minds of many; but I feel sure that time and the good judgment of bee-keepers will see the matter in its true light, and act accordingly.

1 do not desire to mention my new hive or system of management in the reading columns of the BEE JOURNAL (I can do all my advertising in the space I pay for); but if I am called upon to answer questions, giving the results of two seasons' experiments with the hive and its management, I will cheerfully comply with the re-quests to any extent which the BEE JOURNAL thinks its readers demand.

Dr. Miller asks if the new hive is not "fussy?" No; not in its manipu-lation. It is, in that, the simplest and best hive that I have ever used. The space between the two tiers of brood-frames is too low down to he troubled much with brace-combs.

between the two sets of combs is an *advantage* in wintering if two sets of combs were to be used; but again, experience and observation satisfies me that one case is best to winter in. Without any direct experience, Dr. Tinker "fearlessly" asserts favorable answers to Dr. Miller's queries. From experience with the new sectional brood-chamber hive, I will state the following in refutation to the mis-takes in Dr. Tinker's conceptions after reading my book mailed to him on Jan. 8:

1. My hive, made as he describes it, is fully covered by my invention.

2. The way in which he proposes to place the tin-rests, is a practice of Mr. Manum's, and was discussed by him and myself last December. I prefer it as I have it.

3. The screws in my hive press the frames tightly, giving much better control of the cases when handling the frames by cases, and do away with nearly all of the objectionable gluing.

4. As to the preferable size and number of the frames and cases constituting either the brood or surplus department, that is merely optional with the peculiar taste of each beekeeper, as is stated in my book and patent specifications; but experiment has taught that it is best to use two brood-cases (and rarely more) 8 frames wide, both having the combined comb capacity of 10 standard Langstroth frames. Four years' experience in contracting hives compels me to believe that one of the brood-cases gives the right capacity during the period of contraction; all of which is fully explained in my book.

5. As stated in the chapter on the new hive, my double-interchangeable brood-chamber, while two or more broodcases are used, admits of keeping the brood always up close to the surplus receptacles, besides accomplishing almost all the advantages hitherto expected reversing to accomplish, but when the hive was contracted to one brood-case, I found advantages in re-versing that case, and so we did in some instances when two and more brood-cases were united. It is little trouble to make all the cases invertible, and it has many advantages, with no disadvantages, as far as all experiments have yet discovered.

In Dr. Tinker's description of my inventions, experience compels me to say that he has left out many good and valuable features, and in describing and detailing other meritorious points, he has repeated the descrip-tions given in the chapter on the subject, on pages 88 to 106 of my book. In some instances almost my very Words are used. He may have done this inadvertently, but that he has done it, no one who has read the chapter will deny.

The new hive is not without fault, though I now think of but one. It costs more than single brood-chamber hives, and requires very accurate workmanship and material that is perfectly seasoned. I believe that this hive and its new and peculiar system of management will undergo Again, my opinion is, and my system of management will undergo experience proves that the space a reaction, and then a re-reaction in

the minds of bee-keepers. It is so different from all others, both in construction and method of management that its peculiarities have to be learned physically as well as mentally. be All my students disliked it at first, but all gave it the preference after becoming accustomed to it. One trial hive, placed among other kinds, would hardly have a fair showing; but truth will finally prevail. The merits of the hive will defend it; and I hope the honor of our brotherhood will defend its inventor.

Several have written me to know what I claim, and what my patent covers. I think that my patent fails to cover all that I have invented, and that I am also entitled to, but my very able patent attorneys tell me that they think my patent will hold more than I imagine, when forced to legal test. Patent law is also complicated, and perhaps no one can tell just how much I could hold legally without a test case in the United States courts, and this, I trust, will never be needed. Outside of the profession false ideas prevail regarding the legal rights of patentees.

For the past 20 years I have been associated with one of the most successful patent attorneys in our coun-try, and I will, in the near future, write an article on that subject, and from the best authority endeavor to clear up some of the mistaken ideas regarding it, that prevail among our bee-keepers.

Dowagiac, 9 Mich.

### For the American Bee Journal. Consumption of Extracted Honey.

### C. W. DAYTON.

That honey is and always will be considered a luxury, I believe there are ample reason for doubt, especially in the case of extracted honey. In the first place, extracted honey is as cheap, or cheaper, than corresponding grades of cane-sugar. As to the grape-sugar, we need not expect much from that unless it be from the commercial article which, it seems, has already acquired a reputation that bids fair to drive it entirely out of use except as an adulterant. Without question, there will be maintained as wretched a subsistence, as there will also be gloomy times for all parties, when all of our food is com-posed of adulterants. That people do not buy honey and consume as large quantities of it as of cane-sugar, is nothing strange, unless it is that it would be an impossibility. Were the people of the United States to cease using sugar for a week, and use honey in its stead, there would not be enough honey to fill the gap.

The main point for consideration is the limited but growing acquaintance regarding the uses to which honey may be put, and being suspicious of the honest man's enemy (adultera-tion), all wish to know the method by which honey is obtained. Quite all had learned, he went on to market done to as good advantage by bring-of those who buy honey (notwith-standing so many who never use it) which he carried home filled with the bees, and thus prevent swarming

consider it to be honey, and a luxury only, never surmising it to be a con-summate substitute for all the other sweets, and are surprised when in-formed of the fact that it is equally as good, and will go just as far as sugar in cooking.

The objection might be brought to bear that honey is liquid, and con-quently not so pleasant to get along with as a dry material. Why this property should be an objection rather than an advantage, I fail to see, un-less it is in carrying a jug of it on the street; but in such a case very much would depend—whether its liquidity is an objection or not, we must go around it one way or the other, and if it should chance to be the other, we will arrange strainers in the bottoms of our honey barrels, drain the liquid portion out, and get it there in the shape of sugar. This plan was tried the past season, and it was found that granulated extracted honey when that granulated extracted honey when drained dry, sells well and gives satis-faction. I would suggest that when we will need to do this will be when there is enough honey produced to make it an object, and when the time is ripe for it. I say when the time is ripe for it, because I believe it to be with heat because I believe it to be with bee-keeping as it is with other kinds of business, that when it has been carried on in its present ad-vanced state long enough so that people have become acquainted with it as an ordinary industry, and not filled with exaggerations and wonders, then will honey be inquired for, not as a curiosity and expensive luxury, but in a general way and as an ordi-nary article of food. That will be the time to work up a wholesale trade in our home markets.

As has been said before, bee-keepers can do themselves no greater favor than to let the adulteration of honey take care of itself, except in the contradiction of false statements. It is displeasing, if nothing more, to behold the consumption, wholesale and retail, of materials whose whole make-up are well known to be pure and unadulterated frauds; and then the upbraiding of a whole industry accusing it of being connected with fraud in very rare or incapable in-stances, all because it is respectable and a newcomer! This is like and a newcomer! " straining at a gnat and swallowing a camel."

The guarantee which I offer, that my honey is pure, is to label the packages PURE HONEY; but when accosted with the comparatively consol-ing news that honey is adulterated, I inquire what it is adulterated with; tell them to inquire of my neighbors, tell them to inquire of my neighbors, or invite them to act in their own favor by coming to the apiary and profit by what they will see with their own eyes. One day last June, a farmer, living some 18 miles distant, on the road to market chanced to stop at my place for a drink of water, and on speaking of the bees and honey, I took him to the extracting-room and showed bim how it is done room and showed him how it is done. Expressing great surprise at what he

honey. During the fall and winter many a crock of honey went out to the friends and neighbors of this farmer where honey had scarcely ever been used before.

Last fall a customer from that neighborhood told me that those who saw the honey could hardly believe it to be pure, but as their neighbor was here and saw it taken from the combs, they concluded that it must be so. Instances of this kind show that the words of one uninterested person is worth more as a recommendation than all the arguments that might be produced by interested parties; and that extracting honey at Fairs is a capital way to advertise the business.

The great obstacle which lies in the way of our progress toward the introduction of our product is, that ordinary minds are incapable of thoroughly comprehending such sudden advancements as apiculture has brought out. We know how difficult it was to bring into use steam, sew-ing-machines, and certain agricul-tural machinery; those who performed the labor of introducing, declare that a generation had to be raised before they were successful. To a large ex-tent this is true of the Langstroth frame. It is my opinion that we may advertise, talk and write all we please about the good properties of honey, and the bad effects of glucose, and the two methods of offering our honey will still remain—either as a high-priced luxury on a continually glutted market, or as a corresponding-priced substitute for sugar. Which method is preferable ?

Bradford, & Iowa.

For the American Bee Journal.

Lengthening the Swarming Impulse.

### J. E. POND, JR.

On page 86 Mr. Doolittle complains that some were uncourteous in the replies to Query, No. 173. Mr. D. has been so long and so well known has been so long and so well known to all as an honest, upright man, that no one would intimate or even sus-pect that he had indulged in "the tricks of the trade" in order to im-pose on any one. He also gives his views in regard to the swarming im-pulse, and explains his method of our explanation of the state of queen-rearing, claiming that it is superior to that of those who rear queens "artificially." I fail to see the difference, hower; in fact, it appears to me that his method is practically the same as those he condemns.

What is the swarming impulse? Does it or does it not differ from the queen-rearing impulse? In the correct answer to these questions will be found the correct theory of queen-rearing. That the two matters are alike in some respects is admitted; but I claim also that in some respects they are widely different. The they are widely different. The "swarming impulse" is the desire of the bees to "multiply and replenish the earth." This, however, can be done to as good advantage by bring-ing the reason of man to the aid of the bees, and thus means the set of

In the one case Mr. D. forces his colonies up to the strongest position in point of numbers that he possibly can, and then allows them to swarm: the others force theirs up to the same point and then remove the queen. This, however, is not the whole. Mr. D. allows his colonies to rear queens as they may choose, thus running the chance of getting many from aged larvæ; the others, when they remove the queen, remove all brood that could be used to rear queens from, and continue so removing until all the residue is too old to be so used. Then all queen-cells are removed, and eggs-Now these colonies are as strong as they can be made. If honey is not being gathered freely, they are fed to keep up the illusion, and the desire to rear a queen for the purpose of per-petuating the colony is equally as strong as the swarming impulse; why, then, should the results in the one case be so much better than in the other?

No one would pretend to say that Mr. Doolittle would not se the idea of "swarming impulse" for purposes of deception. It is a fact, though, that some do so use it, and such being the case, I do not see anything "uncharit-able or uncourteous" in the replies adverted too. The real fact is that in bee-keeping matters there has always been a large amount of mystery, and theories more or less plausible have been accepted in the past as proven facts; so long as such is the case, just so long will the door to fraud be left open. Let us all indulge in the hope that facts, and not theories, will be the rule of the future, and that every man will be judged for what he does, and not by any general standard. Foxboro,↔ Mass.

### For the American Bee Journal.

### Who Should Keep Bees ?

### MRS. L. HARRISON.

On page 23 Mr. Otis N. Baldwin says: "During the year 1883 bees did well here, as was universally the case. This is what I call a bad streak of good luck, or vice versa, for it gave everybody the bee-fever—the old men, the boys, the cripples, the old maids, and even the hired girls in this sec-tion entered upon the uncertain sea of apiculture."

"The old men :" God bless 'em. once had a dear old father, and a grandfather, too; the idea of any one begrudging them the comfort of keeping bees in their old age ! "The boys:" Friend Otis, thee was

entirely. The queen-rearing impulse is the natural desire of the bees to preserve and perpetuate their individ-ual existence as a colony. In what respect does Mr. D's method differ practically from that of our most successful queen-breeders? In the could not climb upon buildings any more; he must live as well as you and L and he engaged in beerkeeping. and I, and he engaged in bee-keeping. He has limped among his hives to good advantage, and sends to this market beantiful honey, and if I should meet him to-day I would grasp him warmly by the hand, and say: "My brother bee-keeper, although you live 20 miles from Peoria, you are welcome to this honey market, as far as I'm concerned."

"The old maids:" True, their cats might follow them into the apiary and get stung, yet I know some ladies " of uncertain age" in the State of Michigan who have made a grand success of keeping bees, and I hope that the "old maids" of Northeastern Mis-souri will succeed just as well.

"The hired girls :" That hired girls are keeping bees is the choicest bit of news I've heard in many a year, and I roll it " as a sweet morsel under my tongue." They have gotten up from their knees, and left their scrubbing-brushes, and stove-blacking, and stand ing the bee-convention at Detroit, I roomed with a "hired girl"—a neat, intelligent girl (not an old maid), who had done house-work in order to earn money to purchase bees. She had a nice little apiary, and was then work-ing, and obtained leave of absence for a few days to attend the convention. I won't tell her name, for fear some lazy man might think she would be a good investment.

I want women to keep bees, or, as Mr. B. says, "enter upon the un-certain sea of apiculture;" but I do not want them to crowd out the men. I know that we take up considerable room, and we are noisy, too, always putting in a word, but we will try to keep "on our good behavior." Peoria, O Ills.

### The New Reversible Hive.

### G. M. ALVES.

In a recent article I propounded several questions concerning the construction of the new Heddon hive. Mr. Furness has given us his answers to the questions, and as it seems that he has somewhat misunderstood the purpose of them, I take this opportunity to explain.

In asking the questions I directly stated that I did so without offering answers myself. Serious doubts arose in my mind, in reading Mr. Heddon's book, as to some of the details of con-struction, and it would have been manifestly nnreasonable for one, from experiments carried on for a short of his own mind, to pit his conclu-sions against those of men who had "The boys:" Friend Otis, thee was a boy once; thee might be called over the "dark river" to hive bees in another clime, and would it not be well to have them learn to care for bees? When thou art gone, North-

raise the points, and not to declde them.

I thought then, and still think now, that at least some of these points should be met by Mr. Heddon or some one else who has tested the hive : and I now ask Mr. Heddon, has he had no trouble in making and keeping the frames of the precise width? Has he not been troubled with expansion and contraction ? and has not the accumulation of propolis given him trouble at the tops of the frames where they touch, or nearly touch the front and rear of the case, and also at the joints made by the frame, on the thumb-screws' side, with the front and rear of the case ?

It is to be understood that an impediment longitudinally of only 1-16 of an inch will prevent the replacing of a frame, and that an expansion of or an accretion to each frame of 1-32 of an incli will take up all of his spare room. Let Mr. Heddon please tell us to what extent these objections are founded in fact, and to what extent in imagination.

I will state here, and probably it would have been better to have stated it in my former article, that Mr. Heddon's system seems to me in many respects excellent, and if there are real objections in his present details of construction, I have sufficient faith in his inventive genius to believe that he will succeed in removing them.

But I am necessitated to explain further. Mr. Furness, after having been pleased to mention my preliminary remarks as of literary merit, etc., intimates that I am very non-progressive. Now it is somewhat embar-rassing to have attempted to say funny things, and then feel called upon to explain them. The fact was, Mr. Heddon's new hive was ushered into bee-literature with such a flourish of trumpets, and at the same time Mr. Heddon had so wonderfully crossed his old records, that some of us could not but laugh for the fnn of the thing.

However, the subject has now assumed an aspect not to be laughed at. The question has been raised, is the Heddon patent valid? We are now called upon to consider the rights of a man to property claimed by him. It is probably unnecessary to say here that I am no champion of Mr. Heddon's, appointed or self-constituted, but surely all fair men should ever be ready to champion fair play, it matters not whose interests are involved.

I have never seen Mr. Heddon's specifications for his patent, but it requires little intelligence to know that the spirit of his claims includes not only his several precise details of construction, but that it also includes a combination of these details into his special system, and all kindred details that have for their end the carrying ont of his particular system. I lay down the above as a proposition that no man will deny who can think

novel. I affirm that the Heddon principles are novel—that they cannot be found in literature or elsewhere. Let those who deny, adduce the proof. The ruhbish that has already been lugged forward does not deserve a critical man's attention.

In the meantime these questions are pertinent: If Mr. Heddon's ideas are not novel, how happens it, that a system which seems to promise so much, has not before this become familiar? How happens it, that authoritatively informed men respect the novelty of the system?

I wish to enter a protest here against the loose notions some beekeepers seem to have about the patents of their fellows. As long as the laws of our country allow men the privilege of patenting their inshown why inventors of bee-keeping appliances should not be allowed the same right; and a bee-keeper who knowingly uses the property—i. e., patent—of another without legally acquiring that right, cannot be called honest; and the fact that he can appropriate it without the knowledge of the owner, would, if so done, only give additional contempt to the theft. Should an inventor ask me more for the right to use his patent than I was willing to give, I would content my-self without it, just as I would con-tent myself without his horse or cow, should he ask me more than I was willing to pay. It would seem that there are some in this regard, where their business ethics fall short they seek to eke them out with sentimental drivel and religious cant. Let us all try to be simply honest; then if there are any among us who have a super-abundance of sentiment, the balance of us can, with semasher of patience of us can, with some show of patience, listen to its gurglings.

Henderson.+o Ky.

For the American Bee Journal.

Comb Honey vs. Extracted Honey.

### CHAS. DADANT.

In quoting the figures of the report of Mr. Doolittle, as given on page 709 of the AMERICAN BEE JOURNAL for 1885, I could not imagine that Mr. Doolittle had not given all the facts as they were. I could not suppose that the 2 colonies which he credited as having given 388 pounds of extracted honey, had produced 338 pounds only, of *partly poor honey*. I could not suppose that he had impoverished his best colonies by taking brood to rear a great many queens, since he did not figure the proceeds of these queens in his report, as he usually does every year. If I have supposed that his colonies were weak for winter, it is because he manages his bees to have light population in the fall. (See his article on "Those Six-Frame Hives," in the BEE JOUR-NAL for Jan. 30, 1884.)

It is not my intention to contest the figures given anew on his report, but I will prove that the bees worked for

acted honey give nearly twice as

much honey as those worked for comb honey; that the production of comb honey costs more money and more work than the extracted; and I will again look for my proofs in the writings of Mr. Doolitile, in spite of my chances of having the figures corrected again.

In the *Gleanings* for October, 1877, Mr. Doolittle said that 2 colonies worked for extracted honey gave 446 pounds each, while the colonies worked for comb gave an average of 158 pounds. If we deduct one-fourth of the 446 pounds, on account of the evaporation of this honey, which was not altogether ripened, since it was extracted when the bees begun to seal over the cells at the top of the combs (*Gleanings*, 1878, page 12), we have 334 pounds of extracted honey against 158 pounds of comb honey more than twice as much.

Mr. Doolittle denies now that the production of extracted honey requires less work than comb honey. We find in the *Gleanings* for December, 1877, page 335, that he works from early dawn till late at night, averaging about 15 hours work each day, yet he had only 80 colonies. If some desire to know how Mr. Doolittle works his bees, let them peruse the article entitled "Those Six-Frame hives," referred to above. According to our experience, a bee-keeper working for extracted honey can manage at least four times as many hives as does Mr. Doolittle, and without working more than ten hours per day. But we will need some help about three times in the year.

As to the expense: If we work for extracted honey, the same combs are used indefinitely. When, after having been emptied, they are given back to the bees to be dried, they contain yet about 3 per cent of honey; besides, the cappings give about 1½ per cent. of beeswax, and some honey; these returns pay for all the expenses of extracting and buying the barrels.

It is quite the reverse with producing comb honey. We have to buy the sections, the foundation; have to furnish the glassed boxes for shipping, etc., and not a cent of return; not even the guarantee that our wellcared-for sections will, reach the grocer unbroken. But Mr. Doolittle, himself, complains of such expenses, for he wrote in *Gleanings*, for Oct. 15, 1884, that the nicest honey in a onepound section without glass means nearly six times the labor and expense to the bee-keeper that 6 pounds of honey meant 12 years ago. After this quotation I have nothing to add, letting the reader draw the conclusions.

### **Convention Notices.**

The Union Bee-Keepers' Association of Western lowa will meet in Dexter, lowa, on April 10, 1886, at 10 a.m. M. E. DARBY, Sec.

137 A cordial invitation is extended to all to attend the 8th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No hotel bills to pay. B. F. CARROLL, Sec.

For the American Bee Journal. Bee-Keeping in Northwestern Iowa.

### J. C. WHEELER.

I came to this place from Kendall County, Ills., on March 1, 1884, bringing with me 20 colonies of Italian bees. They had been stored in the cellar during the winter, and the weather being so severe they were not out for a flight before being shipped. I use Langstroth hives, and to prepare for the journey I covered the entrances with wire-cloth, bored an inch hole at the top of each hive in the front end (covering them also with the wirecloth), and nailed the bottom-boards on. The hives were then packed snugly in one end of the car, standing with the ends of the hives toward ends of the car.

After the journey of five days (500 miles), it being still too cold for them too fly, they were packed as follows: The hives were placed on the ground in a row close together, and covered with wheat chaff and straw in the shape of a long straw-stack about 4 feet wide. The chaff was kept from the entrances by a 20-inch board placed horizontally one inch above the alighting-board. The first suitable day, heing fully three weeks after arriving, they were uncovered and had a good flight, and all were in seemingly good condition, except one colony that had died from lack of honey.

Last winter, and also this winter, I have wintered my bees similarly to the description of the protection that I gave them the first spring, and I like it very well; but I would prefer a good, dry cellar.

nt very well, but I wonld pieler a good, dry cellar. People said that hees could not make a living in this part of the country, but I still have my 20 bives full of bees and honey, and last season I took 1,000 pounds of honey from them as a surplus. White clover is scarce, but wherever started it does well. I think that in a few years we will have plenty of clover honey. The first season that I was here I put out 500 linden trees, and each year I have sown buck wheat from which the bees stored much honey. Very late in the fall they work on goldenrod and resin-weed. A neighbor has a large patch of sweet clover in his door-yard, which proves that it is at home here as well as elsewhere. I will sow five acres of it this spring. There are no bees nearer than 8 miles away, and but 2 or 3 colonies there.

The first year, my queens being young, I found it necessary to replace only those dying with about half a dozen new ones, and these became fertile without any apparent inconvenience. I supposed that they were fertilized by my own drones, but several of them produced hybrids, so I concluded that there must have been black bees nearer than I knew of. Last summer, with every hive in the apiary containing drones, fully two-thirds of fifty young queens that were hatched and could fly, refused to become fertile. I know they could fly, for I noticed them leave the hive

many times. I can account for this in no other way than that the colony or colonies of bees from which my queens had been fertilized the previous year, had been winter-killed or moved farther away; and that there must be a point not yet understood perfectly, that either the queen does not fly away from home to meet its mate, and the drone does, or vice versa. There are but few in the United States so situated as to test this question fully. I should like to hear the experience of others on this point, through the BEE JOURNAL. I will test it more carefully another season

Oyens, & Iowa.

For the American Bee Journal. When to Put Bees into Cellars.

### T. F. BINGHAM.

On page 739 of the AMERICAN BEE JOURNAL for 1885, Mrs. Harrison states that November is too early to put bees into cellars, etc., according to a vote at the Northwestern Con-vention. Further, she states : " Last year ours were stored on Dec. 1, and fine weather followed, when bees on Also: "Experience teaches us that it is better to store them late," etc. Will Mrs. H. please say whether her early-stored bees came out as well in the output of the store them late. the spring as others in her vicinity not stored so early?

The experiments reported, and theories deduced from them, are of very little weight in the minds of bee-keepers, if the fact is not well established that bees do not need to fly for an almost indefinite and un-limited time, unless exposed to cold the equivalent of freezing water. If such is the fact, and reports have been made from year to year, which, if reports are of value, settles that one point at least beyond controversy.

I will say that, so far as my personal experience goes, bees never winter well in depositories unless stored early—before cold, freezing days come on. If freezing cold is all that renders it important that bees should fly, no one can fail to see that late storing, for the purpose of allowing the bees one more flight, is a de-I will say here, and it time should demonstrate that I am mistaken, my object in this article will be accom-plished just as well as if it should confirm my assertion, viz : that bees confirm my assertion, viz: that bees do not fly-in the sense of a spring cleansing flight-until after a few freezing days and nights in Novem-ber or December, even if left on the summer stands and such moderate days occur as would induce an entire apiary to take wing in February or March.

While I shall not say that this is testimony proving that cold, below freezing, is the cause of the desire of bees to cleanse themselves, I shall offer this fact as evidence that the necessity is not urgent unless such cold has existed.

Mr. Editor, I trust you will not consign this short article to the vawning "waste basket," that is always so handy, because the subject is one at this time not much discussed; but allow it to go forth that we may learn whether bees are wintered on theory, more or less superficial and deceptive, or whether actual experience upon which one may depend lies within the reach of bee-keepers. If 1,000 bee-keepers should report that their bees were carried in after frosty days and nights, as a rule—in order to give them one more chance for flight—and that the bees of 900 of those bee-keepers, so housed, died just the same as those left all winter on the summer stands, the reports would be of value. If, on the contrary, 1,000 apiarists should report that by mere accident, fearing cold and inconvenient housing, they had taken their bees in 2 or 3 weeks sooner than was advisable or necessary, as the weather had un-expectedly turned, should winter their bees without material loss-much better even than those around them who had wintered theirs on the summer stands-their reports would be of value.

Can we not have such reports, short and without theory, sent to the AMERICAN BEE JOURNAL of last winter's inning, and of last clover season's inning? This question does not embrace the honey crop or "ifs" or "buts," or anything else, except the innings to the depository and those ready for the clover honey crop following.

### New System of Bee-Culture.

### FRANK A. EATON.

The Heddon new system demoralizes everything heretofore usedfor pressing foundation into wired frames with the Given Press. If any one but a leader, as Mr. Heddon is, had invented such an arrangement, it would either never be noticed or be laughed to ridicule. If I am right, he goes back on every part of his old system. I suppose he will have no more use for wiring frames, as the frames are so shallow that they will need no support. Then think of two bars of wood and a bee-space in the centre of the brood-nest, closed end-bars to the frames fitting close to the ends of the hive! Why, I would about as soon think of going back to the box-hive! If he wants to run parts of his colonies for extracting he will have to use those shallow frames or have two sizes of frames, which cannot be interchanged—a point which is so advantageous in extractwhich is so advantageous in extract-ing; and then, again, going back to wide-frames and separators for the surplus—I should not be more sur-prised if Mr. Heddon would declare there was nothing in the pollen theory for wintering, but say that it is hibernation that we want; then I think he would be nearer the right

track on wintering, too. I hope that I am all wrong, and that Mr. Heddon has added another step in beekeeping.

### Bluffton, vo O.

[As Mr. Eaton makes very sweeping assertions about Mr. Heddon's "new system," we think it but just that the latter should state his own views on the matter, so we sent him a proof of Mr. Eaton's letter with a request for a short reply, and here is what he says :-- ED.]

In responding to your request, I will say that I hardly know what Mr. Eaton means by "demoralizes." My new hive and system aims to bring about many of the same results realized from the use of the old hive with very much less friction and outlay of time; not only this, but other and better results. It has "section-cases," though of a new style; its frames are as well adapted to the Given press as any other. I think that M. E. muse new approximant that Mr. E. pays me a compliment that I do not deserve, for I do not think that those whose names appear in my advertising column "sneeze because I take snuff." Evidently Mr. Eaton is too hasty. Had he read the chapter on the new hive in my book, he would see that I wire the frames, and that the new hive is eminently adapted to contracting and reversing, and that the shallow cases are exand that the shallow cases are ex-cellent for extracting, as advised in Dadants' excellent pamphlet, and practiced by many for a dozen years or more. The new hive does not necessitute the use of wide frames or separators. Should I find the "pollen theory" incorrect, I would so "declare" it as soon as possible. I think that if Mr. Eaton had tested the principles of my new hive and system for two seasons as I hive and system for two seasons, as I and others have done, the unanimity of belief in its superiority would still remain. While I think that Mr. E. is too hasty and unwarranted in his judgment, his criticism is refreshing, compared with the reviews of those who, having theoretically discovered its advantages, arise and claim them for themselves. Regarding the merits of the hive, they will prove themselves. As to my rights as the inventor, I have little fear but that the fraternity will stand by me.—JAMES HEDDON.

### Convention Notices.

The Illinois Central Bce-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886.

### J. M. HAMBAUGH, Sec.

The next meeting of the Patsalaga Bee-Keepers' Association will be held at Arcadia, Ala., on March 20, 1886. M. G. RUSHTON, Sec.

Let a. g them rd lo

### Local Convention Directory.

Time and place of Meeting. 1886. Mar. 20.-Patsalaga, at Arcadia, Ala. M. G. Rushto, Sec., Raif Branch, Ala. Apr. 7.-Wabash County, at Wabaah, Ind. J. J. Martin, Sec., N. Manchester, Ind. Apr. 8.-Southern Illinois, at Duquoin, Ills. F. H. Kennedy, Sec., Duquoin, Ills. Apr. 10.-Union, at Dexter, lowa. M. E. Darby, Sec., Dexter, lowa. Apr. 27.—Des Moines County, at Burlington, lowa. Jno, Nau, Sec., Middletown, lowa.

Apr. 29, 30.-Western, at Kansas City, Mo. P. Baldwin, Sec., Independence, Mo. May 5, 6.—Texas State, at McKinney, Tex. B. F. Carroll, Sec., Dresden, Tex.

Oct. 19, 20,-11linols Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

17 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.-ED.

Cold and Stormy Weather.-G. M. Doolittle, Borodino, ON. Y., on March 4. 1886, savs :

The past week has been extremely cold and blustering here; in fact, about as rough a week as we ever get. The mercury was from  $5^{\circ}$  above to  $10^{\circ}$ below zero.

Cleansing Foul-Broody Hives and Combs.-Frank Curl, Des Moines, Iowa, writes :

On page 139, Mr. Ward says that by the use of lye he has disinfected both combs and hives which were infected with foul brood, and advises others to try the plan. As Mr. Ward does not state when he made his discovery, I would suggest that others wait until they hear from him next spring, when he may have a chance to make more experiments.

Bad Weather for White Clover .--Geo. Spitler, Mosiertown, ~ Pa., on March 1, 1886, writes:

We are having zero weather with-out snow. Our bees had a chance to fly in February, but all the colonies did not come out, yet all seemed to be in good condition. The present weather will be hard on white clover. Bee-keepers are fearing losses on account of their colonies being short of stores.

Bees all Alive. -II. Clark, Palmyra, Q Iowa, on March 4, 1886, says:

My bees generally bring in the first pollen from April 1 to the 15th. So far I have not lost a colony this win-ter, although the most of them are packed out-of-doors in 8-frame Langstroth hives. I am satisfied that our loss of bees in wintering is caused by having bad honey for stores. Last spring 90 per cent. of the bees were dead hore while were the dead here; while now they all appear to be all right. On Feb. 4 it was 20° below zero.

A Bee-Keepers' Meeting. - Mark Thomson, Canton, & O., writes as follows:

The bee-keepers of Stark County met in Grange Hall, at Canton, O., on March 2, 1886, and effected a tempo-rary organization by electing Jacob Oswalt, of Maximo, President; J. H. Smith, of Canton, Vice-President; and Mark Thomson, of Canton, Secretary and Treasurer. A meeting for retary and Treasurer. A meeting for the purpose of effecting a permanent organization was called for Tuesday, April 13, 1886. The afternoon was spent in a general experience meet-ing, participated in by all the mem-bers present. Much interest was manifested, and great good to the cause promises to result from the organization. organization.

Sectional-Hive Questions.-J. R. desires the following queries answered :

1. When hives are made with square joints between sectional parts, is there no danger of water running in from rains to the injury of the bees? and does it not take more time to adjust or manipulate them than those having lock-joints? 2. What is the right space between frame end-bar and the hive? Is  $\frac{3}{8}$  of an inch not inconvenient to the bees, that is, too long a step, as it were, from hive to frame ? 3. How much play should the top-bar have endwise ?

[1. Long experience declares "no," for both parts of the query.

2. I prefer the standard 3% of an inch for suspended frames. It makes the bees no trouble, but will trouble the operator if less space is used. I would use an inch but for bracecombs.

3. Just enough so that notwithstanding the variations in the lengths of the top-bars, all will go in and out without wedging. The more accurate the work the less allowance needed.-JAMES HEDDON.]

Disinfecting Foul-Broody Hives.-Dr. L. C. Whiting, East Saginaw, O Mich., on March 4, 1886, writes:

Mr. G. J. Pease, on page 137, wishes to know how to clean his hives and roof from foul brood. Heat applied to the hives in some way, equal to the boiling point, is all that is required. If the hives are loose from the bottomboards, build a fire in an old iron vessel of some kind, and make a chimney of them by piling them up one on top of another, and when the wax on the inside is melted and runs down, throw in a handful of sulphur, and place one of the bottom-boards on top to keep in the vapor. In 5 min-utes the hives will be as safe as new frames to the same heat, melt the combs into wax, and scald the honey

fed without heating, it will spread the foul brood to all the colonies fed. If his neighbor's bees get any of this honey before it is scalded, they will have the disease and pass it back to Mr. P's bees by the time they are well started again. So he will see the importance of using great care in all the manipulations. The roof, if painted, is safe, and I think that it would be without.

Short of Stores.- J. A. Pearce, Grand Rapids, +0 Mich., propounds these questions :

1. Is there any way to tell that a colony of bees in the cellar are getting out of stores by the actions of the bees or otherwise? 2. What is the best time of day to put bees out of the cellar?

[1. We know of no better way than to look into the hive to find out whether the bees have enough food.

2. When everything seems favorable for a flight at once, put the bees out, contract the entrauces to the hives, and smoke the bees a little to prevent any great rush from the hives.—ED.]

Condition of Bees in Virginia.-Jos. E. Shaver, North River, & Va., on March 3, 1886, writes :

About half of the bees in this county are dead. The loss was caused by the very poor honey season last summer, this extremely cold winter, and the negligence of some bee-keepers. As there was but little honey gathered last season, some beekeepers gave their bees no attention, and hence their loss. My 25 colonies have wintered nicely thus far. I have them on the summer stands with enameled cloth and cushions on the brood-frames, and corn fodder packed all around the bives, except at the entrances. Most of my queens have commenced laying, although the weather is still quite cold.

Cider and Bees.-R. K. McCune, Fair Water, O+ Wis., on March 1, 1886, writes:

We occasionally see articles in the bee-papers hinting that honey and bees are damaged by pomace at cider-It is true that bees sip at fruit, mills. but it does not necessarily follow that they are gathering it to put among their stores, or even extracting honey from it. We see them in the same way frequenting barn-yards and hog-pens, but no one would for a moment suppose that they were gathering anything to store in their hives. Again, it is frequently said that bees must have salt. Do bees salt their honey? All will say no. Then, I honey? All will say no. Then, I say, neither do they cider it. It may be asked, what do they do with those ingredients? It is a known fact that many kinds of animals and fowls do at times use substances for the same for the same substances. and feed it to the bees in the summer at times use substances foreign to when no honey is coming in. If it is their natural food, as medicine. Why

should not bees use all such things in the same way? For the past 8 years I have run a large cider-mill every alternate year, and have thrown out tons of pomace within a few rods of my bee-yard in which I had not less than 50, and from that to 120 colonies, and I have never seen any injurious effects upon either bees or honey. While we censure fruit-men for ignorantly condemning bees, let us not do the same thing hy ignorantly con-demning cider-makers.

Valuable for Reference.-W. E. Clark, Oriskany, O N. Y., writes :

I desire to state that I think the bee-keepers of America owe the editor of the BEE JOURNAL a vote of thanks for compiling the Convention History and publishing it in such a nice pamphlet. Its value as a reference and record is beyond estimating.

Bees Wintering Well.-B. W. Peck, Richmond Centre, & O., on March 4, 1886, says:

In the fall of 1884 I had 24 colonies; in the spring of 1885, 12; and in the fall of 1885, 34. I sold 4 colonies, so I now have 30, 25 being packed on the summer stands, and are wintering well, and 5 being in a elamp. Last season I took 676 pounds of extracted honey and 66 pounds of comb honey. It was my poorest season since I have been keeping bees. The BEE JOUR-NAL grows better every year, and I shall not keep bees without it.

Queen-Excluding Honey-Boards ----C. E. Boyer, of Ainger, ~ O., writes:

I notice that Dr. Tinker claims the original invention in making the Heddon slat-honey-board to be queenexcluding, by inserting sliding strips of perforated zine into their saw-cuts in the edges of the slats. While I do not doubt its being original with the Doctor, I wish to state that I know that the device was also original with Mr. Heddon and myself. I was one of his students last summer; not an hour after I thought of the plan, he came and proposed it to me, and afterwards received a letter from W. Z. Hutchinson proposing the same thing. But Dr. Tinker freely gives it to the public, as Mr. Heddon and many others have done with similar devices.

Foul-Broody Hives and Fixtures.-Rufus E. Holmes, (22-24), West Winsted, ~ Conn., on March 6, 1886, writes thus:

On page 137, Mr. G. J. Pease wants to know how to cleanse foul-broody hives, etc. I have had all the experi-ence I want. There is no foul brood on his tin-roofs. The sun and rains will take care of all that, and hives and fortunes. Cheap the broad formers

you wish to use again, with earbolic soap-suds, as hot as you can comfort-ably use. Then expose them to the sun and air. Do not feed any of the old honey or let it get where bees can get at it. Foul brood is perpetuated in honey. Honey from a foul-broody in honey. Honey from a toul-broody colony fed to a healthy one will nearly always inoculate the healthy colony. The old honey will make good vinegar. I have tried both the "Cheshire" and the "starvation" plan of curing foul brood. It is not necessary to destroy the bees. I prefer the "starvation" plan.

Do Bees Hear ?- Elias Fox, Hillsborough, +o Wis., on Feb. 26, 1886, writes:

On reading Mr. Osburn's article on bees hearing, on page 120, I was amused at the evidence which he proamused at the evidence which he pro-duces. He says that if bees do not hear, how do they communicate so quickly? My opinion is that they scent the formic acid or bee-poison produced by the sting. His statement does not show in the least that they do hear , paither have L over word or do hear; neither have I ever read or heard any that did. I do not elaim to know that they do not hear, but I would like to see some proof. I would like to ask Mr. O. why bees do not notice a loud noise around their hives, which we all know they do not, but will arouse at the slightest jar, or offensive or inoffensive odor. Let one bee sting you and the others will follow the smell and be more liable follow the smell and be more hable to sting as long as the scent lasts. Let one fasten itself in your veil in an attempt to sting you, and if you pinch it with your fingers you will find a dozen or more dart at the same place, after the first one is dead. I would like to hear from others on this subject.

A Chip .-- W. Z. Hutchinson, Rogersville, & Mich., writes:

Please allow me to thank Dr. Miller for his very timely article on page 132. Also, please allow me to explain that I was not "putting a chip on my shoulder," but was knocking one off of the shoulder of another. (See the closing paragraph of the first article on page 6.)

Hibernation of Bees .-- W. Z. Hutchinson, Rogersville, & Mich., on March 1, 1886, says:

Last fall I piled up in my shop 20 Heddon cases of honey just as they came from the hives. They were uncovered, and remained undisturbed until the last of December, when they were taken into a warm room preparatory to crating the honey. The honey was in the warm room three days before the work of crating com-menced. When crating it, a few straggling bees were found, someand fixtures. Clean the brood-frames by scraping them with a knife or glass thoroughly. Do not try to save any comb, but turn it into wax. Wash thoroughly the hives inside and out, and all the frames and boxes which

and in time became quite lively. They had been hibernating. Bees never enter this state, and must have food and warmth or they perish. They and warmth or they perish. They become quiet, it is true, but they do not hibernate. As Prof. Cook very appropriately says, we need this stronger term to describe a different phenomenon.

Bee-Keeping in Arkansas.-Frank Thiaville, ForrestCity, O+Ark., on Feb. 27.1886. writes:

The season of 1885 was an average one here. We had at least 70 pounds of extracted honey or 35 pounds of comb honey per colony. In June and July we had some honey-dew that spoiled our honey. From 103 colonies I obtained 3 natural swarms. The fall weather was line. On Jan. 7 it turned cool, and for one month the temperature was sometimes as low as S<sup>o</sup> below zero. On Feb. 8 the bees had a good flight, and a great many were lost on the snow. For several rods around the apiary it looked as if a yellow rain had fallen. They spotted the snow very badly, prob-ably having eaten too much pollen. In 106 colonies I had only one queen-less colony. I have lost none so far. Bees at present are doing well, and are breeding very fast. The honey market is dull here, extracted honey bringing 4 cents per pound, and comb honey 8 cents. A great many bee-keepers have lost their bees. They say that they froze, but that is a mistake, for bees never freeze here until all the honey has been eaten.

Good Weather for Bees.-John Rey. East Saginaw, O Mich., on March 5, 1886, writes :

It is four weeks since the bees had a flight, and they are now having another good time. The snow is all gone, and the weather is fine—just right for bees. I think that they will pull through all right now. My bees are bright and healthy so far. I have 68 very strong colonies, but I will not "count my chickens before they are hatched," for they may not be so strong in May.

Flights in Winter - Reversible Frames.-I. N. Boyles, Urbanna.o. Iowa, on Feb. 7, 1886, writes :

I notice that quite a number of bee-keepers have taken their bees out of the cellars for a flight. It has not yet been warm enough here for our bees to fly. There is about 4 or 5 inches of snow in my bee-yard, and it has snowed all day to-day, but it melted as fast as it fell. My bees are in the cellar yet, and some of them are affected with diarrhea. If they do not get a digit soon 1 for the t not get a flight soon I fear that I will lose quite a number of them. Last season was not a very good one for honey in this part of the country. I hope that this year will be better. Much has been written about reversi-ble frames. I think that the extra labor it would take to use them would

think that we would interrupt our bees more by using them than we do in the present management. In the honey season we would work to get all the good honey in the sections and then feed it back to them in the fall to winter on, or let them have the fall honey for winter stores, which would be the cause of their death, nine times out of ten. I want my bees to have good basswood and clover honey to winter on. Another objection I have to the reversible frames is this: If you will uncap the brood and notice, the young bees lie with their backs down; to reverse that frame it would throw them out of their natural position, to which I object.

Bees in Good Condition.-Geo. E. Hilton, Fremont, +o Mich., on March 6. 1886. savs :

I have just finished looking over my 75 colonies in chaff hives, and I find them in A No. 1 condition, not a single one dead yet. A few were short of stores, which was supplied with combs of honey saved from last year's crop for that purpose. There is no sugar feeding in my apiaries. There was but very few signs of diarrhea, and as a rule there was plenty of bees and plenty of stores, and in many of the hives brood on three frames.

My Experience in Bee-Keeping.-D. A. Dimitry, Morgan City, 9 La., on March 1, 1886, writes:

Last spring I commenced with 3 colonies of pure Italian bees, and by purchase and increase I have now 50 colonies, 17 of which are Italians, as many more hybrids, and the balance black bees, which, by the way, have done as well as the rest. I work my apiary for extracted honey. Last August, from 30 colonies I took 54 gallons of beautiful white honey. I use 10 and 6 frame Simplicity hives, which, as you see, cover the two extremes, and I find that one does as well as the other, the smaller being my favorite, as it is easily managed. I lost one colony during the last cold wave, which was the coldest weather known here for the last 15 years. My apiary is located on Shell Island, about 20 miles southwest of Morgan City.

Bee-Keeping in Texas. — J. W. Rounsaville, Brandon,⊙ Texas, on March 1, 1886, writes:

On Nov. 10, 1885, I had 59 colonies of bees, a part of which was in fine condition. I wintered them on the summer stands with the hive-en-trances to the south and east. I examined them on Feb. 27, and have taken off the honey-boxes, confined the bees to the brood-chamber, and out of 16 hives I took 544 pounds of honey. The brood combs are well filled with brood in all stages. I found one bright, new queen-cell. As a common thing, many bee-men have lost bees, and some have lost heavily, for the want of information to handle

them. If all bee-men would read the AMERICAN BEE JOURNAL they would save enough in one year from their bees to pay for several bee-papers for several years. I cannot see how any bee-man could attempt to handle bees without the advice of the prominent bee-keepers who write for the bee-papers. As long as I keep bees I shall consider the AMERICAN BEE JOURNAL one of the indispensable necessaries of bee-management.

Only One Colony Lost.-J. W. Clark, Clarksburg, Mo., on March 1, 1886. savs :

My bees are wintering well so far as I can see. I have lost but one colony out of 76, and that starved with plenty of honey in the hive.

The New Hive and Manipulation. -E. E. Ewing, of Rising Sun, & Md., writes :

Mr. G. W. Demaree, on page 102, declares that there is not a single new feature connected with Mr. Heddon's "new patent hive," I believe that this is correct, but the peculiar com-bination of the old "features" makes something that has never been exactly made before, and that "some-thing" (the hive) makes a manipulation possible that has never before been practiced in working an apiary. When all these results are put towhen all these results are put to-gether, it seems to me that something which the world calls "new" has been created. We are utilizing the knowledge of the past by giving it new combinations, and constructing things that the world and our patent laws call new.

### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

Price of both. Club The American Bee Journal ...... 100.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Mar. 15, 1886. {

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.-Sales have been quite good this month for best grades of comb boney, some bringing 16c. per pound when in perfect order. There is a light supply bere, and now is a favorable time to for-ward shipments. Extracted honey brings 6@8c. BEESWAX.-250/26c. per lb. R. A. BURNETT, 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY.-We note a improvement of sales of honey the past week, but prices continue to rule low. We quote as follows : Fancy white comb in 1-b. paper cartons, 13@14c; the same ia 1-b. glassed or unglassed sections, 12@13c; the same ia 2-b, Rissed sections, 9@10/4c, and fult to good ia glassed 2-lbs, 3@0c. Fancy buckwhest boney ia 1-b. uoglassed sections, 10c; the same in 2-b. sections, glassed, &@9c. Extracted, white, 6½@7½c; buckwhent, 5@6c. BEEESWAX.-27@28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

#### ST. LOUIS.

HONEY.—The market is quiet and the demaad light just now. We quote prices as follows :— Choice comb honey, 10@12c. Extracted, in bar-rels, 44&G5c. Extra fnacy of bright color and in No, 1 packages, ½ advance on above prices. BEESWAX.—Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEY.—There is no speculation whatever in the market, and the demand is slow for extracted honey from manufacturers, while it is fair for honey in glass jars, for table use. Demand for comb honey is slow and the market is well supplied with all kinds. Extracted honey brings 486c, and choice comb honey brings 12@15c. in a jobhing way. BEEESWAX.—The home demand is good, while arrivals are slow. We pay 25@27c. for good yellow to choice.

C. F. MUTH & SON, Freeman & Central Ave.

### CLEVELAND.

CLEVPLAND. HONEY.-There is a sreat improvement in the demand of best 1-b. sections since our last report, and all receipts are finding ready sole at 14 cents, with occasional sale of single crates at 15 cents. Two-ibs are orglected, very little wanted at 13 cts. Old honey, 10@11 cts. and slow. Extracted, 7@8c. BEESWAX.-Scarce at 25c. A. C. KENDEL, 115 Octario Street.

#### KANSAS CITY.

IIONEY.-Sales are improving and we have a good trade la comb, although prices are not as firm, owing to good prospects the Califordia for a large crop baving reduced their prices about 2 cts. We quote as follows : Choice comb in 1-b. sections, 16c.; fair to dark, 12@14c.; in 2-b. sections, 12@14 cents. Extracted is dull and slow. Dark briggs 3 1-2 to 4c.; white, 6@7c. BEESWAX.-23c. CLEMONS, CLOON & Co., cor. 4th & Walnut.

#### BOSTON.

HONEY.—The sale for honey for the past month has been us light as we have ever known it, and prices are weak. One-pound, white clover, 130 lise; 2-pound sections, 11@13c. Extracted, 6@8c. BEESWAX.—30 cits, per lb. BLAKE & RIPLEY, 57 Chatham Street.

#### BAN FRANCISCO.

HONEY.—The market is very dull. We quote as follows: White and extra white comb, 11%@130.; dark comb, 65%@8%c. White extracted, 55%@5%c; amber, 4@4%c; dark and candied, 3%@4c. BEESWAX.—Quotable at 23@25c, wholesale. O, B. SMITH & Co., 423 Front Street.

### DETROIT.

HONET.-The market continues dull and very few sales are reported. Best white in 1-lb. sections can be bought at 13 cfs. per lb. BEESWAX.-It is in good demand at 25@27c. M. H. HUNT., Bell Branch, Micb.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one ean afford to do without it. We will present a Binder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few hours, to get subscribers.

THOMAS G. NEWMAN & SON. PROPRIETORS, 923 & 925 WEST MADISON ST., CHICAGD, ILL.

At One Dollar a Year.

ALFRED H. NEWMAN. BUSINESS MANAOER.

# Special Notices.

To Correspondents. -- It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Perforated-Zine,-We have laid in a stock of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive-194x14½-Price 25 cents cach. cents cach.

Preserve your papers for reference. If you have no **BINDER** we will mail you one for 75 cents, or you can have one FREE If you will send us 4 new yearly subscrip-tions for the BEE JOURNAL.

Beeswax Wanted .- We are now paying 24 cents per pound for good, avcrage, yellow Beeswax, delivered here. Cash on arrival. Shlpments are solicited. The name of the shipper should be put on every package to prevent mistakes.

Are you Entitled to a pension? You may be and may not know it. If you ex-amine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

Our New Catalogne of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it. for it.

To any One sending ns one new sub-scriber with their own renewal (with \$2.00), we will present a copy of the new "Con-vention History of America."

Wire Nalls have advanced in price, as will be seen by quotations on page 159, last column.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

Golden Rules for successful advertis-ing, are these: 1. Attractive display, 2. Sal-ient points clearly stated. 3. Repetition. Don't spend all your money in one unsertion, 4. Choice of the Paper which reaches the people you want to reach. These rules never fail.

Send In orders now for bees, queens, or bees by the pound. I have also a full line of Supplies. Address, F. J. Crowley, Batavia, N.Y.

Dr. Tinker has sent us a sample of his new side-passage sections. They make a fine appearance ; being smooth and accu-rately cut.

Mr. J. H. Mason, of Mechanic Falls, Malne, has sent us a sample of a dovetailed one-pound poplar section, and a smoker, as made by him. Both are of good mechanical appearance.

Sample Copies of the BEE JOURNAL <sup>123</sup> Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to in-terview by sending the names to this office, or we will send them all to the agent.

Frank Cheshire's new book on Bees and Bee-Keeping, can be had at this office in parts. Price, \$3.00.

The Convention History of America and the AMERICAN BEE JOURNAL for one year, will be elubbed for \$1.15.

Cash in Advance is the rule, but no longer than six months of grace can be allowed on the small snm of \$1.00. Subscriptions may commence at any time, and discontinuances may be ordered at any time, when arrearages are paid up.

### Convention Notices.

The bee-keepers of Manitowoe and adjoin-ing counties will meet at Kiel, Wis., on March 25, 1886, for the purpose of organizing a bee keepers' association. J. H. RODERTS.

The Wabash County Bee-Keepers' Associa-tion will meet at the Court House in Wubash, Ind., on Wednesday, Apr. 7, 1886, at 10 am. All bee-keepers ure invited. J. J. MARTIN, Sec.

137 The bee-keepers of Stark and adjoining connties are caraestly requested to meet at Grange Hall (over Farmer's Bank), Canton, O., on Tues-day, Apr. 13, 1886, for the purpose of effecting a permanent organization. MARK THOMSON, Sec.

The Southern Illinois Bee-Keepers' Associ-ation will hold its 3d annual convention in Tearne & Harris's Hall at Duquoin, Ills., on Thursday, Apr. 8, 1856, at 10 a.m. A general invitation is extended. F. H. KENNEDY, Sec.

Bess BEE-FEEDEH.-Sample and full particulars for 30 cents.-For feeding inside of any bive, without distarbing the Bees. T. C. WIRE, 11Ast GRINNELL, IOWA.

Of the Eighteen Different Kinds of North Brazilian honey-bees known to the naturalist, only three possess a sting.

Bulletin No. 11, of the Michigan Agricultural College, is received, and the subject matter is "Making a Lawn," by Prof. W. J. Beal.

Nelson Perkins, formerly of Minnesota, but later of Alabama, died in the latter State very suddenly of a lung difficulty on the 10th inst., and was buried on the 11th inst. He was an experienced apiarist and an earnest Christian, and will be missed by his many companions.

Bees in the Cellar should be left there for some time yet, or until they get uneasy, by reason of warm weather. If put out too soon a cold snap will be very disastrons, for many of the bees are old and have but little vitality. If they go out they soon become chilled and never return to the hive.

We Request our correspondents to send us no more at present pro or con on the Heddon hive. The subject is occupying too much of our space, and subscribers are complaining of this prepooderance. We have now on hand all we can use on that subject for months, and at the same time give the "variety" necessary in a well-conducted periodical.

Everything that will be needed in the apiary should be at once provided, so that when the honey flow comes there may not be any damaging delays in procuring it. Three years ago every supply dealer in the country was so crowded with orders that hives, comb foundation, sections, etc., could not be made fast enough to supply the many orders that were rusbed in all at once. The wise ones will "learn by experience," and order such before the rush comes-for come it will. A word to the wise is sufficient.

The Birds are Here-harbingers of delightful spring. The weather has been so mild and pleasant during the past week, that we feel as though spring had actually come. We may have to pay for it by later storms and cold, but we may as well take all the comfort that can be obtained from the present. The bees have wintered well, and that is encouraging ; for if they have "wintered " well, they will "Spring " safely. The robins and bluebirds are already here, and "the flowers that bloom in the Spring " will soon be spreading their sweet perfome on the air; all -nature having east off her garments of snow and ice, will revivify and the earth will bring forth her generous fruit for man's use and pleasure.

The grassy earpet will be enriched with flowers of gorgeous hues; the trees and shrubs will blossom and bear fruit, and the earth will yield her increase-spreading man's pathway with flowers, and his table with plenty.

The bees wintered on the summer stands are already sporting in the genial sunshine, and enjoying that health-giving exercise. All our reports state that they are in excellent condition, both in the cellars and outof-doors, and everything promises a good year for honey-production. The white clover was not damaged (as was feared by some), and appears quite healthy. We may now take courage and hope for prosperity. The bees are already working on the maples in this vicinity.

A New Uncapping-Knife has been invented in Italy. The following description of it and the manner of operating it, is thus given by Mr. Arthur Todd, in the American Apiculturist :

During the recent meeting of the Italian

During the recent meeting of the Italian bee-keepers at Milan, a machine was ex-bibited which Monsieur Bertrand (of the Swiss Bee Journal) considers an absolute novelty. This was an automatic uncapping-knife Invented by Count Zorzi. It is composed of a blade mounted on a pivot and put in motion horizontally by a cog-wheel arrange-ment moved by a handle. To uncap the combs, they are placed up against the blade, so that as it moves it uncaps. The jury tested its merits in action, and awarded it a gold medal, and stated that it worked well and was enpable of doing good service. To large producers of honey who do not hesitate to spend money to buy time and labor-saving machinery this may be of importance.

importance. Mr. Tartuferi, the owner of 1,000 colonies,

and the largest honey-producer in Italy, expressed himself as greatly pleased at its workings.

Those who have Bees, Queens or Supplies to sell should at once make it known in our advertising columns. Look out for a good trade, and an early one, too. Those who advertise will do the businessothers will look on, be discouraged, and keep their stock. Our columns are open to all hoporable dealers, and should he used liberally. Advertisements may be inserted weekly, alternate weeks, or once a month, as may be desired. See "Rates " on first page.

Golden Rules for successful advertising, are these : 1. Attractive display, 2. Salient points elearly stated. 3. Repetition. Don't spend all your money in one insertion, 4. Choice of the Paper which reaches the people you want to reach. These rules never fail.

Mr. J. M. Shnck, of Des Moines, Iown, has sent os one of his Invertible Hives, with surplus section case, a feeder of the full size of the top of the hive, and also another of largo size for feeding on the bottomboard under the brood-chamber. The hive shows an astonishing amount of ingenuity and inventive genius. It also has a "lifter " for inverting the hives, only one of these being necessary for each operator in an apiary. With it, the inverting of a hive may be done with ease, and so gently that the bees will hardly discover that their house is being handled. Mr. Shuck writes us as follows concerning the hive :

"I ship you one of my hives, etc., for your inspection. I think you will find more pructical invention about it than in any thing in its line that you ever saw in your lite. It conforms to the principles of hives as established by Mr. Langstroth, and yet is different from his hive in the fact that it can be used in four different positions in-stead of one."

Sure enough, there are so many points of practical invention about the hive that we cannot here describe them. Those who desire to know any further particulars should send to the inventor for his descriptive circular, where it is fully described and illustrated.

New Price-Lists have been received from the following persons :

L. J. Tripp, Kalamazoo, Mich.-6 pages-Bees, Queeus, and Supplies.

W. S. Pouder, Groesbeck, O.-1 page-Italian Queens.

Chas. D. Duvall, Spencerville, Md.-12 pages-Bees and Queens.

H. F. Moeiler Mfg. C., Davenport, Iowa.-28 pages-Bee-Supplies.

F. Boomhower, Gallupville, N. Y.-1 pages-Bees, Queeos, and English Rabbits. -12

E. S. Hildemans, Ashlppun, Wis .- 4 pages -Apiarian Supplies.

W. W. Bliss, Duarte, Calif.-16 pages-Supplies for the Apiary.

Shute & Bemont, Meriden, Conn.-4 pages -Poultry.

D. H. Bausman, Lancaster, Pa.-24 pages-Wind Engines.

G. K. Hubbard. La Grange, Ind.-56 pages G. K. Hubbard, La Grange, Ind.—56 pages —Hubbard Bee-Hive, Supplies, etc. To this is added 30 pages devoted to the "first prin-ciples in progressive bee-culture." Price 10 cents, and well-worth it to any beginner.

Aspinwall & Treadwell, Barrytown, N.Y. 32 pages—Bees and Bee-keepers' Supplies.

Martin & Macy, North Manchester, Ind.-20 pages-Queens, Bees, Ponltry and Apiar-ian Supplies.

B. F. Nysewander, New Carlisle, O.- 32 pages-Bec-keepers' Memoranda and Cata-logue of Supplies. Price 10 cents.

Any one desiring a copy of either of them, can obtain it by sending a postal card to the address as given above.

Frank Leslie's Popular Monthly for March comes with its usual variety of readable and valuable articles, attractive stories, and wellexecuted illustrations. Is the Panama Canal a failure ? many ask. The question is answered by Mr. Arthur V. Abbott in "Progress at Panama." The well-known naturalist, C. F. Holder, in his Wooing of the Birds," describes and illustrates some of the strange performances of the feathered gallants when they seek brides in the springtime. Altogether it is a most enjoyable number.

**REPLIES by Prominent Apiarists.** 

"Red Clover" Italian Bees.

Query, No. 221.—Is there any great difference in Italian becs as regards their working on red clover—enough at least to justify one in buying queens for that strain of becs ?—W. M.

Hardly.-G. M. DOOLITTLE.

The difference is more imaginary than real. A "red clover" strain of bees is all "bosh."—J. P. H. BROWN.

I do not know, but as "red clover" queens cost little if any more, the trial of them is certainly not objectionable.—W. Z. HUTCHINSON.

It is so reported. If you contemplate buying "red clover" queens, have the party selling such send you a sample of his bees, and test for length of tongue with the Italians that you have.—II. D. CUTTING.

I have my doubts about it. No bee can reach the bottom of the clover tube. These latter may be so full of honey that any kind of bees can reach the nectar. Italians could get more of it than the blacks, and could reach it sooner. It may be that some Italians do better than others.—A. J. Cook.

### Spring Feeding of Bees.

Query, No. 222. — Describe the best manner of spring feeding in order to hasten breeding. Also, what is the best and cheapest feeder for early spring feeding? Should not the vessel be small, and directly over the cluster?—Mich.

Fill a brood-comb with feed and place it next to the cluster. No feeder can be cheaper; for you have empty combs on hand, so the cost is nothing. --C. C. MILLER.

As before stated, I do not believe in the practice. If I did, I should use any preferred top-feeder, never any other kind.—JAMES HEDDON.

The division-board feeder is the best and cheapest for early spring feeding. Turn the feed in warm and place the feeder at the side of the brood once a day, but only when bees can safely take wing. It is not best to feed on cool or windy days.—G. L. TINKER.

The best feeder that I have tried for cool weather in the spring, to feed liquid feed, is a very shallow box partitioned off to keep the bees from daubing themselves, and having a tube-like passage away up through its centre. But I believe the most powerful stimulant to carly breeding is extracted granulated honey, into which some "oil-cake meal" has been

kneaded, made into flat cakes and fed as candy right over the cluster; and, after all, some colonies that have plenty of sealed honey manage to get these first.—G. W. DEMAREE.

I think that some kind of an entrance feeder (and there are many kinds) used to stimulate the strong colonies, and then equalize by drawing from the strong and building up the weak. This method has several good features. Some very practical bee-keepers feed in the open air.—II. R. BOARDMAN.

The best feeder, like the best hive and best frame, is the one that is liked the best by its owner. If by spring feeding is meant stimulation only, I advise feeding only an ounce or two regularly each night in some feeder that can be bronght close down to the cluster in order that it may be kept warm. If because the colony lacks stores, then add a frame or two of honey; if that cannot be done, then feed a large quantity in a large flat feeder that can be set down close to the tops of the frames.—J.E.POND, JR.

### Tight Ceilings in Brood-Chambers, etc.

Query, No. 223.-1. Is it advisable, in the spring, to have the ceiling of the broodchamber tight, so as to keep the inside warm? 2. In a Simplicity hive, how can we prevent bccs from opening a current of air by gnawing the ends of the enameled cloth? -An Inquirer.

1. Yes.-G. L. TINKER.

1. Yes. 2. This is a practical question, but after years of experience I hardly feel competent to answer it. I have discarded enameled cloth and have gone back to sheeting.—C. C. MILLER.

1. Decidedly yes. I use newspapers, spreading them two or three in thickness over the quilts, and some board weights over them. 2. If you must prevent this, lay some strips of wood, and tit them down closely at the ends of the cloth. With my square-joint hives the cloth is cut out as large as the outer dimension of the top of the hive, and laps on its edges, so that the upper sectional part of the hive rests on the edges of the cloth, thus securing a close-packed joint. — G. W. DEMAREE.

1. Yes, by all means ! Not only to retain the heat but also to create moisture. 2. If any trouble is found from bees gnawing ends of enameled cloth, it can be prevented by binding with tin or tacking it to a thin strip of wood  $\frac{1}{14}$  of an inch thick and 1 inch wide. I cover with enameled cloth and then place a cushion made of 5 or 6 thicknesses of old woolen carpet over all, and have no trouble. Bees will not gnaw much if no light comes through.-J. E. POND, JR.

1. Yes, though this matter is not so vital a one as many suppose, it seems to me. I have seen rousing June colonies that had passed the spring all open at the top of the hive. 2. I

could not be induced to use cloths about my hives in the spring, summer or autumn.—JAMES HEDDON.

## Fertilization of Queens.

Query, No. 224.—1. Which is the best method to insure a queen's mating purely where there are other races of bees in the vicinity? 2. How far will the queen go from her hive on the "bridal tour?"—Elgin, Texas.

2. She often mates with drones 5 to 7 miles away.—G. M. DOOLITTLE.

1. I know of no sure method. 2. Queens will often cross with black drones distant 4 miles. "Clean out," if possible, the "other races of bees in the vicinity.—J. P. H. BROWN.

1. The best practical method is to rear an abundance of pure drones in the home apiary. 2. I have had queens mated with drones whose hives were 1½ miles away.-W. Z. HUTCHINSON.

1. Rear your queens so early that other drones will not be flying. We secure drones early by stimulative feeding. 2. It is hard to tell, but for some miles, as has been demonstrated. —A. J. Cook.

2. It is reported that queens will mate with drones 5 miles away.—H. D. CUTTING.

1. Rear your drones and queens early or late in the season. 2. The queen will go probably a mile. We have seen matings of our Italian drones with black queens 3 miles off, when we first bred Italians, in 1865.— DADANT & SON.

Brood-Frame and Section-Case Covers.

Query, No. 225.—What is the best cover for brood-frames and section-cases? The bees cut cloth, quilts, muslin, etc., and sometimes make a terrible mess of them. I use sticks sawed and planed out of lath, mostly for shutting spaces between the frames, and I like them better than anything I have tried, but I would like something better if I could get it. For sections they will not do; and cloths fullof holes, and sections smeared with propolis are not agreeable. What is better ?—T. M. C.

I use enameled cloth.—G. M. Doo-LITTLE.

I like factory-cloth and chaff sacks from October to May, and a board or Heddon honey-board after that.—A. J. COOK.

If you use good cloth *painted*, you will have no trouble. As a matter of course, it does not last forever, but will last several years. When we use sections, we hang them in broad-frames without any division between the stores. If you use the Heddon crate you must use his honey-board also.—DADANT & SON.

I think it the best way to have the tops of the frames or sections a bee-

\_\_\_\_

space below the top of the hive, and cover with a board. I know of no better flexible substance to place directly upon the frames than enam-eled cloth.—W. Z. HUTCHINSON.

I have used enameled cloth for about ten years with the best of success. The bees very seldon cut a hole in it, and put but little propolis on it, compared to cloth of any kind without the enameled surface. It is cheap, costing 21/2 to 3 cents per hive, and I have some in use that have been used for several years.-II. D. CUTTING.

### Convention Notices.

17 The bee-keepers of Manitowoc and adjoin-ing counties will meet at Kiel, Wis., on March 25, 1886, for the purpose of organizing a bee-keepers' association. J. H. ROBERTS.

17 The Wabash County Bee-Keepers' Associa-tion will meet at the Court Hoase in Wabash, Ind., on Wednesday, Apr. 7, 1886, at 10 a.m. All bee-keepers are invited. J. J. MARTIN, Sec.

The bee-keepers of Stark and adjoining counties are earnestly requested to meet at Grange Hall (over Farmer's Bank), Canton, O., on Tues-day, Apr. 13, 1886, for the purpose of effecting a permanent organization. MARK TBOMSON, Sec.

The Southern Illinois Bee-Keepers' Association will hold its 3d annual convention in Teaxue & Harria's Hall at Duquoin, Ils., on Thureday, Apr. 8, 1836, at 10 a.m. A general invitation is extended. F. H. KENNEDY, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886.

### J. M. HAMBAUGH, Sec.

ter The aemi-annual meeting of the Western Bee-Keepers' Association will be held in Kanaas City, Mo., on Apr. 29 and 30, 1886. It is desired that this meeting shall be better than any of its predecessora. Essays will be read on the leading subjects in bee-culture, which will be announced as aoon as arrangements are completed. Let all who bave bees, queens, fixtures, etc., bring them if possible. Due notice will be given in regard to a hall. P. BALDWIN, Sec.

The Union Bee-Keepera' Association of Western Iowa will meet in Dexter, Iowa, on April 10, 1886, at 10 a.m. M. E. DARBY, Sec.

A cordial invitation is extended to all to attend the 8th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No hotel bills to pay. B. F. CARROLL, Sec.

### Honey as Food and Medicine.

127 To create Honey Markets in every village, town and eity, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and seatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine " are sold at the following prices :

Single copy, 5 cts.; per doz., 40 ets.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-beaper who scatters them) keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is beated near the centre of the State named:  $\delta$  north of the centre;  $\beta$  south;  $\circ$  east;  $\circ$  west; and this  $\delta$  northeast;  $\circ$  northwest;  $\circ$  southeast; and  $\beta$  southwest of the centre of the State mentioned.

For the American Bee Journal

# " Differential Diagnosis."

### N. W. M'LAIN.

Perhaps the reader may inquire what has happened now, which should furnish occasion for an article with such a ponderous and paralyzing caption. I hasten to disclaim any sinister motive, and proceed at once to locate the responsibility where it properly belongs. Dr. G. L. Tinker is the and the occasion was the reply to Query, No. 185, viz: "Are queen's eggs, when first laid, male or female?"

Although the correct answering of the question in the form in which it was probably intended to state it, requires correct observation and exact knowledge of the operation of the most subtile influences and delicate organic structures known to the embryologist, an off-hand opinion on the question, as it was stated, seems to have cost the Doctor no effort what-ever, for he promptly replies: "Yes, of course they are." And I do not hesitate to deny that his answer can be successfully controverted.

I like to think of our bee-periodicals as fruit-baskets, into which are dropped the product of careful, painstaking and well-directed experiment, patient observation and ripe experience. I have distinct recollection of baving found in these fruit-baskets, baving found in these fruit-baskets, at intervals during the past three years, some coccanuts (mark you, not "chestnuts") grown by the aforesaid G. L. Tinker, of "The Wintering Problem" variety," which contained about as much milk and strong meat as any specimens I have had the pleasure of sampling. Apart from the fact that the grain of the fruit seemed a little "coarse," as the hor-ticulturists say, the fruit was to my liking. I suspect that while matur-ing a little too much "nitrogenous matter" had been taken up into its constitution.

Having heen a reader of the various bee-papers for several years, I am quite conversant with the views of many whose names have thus grown familiar; and all will agree, that a very fair presentment of the characteristics of a writer flows from and is outlined by the point of his pen; and that he who habitually reads between outlined by the point of his pen; and spermatozoa from Cyprian, Italian that he who habitually reads between and English bees are to the most re-the lines, will obtain a view in profile fined microscopical examination iden-

of him who writes. By this means I feel that I have had a long and pleasant acquaintance with many who will perhaps read these lines, but whose faces I have never looked upon, and Dr. Tinker is one among that number.

"But," the Doctor says, "a differential diagnosis" of freshly laid queen's-eggs "would floor" bim. Now I submit that it would be inexcusably mean to stand by and, see a friend "floored" by a little thing like a queen's egg, especially so when the egg is fresh. With the assurance that the specimens are of recent produc-tion, we may proceed to inquire what differential principle is revealed by a diagnosis of queen's eggs. I need not here explain that each egg in the ovaries of the queen is generated from a nascent cell; that all eggs when they leave the ovaries are unfecundated, and possess the innate power of producing drones only; that after fecundation the queen may generate two genders; that fluxion of male and female elements produce the female; that sex is determined by the volition of the queen; that the eggs intended to produce drones pass directly from the ovaries through the oviduct to the ovipositor; that those eggs intended to produce females, are, when leaving the ovaries, diverted by voli-tion of the queen, and directed into the fertilizing sack, and that while passing through the folds of this sack, the differentiating, the sex-determin-ing principle is introduced; after which the fecundated eggs pass on through the oviduct to the ovipositor. I have not been able to discover any difference in the shape and superficial appearance of the eggs, whether fecundated or unfecundated. The egg of a queen-bee, as seen through the microscope. is a most delicately constructed and beautiful object.

Mr. Frank Cheshire, in the Journal of the Royal Microscopical Society, of London, England, so aptly describes the appearance of a queen's egg as seen through the microscope, that the object seems verily present before the eye of the reader. He says: "If an egg be removed from either a worker or drone cell by the wetted point of a camel's-hair pencil, and then microscropically examined in water or glycerine, its surface will be found beautifully netted (the chorion), almost as though a tiny pearl had been covered with what the ladies call blonde,' hundreds of the meshes of which are required to coat it completely. Towards one end the netting makes its cells long and narrow and pointing towards a circular spot, just as the cordage of a balloon points toward the upper valve by which the gas is allowed to escape. This circular spot is really an opening called the micropyle, by which the spermatozoon enters and unites its material with the queen-cell, so bringing about fer-

"The tiny spermatozoon not only differentiates the entire creature, but communicates unerringly differences of species or mere variety even.  $\mathbf{The}$  tical, and yet they contain differences which determine almost countless variations in form, color, size. instinct, capability and temper." "That the spermatozoon enters the egg is certain, for it may be found if the latter be carefully examined immediately after deposition." "The head of the spermatozoon is very narrow in order that the micropylar aperature may be passed."

Here, then, within this atom whose presence is revealed to us by the microscope, is latent those subtle yet potent forces, which may have been conserved for months, perhaps for years, awaiting the time and the environment when in complete agreement with the law of its development, it should be called upon to determine. even to the minutest variation, the distinctive characteristics of a new creature. The determination of sex is a matter of choice, a royal prerogative. The limitation of sexual development; the determination of form. function and instinct-reference being had to all female larvæ-is a matter of choice among the workers, the prerogative of intelligence superior to that of the queen. The queen, in the ordinary and normal performance of her function, is simply reproducing ancestral features which must appear in the direct line of hereditary trans-mission. Every unfecundated egg must produce a male larva, and every fecundated egg must produce a female larva. And here, in these direct lines, her prerogative of sexual differentiation ends.

It is here at this stage where a more subtile differentiating influence manifests itself, modifying larval adapta-tion and determining structural features radically different and radically divergent in instinct and function. It is indeed very wonderful that the queen should have the power to vol-untarily control the sex of her offspring, but the marvel consists not so much in the exercise of that function. as in the singular and unique adaptation of the delicate organs by which the function is performed. That secappear, not inherent in ancestral germs, or contributed by ancestral transmission, appears to me far more strange. That this extra differential influence, operating through intelli-gence or instinct-and the partition between these two appears to be very thin-and in no sense through ancestral transmission, should become persistent, is marvelous beyond satis-factory explanation. We look to the future for explanation of how the same organic being may be made to assume either one of two divergent modifications of structure, instinct and function ; and how this specialization for different functions has been made persistent, and from a remote origin transmitted from one generation to another through an anomalous agency.

Every receptive soul is filled with reverence and awe when brought into the presence of stupendous manifestations of power. I have stood upon the shore of the ocean and in the mountain gorge, and on Table Rock;

I have seen the rising sun reflected I have seen the rising sun reliected from the snow-capped peaks of the Rockies, and have found myself say-ing," How wonderful are thy works !" and yet, I could not help adding: "However. I find everything very like what I had expected." I have looked upon the revelations of the telescence and have followed the telescope, and have followed the astronomer as he spoke with familiarity of the millions of miles measuring the inter-stellar spaces, and with mathematical accuracy computed the times and seasons in the great design of plauetary revolutions; and I have tried to lift up my thoughts , and Thave contemplation of "The Great De-signer," whose ways are past finding out. If it be true that the mind is thus filled with admiration and reverence in the presence of the immense and imposing, what shall be the emotions of the receptive soul, when the transcendent grandeur of the minute is disclosed? I have looked upon the revelations of the microscope, and the blood has stopped in its customary courses, and with blanched cheek and downcast eyes, I felt like saying: "Put off thy shoes from off thy feet."

Verily our thoughts should be humbled and our emotions sublimated, whether we contemplate the handiwork of omnipotent power and the sway of immutable law in the creation and ordering of the eccentric solar system, or whether we recognize the presence of that same power and that same law, differently manifested in the unfolding of insect life, and in determining the differentiating conditions, which, with marvelous and delicate precision, establish and perpetuate form, function, and instinct.

"From the drift of a star to the drift of a soul, The world is all miracle under control; The butterfly's wing and man's reverent awe, Alike wear the chain of insertuable law; A law that allures us, but ever eludes, That baffles our groping, but never deludes; We never can hold it; it holds us secure; And the wisest in reading shall longest endure; A Faith-bow of promise, a promise replete— Forever fulfilling, but never complete; We chase where it beckons, and gather the gold, And lo, on before us, new treasures unfold !"

For the American Bee Journal

# "Brethren, Please Don't !"

### WM. F. CLARKE.

Dr. Miller's article on page 132 of the AMERICAN BEE JOURNAL, in which the above pathetic entreaty occurs, reminds me of an incident which happened many years ago at a Methodist Conference in England. A good brother who fisped, fell asleep during the proceedings, dreamed that the Conference was having a big quarrel, "spoke out in meetin " and exclaimed, " Peath, brethren, peath!" A member of the Conference, in a fit of sudden anger, replied by asking in stentorian tones, "Who's at war, you sleepy hog?" It was a very coarse and unchristian rejoinder. I wash my hands utterly of the latter part of it, but beg to ask Dr. M., "who's at war?"

In his anxiety to make out a case, I really think the Doctor does me at least a trifle of injustice. Now, Brother Miller, did I say any thing at all approaching the words you put into my mouth? "As who should say, 'You just dare to say a word against the Heddon hive.'" I started abruptly with very strong language in commendation of the new hive, and then said, I had not spoken rashly, but was prepared to back up my statements with strong reasons and cogent arguments. I invited "any gladiator" who felt so disposed, to "pick up the gauntlet for a friendly tilt over them." A "friendly tilt" observe. Surely, you have no objecto that ! I can truly say I never felt more good-natured in my life than when I wrote the paragraph which has excited Dr. M's alarm. I was just brimful of pleasure, "tickled to death" at having found exactly the hive I had been looking for so long.

If Dr. M. suffered from bee-stings as much as I do, he would be able to appreciate my gladness at having a system of manipulation put before me by means of which I can escape opening the hive, except on rare occasions, and do most of my work in the apiary so quickly, that even an Italian would hardly have time to interview me. When people are full of happiness over some piece of rare good fortune, they are no more quarrelsome than a bee is when full of honey.

There is another place in the Doctor's article where I think he gives me a homeopathic dose of injustice. "It is entirely proper for A to say that no other hive but the Heddon should be used, giving reasons for such belief." To be sure, he quotes A, but the connection plainly implies that he means C. Now, I did not take the ground that " no other hive but the Heddon should be used." I said what implied that I meant to use it, and gave the reasons. I am sellish and wicked enough to hope that everybody won't adopt it right away, because I want to make a little at honey production before the thing is overdone, as I am sadly afraid it will be when my theory of hibernation and Mr. Heddon's hive are generally adopted.

In one point I think the worthy Doctor is inconsistent with himself. He sets out by saying he is dreadfully afraid there is "just a speck of a cloud which begins to threaten" the bursting forth of a storm. This feeling came over him, he says, "as I read what points to a controversy over the Heddon hive." Farther on, he says, "When any man puts before the public a new thing, especially if it he patented, that public has the right to discuss it." Well, I started the discussion by laying down a proposition in favor of Mr. Heddon's book and hive. Was that wrong? I didn't want the discussion to be onesided, and therefore invited all who disagreed with me to "come on" and have a "friendly tilt." I think this is just what the Doctor says the public has a right to do.

I do not know a shade of difference between the meaning of the words

"controversy" and "discussion." I know that controversy is often very hot, especially between rival schools of theology and medicine. I also know that Irishmen sometimes have what they call "a discooshun wid sticks."

Guelph, Ont.

For the American Bee Journal,

Lamn Nurserv vs. the Queen-Nurserv.

HENRY ALLEY.

On page 120, Mr. W. Z. Hutchinson gave some of the reasons why he used the lamp nursery. Some of the rea-sons he gave why he uses the "lamp nursery" are just the reasons why I cannot use such a contrivance for hatching, queen-cells. Any arrange-ment that requires attention as often ment that requires attention as often as once in "two hours," will not do for me. How does Mr. H. manage such an apparatus during the night? If the proper temperature is kept up, queens will hatch as readily in the night as in the daytime.

In the early days of my queen-rear-ing business, I was obliged to watch a "hatching-machine" that required as much attention as the "lamp nursery," and during the season that I was obliged to work the hardest I was deprived of sleep and rest at night in order to save all of the young queens that were about to emerge. Well, I do no watching now-a-days. One day I decided to devise a "queen nursery," and now I can go to bed and get up when I please, as far as hatching queens is concerned.

By the use of the queen-nursery I manage to get along with half the number of nuclei that my queen-rearing business would otherwise require. Each "nursery" of 18 cages is equal to the same number of nuclei hives; if no nursery cages were used, so many more hives would be needed.

I remove a fertile queen from a nucleus, and in 3 days I introduce an infertile one of the proper age to make the mating flight the same day. Sometimes when the weather is unfavorable, I am obliged to introduce virgin queens that are 2 weeks old; but I can do it as well as I can introduce those that have just emerged from the cell. All of my queens are introduced at night, that is, about sunset, by methods that I have given. If the weather is favorable, they are pretty sure to be fertilized the next day. I place the cells in the nursery cages on the day after they are sealed. and before night many of the queens will emerge. After the cells are placed in the nursery, I give no more attention to them until the queens are old enough to make the "mar-riage" flight.

I never saw one word in print that would indicate that Mr. Hutchinson ever used a "queen-nursery." I rather suspect that he is as much of an old fogy concerning the queen "nursery" as I was regarding the bellows-smoker. After using a tin pipe for 20 years, in pollen theory, for in apiculture un-which I could burn only tobacco, it discovered circumstances often strik-was pretty hard to convince me that the "new-fangled" smoker was as tendency in that direction? It is made. The house is 30 feet square,

good as my old pipe; but when a friend sent me an improved Bingham bellows-smoker, and I had tested it, I found that it was superior to any thing I had used for smoking bees. I would suggest to Mr. Hutchinson that he would have less watching to do and less trouble if he should use some good "queen-nursery" in con-nection with his "lamp nursery;" have his queen-cells built so that they can be orgily cond guidely compared can be easily and quickly separated, and place them in cages. No queen would then be lost even if a dozen should emerge at one time. Now, Mr. II, try one of the new "queen-nurseries," and you will not say another word in favor of the "lamp nursery" for rearing queens. Wenham, & Mass.

### For the American Bee Journal.

Northeastern Michigan Convention.

The annual address of President R. L. Taylor was as follows :-- W. Z. HUTCHINSON, Sec.

I congratulate you to-day upon the the strides forward that the vocation to which we are so devoted has made during the year that has lately closed. But few continue to engage in apiculture and attend conventions of bee-keepers who are not deeply interested in all that pertains to the business, so I congratulate you, too, that our vocation is one which our hearts and hands work together with alacrity. Thrice unhappy is he whose heart re-bels at the work his hands must do; thrice fortunate is he whose steps, though quick, lag behind the inter-ested rapidity of his soul. Interested as you are in the honey-bee, and coming here as you do to hear, speak and learn about it, I should but weary you were I to devote the time allotted me to any other subject, or to mere generalities upon this subject, so I shall speak specifically of various matters connected with bee-keeping.

THE POLLEN THEORY.-Many, no doubt, are still interested in this theory. Some have decided for or against it; others are still inquiring. My experience in wintering bees during the last winter-the most disastrous of all winters to bee-keepers-is to my mind a striking corroboration of the truth of the pollen theory. I put into the cellar 195 colonies, all deprived of bee-bread by exchanging their combs for empty ones entirely or almost entirely free from that nitrogenous food. So far as I was able to judge after repeated and thorough examination, I had no normal colony but what wintered perfectly; while during the two preceding win-ters, under apparently more favorable circumstances respecting tempera-ture, my bees that were provided with the ordinary amount of bee-bread and occupying the same cellar, suffered very severely. This is not a demonstration of the truth of the pollen theory, for in apiculture un-

1

amusing to witness the asumption and to examine the reasoning of many of the opponents of this theory. They are heard on every hand, declaring with Mr. J. E. Pond, Jr., viz: "As yet, however, this theory has no proof in its favor;" and that "the fact that bees do survive the severest winters with large quantities of pollen left in their hives, and do not survive at times when they have no pollen at all, is positive proof that the theory is not correct."

What is the pollen theory? Do its enemies claim that it teaches that the " leaving of bee-bread in the hive " by a colony of bee-bread in the nive "by a colony of bees is a cause of imper-fect wintering? or that it teaches that bees always survive the winter if bee-bread is absent? I had sup-posed that it was the consumption of bee-bread and not the "leaving of it in the hive" that the believers in the theory think to be injurious, and I do not understand that they deny that colonies perish sometimes by reason of other causes than that of bee-bread eating.

FOUNDATION IN WIRED FRAMES .-There are many experienced apiarists who are still of the opinion that it is not desirable to use foundation in wired frames. I think that such are in a serious error. If it were a mere matter of convenience—of ease in fixing foundation in frames, and of certainty in knowing that it will stay in place invariably when given to strong colonies, I could understand it; for some men like their own way even with uncertainty. But from my ex-perience during the last season with 185 colonies in which I had in use several hundred combs made from foundation used without wires, along side of those made from foundation on wires, I declare that there is a far more important point involved than mere convenience. It is a question of strength of colonies, and so of success or failure. I believe that the time is near when every intelligent apiarist who uses foundation for brood-combs will use it in wired frames. There is not one comb in a hundred drawn out in strong colonies from foundation fastened into unwired frames in which the cells are not more or less enlarged by the stretching of the foundation ; and this will be found true without reference to the quality of the wax used, or to the manner in which the foundation is made, or to the machine used in is made, or to the machine used in making it. Wax will stretch under the heat and weight of a strong colony unless it is strengthened in some way or made heavier than it ought to be. I found in examining hive after hive repeatedly, that the queen occupied such combs with extreme reluctance even when placed in the middle of the brood-nest, and under compulsion she would fill only about one-half of the comb with eggs; while wired frames, standing next to them, had brood up to the top-bar.

HOUSE APIARIES .- During the past fall I built a honey-house and a bee-

with 12-foot posts, and is built against the east end of my barn, which has also a cellar under it. The new cellar is divided east and west through the middle, and the north half is the part I use for bees. In the west end of it is a cistern  $5\frac{1}{2}x15$  feet, and a door in the east end opening directly into the apiary. The ground slopes considerably to the east, which gives an easy passage without any steps or stairs, and at the same time enables me to bank the cellar up to the sill on the north and east sides, except where the door is. I consider the position of the cellar on the northeast cornertaking the two buildings as one—a great advantage. It is thus protected both from the prevailing cold winds of winter and from the heat of the sun in the early spring. I have in this cellar 219 colonies,

and the mercury has stood almost continually at 451/2° to 46°, Fahr. Continued extreme weather will cause it to vary a little, but not much. I now think that it would have been as well to have put 300 colonies into it. The building itself is divided nearly through the middle into a shop and honey-room. The shop is of sufficient size to accommodate a horse-power and saw-table. The floor and all the walls are filled with sawdust, as is also the ceiling of the honey-room. There is, too, tarred paper in all the outside walls. The windows are hung on pivots at the middle of the sideto let out any bees that may be brought in with cases of honey. Above is a large, well-lighted room for storing, etc. The doors are all bee-proof. The chimney is built from the bottom of the cellar, and in it is a galvanized smoke-flue fitted to receive pipes from stoves in the honey-room. Within the chimney and outside this flue is ample space for ven-tilation, and provides the best conditions for securing that object, which can be taken advantage of when thought necessary by means of the ventilators placed in the chimney, one near the bottom and one near the top of the cellar.

CELLAR TEMPERATURE FOR BEES. The discussion at the Detroit Convention, last December, indicates that a great change is taking place in the opinions of prominent bee-keep-ers with regard to the best cellar temperature for wintering bees. It appears that several bee-keepers have wintered bees very successfully in cellars where the temperature was much above what has hitherto been thought best-sometimes running up even to  $90^\circ$  and  $100^\circ$ , Fahr.; and it seemed to be the general sentiment that it would be better to raise the temperature of our cellars to about 55°, Fahr. Since in bee-culture, circumstances are so likely to alter cases. 1 should raise the temperature of my cellar very gradually.

SECTIONAL BROOD-CHAMBERS. -Two events of the past year in apicul-The view of the past year in apicin-ture demand some attention. They are, the publication of the book, "Success in Bee-Culture," by Mr. James Heddon, and his "new hive." The hive, in its important features, and has had an abundance of discus-

is, I believe, entirely original. Against its originality even Mr. A. I. Root can only say that years ago he thought of making a hive somewhat on this prin-ciple; but his hive was to have no frames—simply slats nailed across to hold the combs.

It was at least 30 years ago, when 1 was but a lad, that my father put me to making bee-hives, for he used to keep a few bees, and I was the me-chanic of the family. He gave me an old hammer and an older saw, whose condition was worse than even its age would indicate, and some rough humber one foot wide. Under his directions I made each hive by cutting four boards about two feet long, nailing them together into a long box without top or bottom, and then sawing it into three equal boxes. I then with saw and jack-knife cut out notches in the top of each part and put slats across. These three sections were to be placed one above another. and to be interchangeable. I suppose when the top one was found full of honey, the honey was to be cut out and the empty one put under the others. I do not remember of helping to cut out any honey. The bees dis-appeared; it was during the time of those renowned winters when bees ber, I claim priority over Mr. Root, But let us return : The brood cham-

ber of Mr. Heddon's hive (or perhaps I should say a single section of it) holds eight frames of the capacity of five Langstroth frames. For a broodchamber, one, two or more of these can be used. They are interchange-able, reversible together or separ-artely, and you could not fail to get refractory bees into the sections for comb honey by putting them between the two parts of the brood-chamber, using a queen-excluding honey-board to confine the queen to one of the parts. There are several other ad-vantages to be derived from it, as it seems to me, on account of its susceptibility to manipulation, and every without handling a single comb. I have faith in the hive. Look out for

have faith in the hive. Look out for a revolution! The book is also new—made on a new plan. It has kept largely out of the fields occupied by other works on apiculture. It has sought pastures new. It has been prepared for the use of the specialist, and the author never loses sight of practical advan-tages to be gained from every opera-tion. Indeed it is a direct answer to tion. Indeed it is a direct answer to the question, "How can the greatest pecuniary success in apiculture be attained ?" and the answer is made full and complete by entering into all the details of practical work. No bee-keeper can afford to be without it. Lapeer. O+ Mich.

> Read at the Indiana Convention. Cause of Loss in Winter.

sion in connection with wintering bees. The best bee-keepers differ widely in this matter, and the problem seems still unsolved. The causes of bee-diarrhea are very likely the same, but appear different because looked at by different persons and under different surrounding circumstances.

Pollen is a nitrogenous food and wholesome; without it the existence wholesome; without it the existence of the bee would be an impossibility. The larvæ derive from it their body; and it is essential to animal growth. Pollen preserves for years its nutri-tious qualities, if kept dry, but it sours in a damp place, like other farinaceous matter, and swells over the brim of the cells. In such condi-tion it has lost its wholesomeness, and is not any more the pollen we and is not any more the pollen we were talking about. Bees will get sick if they are obliged to use it. About the same can be said of boney. It will keep forever in a dry place, even in open vessels, and exposed to the sun; but it will sour in a damp cellar, and the tendency to sour will increase with the beight of the temperature. Sugar syrup will sour in a warm place which need not be damp. Many reports, from a number of beekeepers, stating that sugar syrup would not save the lives of their bees, sustain my argument.

There are several points which we should remember when preparing our bees for winter, viz: Bees can create a great amount of heat when in a a great amount of heat when in a cluster and well supplied with healthy food. The next is that their exhala-tions condense into water when the outside air is colder than the tempera-ture of their hive. The moisture will increase with the falling of the tem-perature, and if it cannot escape as fast as created, the combs and the insides of the hive will become moldy. insides of the bive will become moldy, and their honey and pollen turn sourbecome decomposed. I do not think any one has yet seen a colony of bees that died with the diarrhea without moldy combs and sour honey in those parts

upon which they clustered. Perhaps most of us remember the box-hives without a bottom-board, and each corner standing on a pebble or a block an inch or two above a plank. Moldy combs and diarrhea were unknown to the bees of those fortunate bee-keepers, and if a loss in winter occurred, it was a case of starvation every time. Those igno-ramuses had accidentally an advan-tage over ns scientifics. Let us make a note of it.

If you want moldy combs and your bees to have the diarrhea during winter, cover the hive up tightly and contract the entrance to about an inch or less. The severer the winter the more the bees will be affected. Try it, and if you lose most of your bees by diarrhea, take any scape-goat you please, but do not blame the pollen nor the fall honey. If you want bees to winter well, confine them to their brood-chamber and let each colony have plenty of honey. Fall honey is as wholesome as the best clover, and

Have the hive-entrance wide open, and place in the upper story, on the covers of the brood-chamber, a strawmat or its equivalent. These covers are generally composed of three boards, so-called "third covers." If they fit together very tightly, I should bore an inch hole in one of them, which will admit of the necessary upward ventilation, while the straw-mat on top prevents a draft and keeps off the cold. There will be no moldy combs and no diarrhea. Try it; and if you fail, by this method, to winter your bees as well as did the box-hive bee-men of old. let us know it.

I have recently both read and heard some fine arguments on the pollen and wintering theories, apparently based upon scientific principles, but they could not withstand the solid matter-of-fact arguments brought to bear against them at the Detroit Confacts the most plausible theories must be discarded. Bee-men in the North winter their bees in cellars-in dry cellars, and in damp cellars; have their bees bred up so that when they put them out in April or May their colonies have not only brood in 7,8 or 9 frames, but 7,8 or 9 frames *full* of brood—almost ready to swarm. The veracity of each of these men need not be doubted. The one with a dry cellar maintains in it a temperature not above  $45^{\circ}$  to  $50^{\circ}$ ; while the damp-cellar winterer runs the temperature as high as  $50^{\circ}$  to  $90^{\circ}$ . Pollen is consumed, or brood could not be reared, but no diarrhea develops.

Neither pollen nor honey is the cause of bee-diarrhea, to the best of my observation ; but cause either of them to be decomposed, then it will act like poison, the same as moldy corn would affect your stock, or decomposed meat the human family.

For the American Bee Journal.

# Prevention of After-Swarms.

### R. DART.

There are two ways by which I prevent most of the second or after-swarming. I place my new colony on

swarming. I place my new colony on the old stand, setting the old hive to one side. At the time, or the next day, I place the old hive on a new stand, fronting the hive to the north, and shading it from the sun. My other way of handling is to draw the frames from the old colony, and shake most of the young bees from the combs in front of the new colony, leaving bees enough in the old hive to nurse the young brood. I carry the old hive to a new stand. This way of handling makes more work, but one will get no second swarms from hives handled in this way; the old colonies get strong very way; the old colonies get strong very quickly, and are soon at work in the sections. I use three swarm-catchers for my 60 colonies. If I have a second swarm I let it run into the swarm-catcher and leave it there over night. Next day I rnn them back to the old colony, taking away the young queen as they run in. All the other young queens left in the old hive were dis-posed of on the previous night.

I do not have to climb trees, cut off limbs, scrape swarms off the bodies of trees, and get my bees cross. I have used swarm-catchers for 6 years out of the 30 years I have kept bees, and they save over one-half of the work in the swarming season. Ripon, O+ Wis.

For the American Bee Journal.

Horizontal, Divisible Brood-Chambers.

### E. KRETCHMER.

Finding that much of the BEE JOURNAL is occupied with comments on a horizontal, divisible brood-chamber for bee-hives ; and seeing some of them, at this late day, headed "An Original Invention," I beg permission to add a few scraps of history.

In Knauff's Bienen-Zucht, published over fifty years ago, I find directions for constructing and using such broodchambers; the several parts were made as follows: A sectional cham-ber was constructed of braided straw, 16 inches in diameter, and 8 inches deep, top and bottom consisting of slats to which the combs were at-tached; three of such sections con-stituted a hive. The upper section was designed for the surplus honey, whilst the lower two sections constituted the brood-chamber. In the directions for using, the author directs prior to swarming to equalize the amount of brood in the two chambers by placing the upper brood-sec-tion at the bottom, or exchanging the position of the two sections, and when equalized to make artificial swarms by removing one section, bees and all, and place an empty section under each full one.

Later, under date of July 23, 1867, Letters patent No. 67,123 contains a drawing of a horizontally divided brood-chamber. A few extracts from the specifications may give more light: "In providing a horizontal bee-passage through all the combs." (This is the space between the lower and upper tier.) Next follows the description of the bottom arrangement, on which are placed the brood-chambers described as follows : "The chambers described as follows: "The lower body of the hive is a square box; upon this box I set another similar box...The interior of these boxes I provide with movable brood-frames R, arranged side by side, con-sisting of two vertical pieces M, top-bar K, and bar O... The vertical pieces M are made wide enough to have the edges of the several frames to touch each other. to touch each other....Between the sides of the case I insert a wedge-shaped piece of lath for the purpose of closing the crevices between the frames.

This hive was then called "Kretchmer's alternating hive," and consisted mer's atternating hive," and consisted of three equal chambers, each about 8 inches deep, the two lower cham-bers were used for brood, the upper for surplus honey. In those days, in the absence of comb foundation, we frequently placed the surplus cham-ber under the brood until a start of combs were made, then placed it on top, at the same time the two brood-chambers were alternated, that is,the

upper chamber was placed on the bottom, and the bottom chamber under the snrplus honey receptacle. By this alternating process the centre of the brood-nest was brought next to the snrplus chamber, which caused the bees to enter and begin work in said surplus chamber more readily than otherwise; the honey, if any in the brood-chamber, now in the lower the brood-chamber, now in the lower chamber, was usually removed and placed in the surplus chamber; for artificial swarming the brood in the two chambers were equalized by a frequent alternating, and then the new colony was made by simply re-moving one chamber, bees and all, and placing ap empty clumber under and placing an empty chamber under it; for wintering, both chambers were used, and the space between the two furnished an excellent passage from comb to comb.

The question may now arise, why did we not continue to manufacture this hive? I answer: 1. These shallow frames were denounced by most bee-keepers; many, no doubt, remem-ber the assaults made on the Langstroth frame, which was nearly 2 inches deeper. 2. Central bars in frames, and with it the bars and space in my alternative hive were objected In my alternative inverse objected to as occupying space that should be occupied by brood. 3. This hive costs about one dollar more than a hive with a single chamber, which we were

thus manufacturing. This has not been written in the interest of any patent. This invention is, and has been for years public property, and if Mr. Heddon encounters as many difficulties in introducing his hive as I did 18 years ago, he will dearly earn the small amount he

asks over the cost of manufacturing. In conclusion let me say I have made and used hundreds of these hives, and from actual experience can say that this live possesses points of excellence not found in any live, and if the surplus chamber is made of the same size as one of the brood-chambers, it is the simplest form of a hive, and my advice to all is, give it a fair trial before denouncing it on theoretical impression.

Coburgh, 9 Iowa, Feb. 26, 1886.

### Local Convention Directory.

Time and place of Meeting. 1886. Apr. 6.-Eastern Indiana, at Richmond, Ind. M. G. Reynolds, Sec., Williamsburg, Ind. Apr. 7.--Wabash County, at Wabash, Ind. J. J. Martin, Sec., N. Manchester, Ind. Apr. 8.-Southern Illinois, at Duquoin, Ills. F. H. Kennedy, Sec., Duquoin, Ills. Apr. 10.-Unlon, at Dexter, Iowa. M. E. Darby, Sec., Dexter, Iowa. Apr. 27.—Des Molnes County, at Burlington, Iowa. Jno. Nau, Sec., Middletown, Iowa. Apr. 29, 30.-Western, at Kansas City, Mo. P. Baldwin, Sec., Independence, Mo.

May 5, 6.-Texas State, at McKinney, Tex. B. F. Carroll, Sec., Dresden, Tex.

Oct. 19, 20.—Illinois Central, at Mt. Sterling, Ills. J. M. llambaugh, Sec., Spring, Ills.

Im order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings .- ED.

Bees have Wintered Well.-F. H. Kennedy, Duquoin, 9 Ills., writes:

The bees have wintered well here, and the outlook for the season of 1886 is very encouraging. We think that honey is cheap, but I find sale for all I have to dispose of at 10 cents per pound.

Gone.-B. B. Tony, Holly Tree, & Ala., on March 12, 1886, writes:

Our brother, Nelson Perkins, late of Minnesota, is no more. He was laid away yesterday; his last resting place being but a few hundred yards from the place where he first settled. We miss him in the bee-fraternity. We and our children and all his acquaintances miss his good counsels. Also the M. E. Church has lost a Also the M. E. ohner has tost a brother of undoubted Christian in-fluence. Still we hope his good in-fluence is not lost, but will remain with all who knew him. He is now free from his pains forever-gone over the river-and is waiting for his friends.

Home Market for Extracted Honey. -I. N. Arnold, Richmond, O+ Iowa, on March 10, 1886, writes:

I see so often in the BEE JOURNAL complaints about a home market for extracted honey. I will give my ex-perience which might be of some benefit to bee-keepers who have a poor home trade. When 1 first had extracted honey I took a sample of it and acopy of the BEE JOURNAL to our county-seat and the other smaller towns. I showed the honey, and the picture of the extractor and honeyknife in the BEE JOURNAL, and ex-plained how it was extracted, and told what an advantage it was to the bees to return the combs to them; sugar and fed enough to last them also telling how it had been proven to take from 14 to 20 pounds of honey to make a pound of comb. I tell them it was as fine comb honey as ever was made, before it was uncapped and ex-tracted. When 1 can get a man to

taste my honey and listen to me, if he has a spare dollar I am sure to sell him a bucket of honey. If he buys once I never have any trouble to sell If he buys him honey the second time. I sold 2.000 pounds of extracted honey, and had 1,000 pounds of white clover and had 1,000 pounds of white clover and linden honey in two-pound sections. I sold the 2,000 pounds of extracted honey, and had three-fourths of the honey in sections on hand; so I told my customers that I had a line lot of comb honey which I would sell to them at 14 cents a pound. (I had sold my extracted honey at 10 cents per pound.) Some of them told me they did not want to pay A cents a pound did not want to pay 4 cents a pound to chew beeswax. If I would have depended upon the middlemen or grocerymen working up an extracted honey-trude for me, I am sure I would not have a trade for 1,000 pounds a year, where I have a home trade for 8,000 or 10,000 pounds a year.

Feeding Bees, etc.-E. H. C., Mattsville, 9 Ind., propounds the following queries :

1. How can I tell whether or not my bees are needing feed? I dislike to open the hives in cool weather. 2. Will elm, soft maple and sycamore lumber warp if cured in the shade, and then used for making hives ?

[1. Without seeing the contents of the hive you cannot, with certainty, determine the quantity of honey it contains. You can quess of the amount of honey better than any one not there.

2. That is the tendency of those woods, when compared with pine and whitewood (tulip or yellow poplar). Both of these are good, and have merits peculiar to themselves, but many prefer the whitewood .- ED.]

The Season of 1885.-T. C. Wire, Grinnell, Iowa, on March 8, 1886, writes:

I commenced the season of 1885 with 15 colonies, increased them to 44, and obtained 600 pounds of comb honey in one-pound sections. Bees did very well until the grasshoppers came and robbed the clover of its sweetness. While the grasshoppers were so thick the bees did not gather enough to live on. We had a cold rain that destroyed a good many of rain that descroyed a good many of the grasshoppers, and the bees worked for 2 or 3 weeks as only bees can; then the frost put an end to honey--gathering. I took off the honey-racks and found 11 late swarms with but very little honey, so I made a feeder that I could use without disturbing the bees. As I had nothing to feed the bees. As I had nothing to feed them but white comb-honey worth 15 cents per pound. I bought granulated

inches from the ground, 4 inches apart, and 4 inches from the wall, and pack them with dry sawdust. 1 put a board in front of the hives and tuck around and over it with old carpet, and leave the tops of the hives exposed to the sun. I use chaff cushions in the caps. When the weather is warm enough I turn down the board at the entrances and let the bees fly, and take a hooked wire and help them clean house. They have kept very dry.

Bee-Culture in Maine. - J, B. Mason, Mechanic Falls, 9 Me., writes:

Ten years ago but very little was done in bee-culture in Maine. While it is true that there were a few beekeepers who showed a little interest by trying some of the improved hives. one could see nothing throughout the State but a few rough box-hives in some back place, or half hidden by a stone wall or fence. So little honey was produced that it was very seldom seen in the market, and when it was brought to market it was in rough, unsightly packages. Now, honey can be found in nearly all our markets, and put up in as nice shape as anywhere in our country; and nowhere in the world can a nicer quality of honey be produced. Maine can boast of hundreds of apiaries of from 2 or 3 colonies to hundreds, neatly arranged with movable frame hives all painted nicely, and all the improved imple-ments that are now used in bee-keeping in any State are now used here. Tons of comb foundation are used, and tons of honey produced. There and tons of boney produced. There are several persons in the State who now devote their entire time to the business. For statistics the reader is referred to an article on page 104.

Selling Adulterated Honey.-13-J. W. Bittenbender, (40), Knoxville, 9 Iowa, writes :

It seems that since bee-keepers have made such progress in producing comb and extracted honey some people cannot or will not believe that honey can be sold at the present low price without its being adulterated. In these days of enterprise I do not think there can be any one so ignorant in this direction as to write such articles as have been published in certain newspapers. We all are articles as have been printshed in certain newspapers. We all are aware that there is a class of men who, when they see others pros-per in business, become jealous and immediately endeavor to devise some way by which to injure them. When there have business thed I first began in the bee-business I had to contend with just such persons who tried to injure my business by making false statements about me; but I thought that if I have not proved myself more of a man than that people should believe that I had adulterated my honey, why they must just believe it until they learn better. They finally did learn better, it, and if there are any who sell honey, that are not willing that it should bear their names upon it, such should immediately quit the business. I am glad that Rev. West corrected his mistake.

Bees Enjoying Sunday. – E. T. Medearis, Mt. Sterling, → Ills., on March 16, 1886, writes:

Sunday, March 15, was the first real spring-like day that we have had, and the bees turned out in full force. Last winter I lost S colonies out of 16; they were protected with fodder. For this winter I left them just as they stood in the summer, with nothing around them, and I have lost one. It died before the weather became cold. I will work my bees for comb honey, this year, in one-pound sections for my home market. I can sell more than I will produce, right from my place, 2½ miles from town. Every colony that I have is strong.

When to Ship Bees.—Otto Kleinow, Detroit, Mich., on March 12, 1886, says :

Last autumn I put into winter quarters about 65 colonies of Italian and Cyprian bees, and they seem to winter all right. Some have 2 to 3 frames of brood. They had good cleansing flights several times during the winter, but of course the trying months are March and April. April is generally the most dangerous month for bees, for then they are sure to go out for water and pollen, and the air being chilly, many of them will not return to their hives again. Hence I would advise those who purchase bees, not to have them sent before about April 15, for they may dwindle away.

Two Queens in One Hive.-R. M. Osborn, Kane,+o Ills., on March 9, 1886, writes:

January was the only month so far this winter that gave us zero weather, six days ranging from 2° to 18° below zero. My bees had flights on five days in December, 2 days in January, 5 days in February, and I day in March. My 65 colonies are in splendid condition. I have not lost a colony yet. They are all packed on the summer stands. On Feb. 9 they all had a good flight, when I examined several colonies and they all had young brood in every stage, and eggs. On Oct. 17, 1885, while preparing a certain colony for winter, which contained a pure Syrian queen, I was surprised to find 2 queens, the old queen and her daughter, both on the same comb and on the same side, and both laying eggs within less than 3 inches of each other. It was good luck for me, for the daughter was a beauty, and I just clipped her wings and introduced her into another colony, which was made queenless a few days before by taking off the sections. The queen was on the sections, and I had taken her into the honey-house, but I found her too late. The weather being so cool I

did not think that a queen would leave the brood and go above. Some of my neighbor's bees are in poor condition. Mr. E. Armstrong says that his 95 colonies are wintering nicely. The white clover and winter wheat looks promising for a good crop, at this date.

**Position of the Hive-Entrance.**—F. M. J., of Augusta, ∧ Iowa, asks this question:

If, as some claim, the bees are better protected and commence breeding sooner by having the entrance crosswise of the frames, why not have the entrance to the Heddon-Langstroth hive at the side instead of at the end ? Bees would not have so far to travel to any part of the hive then.

[No. I have used both ranges of entrances for years. This is one of the theories that I could never verify in practice. But theory also says that the entrances, as you propose, would retard summer ventilation. I want the entrance at the end of the hive, and the combs and the sections to run parallel with the frames below, and all slightly pitched forward. I know that both ways have advantages, but the latter has the most. After a bee spends hours in the field, it "travels" in the hive but a moment. If you throw a pailful of water into a lake, there is then a pailful more than before, but not practically SO.-JAMES HEDDON.]

Bees Wintered in a Cave.—S. Stephenson, Gladstone,+0 Ills., writes:

I wintered 102 colonies of bees in a cave. It was 5 feet below the surface of the ground; 1 foot above the surface on the edges, and 4 feet in the centre; it was \$x36 feet, and was covered with inch boards, a layer of hay, and about 1 foot of sand. They are mostly in Langstroth hives, and all have natural stores. Some colonies have not lost a half-dozen bees, and none have lost more than a double-handful. I think it is a bad practice to feed sugar syrup; it arouses suspicion in the minds of honey-consumers, and it ought to be stopped.

**Bee-Business in Iowa.** – I. N. Boyles, Urbanna, o+ Iowa, on March 15, 1886, says:

I have just received the census returns of this State, and thinking that the bee-men of Iowa would like to know the number of colonies in the State, and the number of pounds of honey produced here in 1884, I give them as follows: Total number of colonies, 148,384; pounds of honey, 1,997,931; pounds of wax, 35,064. This report is not very good for Iowa, as it gives only about 13½ pounds of honey per colony. The best county for honey, as reported, is Dubuque coun-

ty, the number of pounds being 48¼ per colony; and the least number of pounds per colony in any county in the State is that of Tama county, which is only 2¼ pounds. I think there must be some mistake about that county. The following is a report of a few counties, showing the difference in the yield of honey in the same year: Tama county, number of colonies, 12,065, pounds of honey, 27,637; Benton county, number of colonies, 3,378, pounds of honey, 66,-550; Monona county, number of colonies, 1,083, pounds of honey, 34,832; and Dubuque county, number of colonies, 1,893, pounds of honey, 91,710.

Bees in Good Condition.—Gardner Boyd, Petrolea, Ont., writes :

I commenced the season of 1885 with 4 weak colonies of bees, increased them to 9, and took 1,000 pounds of extracted honey and 50 pounds of comb honey. I am wintering them on the summer stands in doublewalled, sawdust hives, with 3 inches of packing all around them. The bees are in good condition at present. I am well pleased with the BEE JOURNAL. I would not be without it.

Early Birds.—Dr. C. C. Miller, Marengo, 5 Ills., on March 17, 1886, says :

Robins and bluebirds are here, and unless the weather changes bees may be out in a week. So far they seem to be in good condition.

House-Wintering of Bees. - W. Mason, Fillmore, 10 Ind., on March 17, 1886, writes:

My bees have had high times in the past three days, all being in fine condition, except 3 colonies that have dwindled, one being queenless, one having an infertile queen which was left out on the summer stand as a test from that of house wintering; the other seems to be afflicted with diarrhea. My house-wintering proved very satisfactory. The bees consumed but a small amount of honey, only about an average, per colony, of 7 pounds for  $3\frac{1}{2}$  months. I have 31colonies. They carried in rye meal yesterday.

Successful Wintering.—A. Wortman, Seafield,∞ Ind., on March 17, 1886, writes:

My bees had a good flight on March 14 and 15, and all have wintered without the loss of a single colony so far. They appear to be in a healthy condition. I have them nearly all covered with boxes without top or bottom, made about 2 inches larger than the hives, and the space packed with forest leaves, with chaff cushions on top and a wide board to cover the box to keep the rain and snow out. They are protected on the west and north, from the winds, by sheds and highboard fences. The hives are ventilated at the bottom by a hole 4x4 inches square cut in the bottom-board and covered with wire-screen. They were packed about the last week in October; but they have had a flight every 3 or 4 weeks since they were packed, which I think beneficial, for safe wintering on summer stands.

Good Prospects for 1886.-Frank A. Eaton, Bluffton, ~ O., on March 15.1886. says:

My bees had a fine flight yesterday and to-day. Those on the summer stands-40 in all-were bringing in pollen. The 100 colonies in the cellar were never in healthier and finer condition at this time of the year. Prospects are good for the bee-business the coming season.

Bees all Right.-Chas. Haas, Lower Salem, O., on March 8, 1886, says :

I have 48 strong colonies of Italian bees in two-story chaff hives, all win-tering well so far on the summer stands. They have plenty of stores. I fed each colony \$1 worth of sugar last fall. I lost but one colony, where one puer we a droug layer. We whose queen was a drone-layer. We have frequently had nice summer days so the bees would often get a flight. From all appearances we may have a good season for honey this year.

Bees and Flowers.-Prof.A.J.Cook, Agricultural College, 9 Mich., writes:

The interesting article by Mr. Latham, on page 153, contains some points that I think need confirmation. I believe that all botanists now hold that all flowers which are showy or contain nectar, either need insects absolutely or else are materially benefited by the visits of insects. Without donbt this was always true. I know of no authority in geology nor any reason to believe that there were reason to believe that there were showy flowering plants prior to flying insects, or even to sweet-loving in-sects. In the economy of Nature one without the other would be like a button-hole and no button. Geology shows conclusively that there were no terrestrial plants until the upper Silurian time, and no true flowering plants until the Cretaceous period, or near the close of the Mesozoic or Middle life time. The only flowering plants before that era were conifers, whose pollen is easily carried by the winds. Even as soon as such flower-ing plants (the inconspicuous ones) appeared, there were lace-wing and locust-like insects which had good powers of flight; and quite likely fed in some part on pollen. We have positive knowledge that showy flowers, and the secretion of nectar were synchronous in time of appearance with Hymenoptera (bees and wasps) and Lepidoptera (butterflies and moths). This fact is loud in praise of the importance of bees in Nature, and should never be misrepresented, as too much of value depends upon it. Destroy bees, and other sweetloving insects, and you strike down much of our most valuable vegetation. No point in geology or biology is better sustained.

923 & 925 WEST MADISON ST., CHICAGO, ILL, At One Dollar a Year.

ALFRED H. NEWMAN, BUSINESS MANAGER.

## Special Notices.

To Correspondents. — It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at aother, be sure to give the address we have on our list.

We take pleasure in calling the atten-tion of our readers to the advertisement of Montgomery Ward & Co., Chicago, which ap-pears in our paper. This is an old and relia-ble bouse, and their immense business is but the natural result of the careful and, bonorable manuer in which it is conducted.

**Perforated-Zinc.**—We have laid in a stock of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 fcet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive—19¾x14½—Price 25 cents each cents each.

Beeswax Wanted .-- We are now paying Beeswax Wanted.--We are now paying 22 cents per ponund for good, average, yellow Beeswax, delivered here. Cash on arrival. Shippents are solicited. The name of the shipper should be put on every package to prevent mistakes.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it. for it.

Wire Nails have advanced in price, as will be seen by quotations on page 159, last column.

To any One sending us one new sub-scriber with their own renewal (with \$2.00), we will present a copy of the new "Con-vention llistory of America."

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

Preserve your papers for reference. If you have no **HINDER** we will mail you one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscrip-tions for the BEE JOURNAL.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., Mar. 22, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.-Comb scarce. Some 15, sections bave brought 17618c. Extracted, plenty and dull, 667c. California comb honey, ho 2b. frames, 8642c. BEESWAX,-22@25c. per lb. Not much offered. R. A. BURNETT, 161 South Water 5.

#### NEW YORK.

NEW YORK. HONEY.- We now quote : Fancy white comb in 1-b. paper cartons, 13@14c.; the same in 1-b. glassed or unglassed sections, 12@13c; the same in 2-b. glassed sections, 19@10½c., and fair to good o glassed 2-bs., 8@0c. Fancy buckwheat boney io 1-b. unglassed sections, 10c.; the same in 2-b. sections, glassed, %@9c. Extracted, white,6½@7½c; buckwheat, 5@6c. BEESWAX.-27@28c. McCAUL& HILDBETH BROS., 34 Hudson St.

#### ST. LOUIS.

HONEY.-Choice comb, 10@12c. Extracted, in barrels, 4½@5c. Extra fancy of brikht color and in No, i puckages, 4½ advance ou above prices. BEESWAX.-Firm at 22½c. for prime. D. G. TUTT & CO., Commercial St.

### CINCINNATI.

110NEY.-Extracted boney brings 4@8c., and choice comb boney brings 12@15c. in a jobbing way. BEES WAX.-In demand at 22@25c.for yellow. C. F. MUTH & SON, Freeman & Central Ave.

#### CLEVELAND.

110NEY.—One pouad sections, 14@15c.; 2-lb. 13c Extracted, 7@sc. BEESWAX.—Scarce at 25c. A. G. KENDEL, 115 Ontario Street.

#### KANSAS CITY.

E

HONEY.-We quote : cholee comb, 1-lb. acctions, 160.; fair to dark, 12@14c.; ln 2-lb. aections, 12/214 ceota. Extracted ta dull and alow. Dark brings 3 1-2 to 40.; white, 6@7c. BEESWAX.-23c. CLEMONS, CLOON & CO., cor. 4th & Wainut.

#### BOSTON.

HONEY.—One-lb. sections, white clover, 13@15c; 2-pound aections, 11@13c. Extracted, 6@8c. BEESWAX.—25 cits.per lb. BLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

# W.Z.HUTCHINSON,

In order to more fully supply the wants of his en-tomers, has entered into partnership with his neigh-bor, R. L. Taylor, and will offer for sale, bees (tall colonies, or by the pound), queens, Given founda-tion, white poplar sections, hives, cases, feeders, empty combs, etc., etc. Also hens' oggs, for hatch-ing, of three varieties. For circular and price-list, address W.Z. NUTCHLINSON, 8Etf ROGERSVILLE, Genesee Co., MICB.

Job Lot—Cheap! WE have received a Job Lot of 25,000 W One-Pièce Sections with square groove, which we will close out at \$4.00 per 1,000, or \$2,50 for 500. The size is: top and bottom, 6 inches; sides, 5¼ inch; width of section, 1% inches-narrow tops.

THOS. G. NEWMAN & SON,

923 & 925 West Madison St., CHICAGO, ILL.

### Fruit-Farm & Apiary FOR SALE CHEAP!

96 ACRESS, bill-land, ½ well-stocked with apples, peaches, pears, plums, quinces, grapes, and smail fruit, in fine bearing condition, The remain-der is in pasture, grass, grain, etc. Aplary contains 140 11A LIAN COLONIES in Langstroth hives. Bee-house and sil modern appliances for aplculture, in as good location for bees and honey as can be found. Good 10-room bouse, beautifully located, commanding a view of the city, river and surrounding country. New barn and out-buildings, cistern, never-failing springs, etc. Reasons for selling—age and lit-bealth.

### Alley's Drone and Queen Trap.

Price, by Express, 50 cts.; by mail, 65 cts.; 12 in the flat, and one nailed (13 in all), \$3.50; 50, in the flat, \$12.00. Address,

THOS. G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL.

Now is YOUR TIME, if you want to secure some of the Fines( Italian and Albino Bees in the world. You can get them of me. My bees are boss on red clover. Two and 3 frame Nuclei a speciality. Circulars free, Address, 12A1t F. BOOMHOWER, Gallupville, N.Y.

## The NEW Heddon

We have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

The engraving gives a good idea of the hive. The brood-chamber is in two sections: also the surplus arrangement, which may be interchanged or inverted at will. The cover, hottom-board, and top and bottom of each sectional case has one-balf of a regular bee-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this bive are perfectly interchangeable. The brood-transes will ALL be bored for wires.

ALL be bored for wires. A SAMPLE IIIVE includes the bottom-hoard and stand : a slatted honey-board, and cover ; two 6-meb brood-chambers, each containing 28 frames ; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separa-tors, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

54.00, complete. It is absolutely essential to order one natice hive as a pattern for patting those in the flat together correctly. IIIVES READY TO NALL—In tillingorders for these hives, in the flat, we make 6 different com-binations, so that our customers may make a selection from the sample nauled hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers : No. 1 corrected the construction that the different to known be the order of the stand bottom board

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 frames, and the slatted honey board. Price, \$1.55 each. No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators-interchangeable, but not reversible.— Price, \$2.00 each.

Price, \$2.00 each. No. 8 is the same as No. 2, with *two* surplus stories as therein described. Price, \$2.50 each. No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-commbers. Price, \$2.30 each.

No. 5 is the same as No. 4, with two surplos arrangements as therein described. Price, \$3.90. No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each.

sumple nailed hive. Price, \$2.75 each. Those desiring the bives without the stand, honey-board or sections, may make the following deduc-tions from the above prices : Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at ½ cent each, respectively, We will also make the following deductions on quantities ordered all at one time : For 10 or more hives, 5 per cent, discount; for 25 or more hives, 7 1-2 per cent, if or 50 or more, 10 per cent.

von.

The Weather still continues line, and the bees are still reported as generally in excellent condition.

The Convention History of America and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.15.

Look Out for the colonies that may be short of stores. The bees are consuming considerable honey now, and if necessary should be fed liberally.

An Ingenious Clock, moved by electricity, is now creating a sensation in Paris. The dial resembles a tambourine, on which the figures are represented by painted flowers. Instead of the hands, a couple of bees—one large and the other small—serve to indicate the hours and the minutes. They are set in motion by concealed magnets, and erawl from flower to flower, all round the dial in twenty-four hours and one hour respectively.—La Sitele.

**Criminal Carelessness** was illustrated lately by the following which we notice in a daily paper. A farmer by the name of Hutchinson went from Kentucky to Kansas, and concluded to take some bees—but not knowing enough to close them into the hives, raised great consternation. The payer says:

says: He chartered a box-car at Bloomfield, and Wednesday put in eight horses, with his two sons and a dog to take care of them. There was pleuty of room, so he also placed in two bee-hives. When the train had fone about five niles the bees got warned up, poured out of the hives, and a bir row followed among dog, horses and bo<sup>2</sup>. The train also carries passengers, and Some of the infuriated bees got into the cars and stung several people sevely. When it was stopped Mr. Hutch of family were liberated, but they wer in a feartul condition. It was only atted the stock placed back in the ear. The the beind time.

Comb Foundation, when it was first produced, was by some thoughtlessly called "artificial comb." To this inexcusable blunder may be charged the many stories now afloat about "comb being made, filled with glucose, and capped by machinery." Prof. Wiley took this as the cue for his wonderful but untruthful story, and many others, when pressed for proof of their assertions about this matter, have to refer to the manufacture of "artificial comb," as they ignorantly term it, to attempt to prove their stupid and ignorant assertions ! Thus, bee-keepers have some of their own number to thank for making a basis for such lies by their foolish hlundering.

To add to the complication, awhile ago some persons advised the use of glucose for feeding bees when honey was scaree, for building up in the spring, etc. This gave the opportunity for some to say that beekeepers were adulterating their honey, and for proof many of the daily papers pointed to the fact that glucose manufacturers were filling orders for tons of it, to be used in apiaries. The BEE JOURNAL made a vigorous fight against its use, and it is now generally abandoned by bee-keepers.

Another difficulty now presents itself. Some enterprising reporters for the eity newspapers have already stated that sugar is being consumed largely by bee-keepers, who feed their bees sugar; that the bees filled the combs with it, and it was sold for honey 1 In their ignorance several have declared that this is easily proven by the fact that so much liquid honey is now "turned to sugar." They mean the granulated honey, but are not aware that nearly all *pure honey* will granulate on the approach of cold weather !

We sold some granulated honey to a man, in this city, a short time ago, and a minister. who was partaking of a meal at the house, remarked as he ate some of that granulated honey, that it was sugar fed to the bees, a ... had "turned to sugar again;" that, the "liquid honey" on the market was p are, but it disagreed with his stomach, an , be could not eat it I so he preferred the a "ulterated ! I The gentleman who bought t' , e honey of us, came to the BEE JOURN AL office and informed us of what "'As reverence" had asserted. We could, but laugh at such "ministerial" ign rance about honey, and told our friend that the granulation was proof of purit setliat nearly all the "liquid honey" for ad at this time of the year, was adultoraf, ed with glucose-and that its being adulte ... ated accounted for its being a liquid !

Now the BEE JOURNAL gives this caution: T.e use sugar for feeding bees gives an opportunity for those who "know much less that they think they know" about hency, to sdy that they "know a bee-keeper who buys barrels of sugar to feed the bees, which store it in surplus sections, and it is sold for honey !" To "avoid the appearance of evil," use honey, and honey only, for feeding bees ! In this way we may deprive the enemies of our pursuit of one of their pet arguments, in attompting to prove that the bees or their ewners are adulterators of honey.

The Virst Volume of the Canadian Bee Journal was completed with last week's issue, "We wish it long life and prosperity.

A Fire, on March 7, destroyed a warehouse filled with bee-keepers' supplies, belonging to Mr. A. I. Root, Medina, O. As it was a building without a chimney, and never had a tire in it, the conclusion is that it was the work of an incendiary. Mr. Root remarks thus in the last issue of *Gleanings*:

Somebody deliberately took down the stout bar across the doorway, swung the doors open, unbuckled the bead-straps to the halters, turned the borses loose, and then set fire to the hay, straw, and combustible goods stored near it, even while he felt the stiff southern breeze blowing strongly toward the long rows of seasoned lumber piles, on each side of the railway track, from the warehouse to the factory.

The loss is about ten or twelve thousand dollars—something less than \$5,000 more than the insurance.

As Mr. Root went home, while the fire was still in progress and the firemen were working to quench it, and went to sleep, it did not seem to worry him very much. How he could have done so, however, is more than we can imagine !

There will be a Rush for supplies needed in the apiary "after awhile, and vice cannot do better than to urge all to 'look over their stock, ascertain what "will be needed, and get it on hand before is is neeessary for use-thus avoiding the perplexity consequent upon its possible d elay in reaching them in time.

A Chinese Verst n of the saying, "How doth the little bus p hee," is as follows, and was sent to us  $\frac{1}{2} g$  one of our subscribers :

How? Sie, belly small thin thin sting-bug Jm-im-i aplove ebly slixty minnit all a time. Go, p', skee up sting-bug juice all a day All ain' places 'loun' flowels just got busted.

New Price-Lists have been received from the following persons :

Watts Bros., Murray, Pa.-48 pages-Bee-Keepers' Supplies, and "a short but practical treatise on the art" of bee-keeping.

T. S. Sandford, Bradford, Pa.-8 pages-Bees, Queeus, and Supplies.

A. O. Crawford, South Weymouth, Mass.— 16 pages-Honey Labels and Apiarlan Snpplies.

W. H. Osborne, Chardon, O.-8 pages-Fowls, Bees, and Apiarian Supplies.

S. Valentific & Sons, Hagerstown, Md.—26 pages—Albino and Italian Bees, Success Bee-Hive and Apiarian Supplies.

Any one desiring a copy of either of them, can obtain it by sending a postal card to the address as given above.

Frank Leslie's Sunday Magazine for April is an exceedingly interesting number, containing articles to please all tastes. It is especially rich intengravings from paintings and drawings, and the art lover will also find congenial matter in the sketch of Leonardo Da Vinei, with its two accompanying portraits. There are portraits of Bishop Hannington, who is supposed to have been martyred in Africa, Archbishop Gibbons, of Baltimore, the second American [Cardinal, and the Inte Vice-President\_Hendricks, whom Dr.', Talmage eulogizes as a "Christian Politician," There are many other articles of present and future interest, and the number is full of beautiful pictures which please all, young and old.

**REPLIES by Prominent Aplarists.** 

### Cause of Bee-Diarchea.

Query, No. 226.—I should like to ask whether it is generally considered necessary that bees should void a dark feees to have diarrhea? This liquid voiding is in consequence of impaired digestion. Would not the pure honey, if imperfectly digested, assimilated and voided, cause diarrhea?—H., Ont.

I think that the disturbance of brood-rearing in a low temperature always causes more or less of what is known as bee-diarrhea. Of course this question opens an inexhaustible field for discussion.—II. R. BOARD-MAN.

It is not. After a long confinement healthy bees often void a dark semisoli'd feces on the first spring flight. Mr. S'. Corneil has proved this beyond dispute. The liquid voiding is due to the principal causes—dampness in the hive and cold. If such a thing could be as 'imperfectly digested and assimilated as 'honey in bees wintering under good conditions, I answer no to the latter question.—G. L. TINKER.

It is hard to say jOst where diarrhea or disease begins. Bees will hold a certain amount of fecal accumulations for a certain length of time and not become sufficiently diseased to peril the life of the colony, but if these accumulations are too great, the bees become diseased; and when they are filled almost to bursting, against their instincts, they void in the hive, and their excreta is found replete with pollen. Beyond these well known facts, let each one speculate and experiment for himself, till we finally find out and all agree on the exact conditions that will avoid the accumulation of fecal matter, in all places and at all times. I consider the problem practically ours.—JAMES ILEDPON.

Pure honey will not cause diarrhea. The voiding of feees in spring is not bee-diarrhea. That disease is a voiding of feces in the hive, accompanied with lack of strength. The one is simply natural; the other a disease, and is probably caused by impure stores; ordinarily I thiuk by fermented honey, owing either to not being sealed up in the fall, or else not properly ripened before sealing. Excess of moisture accompanied by extreme cold would produce the disease.—J. E. POND, JR.

I cannot say what the general opinion is on the point you mention. But at the close of the terrible blizzard we had here in January, after confinement of only about ten days, I had the pleasure (grim pleasure, you say) of seeing bees so distended in body that they could hardly drag themselves on

the alighting-board. The abdomens of these bees contained nothing but a transparent liquid, with no solid matter visible under a glass of considerable power. These bees had been fed on sugar syrup. I had one colony that was fed on sorghum syrup, their discharges, though small in quantity. were dark in color; those fed on natural stores discharged a yellow substance, while the sugar-fed bees, the heaviest loaded of all, discharged a transparent liquid that might have evaded notice had it not been for the snow on the ground.—G. W. DEM-AREE.

I think no, to the first question; to the second, yes; but there comes another question, is pure honey ever imperfectly digested ? and then comes the question, what is meant by pure honey ? I might take oath that I believed a comb of honey I offered for sale was pure honey, yet if I fed it to bees they might take oath it was part pollen. Besides there may be a difference in pure honey. On the whole, I give it up.—C. C. MILLER.

### Bees Drowning in Sap-Pails.

Query, No. 227.—How can we prevent such heavy loss in spring by bees drowning in sap-pails during sugar-making time. Can we feed sweet water or anything to keep them husy? If so, should it be fed in the hive or out-doors? Or would it excite them to hunt further and increase the trouble? We lose quite a number every spring in our sugar-camp, and those of our neighbors'?— W. L. J., Iud.

Yes, it would excite them to hunt further, and increase the trouble. It would be better to throw a mosquitobar over the pail, or a square piece of ,vire-cloth, and let the sap run through the meshes. This wire-cloth could be used several years.—DADANT & SON.

I do not think that feeding near home would cause the loss of many bees. The only way I can see of doing is to furnish covers for the pails. You might sue the sugar-makers for damages. (?)—W. Z. HUTCHINSON.

Covering up the pails will prevent the loss; or will that cost more than the bees are worth? If you feed at that time, it will cause them to go further in search of food.—H. D. CUTTING.

I know of no way unless we kep them in a cellar. The sugar-makers ought, for their own good, to cover the buckets, in which case all would be safe. I have a sugar-bush of 600 trees. All the buckets are kept covered. Then all dirt, leaves, rainwater and snow are kept out. This is what makes the syrup nice.—A. J. Cook.

An answer to this question is what I have been seeking after for years, and the only practical one I have found is to keep them in the cellar until this danger is past. Feeding seems to make the matter worse,—G. M. DOOLITTLE.

### Sections with Side-Openings.

Query, No. 228.—What has been your experience regarding the use of one-pound sections with openings on 4 sides ?—W.H.W.

I have not as much confidence in them since trying a few (perhaps a hundred) as I had before.—C. C. MILLER.

I have not tried them, but their peculiar construction would defeat my idea of concentration.—G. W. DEMAREE.

I have not used such sections, but recommend them on the authority of a number of eminent Canudian beekeepers who believe side-openings to sections of great advantage. But for that matter, judgment on a question of this nature hardly requires the test of experience. It is self-evident that the side-openings will overcome several of the greatest objections to separators, as the preventing of nearly all sticking of the sections and separators by propolis, and allowing the bees to cluster practically in a solid body in the super.—G. L. TINKER.

In my experience with open-topand-bottom sections, I have encountered no deficiency that open-sides could supply. I readily imagine troubles that they might bring us. Many will test them the coming season and report results. They increase the number of angles for glue, and most of all, acute angles. Only experience can decide. If they come into general use, I am wrong; if not, I am right in my theory regarding them.—JAMES HEDDON.

## Feeding Bees-Granulated Honey.

Query, No. 229.-1. What is the cheapest food for stimulative feeding of bees in the spring? 2. Why does some white clover honey granulate sooner than other kinds?-R. G., Mo.

1. That depends on prices. In some places, honey; in some, granulated sugar. 2. Ripeness may have something to do with it.—C. C. MILLER.

1. Good dark honey, such as is quoted at from 4 to 6 cents per pound. 2. Honey varies in chemical composition, even when gathered from the same class of flowers. Perhaps owing to atmosperic causes. The variation in composition is sufficient to account for the difference in tendency to granulate.—G. W. DEMAREE.

1. Second quality of extracted honey. If it is purchased in the open market it should be boiled at least 10 minutes before feeding to the bees, as a safe-guard against the introduction of foul brood.—G. L. TINKER.

1. The chapest grades of honey. Honey contains nitrogen, cane-sugar does not. Nitrogen is a necessary element to the production of tissue brood-rearing. 2. Probably because it is not so well ripened, and contains less acid. Raw bonay, if not too thin, will candy sooner than well ripened honey. The presence of acid is a prevention of granulation.— JAMES HEDDON.

1. If one has in stock frames of honey it is the cheapest, because most handy. Honey diluted one-half with pure water is probably as cheap as anything; for while it may cost a trifle more than sugar, a gain will be found to more than compensate in the larger amount of brood reared therefrom; at least this is my own experience. I am not an advocate, however, of early stimulative feeding. Like a two-edged sword, it is liable to cut both ways.—J. E. POND, JR.

### Are the Drones Pure?

Query, No. 230.—Will the drone progeny be pure from a pure Italian queen, if she is fertilized by a black drone ?—C. T.

Yes.-H. D. CUTTING.

Yes.-W. Z. HUTCHINSON.

Practically so.-G. M. DOOLITTLE.

I think so.—A. J. COOK.

According to parthenogenesis they will be pure. This is doubted by some. When breeding queens I always avail myself of the doubt and reject such drones.—J. P. H. BROWN.

Yes. Some will tell you that the mating stains the queen as it stains the hen, but queens cannot be compared to hens; since in the hen the eggs are fertilized before they are full grown; and in the queen they are not fertilized till they pass by the sperm-sac on their way out. The contents of the sperm-sac cannot stain the queen. since there is no exchange of blood between the egg and the mother after the fertilization of the egg.— DADANT & SON.

#### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

### The Hibernation of Bees.

### WM. F. CLARKE.

At last Prof. Cook has spoken! Goaded by the imputation of "contemptuous dogmatism," he can keep silence no longer. The Professor begins by ladling out considerable taffy, an article in which I do not deal. My forte, if I have any, is plain English. In the present case, it seems to have been too plain. I have committed the unusual blunder of calling a spade a spade. Is it not "dogmatism" to assert unqualifiedly that bees do not hibernate, and is it not "contemptuous" dogmatism to do this without any condescension to proof or even investigation?

I do not see the point of the ox story, and think it was a bull to tell it. Dr. Tinker speaks positively, but he has facts behind him, which gore without mercy. An ox cannot gore without sharp facts to act as horns.

without merey. An ox cannot gore without merey. An ox cannot gore without sharp facts to act as horns. The Professor's article may be briefly summed up in two words. He admits the condition, but wants another term than hibernation to express it. I do not see how he can be accommodated until another English word is coined having precisely the same meaning. The compound phrase "winter torpor" might do, but why use two words when one will suffice?

The only semblance of proof that bees do not hibernate is furnished in the assertion that they do not act exactly like wasps. But do wasps hibernate? The Professor assumes that they do, and I shall not deny it. In this state they are quiet. There is "profound coma." Is not the same true of bees? Outward signs of life there are none, but on being subjected to warmth, a slight movement takes place, and there are signs of returning activity. In a winter cluster the bees are constantly changing places with each other. This is a sign of life surely. Motion indicates life. The bees breathe and move, a very little. But the Professor thinks that bees do not hibernate because exposure to greater degrees of cold arouses them, while it only makes the slumber of the wasp more profound. The reason for the difference is obvious. The wasp has no stores with which to get up a glow of heat, while the bee only

needs to consume honey, and its warmth at once increases.

It is not necessary to withdraw food altogether to prove hibernation, for it is not contended that in this state they fast wholly, but only that they eat sparingly, and at intervals of considerable length. The Professor tells us that a hibernating wasp will not sting, while a hibernating bee will. Even a dead bee will sting. The slightest pressure sets the deadly machinery a-going, and woe betide the hand that is near it l The Derforcem and beging that the

the hand that is near it 1 The Professor only desires that we will not persist in using the word hibernation, when winter quiet or quiescence is just as good—he thinks far better. But hibernation is more than quietude, it is partial suspension of the guide state of the primum than dufettude, it is partial suspension of the vital processes; "the minimum of functional activity," as the Profes-sor himself has phrased it. It is a state peculiar to the winter season. Bees are often quiet in summer, but they do not hibernate then. The sea-per of the user fashide their doing ea son of the year forbids their doing so. The Professor wishes the term hibernation to be reserved for "another phenomenon more startling and won-derful." What is it, pray? On ana-lysis it will be found to be, in all its essential features, one and the same with that witnessed in the case of the bees. Sleep cannot properly be termed hibernation any more than trance can be called sleep, because the faculties are all awake, though in a state of inaction and repose, both during hibernation and trance. The subject of both these phenomena is quite conscious, knows all that is going on, has the full use of the senses, and needs only to have the strange embargo on doing as busily as ever. Trance might do as a substitute for hibernation. do as a substitute for internation only it does not express the winter idea, for trances are as common in summer as in winter. I see nothing for it but that the Professor will have to get his throat capacity enlarged so as to swallow this word of four syllables, without making any wry faces over it.

Guelph, Ont.

For the American Bee Journal. Managing Bees in the Spring.

C. W. DAYTON.

When I first began keeping bees I did as some others do, viz: let the bees go it in hives the full size. While practicing this plan it was not very unusual that colonies swarmed out in the spring, especially when they were a little weak or diseased. After awhile I came to the conclusion that the contraction of the brood-chamber was at least a partial preventive. With this conclusion I have found nothing that appeared to be at variance, so I continue (as I have done for the last two years) contracting the brood-chambers as fast as the colonies are brought from the cellar to the number of combs that contain brood, which is generally two, and never more than three. In this way the colonies are kept contracted until about May 10, when it is time for their combs to be filled with brood so entirely that the queen deposits her eggs right down around the bottom of the combs, and up the other side clear to the top-bars. At this time the insertion of another comb is necessary.

In contracting to so few combs it may be seen that there is but little if any room for stores. Formerly each colony would have from 1 to 15 pounds of honey, and as it was so hard to know how long it would last, or which colonies had the most, without going over the whole apiary, sometimes a over the whole apary, sometimes a colony would get entirely out of honey, destroy the brood, and consequently be unprofitable for the season. This suggested the contraction of the brood-chamber, and feeding every day enough diluted honey to last until the nort. the next.

With the right arrangements the above proves to be quite an agreeable method of management. as it requires but one hour to feed 50 colonies. – I t stimulates brood-rearing, facilitates great contraction of the brood-chamber, which is so necessary in spring, and what is more, no innocent bee is obliged to retire with an empty stomach.

The feeders which I nse are made by inserting an extra cross-bar some distance below the top-bar of a broodframe, and enclosing the sides with a thin material so as to form a sort of trough. The feed is put in with a funnel through a hole in the quilt and the top-bar of the frame. The feed should consist of two parts of water to one part of honey, and in amount should be about 3½ ounces. I believe that there are few colonies so small in the spring that it will not pay to nurse them up, as they afterward make very paying colonies; while colonies that were crowded with brood and bees barely make a living.

The time during which I feed the bees daily is from May 1 to June 10. The following is a record for 1884, of the average number of solid combs of brood per colony, taking the apiary through: May 1, about  $1\frac{1}{2}$ : May 10,  $2\frac{1}{3}$ ; May 18,  $4\frac{1}{4}$ ; May 27,  $6\frac{1}{2}$ ; June 5, 8; June 15, 11; and June 25, 12. Contracting the brood-chamber and feading warm for barrier barrier. feeding warm food just before night, is the best safe-guard that I know against absconding or "spring dwindling." From the above may be understood what I call solid combs of brood.

Bradford, & Iowa.

For the American Bee Journal.

### Length of a Queen's Fertility.

### GUST. MURHARD.

I have within the last few years had occasion to discover some prevailing errors which need correction. One is the prevailing opinion that the fertility of a queen of any of the yel-low-banded varieties of bees is good for five years. Another error is that an issued first swarm of bees should

he returned to the parent colony to store honey there, instead of establishing a new colony of bees; and still another error is, that Mr. H. Alley, in his "Handy Book," claims to know that he can give to a colony of bees, which he has deprived of of bees, which he has deprived of their queen and combs, and so re-duced to the most helpless and mis-erable condition bees can be put into, the true natural "swarming impulse" (of preservation of race through colo-nial propagation or reproduction), by confining them in an empty wired-box for some length of time before giving them fresh broad to start rova cells them fresh brood to start royal cells. I will speak here but of the first error and reserve the other two for a future time.

It is a well-known fact that some varieties of bees are more inclined to swarm than others, and that the swarming propensity in a variety of bees makes that variety objectionable bees makes that variety objectionable to the honey apiary, as bees that are inclined to swarm cannot well furnish much surplus honey. I have tried the blacks, the Italians, the Cyprians, the Holy-Lands, the Mt. Lebanons, the Albinos, and the Carniolans, and have found the blacks the least in-ligned to take to swarming in my clined to take to swarming in my large hive, which is a composition of the Langstroth and Quinby hives, having the suspended brood-frames of the former, and the surplus-honey arrangement of the latter.

The next least inclined to swarm I have found to be the Mt. Lebanon colonies that had prolific young queens of the previous season's late rearing. I have had occasion to ob-serve those queens and their fertility very closely, and I found that with the end of the first season's service in my large hives, a Mt. Lebanon queen has reached the meridian of her life fertility and usefulness, and henceforth is on the decline, and will give entirely out in the early part of the third season, when the sagacious workers will ball and supersede her. As with the expiration of the first season's service in the honey apiary the queen has come to her decline, she is, although her fertility is but half exhausted, still no longer fit for the honey apiary, as her decline is liable to show signs in the early part of the next season, when the natural instinct of the double self-preserva-tion, as well of the colony as of race, will prompt the workers to swarm; it would be as well to establish a new would be as well to establish a new colony as to try the vital strength of the old queen, which had better be lost at that time than any other sea-son of the year, in case she cannot stand the swarming. Each colony in a honey apiary should, at the expiration of the honey cases of the year be furnished with a

season, either be furnished with a season, either be furnished with a yonng queen reared that season, or the colony be taken to the queen nursery to make use of the queen's remaining half of fertility, by furnish-ing brood for the nuclei, when, at the end of the season, the colony with a reared young queen may be taken a reared young queen may be taken back to the honey apiary to serve next season again for surplus-honey gathering. Portland, ~ Oregon.

### The Honey Market.

WM. F. CLARKE.

Combine, combine, bee-kcepers all, Whether your "biz" be large or small, Keep up the rates of honey; Ten cents extracted is the price, Eighteen for section-boxes nice, And see you get your money !

Beware, beware the dangerons den Of hard and grasping middle-men-Sell honey "straight," as whisky Is ewallowed down the leathery thr Of tongh, saloon-frequenting bloats-All other modes are risky. throats

But now that sugar is so low, And may, perhaps, yet lower go, Before it finds rock-bottom, Had we not better face our fate-Let the extracted go for eight? And-comb-well if you've got 'em,

You'll see the prices current veer From eighteen there to thirteen here, "I'll men of wisdom wonder Whether it is not time to "get," And, for their parts, consent to let Bee-keeping go to thunder !

Sweet friends, cap we not find a field That will a flow of honey yield, Our present one to double; Also a way to handle bees, Doing our work with greater ease, And balf the time and trouble?

The laws of trade are bound to rule, And he who doubts it is a fool-Low prices catch the masses : If we intend to "take the cake," Honey we must as low-priced make As sugar or molasses.

Dear friends, I hate to see you wince Because the truth 1 cannot mince, But must your pet corn tread on ; Yet still a living you can earn, If you at once turn to and learn Bee-keeping *a la* Heddon.

If this we do, glucose "must go," For we will honey sell as low As that nefarious mixture : Oh ! won't it be the jolliest fun, To the arrant humbug run And honey stay a fixture ?

Poetic justice will be doled To those who have the public sold When glucose thus goes under : Then give them competition hot, And send their syrup shops to pot, "Mit blitzen and mit dunder."

Mead and metheglin then will be Drunk by the multitude like tea-Hams will be cured with honey; No bee-man wear a down-dast look, But each possess a pocket-book Which has some ready money ! Guelph, Ont.

Fur the American Bee Journal.

### Keeping Bees Near a Railroad.

### J. A. GREEN.

I see by the answers to Queries No. 198 and 199, that some of those re-sponding think that the smoke of passing trains would be detrimental to an apiary situated near a railroad. I can give some facts from experience.

On the west side of my apiary, and only 200 feet away, is the railroad station, where a much larger quantity of smoke is discharged than at any point away from the station. On the east side, at the foot of the bluff, on the edge of which the apiary is located, are the kilns of the drain-tile works, with the tops of their chimneys nearly on a level with the apiary, and less than 200 feet away. During the summer these chimneys pour forth almost constantly a heavy volume of smoke. Whenever the wind is from the east, each puff of wind blows a cloud of smoke into or over my apiary; and the same thing happens whenever the wind is in the west, and there is a locomotive at the station.

While this is very unpleasant to me, I have never been able to dis-cover that the bces are injured by it. When there is a beavy cloud of smoke above the hives, the incoming bees will wait until it lifts a little, when Will wait that it it is a ruch, when they will come in with a rush. Pos-sibly during busy times there might be some loss by the time spent in this way, but I think it is insignificant.

In regard to the jar of the trains: There is a heavy grade here, and often a passing train will shake the whole house. The jar, however, certainly does not injure the bees during the summer, nor when wintered outof doors. As I never have wintered bees in the cellar, I cannot say in regard to that.

Dayton, & Ilis.

For the American Bee Journal. My Improved Section-Case.

G. W. DEMAREE.

I have tried nearly all kinds of cases and racks to hold sections, and have invented several new ones, all of which in their use revealed some objectionable feature about them. My last improvement, however, a descrip-tion of which I give below, seems to me to be well-nigh perfect. I will describe it as I make it for my standard Langstroth hive, though it can be figured to suit almost any hive.

The case is simply a shallow box made of %-inch stuff. The sides are nailed to the end pieces. It is  $4\frac{5}{3}$ inches deep, 14 inches wide, and  $18\frac{1}{3}$ inches deep, 14 inches wide, and  $18\frac{1}{3}$ inches long, inside measure. It is intended to hold  $324\frac{1}{3}x4\frac{1}{3}x1\frac{3}{3}x4$  sec-tions without separators. Being the same size of the top of my standard Langstroth hives, it sets on them with a source joint and needs no over Langstroth lives, it sets on them with a square joint, and needs no over cap or super. The case has two saw-cuts all around it on the inside, the lower one being 3-16 of an inch above the bottom edges of the case, and the upper one 3-16 below the top edges of the case as the table the process of the case. upper one 3-16 below the top edges of the case, so that the space between the two saw-cuts is just  $4\frac{1}{24}$  inches, and will just take the sections be-tween them. The saw-cuts are  $\frac{3}{8}$  of an inch deep. Of course the saw-cuts are made when the material for the cases is being cut out by ma-chinery. At the bottom of the case strips of tin  $\frac{1}{24}$ -inch wide and 14 inches long are slipped into the saw-cuts at the ends of the case and nailed the ends of the case and nailed through the wood and tin ; this holds them firmly, and leaves the tin to project 1% of an inch as supports for the sections at the ends of the case.

The case is divided into three divisions lengthwise, and pieces of folded tin <sup>1</sup>/<sub>2</sub>xl inch are nailed in the saw-cuts at the proper places to sup-port three partitions in the cases. The partitions are scant <sup>3</sup>/<sub>8</sub> of an inch thick, and each partition is made in two pieces. I cut the bottom pieces 3½ inches wide, and the top pieces 34 of an inch wide, so that one wide and one narrow piece, when put together, makes the partition 414 inches wide. Both the broad and narrow pieces of the partitions have tin-rests 3% of n

inch wide nailed to one of their edges. To fill the case with sections, place To fill the case with sections, place the broad pieces of the partitions in the case—tin rests down—the ends of the partitions resting on the tin-sup-ports at the sides of the case, at the bottom. Fill the case with sections and put the narrow pieces of the partitions into place between the rows of sections. Let these be a little scant in width, so that the tin sup-ports will come flat down on the ends of the sections.

of the sections. To make the case invertible, slip right over the ends of the partitions, and a strip of tin in each of the sawcuts at the ends of the case.

I claim as new and original in my improved case the following: First, the saw-cuts extending all around the case at the top and bottom of the sec-tions; second, the partitions made in two pieces, each piece having a tinsupport nailed to one of its edges, and the mechanical combination by means of which the sections are confined in a central position in the case. The idea of a shallow space at the top and bottom of the hive or case is original with myself, though the idea is original with others also. The case I have described is the nicest working thing I ever handled in the apiary.

Christiansburg, 5 Ky.

For the American Bee Journal.

The National Bee-Keepers' Union.

### W. Z. HUTCHINSON.

MR. EDITOR :- Your remarks, on page 131, in regard to what has been done, and will be done, by the National Bee-Keepers' Union, reminds me of something that I ought to have said long ago. At the Detroit Convention some member (I think that it was Mr. Barber), in open convention, said that the reason why more did not join the Union was because of Article IV of the Constitution. No one seemed to take notice of what he said, and no explanation was asked or given.

At the noon intermission I ques-At the noon intermission 1 ques-tioned several as to what was meant by the objection, and learned that they objected to the clause which stated that the officers should "cause such assessments to be made upon all the members as may become neces-sary for their defense." Said they : "We do not propose to give the offi-cers power to assess us for any amount. We are able to pay the assessments to the amount of perhaps thousands of dollars; if we are not *willing* to pay some large assessment willing to pay some large assessment, it can be collected of us, and we do not propose to give the officers any such power to claim our property, especially so when A, B, and C, who join the Union, and enjoy its protection, are perhaps possessed of no property that can be claimed by law."

I explained to them that, as I understood the matter, the payment of assessments was entirely at the op-tion of each member, and their non-payment simply excluded him from to know what Mr. Heddon's hive is.

the Union and the enjoyment of its the Union and the enjoyment of its protection; that the joining of the Union, the payment of dues and as-sessments were all voluntary acts; and that the joining of the Union did not give *it* any *legal* claim upon the property of its members. So long as a man pays his dues and assessments be is a member and entitled to prohe is a member, and entitled to protection; when he tires of paying he can stop, and is no longer a member, and that is all there is to it. "If this is true," said my hearers, " then there should be an explanation given of the matter, as hundreds are kept out by reason of this very clause." Was I correct ?

Rogersville, & Mich.

[You were quite correct. The Union is a voluntary affair. To remain a member requires 25 cents a year annual dues, and to pay the assessments called for. If the assessments or dues are not paid within the specified time-membership ceases; all claims against former members are lost, and all claims to the protection of the Union are dissolved. Annual dues will be called for on July 1, 1886, and probably another assessment of \$1 at the same time. It is not intended to have more than one assessment a year, unless some urgent case should make it necessary, and then there are but few who would not cheerfully respond to a call for an extra dollar.-ED.]

For the American Bce Journal

### Patents on Bee-Appliances.

### J. E. POND, JR.

There is a feeling among bee-keep-ers generally that patents on bee-hives and appliances savor somewhat of humbuggery; this is perfectly nat-ural, as there has been in days past, ural, as there has been in days past, fully as many swindles perpetrated in this direction as in any other branch of trade, and any mention of patents in connection with the apiary is viewed with suspicion. This being the case, it should not be considered strange, that when a newly-patented hive is offered to the public—coupled with the claim that it is so far superior to all others in use as to leave them all others in use, as to leave them completely in the shade—that such hive, and its claims to both merit and patentability should be discussed and criticized; and I see no reason (though some others seem so to do) why the Heddon hive-so-called-should not be submitted to such a test; and I propose to discuss this hive, not as regards its claims to merit, for of that I know nothing; it has yet to be tested by use, and by such use only can its merits be ascertained. Its claims to originality and newness, therefore, will form the subject mat-

As I have never seen it, I can only judge of it from his own published description, and the claims filed in the United States Patent Office. From these, I find that it is a shallow outer case, with either a fixed or movable bottom-board, capable of being tiered up to any desired height, with holes in the sides in which to place screws for the purpose of keying up either brood or section frames in order that the whole may be reversed without displacing the contents; this case being made of stock of varying thickness. The brood department of this hive contains eight close-ended frames (but no special claim is made in regard to that particular number). Each outer case is like every other. and is intended that all shall be exact duplicates; the cases intended for surplus storage are filled with sections eitlier in wide frames when used for surplus comb honey, or with ordinary brood-frames when used for extracting. There are some other peculiarities connected with this hive, such as a slatted honey-board, a peculiar for-mation of cover, etc., that I believe are deemed by Mr. II. of some importance, but as they have been publicly described by him, and were put in general use several years ago, they cannot be honestly claimed as new and patentable.

Now the question naturally arises, what is there new and that can be the subject of a valid patent, in the hive above described ? I say "valid patent" for the reason that while patents are easily obtained, the Government only protects those that are susceptible of being proved new, original and useful. How will the Heddon hive stand this test? What is there new in a shallow outer case capable of being tiered up to any height; and how far different is it from the Simplicity hive of Mr. A. I. Root? The only difference I can find is in the depth (it being shallower), and that the ends, sides, and bottom are composed of wood of different thickness. Does it require invention to make one box deeper than another, or to construct its sides from lumber 1% or 1/4 of an inch thicker or thinner than its ends? Even if so, Mr. Bingham has used a shallow hive for years. In what do the frames described differ from those originated years ago by Mr. Quinby? both are close-ended, and both are reversible. What is there new in the idea of keying frames tightly into an inner case ? Such keying has been made use of in my own apiary for years. These frames are not only reversible singly, but by being keyed tightly in the outer case, they can all be reversed at once. Is this idea new? Mr. J. M. Shuck has advertised and used an invertible hive for years. Ilis hive is also made with a shallow sectional outer case, capable of being tiered up to any desired height. He uses, however, ordinary hanging frames.

I need not discnss the matter arther now. Slatted zinc honeyfurther boards, with bee-spaces between them and the tops of the frames; the claim that two outer cases are required to make one hive, and various other under his patent, and I feel sure, if it peculiarities connected with the Hed-lis just, it will be finally conceded.

don hive, may demand some explanation hereafter, but the main points are covered by onter shallow sectional cases, and close-end frames keyed tightly into such cases. In the above I have written of the

matter as I understand it. If I am wrong or have stated anything in-correctly, I am desirous of being set right, and ready to make an ample apology. Assuming that I am correct. 1 ask what is there in the Heddon hive, that is either new or original in the details of its construction, or the the details of its construction, of the subject of a valid patent, either singly or in combination? The question is not now whether 'the methods of manipulation used by Mr. II. are better than those heretofore used; or whether ''my friend" or ''my students" deem them more rapid and economical or not. With that mat-ter, as I stated at the start, I have nothing to do. I am desirous of gaining all the information I can in regard to an article of trade, that is claimed to be new and original, and testing that claim, by the "state of the art." as shown in the past history of apiculture; and with my present understanding of the matter, 1 can see no reason why the wood of which the hive is constructed, or the nails and paint used in its construction are not as susceptible of being patented as the other features described.

It is unfortunate that bee-keepers are inclined to look upon adverse criticisms as being personal; why this is so, I cannot imagine; 1, however, can only judge of matters as I find them, and in the criticisms above I have simply made a comparison of Mr. H's details, with those that have been made familiar to us by apicultural history. Mr. Heddon can find no fault with courteous criticisms. and the questions asked in this article. if answered correctly, make the criti-cism just; if not, correct auswers given to them will set the public right by furnishing such information as is called for.

Foxboro, O+ Mass.

[The BEE JOURNAL does not propose to discuss the *validity* of any patent-the U.S. Courts are the ones to decide that. Until these Courts have decided otherwise, every law-abiding citizen will respect a patent granted by the U.S. Government. Does not the following from Dr. Tinker pretty clearly answer Mr. Pond ?-ED.]

For the American Bee Journal.

### Sectional Brood-Chamber Hives.

### DR. G. L. TINKER.

The remarks of Mr. Heddon, on page 165, call for an explanation, although I do not propose to enter into anything like a discussion at this time. The hive I have described on page 153, Mr. Heddon claims as his invention. This claim will probably bring to an early settlement his rights bring to an early settlement his rights

The general welfare of the fraterand contention, would seem to de-mand such settlement. I should be pleased to see the harmony and goodwill that prevailed at the late Detroit Convention spread like a contagion among bee-keepers until all ill-will and disaffection is swallowed up in kindness, and a disposition to do right and accord exact justice without prejudice and without reserve. Let us be a great brotherhood of beekeepers, not only in name but in fact.

Now the question in every mouth is, what are Mr. Heddon's rights re-garding his new hive and system of management? In the past few weeks 1 have had lengthy correspondence with him on this subject, and find him disposed to do and to ask only what I am prepared to acknowledge is just and right.

First, he has invented a new hive of original features and original con-struction, having a sectional brood-chamber in horizontal divisions, each being invertible and provided with movable-comb frames. His patent covering the above construction is nndoubtedly valid.

2. In his book. "Success in Bee-Culture," he has presented a new system of management involving what have everywhere been conceded, "my principles" of procedure in beeculture.

3. Although he may not be able to control by patent every construction of hives whereby his new principles may be carried out in practice, still, all will feel, who do practice them, that they are profiting by what he has promulgated, if not directly by what he has invented.

The above are simple facts that cannot well be denied, and under this circumstance it only remains for each one to decide if they shall make use of the new system or not. If they do, it will be only fair to obtain a privilege to use or to manufacture, as the case may be, whether it be a hive covered by Mr. It's patent or one that may be used in the same manner. It is, of course, understood that whoever purchases a hive of any manu-facturer, purchases the right of use with it; and as my hive described on page 153 cannot well be operated ex-cept by the new system. I have pur-chased the right of manufacture under the Heddon patent.

On March 15 to 18, I transferred five strong colonies into these hives, and I am highly pleased with them. They give unmistakable promise of all the advantages I have from the first conceived of such a hive. It opens up new possibilities to the practical beekeeper, new methods and new hopes. It may cheapen our products because of larger production, but more honey will be consumed in lieu of other sweets, while the cost of production will be reduced to the lowest figure. Though we have hosts upon hosts of bee-keepers in the land, I believe the present outlook for their general prosperity has never been so promis-

ing. New Philadelphia, 0+ O.

### How I Winter my Bees.

### D. L. SHAPLEY.

I use the Quinby hive and the Quinby standing frames, the out-side dimensions of the hive being 22x24 inches, but the majority of them I have made 24x26 inches, as it gives more space for packing for winter-ing. The height of the hive is 18 inches; the covers are roof-shape with 3 rafters, and project over the front of the hive 6 inches. The outside dimensions of the frames for the brood-chamber are  $175_{\times}113_{\%}$ . I use 7 or 8 frames for each colony of bees. according to the size of the colony. use a 1/2-inch board with cleats on it. on each side of the frames, and the whole is held together with a cord; that leaves 3 to 4 inches on each side for packing, and 6 inches on top. During the winter of 1882-83 I used oats chaff, and out of 16 colonies I lost only 1, and that by carelessness or ignorance. It was a late swarm, and did not have its hive over two-thirds full of comb, so I took a frame well filled with honey from another colony and gave it to them, and on April 1 I examined them and found them about out of honey. I then gave them, as I thought, sufficient to carry them through, but about May 1 they starved to death.

During the winter of 1883-84 I nsed newspapers from 2 to 4 in thickness at the ends of the frames, and used more straw with the chaff; the chaff alone collected too much moisture the winter previous, especially in those hives that were packed the most solid. I found I had to be very care-ful to pack the chaff but very little. I did not lose any bees that winter.

For the winter of 1884-85 I packed the hives with oats straw, cut with a is used to line buildings with. I win-tered 22 colonies and did not lose any in wintering. One was queenless, and the root of one hive leaked, the comb molding badly, and consequently the colony was very weak; they were robbed the last of April. The colony that was queenless was the only one that showed any signs of diarrhea, and I attributed that to their being uneasy on account of the loss of their queen. There was a large number of bees that died in this section of the State, and I think my success re-markable, and cannot account for it in any way, except as I packed them for winter.

I have now 40 colonies similarly packed, except that I have this win-ter raised the brood-frames about 1% inches from the bottom of the hive to leave more space for dead bees. etc. Winters previous to this, every week or ten days I cleared the en-trances to the hives, of dead bees, with a wire hook; this winter I have cleared them but twice—the last time about two weeks ago, and I found in young bees dead (that were nearly 31; I did get 965 pounds of honey; ready to hatch), showing that there is now brood in most of the hives. too. I can prove it if need be. Last

There is no signs of diarrhea yet. contract the entrances as soon as I think they have brood in the hives. T place a board 12 to 14 inches standing over the hive-entrance; it is nailed to a V-shaped piece on each side, and to a v-snaped piece on each side, and if pains are taken to set it close up to the front of the hive, it effectually prevents the entrance from being stopped up, especially if a little snow is put around the bottom. I think that if H. C. P., in Query, No. 196, will try this, he will find it will be satisfactory satisfactory.

Randallsville. ON. Y.

### Prevention of Swarming, etc.

### 6-WM. MALONE, (5-31).

I think that I have discovered how to prevent bees from swarming while working for comb honey. It is as follows: Get the lower story full of bees and brood, then select a comb of unsealed brood and eggs and place it in the front end of the upper story. Put in 3 wide frames filled with sections and starters, with tin separators next to the brood-comb; then a division-board next that must fit closely so that the bees cannot get behind it. Then cover all up snugly, and as soon as you find the first frame of sections sealed, take it out, slip the other 2 up to the brood-comb, put in the empty one next to the division-board, and so on.

After the colony gets stronger give them another wide frame, but not too fast; I seldom use more than six at a time. When the brood is all sealed in the comb, exchange it for one filled of sections in after the honey is sealed. The secret is to keep a frame of unsealed brood and as much unsealed honey in the hive. If honey is coming in freely you will take out one frame every day, and some days more, after you get a start.

after you get a start. I have only one chaff hive, and I have used it for producing comb honey for four years, and I have never had a swarm from it. I believe I could manage 50 with the same re-sults. I also believe that we will overcome this swarming difficulty yet. I would like to have others try this plan and report results.

In November I buried 9 colonies of bees in clamps. About Dec. 20 it caved in, and I did not notice it until Jan. 5, 1886. The hives were in water 6 inches above the entrance. Snow was on the ground, and a north wind blowing on the day I took them out.

Twice the mercury was 26° below zero in January, and they had no flight until Feb. 7. The hives were nider snow for 3 weeks, and the en-trances frozen full of ice. They are all alive and in splendid condition.

In reply to C. W. Dayton, on page 725 of the AMERICAN BEE JOURNAL for 1885, I would say that I did in-

year was the best for honey that I have ever seen, taking the season through, from April 15 to Oct. 15. Oakley, 9 Iowa.

For the American Bee Journal.

### Prenaring Bees for Winter.

### WM. M'KENZIE.

I prepare my hives in the early part of the fall, before the bees begin to cluster for winter; of course, always knowing their condition previously as to strength of the colonies and the amount of stores. In preparing the hive itself I use from 3 to 4 inches of fine, dry basswood shavings, which makes a good absorbent of moisture. In the morning of the day that I in-tend putting the bees into their win-ter quarters, I raise the hive an inch from the bottom-board (which I have found from practical experience to be of great value in keeping all moisture from the hives), and giving them at the same time plenty of fresh air, without causing any current of air through the hive, or taking away from its warmth, which are three very essential factors in successful winter-

ing. The bee-cellar is prepared as fol-lows: There are two ventilating lows: There are two recently from tubes, one leading under-ground from the outside about 30 feet from the cellar; the other leading from the cellar about a foot from the floor, up through two stories into a chimney above, by which means there is a constant current of air passing in and out of the cellar; and in placing the bees in the cellar I have the hives raised about 2 feet from the floor, and have it covered with 2 or 3 inches of dry sawdust, which prevents any jar or noise, when it is necessary to look at them during their confinement.

In taking them from the cellar in the spring, I place them in rows on the south side of the house, and between and at the back of the hives I are but put plenty of hay, which I have found of decided benefit on account of the cold nights we have to contend with in this section of the country, and especially after taking the bees from their warm winter quarters. It is also a great preventive against "spring dwindling," to which our bees are so liable if not kept sufficiently warm during the changeable and trying time of early spring. By the above method I have suc-

cessfully wintered my bees for the last 2 years, and now they are in fine condition; there is no appearance of moisture about the hives, and the bees themselves are hanging down below the frames. and in many cases touching the bottom-boards.

### Local Convention Directory.

Time and place of Meeting. 1886. Apr. 6.-Eastern Indiana, at Richmond, Ind. M. G. Reynolds, Sec., Williamsburg, Ind.

Apr. 6.-N. E. Kentucky, at Covington, Ky. Alex, W. Stith. Sec., Portland, Ky.

Apr. 7.-Wabash County, at Wabash, 1ud. J. J. Martin, Sec., N. Manchester, 1nd.

Apr. 8.—Southern Illinois, at Duquoin, Ills. F. H. Kennedy, Sec., Duquoin, Ills.

Apr. 10.-Union, at Dexter, Iowa. M. E. Darby, Sec., Dexter, Iowa.

Apr. 27.-Des Molnes County, at Burlington, lowa. Jno. Nau. Sec., Middletown, lowa.

Apr. 29, 30.-Western, at Kansas City, Mo. P. Baldwin, Sec., Independence, Mo.

May 5, 6.—Texas State, at McKinney, Tex. B. F. Carroll, Sec., Dresden, Tex.

Oct. 19, 20.-Illinoia Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

10 order to have this table complete, Secretarles are requested to forward full particulars of time and place of future meetinga.-ED.

Loss from Starvation. - Messrs. Redd & Wilburn, Wewahitchka,~ Fla., on March 12, 1886, write :

Bees have done poorly here so far. Starvation has been the main cause of the loss, which is about one-half, anyway.

Joyful Bees .- J. M. Jenkins, Wetumpka, O Ala., on March 22, 1886, savs :

My bees are having high old times now-have been bringing in pollen since Jan. 14, whenever the weather was favorable. All came through in good condition except 2 nuclei colonies in full-sized hives (an experiment). They "friz."

Bees in Fine Condition.-M. M. Aldrich, Geneseo, vo Ills., on March 19, 1886, says :

My bees are in fine condition. I took them out of the cellar to-day, and within 5 hours after being placed on the summer stands they brought in pollen. I am one of those cripples that Mr. Otis N. Baldwin mentioned on page 23.

Loss of Bees in the South.-G. W. Demaree, Christiansburg, & Ky., on March 18, 1886, writes:

We are having nearly a summer temperature here. Bees are carrying in pollen, and the earth is turning green. I think it is too early to last long without a backset. The raingreen. I think it is too cata, long without a backset. The rain-fall has been unusually light so far this spring, and the way is not clear yet. I now expect to attend a con-yet. I now expect to attend a convention of bee-keepers at Franklin, Ind., April 3. I now believe that the loss of bees in the South will be greater than in any winter since 1869. Light scattered stores, with unusual cold weather did the work. I have in a day or two from maples.

not heard of the loss of a single colony that had plenty of stores properly located in the brood-nest.

How to Feed Bees .- J. H. Andre, Lockwood, 9 N. Y., writes:

The season for feeding bees is at hand, and all colonies, no matter how well they may be supplied with natural stores, should receive from one to two gills of syrup on each day warm enough for them to fly, until the flowers afford enough to supply their daily wants, which, in this latitude, is about the time that the apple trees begin to blossom. For such feeding I have found the following way the most convenient: Take a box 6 inches square and 4 inches deep, with a loose cover, and cleats across the top to keep it from warping. Saw a notch in one side of it 2 or 3 inches deep; bore an inch hole in the back side of the hive, tack on the box so that the hole and notch correspond, and have a plug in the hole. Put into the box a comb containing syrup, pull out the plug and put on the cover.

Thornless Honey-Locust.-W. C. Lyman, Downer's Grove, & Ills., desires replies to the following questions:

1. Is there in Michigan or else-where, a variety of the honey-locust tree that is thornless? Does seed from the common honey-locust ever produce trees that are thornless? We have here a very fine, strong growing locust that is much like the common thorny kind, except that it is without thorns. The bees work upon it as they do on basswood. It is a beauti-ful shade-tree, and I should be pleased to find out just what it is.

[There is a thornless variety of the common honey-locust, Gleditschia triacanthos, which Gray calls variety inermis. It is substantially like the thorn-bearing variety, except in the absence of the spires. I presume that the tree referred to by Mr. Lyman is this thornless locust. It would be well to sow the seed, and by selection, if necessary, secure this beautiful tree free from the thorns.—A. J. COOK.]

Working on Corn-Meal.-Wilson Sherman, Chester Centre. O Iowa, on March 20, 1886, writes:

Winter is past and spring is here in Central Iowa. My bees had several ilights during February, when they needed it. On March 16, I placed my colonies on the summer stands to stay. My bees were wintered without loss in a cellar where the tempera-ture was kept between 48° and 52° above zero. From 21 colonies there was not a pint of dead bees to be found. My colonies are all very strong. I have spread 3 or 4 bushels of gorm meal or how there there They work so thickly on the meal that it really looks black. I think they will be able to get natural pollen

Encouraging Prospects.-E. Armstrong, Jerseyville,+0 Ills., on March 19, 1886, says :

For all the severe winter and spring that we have had, my bees, and others as far as heard from in this locality, have come through in good condition, and with but very little loss. This has been one of the best weeks at this time of the year, for the little workers, that I have ever known. The weather has been delightful. Maples are in full bloom, and they are just alive with the bees from morning until It makes one feel good to night. hear the hum of the bees once more, after their long confinement. Our prospects were never better for a good season. The white clover—our main dependence—is not injured at all, and is looking fine.

Fine Weather-Weak Colonies.-Alex. W. Stith, Portland, & Ky., on March 20, 1886, writes :

I commenced the winter of 1885-86 with 80 colonies of bees in fair condition, and have lost 8 colonies, mostly by starvation, with a limited amount of honey in the hives. My loss was mainly caused by the bees being clustered, during the extreme cold weather, away from the main bulk of honey. The weather for the past 3 weeks has been the finest I have ever seen in March, the mercury being 78° in the north shade. My bees, for the past few days, have been gathering pollen from elm, but they are rather weak for this time of the year. The the death of a large portion of bees from most of my colonies.

Drones Flying.-W. J. Roberts, Keokuk, Iowa, on March, 18, 1886, savs:

My bees, wintered on the summer stands, have come through the season of cold, snow and ice all right. I use a hive made on the Langstroth plan, to hold 12 Gallup frames. The bees are bringing in the first pollen of the season. I am not old enough in the business to say the fact is a re-markable one, but I was surprised to see a large, healthy-looking drone flying about with a very happy and contented buzz.

### The Wintering Problem.- F. M. Taintor, of Coleraine, +0 Mass., writes:

How to winter bees successfully has been to bee-keepers their most vexa-tious problem, and it may be safely said that failure in bee-keeping is owing chiefly to defective wintering. We cannot expect very much from our bees during the summer unless we commence the season with strong colonies, and to insure this condition they must be wintered well. While there is much to learn yet about win-tering bees, I hope the time is not far distant when we can all winter them without loss. The fitting of the colo-nies for winter should be borne in mind during the entire season, and

they should be prepared for winter early—certainly by Oct. 1, and before if they need feeding—so they will have time to evaporate the honey and goal it before the honey and seal it before cold weather sets in. Many colonies are lost that are fed so late as not to have time to evaporate the honey, and it sours and kills the bees. There are also cellars that are damp and cold where bees are wintered. Objections to wintering in a cellar often arises from a lack of understanding of some of the requisites. The hives are often placed so close to the wall that they absorb moisture and become moldy and unhealthful; sometimes they are placed on shelves attached to the sleepers overhead, and are thus subjected to every jar from the room above them with bad results. Dry, pure air and a proper and even temperature are the prime essentials in successful wintering; and these cannot be so perfectly controlled out-of-doors as in a suitable cellar. The room should be partitioned off with matched lumber, so that it will not admit a ray of light, and be kept as nearly a temperature of  $45^{\circ}$  as possible. I find them most quiet at  $45^{\circ}$ .

Gathering Pollen and Rearing Brood.-Louis Werner, Edwardsville, 9 Ills., on March 18, 1886, writes :

My apiary fronts to the south. I have just finished examining my bees, and they are in fine condition. They have been working on soft maple and red elm for the past 5 days, and are rearing brood. I have some colonies full of brood. I have never seen a finer spring than we are having now, and the outlook for a good season is excellent. I have wintered 91 colo-nies on the summer stands. I found one that was queenless; the others are all right.

Working on the Maples.-J. G. Norton, (32-50), Macomb,+o Ills., on March 18, 1886, says :

My bees have come through another hard winter without loss, and are in fine condition. They were all work-ing on maple to-day. White clover looks the finest I ever saw it at this time of the year.

Perspicuity in Writing, -S. D. Webster, Kirkwood, O+ Mo., says :

On page 153 I find the following sentence: "That the flowers of many species of the vegetable world do not require insect aid in the process of fecundation is evident; and that any species of the melliterous flora is absolutely dependent on the insect tribes for their fecundation, I am not prepared to accept as an axiom from which deductions may be drawn that harmonize with the principles of sympathetic reproduction as unfolded in cosmogony." If there is one thing, in cosmogony.<sup>5</sup> If there is one thing, Mr. Editor, that I admire more than

another boy about whether it should be pronounced "bile," which led to a reference to the "Unabridged." There I found that a "boil" "was a circumscribed, sub-cutaneous pustule, characterized by a circular-pointed tumor, suppurating with a central core; a perencutus." I do not ex-actly know yet what a "perencutus" is; but the lucidity of the definition was so striking as to cause it to cling in my memory through all these years in my memory through all these years. If we cannot have the principles of sympathetic reproduction either of the flora or hymenoptera harmonized when cosmologically unfolded, we do not want them at all.

Successful Wintering of Bees.-Charlie W. Bradish, Greig, 5 N. Y., on March 17, 1886, writes :

I have kept bees for 15 years, and can say that the season of 1885 was the poorest season for honey during that time. I had wintered 90 colonies out of 93, sold 12, and united some weak ones, so that when the honey haivest began I had 70 colonies to commence with. I increased them to 128, and took 2,500 pounds of comb honey, 500 pounds of extracted honey, and 1,800 unfinished sections. I put my bees into the cellar in November, and they are wintering well. I have lost only 7 colonies in 8 winters, and 4 of them were destroyed by mice. I shall move about 10 miles from here, this spring, to a better location.

Merry Bees.-I. J. Glass, Sharpsburg, O Ills., on March 22, 1886, says :

I carried my bees out of the cellar last Friday, after a confinement of 105 days. Out of the 61 colonies I found one that had starved, and one had deserted its hive and left plenty of stores. The day was pleasant and the air was soon filled with myriads of merry bees taking their first flight after so long a confinement, and very little signs of disease was noticed, and by the middle of the afternoon they began to carry in pollen. On examining them at night I found that 2 colonies had absconded, one of them leaving considerable brood and a fair quantity of stores. The same day, only a short distance from here. a swarm of bees passed over some workmen, who, following them some distance, failed to stop them. To sum up: I lost one colony by starva-tion, and 3 from ' swarming out," leaving 57 colonies in good condition.

Wintering Bees in a Chimney.-Geo. II. Hayes, Kittery, 9 Maine, on March 16, 1886, writes :

My bees are all in the cellar, and are quiet. If it continues to be warm I shall let them have a flight. They have been in the cellar since last November. I weighed them last In cosmogony. If there is one thing, November. I weighed them last Mr. Editor, that I admire more than another it is clearness of expression; and I always feel under obligation to your correspondents when they so forcibly express their opinions. I had some trouble, when a boy, from a boil; and some more trouble with

now have a standard Langstroth hive, and I like it. I have lost no bees yet. neither do I expect to. A man came to my house a few weeks ago and wanted me to get my bees out of his chimney. They are all right in the top of the chimney. There is a board nailed on the top, with a 6 inch hole in it. The bottom is all open with a fire-place in the lower story. The people do not use the chimney. It has been 21° below zero at times, and below zero for a week at a time, and I do not believe in it, all the same.

Upward Ventilation in Winter.-W. J. Davis, Youngsville, vo Pa., on March 22, 1886, says:

Bees have had a good flight, and have come through the winter in fine condition, with very small loss, caused by loss of queens. I cannot winter bees in good condition in this locality, without upward ventilation. I am also satisfied that the quality of the bees, as well as their stores, has much to do with successful wintering.

Hutchinson on Hibernation.-Wm. F. Clarke, of Guelph, Ont., writes:

Hutchinson has apparently made a strong point against hiberna-tion, but has not killed the theory. May not bees require to cluster in order to hibernate, while other insects can do it singly? It is quite certain can do it singly? It is quite certain that bees never hibernate except in the cluster. I am sorry that Mr. II. has taken up and put on the cast-off garment of positivism belonging to Prof. Cook, and says, "Bees never enter this state." He should add, to make the sentence right, "in my opinion." Mr. Hutchinson should opinion." Mr. Hutchinson should also know that it has all along been contended that " bees must have food and warmth," in order to their kind of hibernation. Starved and chilled bees do not libernate, in my opiuion, as I have stated more than once in the BEE JOURNAL.

Shallow Hive in Sections.-Fayette Lee, (65-124), Cokato, Minn., on March 20, 1886, writes :

A Mr. Carlson invented a sectional hive 12 years ago, 14x14 iuches, and 5<sup>3</sup>/<sub>4</sub> inches deep, containing 9 frames, 5x12. The hive consists of from 2 to 6 stories which may be interchanged at pleasure, those for brood and surplus being just alike. It is a good hive, for either comb or extracted honey, but is rather an expensive one to make. I have never seen it men-tioned in the AMERICAN BEE JOUR-NAL. I always put my bees into the cellar before trost, and never lose any of them. In my letter, on page 137, the 4th line should read : "Upper story for extracting," instead of first story, etc.

Bees in the finest Condition.-A. J. & E.Hatfield, South Bend, & Ind., write:

Our 250 colonies of bees are still in the cellar, in the finest condition.

### Convention Notices.

(37) The bee-keepers of Machtowoc and adjoin-ing counties will meet at Kiel, Wis., on March 25, 1886, for the purpose of organizing a bee-keepers' association. J. H. ROBERTS.

The Wabash County Bee-Keepers' Associa-tion will meet at the Court House in Wabash, Ind., on Wednesday, Apr. 7, IS86, at 10 u.m. All bee-keepers are invited. J. J. MARTIN, Sec.

28 The bee-keepera of Stark and adjoining counties are carnestly requested to meet at Grange Hall (over Farmer's Bank), Canton, O., on Tues-day, Apr. 13, 1886, for the purpose of effecting a permanent organization. MARK THONSON, Sec.

The Southern Illinois Bee-Keepers' Association will hold its 3d annual convection in Teague & Ilarris's Hall at Duquoin, Ills., on Thursday, Apr. 8, 1886, at 10 a.m. A general invitation is extended. F. II. KENNEDY, Scc.

Contral Bee-Keepers' Associatiou will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. M. HAMBAUGH, Sec.

127 The semi-annual meeting of the Western Hee-Keepers' Association will be held to Kansas City, No. on Apr. 29 and 30. 1836. It is desired that this meeting shall be better than any of its predecessors. Essays will be read on the leading subjects in bee-culture, which will be announced as soon as arrangements are completed. Let all who have bees, queens, fixtures, etc., bring them if possible. Due notice will be given in regard to a hall. P. BALDWIN, Sec.

The Union Bee-Keepers' Association of Western Iowa will meet in Dexter, Iowa, on April 10, 1886, at 10 a.m. M. E. DARBY, Sec.

\*\*\* A cordial invitation is extended to all to attend the 8th annual meeting of the Texas State Bee-Keepers' Association, to be held at Jadge W. II. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No hotel bills to pay. B. F. CARROLL, Sec.

The next annual meeting of the Western N. Y. and Northern Pa. Bee-Keepers' Association will be held at Randolph, N. Y. on May 4, 1886. A. D. JaCOBS, Sec.

The Progressive Bee-Keepers' Association will meet in Macomb, Ills., on Friday, Apr. 9, 1886, atternoon and evening. Essays will be read and an uddress will be given by Rev. E.L. Briggs, of Wilton Junction, Iowa. Other speakers of note will be present. It is desired that all interested in bee-keeping should be present. J. G. NORTON, Sec.

17 The DesMoinea Co, Bee-Keepers' Associa-tion will meet at the Court Honse in Burlington, Iowa, on Tuesday, Apr. 27, 1886, at 10 a.m. Any articles sent to the President, Mr.Geo, Bischoff, at Burlington, for exhibition, will be well cared for and returned or sold, as the seeder may direct. A cordial invitation is extended to all interested in bee-keeping. JOHN NAU, Sec.

### Honey as Food and Medicine.

129 To create Honcy Markets in every village, town and city, wide-awake houey producers should get the Leaflets "Why Eat 11oney" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and seatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine " are sold at the following prices ;

Single copy, 5 ets.; per doz., 40 ets.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them) keeper who scatters them)

To give away a copy of "Honey as Food and Medleine" to every one who buys a package of honey, will sell almost any quantity of it.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL Monday, 10 a. m., Mar. 29, 1886.

The following are the latest quotations for honey and beeswax received np to this hour :

#### CHICAGO.

HONEY.—Comb is coming forward more freely and prices now are 15\omega10c, for 1-lb, sections. Ex-tracted is in light demand at 5\omega7c. Comb honey, in 2\omega, sections, 9\omega12c. BEESWAX.—24\omega28c, per lb. Not much offered. R. A. BURNETT, 161 South Water St.

NEW YORK.

HONEX.-We now quote : Fancy white comb in 1-lb. paper cartons, 13@14c.; tbe same in 1-lb. glassed or unglassed sections, 12@13c.; the same in 2-lb. glassed sections, 9@104/gc, and fair to good in glassed 2-lbs. %@9c. Fancy buckwheat honey in 1-lb. ng/lassed sections, 10c.; tbe same in 2-lb. sections, glassed, 8@9c. Extracted, white, 6%@7%c; uckwheat, 5@6e. BEESWAX.-27@28c. MCCAUL & HILDAETH BROS., 34 Hudson St. but

#### BOSTON.

HONEY.-One-lb. sections, white clover, 13@15c; -pound sections, 11@13c. Extracted, 6@8c. BEESWAX.-25 cts. per lb. BLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

HONEY.—White and ex. white comb, 11%@13c.; dark comb, 6%@8c. White extracted, 5%63%c.; amber, 4@4%c.; dark and caodied, 3%de4c. BEESWAX.—Quotable at 20@23c., wholesale. O. B. SMITH & CO., 423 Front Street.

#### DETROIT.

HONEY.-Stocks are being slowly reduced, some salea reported at 13 and 14 cts., the latter being for best knowy in 1-lb. sections. BEESWAX.-Scarce at 25c. M. H. HUNT., Bell Branch, Mich.

#### ST. LOUIS.

HONEY.-Choice comb, 10@12c. Strained, in barrels, 4@5c. Extracted in barrels, 5@5½. Extra fancy of bright color and in No, 1 packages, ½ ad-vance on above briesa.

BEESWAX.-Firm at 22%c. for prime. D. G. TUFT & CO., Commercial St.

### CINCINNATI.

HONEY.—Extracted honey brings 4@8c., and choice comb honey brings 12@15c. in a jobbing way, BEESWAX.—In demand at 22@25c. for yellow. C. F. MUTH & SON. Freeman & Central Ave.

#### CLEVELAND

Е

HONEY.—One pound sections, 14@15c.; 2-lb. 13c Extracted, 7@8c. BEESWAX.—Scarce at 25c. A. C. KENDEL, 115 Ontarlo Street.

#### KANSAS CITY.

HONEY.—Sales of comb are good, while extrac-ted is very dull and low. One-pound sections are acarce; stocks of all other grades are well supplied. Calif. 2-bs. bring 11@12c.; Eastern 2-bs., 12@13c.; 1-bs., white, 14@15c.; dark, 12@13c. Extracted, 5@6c.; Southern, 3%@4c. BEESWAX.—22c. CLEMONS, CLOON & Co., cor, 4th & Walnut.

#### MILWAUKEE.

IIONEY.—The supply of choice comb in sectons is not equal to the demand. We quote : White 1-b. sections, 16@18c; common, 14@15c; dark, 12@ 14c. White extracted in kegs or barrels, 8@9c. BEESWAX.—Scaree at 25@26c. A. V. BISHOP, 142 W. Water St.

Golden Rules for successful advertising, are these : 1. Attractive display. 2. Salient points clearly stated. 3. Repetition. Don't spend all your money in one insertion, 4. Choice of the Paper which reaches the people you want to reach. These rules never fail.

Those who have Bees, Queens or Supplies to sell should at once make it known in our advertising columns. Look out for a good trade, and an early one, too. Those who advertise will do the businessothers will look on, he discouraged, and keep their stock. Our columns are open to all honorable dealers, and should be used liberally. Advertisements may be inserted weekly, alternate weeks, or once a month, as may be desired. See "Rates " on first page.

THOMAS G. NEWMAN & SON. PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

### ALFRED H. NEWMAN. BUSINESS MANAGER.

## Special Notices.

To Correspondents. -- It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any oue desiring a copy. Send name and address, plainly written, on a Postal Card for it.

Wire Nails have advanced in price, as will be seen by quotations on page 159, last columu.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any oue sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable hook.

Perforated-Zine.-We have laid in a stock of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 ceuts per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive-19%x14½-Price 25 cents each.

Frank Lesife's Popular Monthly.-The prolonged winter made Ice-yachting possible even into what is generally regarded as spring, so that the attractions and perils of this peculiar amusement are still fresh in the mind. Mr. Stephens, in the April number of FRANK LESLIE'S POPULAR MONTHLY gives the history of these vessels, their present popular forms, and describes vividly the exhilerating sensations of a spin over the glassy ice in one of these fleet vehicles. Mr. F. B. Mayer takea us from the ice and its pleasures to the balmier Chesapeake, and introduces us to the old towns and manors of the western above of Maryland, giving illustrations from his own artistic pencil. Also many other very interesting articles.

13Dff

Alsike Clover Seed .- We can furnish Alsike Clover Seed at \$8.50 per bushel-pr \$2.25 per peek. These prices will take the place of those published in our Catalogue, until further notice.

To any One sending us one new subseriber with their own renewal (with \$2.00), we will present a copy of the new "Convention History of America."

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club cau have sample copies sent to the persons they desire to interview by sending the names to this office, or we will send them all to the agent.

Are you Entitled to a pension? You may be and may not know it. If you examine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

Kendall's Horse Book .-- No book ean be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprenensive manner. It has mauy good recipes, etc. Price, 25c., in either English or German.

206

He that Blows the Coals in guarrels he has nothing to do with, has no right to complain if the sparks fly in his face. . . . . . .

An Old House in California, which had been abandoned to several swarms of bees, yielded 900 pounds of honey of excellent quality, so says an exchange.

Mr. J. M. Shuck, of Des Moines, Iowa, bas been allowed another patent on his invertible hive.

On page 183, Ist column, in the 17th line from the bottom, the word "eighth" was omitted by the printer. The sentence should read thus: "I place the cells in the nursery eages on the eighth day after they are sealed, and before night many of the queens will emerge."

The Congressional P.O. Committee has instructed a member to report the "Double Fourth-Class Postage Bill " adversely to the House. It is very similar in its provisions to the Bill offered in the Senate by Mr. Wilson, of Iowa. The "stir" made by business men (bee-keepers included) has killed that very unjust and unreasonable measure. Let us be thankful for that ; now some one ought to move that it be decreased to one cent for each 2 ounces.

"Bees and Bee-Keeping; Scientific and Practical. A Complete Treatise on the Anatomy, Physiology, Floral Relations and Profitable Management of the Hive-Bee," is the title of the new work on bee-keeping, by Mr. Frank Cheshire, and is published by L. Upcett Gill, 170 Strand, W. C., London, The first volume contains the scientific part, and is now complete. It has 336 pages, is elegantly printed, beautifully illustrated, and handsomely bound. The subject-matter is comprehensive, the information recent, and the style faultless. We can supply this volume at \$2.00, postpaid. We will publish a roview of this work as soon as space will permit.

Notwithstanding there has been no severe cold weather during March, says the Indiana Farmer, the weather has been sufficiently cool to retard all vegetation, and the chances are in favor of the bees being able to reap a rich harvest from the maple and early willow blonm, giving them an exceptionally good start for the season.

So far us we are 'new able to foresee, the prospects are very encouraging for the bees and their masters. The losses have been light, and bees in the main have come through the winter in fine condition.

Colonies that are a little weak build up very slowly during the cool wentber of early spring, the small number of bees being unable to create the required amount of beat except over a very small patch of brood. They may be assisted very materially by decreasing the size of the brood-chamber with division-boards, and by a covering of some warm material. Old pieces of earpet, bagging, or any thing that will retain the heat answers the purpose.

We have tried many substitutes for pollen. but give the preference to rye-meal, as the bees seem to like it better. The menl should be sprend in shallow boxes in a sheltered. sunny nook, out of the wind. If the bees do not take to it readily, some scraps of old comb laid in the box will attract their attention. After one or two commence work others are sonn attracted by the hum of their busy wings, and in a short time the box will be full of their wallowing dirty bodies, offering one a good opportunity to study the process of gathering and storing pollen. They of course gather only the finer particles of the meal, leaving the balls as offal, and it is surprising to see what a quantity they can carry away in this manner in a few short hours.

From Norway comes this from an ardent admirer of American apicultural progressiveness. Mr. Ivar S. Young, editor of the Norwegian bee-paper at Christiana. writes thus : "I have received the History of the North American Bee-Keepers' Society, and have read it with great pleasure : but I regret not having been able to be present at the enthusiastic meeting in Detroit, last December. I feel now more than ever the need of seeing, hearing, and living with the most advanced bee-keepers of the world." We should be pleased to have our European cotemporary attend the next meeting at Indianapolis, Ind., next fall.

A Man in Texas has just taken out a patenton a honey extractor consisting of n revolving comb-basket in a "can" or barrel, with a long spindle running up through a wooden cover turned by a string being wound around it, the ends of which is held in the operator's hands, and when one end is being pulled the comb-basket turns one way, and then by pulling the other end of the string, it revolves the other way. Such might have been an invention 50 years ago, but now it is a quarter of a century behind the times. The "inventor" must be a veritable "Rip Van Winkle," who has been sleeping for 20 years and has just awoke. The patent was issued less than two menths ago.

The Auti-Adulteration Bill now before Congress, has been read twice, and is likely to pass. The Bill is certainly one of the most necessary for the protection and advancement of public health. They have a stringent law in France, and it is excented with vigor. We ought to have a similar one. for an adulterator of any article of food or medicine should be sent to State's Prison.

Paris has a superb Municipal Laboratory, the offices, analytical chemists' rooms, and other departments of which are on the ground theor of the *Prefecture de Police*, or Central Police Office. To this laboratory anybody who doubts the genuineness of an which of food that he here nurchessed more article of food that he has purchased, may bring it for analysis. It will cost him nothbring it for analysis. It will cost him nothing to have it analyzed. Two inspectors from the laboratory go to the shop-keepers' place of business, and take samples of the kind of goods already analyzed and found to be adulterated. If the analysis of those samples agree with the one previously made, the shop-keeper is rigorously pro-ceeded against at once. He is liable to be heavily fined, imprisoned, deprived of the few civil rights he is supposed to be other-wise entitled to, and has to display consplicu-ously in his store window or on his door. for ously in his store window or on his door, for a year, a large placard bearing the words, "Convicted of Adulteration."

Another New Work on Bee-Culture. -Dr. C. C. Miller, of Marengo, Ills., has written a new book, entitled, "A Year Among the Bees : being a talk about some of the plans, practices and implements used by a bee-keeper of 25 years' experience, who has for eight years made the production of honey his sole business." It is thus described by the author:

It is intended, as near as possible, to go over the whole ground of what I do from the one end of the year to the other; just what I should expect a bee keeper to observe if he made me a visit of a year. There is nothing published that occupies exactly this field, and i often think how much I would have given for such a work 25 years ago.

We are now printing it and it will be ready for delivery in about 3 weeks. It will contain about 128 pages, and will be nicely bound in cloth. Price, 75 cents by mail, postpaid. It is a valuable work, thoroughly practical and progressive, just the thing for beginners, and will obtain a large sale.

New Price-Lists have been received from the following persons :

-----

**REPLIES by Prominent Apiarists.** 

### Transferring Bees.

Query, No. 231.-I have a number of colonies of hees to transfer to Langstroth hives, and would like to know the best method of doing it, and when it should be done. I desire replies by prominent apiarists.-Va.

I think that I should use the plan which James Heddon employs. It -C. C. MILLER.

The method recommended by James Heddon is good. Transferring can be done at any time, but I prefer to do it when the apple trees are in bloom.-H. D. CUTTING.

Drum out the bees from the old bive, and hive them in the usual way, by shaking them in front of a hive containing combs or foundation on the old stand. The best time to do this is when the honey is coming in moderately at the beginning of the (white clover) honey season.—H. R. BOARDMAN.

Transferring should be done in the spring, and when fruit trees are in bloom is the best time to do it. For detail of a method consult any work on bee-keeping .- J. E. POND, JR.

I transfer bees during apple bloom with the least possible trouble. The combs at that time contain less honey than at any other time, and are tough without being soft or brittle. If the combs are not too old and crooked, it bas always paid me to transfer all the worker combs. If any of them turn out to be unsatisfactory they can be removed afterwards at little cost. It will pay dealers in bees and supplies to use foundation in place of the combs, but it does not pay the be-ginner to go too fast. Any of the text books give the modus operandi.— G. W. DEMAREE.

### Sowing Melilot and Alsike Clover.

Query, No. 232 .- Will it pay to sow melilot clover with Alsike clover in March on fall wheat, letting them stand two years? White elover blooms in this locality from May 20 until July 1. Can I prevent the Alsike from blooming until after this time, by pasturing until the middle of May? Will it then bloom in time for me to secure the seed ?-Ind.

Alsike can be kept from blooming in the way mentioned, and a crop of seed secured,-W. Z. HUTCHINSON.

I think it will pay to sow the Alsike; but I should prefer to sow this upmixed. By fordurable off, its Alsike; but I should prefer to sow the dividing is to take 2 or 3 combs of time of bloom can be deferred. My brood with adhering bees from 2 or 3 dividing is to take 2. The best plan of brood with adhering bees from 2 or 3 dividing is to take 2. The best plan of brood with adhering bees from 2 or 3 dividing is to take 2. The best plan of brood with adhering bees from 2 or 3 dividing is to take 2. The best plan of brood with adhering bees from 2 or 3 dividing is to take 2. brother has tried Alsike with great success.—A. J. Cook.

We do not think it will pay, as the melilot grows too coarse, and will spoil the other for hay. It is far better to sow them separately. Melilot is good for land which has been ruined by bad cultivation. Its roots are very large, and it promptly enriches the soil.-DADANT & SON.

Query, No. 233 .- Where box-hives are used with immovable bars to support the combs, % of an inch thick, would not % of an inch space between the combs be as good or better than 1/2 of an inch, giving less lurking place for the bees in the hive, and sending more bees to the surplus boxes? If not, what are the objections ?-F.

Yes, 3% of an inch is enough .- H. R. BOARDMAN.

I think your plan might be good if the bees would follow, but I have tried it a little with movable frames, and the bees changed the space as they built down. But surely—surely —do you take a bee-paper, and are you going to make box-hives ?—C. C. MILLER.

Yes, undoubtedly. In fact I find it to be the case with frames. I find also that when a bee-space only is left between the frames, brood is deposited close to the top; when, it they were wider apart, the comb would be used for the storage of honey. I prefer thus spacing the frames to reversing as it can be more frames to reversing, as it can be more easily and cheaply accomplished.-J. E. POND, JR.

I have worked the combs from  $1\frac{1}{4}$ to  $1\frac{1}{2}$  inches apart, from center to center of the combs, with success. For stationary combs,  $1\frac{3}{6}$  is exactly right. If the bars are  $\frac{3}{6}$  of an inch wide they will be  $\frac{1}{2}$  of an inch apart. When constructing hives with fixed combs, you must remember that one advantage may be offset by some dis-advantage. Thus, if close combs force the bees into the surplus department, the narrow spaces will spread the bees too thinly when in winter quarters.—G. W. DEMAREE.

### Swarming and Dividing.

Query, No. 234 .- Are bees liable to swarm after they have been divided, if plenty of surplus room is given them? What is the best method of dividing ?-Wis.

Yes. There are too many "ifs," "buts" and "ands" to give the best method in this department.—W. Z. HUTCHINSON.

1. They are in this locality. 2. By allowing natural swarming and doing away with after-swarms.-G. M. Doo LITTLE.

colonies and unite them, giving them a queen.—H. R. BOARDMAN.

They will often swarm after being divided, though if given plenty of room they are not apt to do so. With reversible hives I think that the swarming can be easily prevented. For increase, unless we permit swarming, I prefer to build up nuclei.-A. J. COOK.

Bees are as liable to swarm if divided after they get the swarming fever, as if they were left alone. If divided before they get the swarming impulse, the dividing may prevent swarming. It would take 3 pages for the methods of dividing.—DADANT & SON.

This is a question that requires more space to answer than this de-partment can afford. I have given my experience regarding it in my book, "Success."—JAMES HEDDON.

### Convention Notices.

27 The hee-keepers of Stark and adjoining countics are carnestly requested to meet at Grange Hall (over Farmer's Bank), Canton, O., on Tuea-day, Apr. 13, 1886, for the purpose of effecting a permanent organization. MARK THOMSON, Scc.

127 The Southern Illinois Bee-Keepera' Associ-ation will hold its 3d annual convention in Teague & Harris' Hall at Duquoin, Ills., on Thursday, Apr. 8, 1886, at 10 a.m. A general invitation is extended. F. H. KENNEDY, Scc.

The Union Bee-Keepers' Aasociation of Western lowa will meet in Dexter, lowa, on April 10, 1886, at 10 a.m. M. E. DARBY, Sec.

A cordial invitation is extended to all to attend the 8th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No hotel bills to pay. B. F. CARROLL, Sec.

The next annual meeting of the Western N. Y. and Northern Pa. Bee-Keepers' Association will he held at Randolph, N. Y. on May 4, 18\*6, A. D. JACOBS, Sec.

The Progressive Bee-Keepera' Association will meet in Macomb, Ills., on Friday, Apr. 9, 1886, afternoon and evening. Essays will be read and an address will be given by Rev. E. L. Briggs. of Wilton Junction, lows. Other speakers of note will be present. It is desired that all interested in bee-keeping should be present. J. G. NORTON, Sec.

17 The DesMoinea Co. Bee-Keepers' Associa-tion will meet at the Court Honse in Burlington, lowa, on Tuesday, Apr. 27, 1886, at 10 a.m. Any srticles sent to the President, Mr.Geo. Bischoff, at Burlington, for exhibition, will be well cared for and returned or sold, as the sender may direct. A cordia, invitation is extended to all interested in bee-keeping. JOHN NAU, Scc.

The semi-annual meeting of the Western Bee-Keepers' Association will be beld in Pythian Hall, N. W Corner of Main and Itb Sta., (entrance on 1th St.), at Kansus City, Mo., on Apr. 29 and 34, 1886. The Cable Line can be taken from the Umion Depot for 9th and Main Sts. The following essays will be read: "The Honey Market," by Clemona, Cloon & Co.; "Bee-Keeping in Iowa," by C. Kretchmer: "Beet method of bandling bees for comb honey," by A. A. Baldwin; "Missouri Bee Keeping," by J. Pearce; "Does bee-keep-ing pay as a pursuit?" by Jos. Nysewander; and "Invertible Frames and Hives," by J. Shuck. P. BALDWIN, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. N. HAMBAUGH, Sec.

**Explanatory.**—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of eolonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark  $\bigcirc$  indicates that the apiarist is located near the centre of the State named:  $\eth$  north of the centre;  $\blacklozenge$  south;  $\circlearrowright$  east;  $\circlearrowright$  west; and this  $\circlearrowright$  northeast;  $\circlearrowright$  northwest;  $\circlearrowright$  southeast; and  $\blacklozenge$  sonthwest of the centre of the State mentioned.

For the American Bee Journal.

## Replies to Inquiries about my Hive.

### JAMES HEDDON.

I deplore the necessity of writing so long an article upon this subject. I will endeavor to answer the questions of Messrs. Alves, Kretchmer, and Pond, most of which relate to our United States patent laws and rulings. For the past 20 years some of my study outside of apiculture has been that of patent law; being led in this direction by association with a near friend, who is one of the leading solicitors and counselors in this country. Before penning my replies, allow me to quote the following from the Supreme Court decisions, and other high authority, numbering the quotations in sections, references to which will save time and space; for I am sorry to say that brevity and justice to the subject are not possible partners when discussing this question, and answering many inquirers in one article.

In view of the fact that bee-keepers have received some false impressions regarding the object and worth of our patent system, and that almost all believe the erroneous doctrine that the breadth and validity of a patent may be determined by subjecting its claims to a few sharply-defined, dogmatic statutes. I offer the following quotations:

SECTION I.—The right of property which an inventor has in his invention is excelled in point of dignity by no other propertyright whatever. The henefits which he confers are greater than those which be receives. He receives from the Government nothing which costs the Government or the people a dollar or a sacrifice. He receives nothing but a contract which provides that for a limited time he may exclusively enjoy his own. Letters-patent are not hurtful monopolies.

II.—Old desires newly attalned are evidence of invention.

III.-Combining old devices into a new article constitutes invention, when such combination produces a new mode of operation.

IV.-According to a principle in patent law-one prominent in determining patentability-the public adoption or desire to adopt a new device affords evidence of nevelty and patentability.

V.-Patent law deelares that the fact of abandenment and subsequent adoption of things claimed to be alike, is evidence snfficient to negative that claim.

VI.—Novelty of a thing is not negatived by any other thing fundamentally ineapable of the functions of the first.

VII.—Novelty and patentability are not negatived by the fact that every part of the thing is old.

(By virtue of a new combination of the old 26 letters, this issue of the AMERICAN BEE JOURNAL is new.)

VIII.—Novelty of any thing is not negatived by another thing which was not designed or used to perform the functions of the first. Everything favors the patentee on account of perjury.

1X.-Infringement or desire to infringe, are either or both, prima facie evidence of ntility.

X.—Addition to a patented machine or manufacture does not enable him who makes, uses or sells the patented thing with the addition, to avoid a charge of infringement. The above is true, even when the addition is a great improvement, and patentable or patented.

X1.—Changing the relative position of the parts of a machine or manufacture does not avert infringement where the parts transposed perform substantially the same respective functions after the change as before.

XII.—Any claim wilt hold its equivalent, for tew combinations new exist, or ean hereafter be made, which do not contain at least one element, an efficient substitute for which could readily he suggested by any person skilled in the particular art.

XIII.—The state of the art te which au invention belongs at the time that invention was made, must be considered in construing any claim for that invention.

XIX.—The original inventor of a machine will have a right to treat as infringers all who make, use or sell a machine operating on the same principles or performing the same functions by analogons means or equivalent combinations.

XX.—A patent combinations. XX.—A patent should be construed in a liberal spirit to sustain the just claims of the inventor. Novelty and utility constitute patentability. Whether mentioned therein or not, all claims hold all equivalents and all constructions, the arrangements and functions of which are substantially like the thing claimed.

By the foregoing it will readily be seen that our patent statutes and rulings are very elastic; made so for the purpose of doing justice in all the varied cases; and further, that a patent covers much more ground than usual where it relates to a manufacture which is adapted to and invented for carrying out a new mode of operation or system of management.

Space forbids the mention of the many decisions in actions in equity, which go so far toward doing justice to those who give the public something of value.

In reply to Mr. Alves' questions on page 72, I will say that the only trouble I have had in any of the ways he mentions, has been to get all the parts of the hive of accurate measurement, and thoroughly-seasoned material. After that, everything stays in place, and I have less trouble with bee-glue than when using the suspended frame. So say all who have used the new hive. I desire to thank Mr. Alves for his candid and intelligent article on page 167.

Regarding Mr. Kretchmer's patent: By adopting the following method in replying to him, I do so to save space, and because the case at point is so clear. I have a copy of his patent. No. 67,123, cited by him on page 211 of *Gleanings*, and page 185 of the BEE JOURNAL. I have studied his specifications, of which the drawings form

a part, and carefully read the four declarations which he says consti-tute the nature of the invention. None of them anticipate or conceive of one single principle connected with the construction, manipulation, or new functions of my hive. The broodchamber is not in two parts, it has a fast bottom, is utterly incapable of being inverted, "alternated" or interchanged, and not a word pointing to the conception of such a thought is anywhere found in the specification. The upper surplus apartment has tight-fitting top-bars. The wedge of which Mr. Kretchmer speaks, is not the equivalent of a screw, is not used substantially in the manner nor for any of the purposes for which I employ the use of the screw, except as it presses the frames together, tending to lessen the deposit of bee-glue between them, which has been used for vears in wide-frame supers, and for which no one has ever claimed a patent.

The break-joint principle of my honey-board is shown very differently arranged, not substantially as I use it, nor for any of the purposes except that he mentions its having a tendency to prevent the queen from going above, while I use it mainly for the purpose of preventing the attaching of brace-combs to the bottom of the surplus receptacles; for which a patent was granted to me when used in combination with the new hive.

Now, Mr. Editor, in order to save time and space I mail you a copy of Mr. K's patent as cited, also of my own, and request you to hand them both to the foreman of your manufactory, or any patent lawyer, or any one else competent (If for any reason you would rather do so, than examine it yourself), and in a foot-note to this article, give the results of that examination in fewer words and less space than would be required to copy our several specifications and claims, and state whether or not my declarations as above are correct, and if you can find one single feature or principle anticipating the construction or purposes of my late invention.\*

In point of connection let me refer the reader to many of the sections above quoted.

Referring to Mr. Pond's article on page 199, the sections I quote above, as well as Dr. Tinker's candid article, seem to me to fully answer Mr. Pond's questions. Mr. P. sees little difference between my arrangement and Mr. Root's Simplicity hive, except in depth, which the latter constitutes no invention. I certainly can and should have no objection to the continuance of a public use of Mr. Root's Simplicity hive in any depth, or the use of anything else that has been in use, or anything that may come into use that does not use substantially any of my combinations as and for the purposes specified. I should not, could not, and do not claim anything based upon depth, size, number. or thickness of parts.

Although the idea of inverting combs by series rather than singly, originated with me (whether prior to 214

originating with others I cannot say). I make no claim to the principle, ex-cept when operated by the mechanical construction described in the

specifications of my patent. Mr. Shuck's patent, though filed be-fore mine, was issued later than mine, and like it, is perfectly valid; it in no way interferes with mine - neither one being cited to the other during the pending of our applications. Mr. Shuck is working in one way and I in another for the accomplishment of ends which our experience has taught us are valuable. Wedges are not equivalent to screws, and practically incapable of performing the functions of the latter when used for the purposes for which I use them, as specified in my patent.

I am astonished that Mr. Pond should interpret patent principles as he does. In reply to his question as to what is new in my hive, and what I claim as my invention, I will enumerate them :

I. The set-screws in combination with closed end brood-frames, or wide frames for the purpose of securing them tightly in the case, for the purposes of supporting the frames when inverted.

2. Arranging frames within a case (which is bee-space deeper than the trames) in such manner as to leave one-balf of that bee-space ou either side of the frames, or arranging them so they can be quickly adjusted to one side or the other, thus reversing the bee space at will.

3. The combination of my honey-board containing a bee-space in one of its surfaces, or divided between each surface containing slats arranged to cover the spaces between the brood-combs below, with the cases as above described.

A cover with one or 1 oth surfaces contsining a bee-space, or partial bee-space, when used in combination with the cases above described.

5. The combination of the cases, as de-scribed with the bottom-board and bottomstand, as described in the specifications.

6. In a bee-hive a brood-chamber composed of two or more horizontally, separable and interchangeable sections, when said sections are made invertible.

The above constitutes most of that part of my invention which I believe is not anticipated by anything inside of the Patent Office, nor outside of it, so far as the state of the art is now known. All of which is shown in my specifications, much covered by the claims, and the rest open to re-issue. I could have claimed and held all double brood-chambers, no matter how they are constructed, had it not been for the existence of older con-structions in impractical form, and which died of that derangement. This limited me to what I believe to be the best construction of it. However. I claim an honorary right to all double brood chambers when used for the purposes specified in my patent. The matter stands like this: Arnold owns a horse. Ilis horse dies. (A dead horse is burial-expenses worse than worthless.) Thompson has the power to bring that horse to life; and with much effort he succeeds in doing so. Now, who owns that horse? Morally, Thompson; legally, Arnold, and he will likely keep him, if he is a de-scendant of "Benedict."

As this article is already too long, I

said, and is being said, regarding this invention, amounts to the best of evidence in favor of its novelty and utility, and I cannot yet believe that many bee-keepers wish to avail them-selves of the results of my labor, either as an inventor, promulgator or advertiser; and I do believe that any who may attempt it, will by so doing tose more than they will gain, such is the dispostion of most bee-keepers to do justice and give " honor to whom honor is due.

Dowagiac, 9 Mich.

[\*As we prefer not to be "mixed up" with this hive controversy, we handed the two patents to our foreman for critical examination. He gives his opinion thus: "After carefully reading the specifications of both hives, and the proof of the above article, I fully coincide with the opinion of Mr. Heddon, and do not find one single principle in the Kretchmer specifications anticipating the construction or purposes of the Heddon hive."-ED.]

The Marshali County Bee-Keepers' Association met at the Court House in Marshalltown, Iowa, on Feb. 20, 1886, with the President, Mr. O. B. Barrows, in the chair. The minutes of the previous meeting were read and approved. There being but few present, it was thought best to defer the regular programme until the after-noon session. The convention then adjourned to meet at 1 p.m.

At the afternoon session the President made quite a display of tools from his apiary, that are of conven-ience to the practical bee keeper. The exhibition seemed to interest all present. The regular programme was then taken up.

By request the Secretary read Mr. L. Koeper's essay as follows, on

#### HONEY-PLANTS OF IOWA.

The soft maple is the first bloom in the spring, but it is often lost on ac-count of the cold weather. The dan-delion is the next to bloom, but it is not of much importance, as the honey is dark and of a bitter taste, and makes the bees very irritable. The makes the bees very irritable. raspberry is a good honey-producer, and yields a very good honey that is excellent for the queen in the laying season.

During the past three years the most important honey-plant has been the white clover. It is abundant, and produces a clear, white honey. Sumac yields a dark honey, and very poor bee-bread. The willow yields some honey, and the best bee-bread of all the different honey-plants, yet it would have been better had we never known the white willow, on account of the plant-louse, which is sure destruction to the bees.

The basswood affords a fine aromatic honey which is a medicine for man and bees, especially the queen-bee, when she is exhausted from laying so As this article is already too long, 1 and bees, espectany the quaying so of the outside frames at first, and on sections 2 to 8 inclusive, and add that many eggs daily. Second-crop red every second day, getting from 4 to 11 it seems to me that all that has been clover produces good, thick, brown pounds per colony in two days. He

honey. Alsike clover is a good honeyplant, and lasts through the early part of the summer; but being a biennial plant, it lasts only for two seasons. Goldenrod is the richest honey-flower here, and if there are plenty of flowers, the bees will store 5 pounds of honey from this in the same time that they would gather 3 pounds from white clover. The only pounds from white clover. The only one of importance remaining is the buckwheat, which yields a thick, brown honey.

Gooseberries, plums, fruit-blossoms, elms, hard-maple, box-elder, corn, cucumber, melon, squash, cane and many other plants produce honey, but not in paying quantities.

The essay was of interest to all present, and called out a number of questions which were satisfactorily answered by Mr. Koeper. One was, "Why is the willow injurious to to bees?" Mr. Koeper replied that the willow was the natural home of a plant-louse or aphis; and this aphis was a great producer of the so-called honey-dew, as well as are many other aphis or minute insects of other trees dew by exudation. This substance is often gathered by bees. It is of very poor quality, and poisonous to the bees when stored in their hives. It is no uncommon thing for whole colonies to be killed by it. In Ger-many he had seen 16 different kinds of aphides examined by a powerful microscope, and all showed this socalled honey-dew, some of the smaller ones producing the most. He said this was the only way that honey-dew was produced.

The Secretary stated that, from reports, in many parts of the country during the season of 1884, whole apidaries were badly injured, or entirely destroyed by this honey-dew. He said if there was such a thing as honey-dew, as many believe there is, it would be on all kinds of vegetation alike, just the same as the common dew.

G. W. Keeler, on the subject of ex-tracted honey, said that he was not prepared with an essay, but would tell how he worked his own apiary. He used a two-story hive, the lower story being 11 inches deep, and the upper 7 inches. He extracts entirely from the upper story, unless there is a crowding of the brood-chamber, in which case he extracts the extra honey and puts empty combs in the centre of the brood-chamber. He extracts the honey when the combs are partially sealed; puts the honey into barrels, and covers them with a cloth so as to allow the honey to cure well, keeping it in a warm, dry place.

Mr. L. Koeper extracts as soon as the combs are full, and before it is capped. This saves the trouble of uncapping, and he thinks he can get much more honey than to wait for it to be capped. Ile lets it ripen in open vessels. He uses a one-story hive with a large brood-chamber with 15 frames; takes the honey from 4 to 6

likes taking it before it is capped, for by that means he gets each kind of honey separate. His idea is that the honey ripens by evaporation, and is just as good as when allowed to ripen in the combs.

in the combs. Mr. G. W. Calhoun preferred to extract the honey after it is capped. The Secretary stated that he likes

The Secretary stated that he likes to have the upper story the same size as the brood-chamber, so as to exchange frames if necessary, on account of its being so convenient to have the frames all of one size. He often found it necessary to extract from the brood-chamber of a 10-frame Langstroth hive, so as to allow ample room for the laying of the queen.

The subject, "Spring Management," was then taken up as follows:

Mr. Cover puts his bees out as soon as the weather will permit in the spring. He puts out a little honey to attract them to their pollen feed. He uses rye, corn and oats well ground, and feeds some honey where they need it. He keeps them supplied with this pollen feed until they begin to gather from the timber. One spring his bees gathered natural pollen for 3 days in February, and all thought that this was an unusual thing for bleak (?) Iowa.

bleak (?) Iowa. Mr. Koeper prepares his bees well before the time to put the hives on the summer stands. Then on some warm day, but not too early, he lets them have a good flight, and on the next day, if it is pleasant, he goes over them and cleans all up, giving each one its necessary attention. He aims to get all colonies strong by the time the white clover comes. He places empty frames in the centre of the brood-chamber as fast as they are needed, and uses artificial pollen to stimulate breeding.

Mr. Keeler, Mr. Calhoun and others said that they used about the same methods as had been given. The Secretary called the attention to the use of a division-board with rubber on the ends, so as to make it fit close and be easily moved in contracting the size of the hive to suit the colony.

Nearly all present reported that they put their bees into winter quarters about Dec. I, and the report of all was that their bees at this time were all right, or appeared to be in fine condition.

The whereabouts of Mr. F. H. Hunt were inquired for, and whether the honey that was sent to the State Chemist had been heard from. The Secretary replied that Mr. Hunt left the State, and that Mr. Tamblin, of Lincoln, Neb., the one who had the honey forwarded to our State Chemist at Iowa City, had died early last spring. The Secretary had received no report from the chemist. A number present were of the opinion that all was not right with the man who was once an Iowa bee-keeper. This Association denounces all fraud or the appearance of it.

the appearance of it. The subject for discussion at the next meeting, is "The summer care of bees." "How to control swarming" will be treated of by Mr. L. Koeper. The annual election of officers will occur at the next meeting.

The convention then adjourned to meet at the same place on Saturday, April 17, 1886, at 10:30 a.m. Beekeepers of other counties are invited to attend. J. W. SANDERS, Sec.

For the American Bee Journal.

### The Quiescence of Bees in Winter.

### 17-G. M. DOOLITTLE, (40-95).

About the time I gave my report of my winter loss of bees in my beecellar, during the winter in which I kept the temperature of the cellar at  $50^\circ$  or more by the use of an oil-stove, I told how I always found the bees active every time I went into the beecellar, and how, upon raising a quilt over any colony, the bees were always ready to come out to meet me and buzz against the lamp. From this I prophesied that I should lose those bees, for heretofore, during winters in which the temperature of the cellar had been from  $40^\circ$  to  $45^\circ$ , I had always found the bees inactive, and in a very quiet state.

A short time after this, Rev. W. F. Clarke wrote me that he "was sorry for my loss of bees in my bee-cellar, but that my experiments had been the means of his making a great discovery, which I would soon see in print." He also added, if I mistake not (I quote all from memory as I have not the time now to hunt up the letter), that if I "did not fully accord with his views he hoped I would not be hasty in harshly criticising them," to which I replied that I would take time before I said aught of his "great discovery," whatever it might be. It soon appeared that the "great discovery" was his "hibernation of bees," and as several years have elapsed since he made that discovery, I feel that I have kept my agreement with him, and am at liberty now to say a few words on the subject.

During all this time I had been trying to find out just what Mr. Clarke meant by his word "hibernation," but I could not fully do so until I read Dr. Tinker's article on page 5. To this, Mr. Clarke cried "Eureka!" "Henceforth 'HIBERNA-TION' is the word," expressing the quiescent state in which Dr. T. found his bees. When Mr. McNeil wrote in the BEE JOURNAL, a year or so ago, that Mr. Clarke had made no new discovery regarding the hibernation of hees, Mr. C. replied : "What I did was this: I called attention to a fact or principle in bee-life, not unknown, but practically overlooked in our theories of wintering....In this condition (hibernation) their consumption of honey is very trifling, and if we can find out how to get them into it, we shall secure their wintering at the smallest possible cost." When I read this I said to myself, "I believe Mr. Clarke is mistaken in thinking that the above conditions had been ' practically overlooked." Thinking that the above conditions had been ' practically overlooked." Thinking that the above conditions had been ' practically overlooked." The 'alled attention ' to them;" but I was not positive of it until he accepted Dr. Tinker's definition of the "hibernation of bees." As soon as he did this. I turned to page 145.

Vol. III of the AMERICAN BEE JOURNAL, where I found these words written by my old teacher in bee-culture, E. Gallup, who, by the way, ought to receive greater credit for his practical articles of 15 years ago than we are giving him. The words are these:

"Walk down into my cellar and see the bees, it will take but a few minutes. Step up and look at them by the light of the lamp. Do you see the striped fellows in this bive? 'Yes, but Galinp, they are dead as a door nail.' Not a bit of it. 'Well, they don't stir.' Let us breath on them a trifle. 'They are alive; that is a fact. Do they keep as quiet as that all winter?' Certainly. And that is not all; they scarcely consume any honey all winter.'' The title of the article from which I have quoted is "Prevention of Bee-Diarrhea," and J request that it be republished entire, so that Mr. Clarke, Dr. Tinker, and *all* may read how to winter their bees in safety, for I know from an experience of I7 years that the vital principles regarding the safe wintering of bees are found in that article.\*

The reason why I knew that my bees were going to die that winter, was because they were not in the quiescent state which Mr. Gallup describes as a requisite to safe wintering—the state mine had always been in when I had been successful in cellar wintering. I have just seen my bees that are in the cellar, and I find that all those which are properly ventilated are entirely motionless, except as they are disturbed by being breathed upon or otherwise, while a few that I tried to keep warmer by confining the heat in the hive, are not clustered as compactly, and are easily disturbed by the rays of the lamp. The temperature of Mr. Gallup's articles, he says that his was 40°.

I should like to tell the readers all about how the different colonies of bees act in my cellar; how they compare with their actions of other winters; how I have watched them for hours to see the change in the cluster, of which Prof. Cook speaks, etc.; but it would make this article too long were I to do so. But I must say that, with Prof. Cook, I object to "this winter quiet of bees" being termed "hibernation." Any thing that ean be aroused to activity by a simple breath of air cannot be said to hibernate, according to my understanding of the word. Prof. Cook illustrates hibernation on page 87, by means of the wasp. I wish to illustrate it a little more by telling a story of a colony instead of an individual, as some might say that there would be a difference. It is as follows:

During the fall of 1875 I built a new house on my present location, 40 rods from any other building. In 1876 I built my shop and put in a steam engine. Where I had formerly lived I was bothered with black ants which I supposed were the same as those which throw up mounds of earth in meadows and elsewhere in this locality; so I expected to soon have them about in my new location, as I noticed these earth-mounds all about. Much

to my delight no ants appeared until the summer of 1878. During the win-ter of 1877-78 I cut an aged maple tree in the woods and drew it in "drags" down by the shop to use for fuel for my engine. In cutting up the dead and somewhat dozy top of the tree, I came across a colony of ants. These ants appeared as dead as any dead insect I ever saw. I looked them when my curiosity was satisfied, threw all on the snow where I saw them every day for about a week, when a snow covered them up. As spring thawed the snow away

my ants laid on the ground in a pile near the sill of the shop, when I again boked them over and examined the "dead things." In a few days the sun came out hot, and that evening, in passing the shop, I noticed that my pile of ants was gone, and soon found, much to my sorrow, that they had taken up their abode in the sill of the shop and elsewhere, wherever they could gnaw into the wood, where they still exist to torment me every summer. These ants were HIBERNATING. gave off no warmth, lay motionless all winter, did not stir when their home was split open, and no amount of disturbance could arouse them. If Mr. Clarke or Dr. Tinker can get a colony of bees to pass the winter in like state, then we will all willingly call it "hibernation," and besides, shower them with honors for making a "great discovery." Till then, frends, please use the word "quies-cence" instead of "hibernation."

Since writing the above I chanced to split another colony of ants out of a decayed log. These appeared as dead as those spoken of which I found several years ago. I took two in my hand and breathed upon them three times, as long as I would to revive chilled bees, but there was no signs of life. I then took 10 of them and bottle near the steam-engine where a temperature of 85° was maintained. At the end of 3 hours no life was shown, but in 5 hours from the time they were left there all were as lively as crickets. This was hibernation, not quiescence.

Borodino, ON. Y.

[\*As soon as space will permit, we will republish the article.-ED.]

For the American Bee Journal.

### Telling the Bees.

### W. F. CLARKE.

I supposed that the superstitious custom of "telling the bees" belonged to a by-gone age, until the other day, when I made the unexpected discovery that there are some remains of it, even in this era of light and knowledge.

Calling on an aged English lady, an old maid—it is no libel to call her such, for she is in her ninety-third year—the conversation came some-

my father died, I went to the hives and rapped on each one, saying "death, death, DEATH!" When my mother died, I was so troubled and worried that I forgot to tell the bees, and every one of them died."

"I do believe its all a blatther o' of about seventy. "I tell thee, Henry, its nuthin' o' the kind. Its true as Bible. Why, there's William D." (resident about two miles away), " who used to keep bees; he got married, and did n't tell the bees. Well, his wife got cancer and died, and every one of the bees died, too."

It was of no use arguing with a lady of her age and experience, for "If she will, she will, you may depend on't ; And if she wont, she wont, and there's an end on't."

So I left her to hug her pet superstition during the rest of her waning eve of life.

### Causes of Loss in Winter.

### JAS. A. MINICH, M. D.

We can scarcely pick up a bee-paper that has not something to say on this subject. We hear it discussed ad*infinitum* at our conventions; and of remedies to guard against winter loss, there is no end. It is amusing to see how widely apiarists differ and the variance of their opinions the variance of their opinions. I have listened patiently, and have faith-fully read all the theories. I do not object to, any and all the plans that have been given from time to time; they are all good enough as far as they go. It is well to put chaff-cush-ions, forest leaves, or any good ab-sorbent in the upper story of the hive; or to pack straw or sawdust, or chaff around the outsides of the hive; contract the brood chamber to five or six frames; make passage ways through the combs, or place sticks on top for the same purpose; and put them into a suitable cellar. All these most of them necessary to success. The bees will generally winter well and come out in the spring all right, and every bee-keeper feels as though he had solved the winter problem, and is on the road to success, and even to fame, and he cries " Eureka !

But sooner or later an epidemic comes and the bees die in spite of all the above plans and remedics, and a · change comes o'er the spirit of his dreams." And again the discussion begins—" too much pollen." too much ventilation, or not enough: too much heat or too much cold, or too damp; and more remedies are offered. Now. why is it that these epidemics will come every few years? In my opinion the main reason has been overlooked. I have observed that every epidemic among bees has been preceded by a *drouth* the summer or fall previous. I wish every apiarist to make a note of this. This was the case the summer this. This was the case the summer and fall of 1880, and it was followed how to turn on bees. "I used to keep and fall of 1880, and it was followed them," said the old spinster, " and in the winter by great fatality among I'll tell you how I lost them. When the bees. It was the case 13 or 14

years ago-I cannot tell the year-and the bees were almost annihilated the following winter in Central Indiana. And in the summer and fall of 1884 there was sufficient drouth at the proper time to bring about the same result.

But how could it affect the bees? you ask. In two ways: 1. It is a well known fact that flowers will not bloom and honey will not flow in dry weather, and consequently the queens cease to lay eggs, and breeding stops. Now one can readily see that colonies will have to go into winter quarters with old June and July bees which were ready to die from old age and exhaustion; or perchance a few of them might linger a few weeks longer, and "one by one they pass away" in the spring — "spring dwindling" caused by old age.

2. Dry weather is conducive to the secretion of honey-dew or "bug-juice," and bees will gather it and store it away for the winter, which causes diarrhea among the bees and

consequent death. The remedy: Taking the above to be facts, the remedy is now plain enough; the winter problem is solved. When dry weather sets in, and the honey-flow ceases in August and September, the bees should be fed regularly so as to stimulate late breeding. This should be done regularly, or the queens will not have much confidence in the future outlook, and will stop laying. Honey-dew should be ex-cluded in every way possible. It can be detected as soon as the bee-keeper sees it. Take it out and feed them bountifully on cane-sugar syrup. Now, fellow bee-keeper, if you will

Now, fellow bee-keeper, if you will be as careful in this respect as you are in others, you will have no losses. Remember that your greatest trouble is caused by drouths; and that if your colonies can go into winter quarters with young bees; with pure honey or syrup; cushions of chaff or leaves on top; passages for the bees to travel from comb to comb; and keeping from comb to comb; and keeping them quiet, and not bothering them at all in their long rest, you will see them all come out booming in the spring. No matter how severe the winter may be, they will survive and come out all right, on the above conditions.

Indianapolis. O Ind.

For the American Bee Journal. A Sample of "Cheap" Honey.

### W. J. CULLINAN.

I have frequently noticed honey I have frequently noticed honey quoted at 6 to 8 cents per pound in the markets, and as often wondered how *pure honey* could be produced and sold at a price that would justify the dealer in offering the same at these (as I supposed) ruinous prices. My wonderment was still further augmented when I learned, the other day that a dealer in grogeries at this day, that a dealer in groceries at this place was selling California (?) honey, which he purchased in New York, at 11 cents a pound. I did not go to see the stuff, which 1 learned resembled a poor grade of white sugar wet with

water, and forming a tasteless compound bearing no resemblance to honey. And yet the dealer was ignorant enough to say "they (meaning his customers) might know it was white-clover honey, as they could taste the comb in it."

'Again, I noticed honey quoted in the BEE JOURNAL at 4½ to 5 cents per pound, and I then concluded to ponder no longer in the dark, but immediately sent for a sample of the "four-and-half-to-five-cent honey," and to-day I received by express a package in which were two little bottles containing what I supposed to be honey, but which I found upon exanination to be an admixture of coarse, dark, brown sugar, glucose. ad infinitum, wet up to a stage resembling in an exceedingly remote degree, partially granulated honey.

It is needless to add that my wonthis needless to add that my won-derings at the possibility of selling "honey" at such rates were now at an end, but still I wondered; my wonderings now, however, were of a different order, viz: I wondered now how it was possible for them to get customers even at this low (2) price. customers even at this low (?) price !

It seems to me it is a bold affrontery npon a trusting public, for men (if men they should be called) to make and sell such stuff as an article of diet; but is it not a vile, yea, villainous imposition upon the bee-keeping fraternity for the manufacturers of those repulsive compounds to herald them to the world as *honey*, bringing disrepute upon that God-given nectar, gathered from the cells of flowers-Nature's own repository-by the "little busy bee," and stored in clean, white comb to be converted to the use, health, and happiness of mankind; thereby damaging the interests of the thousand-and-one honest men engaged in the noble pursuit of bee-keeping?

The manufacturers of oleomargarine are no longer allowed to call this vile mixture of tallow, lard, etc., by the name of "butter;" and why should that other class of impostors be permitted to heap odium upon the heads of bee-keepers by styling their noxious and repulsive compounds as " honey?"

Surely our Legislatures, if not our General Government, should be importuned to protect and sustain us in this one of the noblest pursuits of man.

Mt. Sterling.+0 Ills.

For the American Bee Journal. The Sectional Brood-Chamber Hive.

### 13-J. V. CALDWELL, (125-165).

This new hive seems to be undergoing a fiery ordeal, and in view of the claims put forth by its friends and champions, it is but right that such should be the case. Any hive or other implement used in the apiary, and for which it is claimed will effect and for which it is claimed will effect let it benefit "whom it may," I do up of any part of the State is a benefit a complete "revolution" in our busi-this even at the risk of being classed among the "property-owners who criticized. I think that no candid have lands for sale." But to escape the consequences of this grave charge this. I believe that Mr. Heddon is working for the good of the cause, on record that I often recommend interval and the state is a benefit to it as a whole, it is a narrow, near-sighted policy that tries to build up one section or industry by defaming another. 4. "Take away the honey and orange interests of Florida, and there

and in proof of this witness his careful and often losing experiments in wintering; and taking these things into consideration, the claims he puts forth regarding this hive must have a fair and unprejudiced hearing.

We who have read carefully Mr. Heddon's articles during the past year, know that he has been trying to handle his apiaries with as little labor handle his aplaries with as hitle labor as possible, knowing as he does that honey so produced must be cheap, when compared with honey produced by much high-priced labor. And as our product is yearly becoming cheaper in the markets, it is an idea of no little importance of labor to up of no little importance-at least to us who are making a specialty of the business.

I like the idea of a shallow frame, and, in fact, for the past ten years I have used and like much the best a frame but  $7\frac{1}{4}$  inches deep, inside measure. I have also a good many bees on Langstroth frames, but they are too deep for me.

But concerning this new hive, as Dr. Miller says, there are some things I do not understand. We, who winter our bees in cellars, want to know if we must carry all the double lower story into the cellar; if not, will one of the divisions hold enough honey to safely carry the bees through the winter, or at least until it is time to place them on the summer stands ? Again, will not the bees be clustered in both parts so we must pull them apart in cold weather when putting them into winter quarters? We who are asked to throw away our old hives and adopt this new candidate for public favor, would simply like to know how much more comb honey can be taken on an average than from our old hives, other things being equal; for, in the end, honey and not bees is what we are after. Doubtless Mr. Heddon can enlighten us on these things, as we must know all we pos-sibly can about it before we spend our hard-earned dollars for any new bee-hive. But on the other hand, if it will be a benefit to us, of course we want it.

#### For the American Bee Journal,

### Honey-Interests of Florida, etc.

### W. S. HART.

"The mangroves have been en-tirely destroyed by the recent cold wave," so wrote Mr. Jno. Y. Det-wiler, on page 60; and on page 102, about the greatly damaged honey-interests of the Florida coast. I do not wish to enter any prolonged controversy over the effects of the cold in this State, but as I believe Mr. D. is inclined to look upon and present to others the dark side of this matter. I would ask permission to "state plain facts," also "let it injure"—no, let it benefit "whom it may." I do this even at the risk of being classed

good people to go to other parts of the State where I have no property, and in what I write herein I will give references and figures that can be traced up and proven false if they are so.

First, he states that "the mercury is reported by various parties as being as low as 10° to 20° above zero." True, such were the reports, and at the date of his first writing it could not be satisfactorily proven false, but as the  $10^{\circ}$  report was from only one person, and he living on the peninsula near Mr. Detwiler, who reports "on the peninsula the mercury was 20° above zero," I feel sure there was a mistake of some 10° in the lowest report. As further evidence 1 will state that the lowest point indicated by my ther-mometer was 23° above zero, at 3 a.m., on the morning of Jan. 10. The lowest reported here at Hawk's Park. from the thermometers in the most exposed positions, was 20° above. At New Smyrna, two miles north, with the exception of the 10° report, the lowest showing was from a thermometer hung in the most bleak place to be found on board of a steamer moored to one of the wharfs. It registered Is<sup>o</sup> above. At Jacksonville, 100 miles north of here, the Signal Office report at 6 a.m. on Jan, 12 (the coldest day there), was  $15^{\circ}$  and 3 minutes, which was the coldest registered since 1835. On the place where the 10° report came from, 1 am told that the little nursery trees retained their leaves, and look as thrifty as ever. Evidently there was some mistake.

2. Notwithstanding the "personal examination," I believe that much of the margrove here is still alive, and if the blossom buds of the surviving trees are not blighted, we may get a small crop of mangrove honey even by Messrs. O. O. Poppleton, A. S. Brown, H. W. Mitchell, myself and others, shows quite a per cent. of the black mangrove trees still alive, some of them not having even a twig hurt. It is true that the tree is a slow grower, but as all the bees kept here could take but a small part of the honey heretofore produced by the mangrove, I think there will very soon be enough for them again. In the lower part of the State the mangrove, and even tomatoes, pine-apples, cocoanuts, etc., have escaped unhurt. Some bees and fixtures are offered for sale, for in this as in every other industry, there are some weak-kneed parties that are ready to wilt as soon as the starch of success is withheld for a time.

3. As to the interior's having "suffered much more than admitted," seems to me that people from all parts of the State have been unusually candid in their statements of the losses, and as each locality has its peculiar advantages, and the building up of any part of the State is a benefit

is but little left for humanity to subsist upon except the food-resources of the coast and the genial climate, which, in many instances, prolongs life when disease has taken a firm hold upon the system." Well, the last part of this quotation is undoubt-edly true, and I will vouch for it, but the first half will truly be a surprise to most of the good people of this State who claim to know something of her resources. Let us compare some of our other industries with the two mentioned, and see where they stand in relative production and gross income : Manager Ives, of the Florida Fruit Exchange (than whom no one is better able to judge), estimates the crop of Florida oranges for 1885-86 at 1,000.000 boxes; this at \$2.50 per crate ready packed, which is surely a liberal average, would give the State \$2,500. 000 for the year's crop. In 1884, prob-ably the honey crop of the State was heavier than ever before, or than it was the past season. The State sta-tistic for the year's crop of the state stapounds for that year, about one-half of which was produced in this immediate neighborhood. As most of our honey is extracted, I consider 10 cents per pound a fair price at which to estimate the crop; that being some higher than extracted honey sold for that year, and considerably lower than the price of comb honey. Stating it thus, 210,357 pounds at 10 cents per pound, amounts to \$21,035.70, making our best showing in the way of a honev crop.

By referring again to statistics of Florida's production in 1884, we find that there was produced of corn, 3,557,200 bushels (worth from 60 to 70 cents per bushel in Jacksonville); potatoes, 70,848 bushels; oats, 494,000 bushels; cotton, 60,000 bales; molasses, 1,290,560 gallons; tobacco, 224,239 pounds; lumber, \$3,060,291 worth. We have shipped to Cuba during the last ten years 167,736 head of cattle, bringing \$2,469,747 to the State, besides what has been used at home and shipped elsewhere. In 1881 eight counties in this State owned 205,714 neat and stock cattle.

Of the 60,000 bales of cotton 24,987 bales were "sea-island;" over onethird more than was produced in all other sea-island localities put together, and worth more than double the price per pound of "short staple." Our sea-island cotton is of such superior quality that the Coat's Thread Company moved down to the cotton fields so as to be sure of a good supply of it. The cotton crop of 1884 brought \$3,000,000, notwithstanding the low prices then ruling. Five hundred thousand crates and barrels of garden truck and 300 car loads of mellons were shipped the same year, and from West Florida alone a business of \$633,388 was done by her fisheries. Jacksonville hotels entertained 60,011 guests, to say nothing of her scores of boading-houses, and the increase for this season is some 20 per cent. over that of last season, up to this date.

Our timber interests are immense, and count away up among the millions, pine being found in the greatest

quantity, but cypress, live-oak and cedar also being of great importance. Live-oak enough to amount to more than all the honey ever shipped by Florida, all taken together, has been taken from this (Volusia) county in one winter, for Government shipbuilding. Yes, this has been done several seasons. The cedar for the pencils of the world came from this State. The Faber Pencil Company moved their manufactories into the cedar woods of West Florida to secure their supply of it. Our naval stores, sugar, cigar, sponge, fibre, rice, lemon, pine-apple, cocoanut, grape, strawberry, poultry, and many other industries are of as much importance, and some of them vastly more, than that of bee culture. Verily, Florida need not hang her head in shame for lack of inducements for immigration, even were the orange and honey interests taken from her. Give us energetic men to develop our resources and we will surprise our sister States.

5. Now of her losses by the late freeze: The orange crop was the principal and almost only one really worthy of serious consideration by the people of the State at large. True, most of the tropical trees and fruits in this tier of counties, and farther north, were killed, but they are only grown here mostly for home use. In the lower portions of the State, where they are grown as field crops, they are still alive and flourishing.

Of the 1,000,000 boxes of oranges produced this year, Manager Ives, *Bradstreet's*, and others of the best informed, estimate that one-half were still upon the trees when the freeze came, and that 90 per cent. of that was lost. These oranges were of best quality, and would, according to the estimate of the editor of the *Florida Times*, have netted the growers \$2.30 per box, or \$1,035,000; add to this the loss to pickers, packers and transportation lines, and still the loss is less than  $1\frac{1}{4}$  million dollars, and this is purely a money loss.

From the same cold wave Texas lost \$3,000.000 by the freezing and starving of her cattle alone, while from the States north of her come reports, not only of loss of property, but harrowing tales of suffering and loss of life, whole families having perished together. And now the papers are full of the great losses in Massachusetts by the floods—much greater losses than ours in value of property—coupled with statements of homes destroyed, and whole neighborhoods of people driven into the streets to subsist on the charity of others. How often are our sympathies excited by such tales coming from the West—often accompanied with the list of those who perished in the flood—the wreck-strewn track of which shows losses amounting to many times that of the Florida orange erop.

Drouth and grasshoppers have may be and may not paralyzed for years in succession the prosperity of whole States, and brought the cultivators of the soil to want, and in many cases starvation was only prevented by the timely both be sent for \$1.30.

help from other States that for the time being were more prosperous. The word "cyclone" covers so much of loss and suffering that many people in the West shudder to hear it. Florida residents do not expect eternal exemption from misfortune, but feel thankful that by reason of our climate, many of the more serious ills of the North and West can never reach us here.

We feel the loss of our oranges, but it has increased our confidence in orange culture by showing us that the trees will stand a lower temperature without injury than we had supposed. The great tumble in real estate that many expected, has not come, but on the contrary, land is selling readily at as high prices as before the cold snap, and new groves are being planted in all directions. In Levy county 175,000 acres of land changed hands within 30 days after Florida's great freeze. Hawk's Park, O Fla.

For the American Bee Journal.

### New and Novel Principles.

### PROF. A. J. COOK.

MR. EDITOR :-- I wish you would repeat the excellent words of Mr. G. M. Alves, found on page 168, which are as follows: "I affirm that the Heddon principles are novel and cannot be found in literature or elsewhere. Let those who deny adduce the proof. The rubbish that has already been lugged forward does not deserve a critical man's attention."

deserve a critical man's attention." Mr. Editor, I have no interest in this matter at all, only the grand interest of justice and fair play. For shame on us, if we are to repeat the Langstroth outrage! There is no bee-keeper of intelligence in the United States who has the faintest shadow of an idea that this hive, method or discussion would have been brought forward had Mr. Heddon kept silent. Mr. Heddon told me a year ago that he had a method that he believed would revolutionize our business. Why did I have to wait a year to know what it was? Only because it was original with Mr. H., and remained locked up a year longer. If any one honestly believes it, let him say it is a worthless hive and system. But, alack the day ! when any considerable number of beekeepers say it is not Mr. Heddon's. Firmly believing Mr. Langstroth to have invented the practical movable frame, I have ever stontly maintained it; and I as truly believe Mr. Heddon to be the originator of the new system, and if found valuable, as I firmly believe it will be, I shall ever defend his rights.

Agricult. College, 9 Mich., Mar. 23.

Are you Entitled to a pension? You may be and may not know it. If you examine the Guide and Hand-Book you will soon find out. Thousands of things worth knowing will be found in it. The BEE JOURNAL for 1886 and the Guide Book will both be sent for \$1.30.

### Local Convention Directory.

1880. Time and place of Meetino.
Apr. 8.—Southern Illinois, at Duquoln, Ills. F. H. Kennedy, Sec., Duquoln, Ills.

May 20.—Wis, Lake Share Center, at Kiel, Wis. Ferd Zestrow, Sec., Milhome, Wis.
Oct. 19, 20.—Hilmois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., String, Ills.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Bees Never Wintered Better.— John Rook, Muscotah, & Kans., on March 23, 1886, says:

My bees have wintered finely—never better. They commenced to gather pollen from the soft maples on March 17, and worked nicely for 3 days, but on March 20, on account of a snow storm, they all stopped, and as yet have not returned to duty.

**A New Bee-Association.** — Ferd Zastrow, Millhome, **c+** Wis., Secretary of the Association, writes:

The Wisconsin Lake Shore Centre Bee-Keepers' Association was organized at Kiel, Manitowoc County, Wis., on March 25, 1886. The following officers were elected: E. Petermann, of Waldo, President; Jesse Roberts, of Meeme, Vice-President; Ferd Zastrow, of Millhome, Secretary; and Henry Peters, of New Holstein, Treasurer. They will have their first meeting on Mav 20, 1886, at Koering's Hall, in Kiel, Wis. Any bee-keepers in the counties of Manitowoc, Calumet, Fond du Lac, and Sheboygan, may become members.

Eggs that Produce Queens.-T. F. Kinsel, Shiloh, & O., writes :

On page 181, Mr. N. W. McLain correctly quotes Query, No. 185, as intended by me. I omitted the proper writing of "queen's." The question was caused by reading "Dzierzon's Theory "—a wonderful work—and from the answers to it, apicultural savants of the present, it seems, do not agree. I take it that the Query Department is for information, and so 1 propounded the question for that purpose. I thank Mr. McLain for his article; also others for opinions on the same.

Too Much Swarming.—Alex Rose, Sullivan, O Ills., on March 26, 1886, writes:

I had 11 colonies of bees last spring, and now I have 23, all in good condition. I lost onc. They went up into sections, ate all the honey, and them starved and froze, with about 25 pounds of honey below. I got about 1,000 pounds of comb honey last year. I am feeding my bees granulated sugar in empty racks and sections. I feed them in the hive in the evening to prevent robbing. My trouble with bees is to keep them from swarming to death. I cut out queen-cells and put back 40 swarms last year. I want a remedy for it.

Surface Measure of Foundation.— T. B. Longbottom, Kettleby, Ont., propounds this question :

Please state in the BEE JOURNAL the superficial measurement, per pound, of comb foundation—both for the breeding apartment and for surplus honey.

[For the brood-chamber it is usually made from 5 to 6 feet to the pound; thin, for surplus honey, measures from 9 to 10 feet to the pound; and the extra thin is from 11 to 12 feet to the pound.—ED.]

### Disinfecting Foul-Broody Hives, etc.-A.W. Osburn, Cuba, W. I., says:

In answer to Mr. Pease's letter, page 137, I would say, in my opinion the roofs are not infected with the foul brood (unless it might be close around where the hives stood). With a coat of paint near where the hives stood, I think I would risk it. Knock the hives to pieces, and boil them well. Do not be afraid of boiling them too much. Put them together again and paint them. Extract all the honey you can, boil it, and keep it to feed to bees when needed. Melt the candied honey with a very little water; the wax will rise to the top, and the honey, with little evaporating, will be ready to feed. Serve all supers that are worth the trouble the same as the hives. The sections will make a bonfire—nothing else. If the work is done well, there will be no further trouble. Do not let your bees, or any one else's, get at your honey before it is boiled.

Uneasy Bees, etc.—G. B. Olney, Atlantic, 9 Iowa, March 25, 1886, says:

Last year 1 got 306 pounds of extracted honey from one colony of ltalians, and sold 271 pounds of it at 16% cents perpound, and the balance, thirty-five pounds, at 15 cents per pound. In the spring I started with 8 colonies, increased them to 20, by division. Three natural swarms absconded during my absence. I secured nearly 1,200 pounds of honey, 300 of it being comb honey, and the balance extracted. The extracted honey shows no signs of candying yet. It was

gathered from heart's-ease. The interest in apiculture is increasing here, some are getting enthusiastic, some are talking Tennessee as the place to go and make bee-keeping a specialty. I received a postal card on March 19 I received a postal card on March 19 saying, "Come, come, and tell me what to do with my bees; they are all crazy." I found them, 55 colonies, in a cellar 12x14x6 feet, tiered np one on top the other from the ground up. The brood-chambers were 12x14x14 inches in size. The bottom of the cellar was covered with dead bees; a few hives were polluted at the en-trances, and some with a large cluster in front. Many bees were crawling around and were noisy. The tempera-ture was about 45°. I recommended putting out the hives on the summer stands, so as to allow the bees a flight. The hives were quite full of honey when put into the cellar on Nov. 1; some also had brood. No extractor was used; but if it had been I think it would have been better for the bees, as the hives were undoubtedly too full of honey.

Drones Hatched in Worker Comb, etc.—T. J. Bell, Opelousas,⊙ La., on March 23, 1886, writes :

Bees in this part of Louisiana did very well last year. With 90 colonies to commence with, I increased my apiary to 106 colonies, and they gathered 9,600 pounds of honey, or nearly 100 pounds per colony. I lost 6 colonies by the heavy frost last January. My colonies have plenty of young bees, and they are still rearing brood fast. Our honey season is a month hat this year. Will drones hatch out and develop in worker comb?

[Yes; but the drones will be correspondingly smaller, and Dzierzon claims that they are not fully developed.—ED.]

A Brood-Chamber in Sections.—A. A. Fradenburg, Port Washington, o+ O., writes:

Six years ago 1 was called to a place 6 miles from here to transfer some bees, and among other hives there I found two that particularly attracted my attention then, and have very often been the subject of my study ever since. Out of one of them I took the bees and comb at the time; from the other the comb only, as the bees had died the preceding winter. The hives were well made of good lumber, and, by appearances, had been used several years. The brood-chamber was made in sectional parts; I should say that each sectional part was about 14 inches wide, I3 or 20 inches long, and 5 inches high, and the parts were interchangeable as well as reversible, if any one had thought of reversing at that time. Each hive had three sections or tiers on, but of course they had no thumb-screws to clamp the frames together. If I remember, they had stationary frames or strips fastened to hold the top and bottom edges of the combs. I do not know who made them, or whether they were patented.

Discussion and Controversy.-Dr. C. C. Miller. Marengo, & Ills., on Mar. 25, 1886, says:

I am glad to know that Bro. Clarke is in such a happy frame of mind, and that the appearance of warlike intent was only the ebullition of an unusual amount of good nature. I beg to assure Bro. Clarke that whatever the assure Bro. Clarke that whatever the connection may imply, I had no thought of him in my mind, nor in-deed of any particular individual in referring to either A or B. With re-gard to the meaning of the words "controversy" and "discussion," I used them as synonymous, and did not object to either unless of the not object to either, unless of the kind "we do not want." Neverthe-less, Bro. Clarke, I think you will see "a shade of difference between the meaning of the words." You might discuss a subject upon which no one held opposing views, but can you imagine a controversy in which the idea of opposition is not involved? If you can, I should like to discuss it with you, and controvert your views, when next we meet.

Strong Colonies.-J. H. Larrabee, Larrabee's Point,+0 Vt., on March 24, 1886, writes:

I have 17 colonies of German hees. To-day I examined 2 colonies in chaff hives on the summer stands, and I found them strong in numbers. One that I could not see had eaten 5 pounds of honey; the other had con-sumed more honey, but had "rushed the season," having some capped brood. The past winter has been quite favorable for out-door wintering here; bees had several cleansing flights.

Snow-Storm, Reversing Frames, etc.-H. Clark, Palmyra, 9 Iowa, on March 30, 1886, writes:

A snow-storm reached us on Sunday, March 28, at 6 a.m., with an eastern wind, and it snowed 8 inches deep. The bees brought in pollen on March 24 and 25 from the soft maples. My bees have wintered finely. Mr. I. N. Boyles, on page 172, says that to reverse frames it turns the young bees with their backs downward. I would like to hear from others about this.

#### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of hoth. All postage prepaid.

BARNES' FOOT-POWER MACHINERY.Example of the second s

THOMAS G. NEWMAN, EDITOR. Vol. XXII. April 14, 1886. No. 15.

Alm at Excellence, and excellence will be attained. This is the greatest secret of success and eminence. "I cannot do it" never accomplished anything. "I will try" has wrought wonders.

-----

Mr. N. W. McLain's Report on experiments in apiculture, which was read at the Detroit Convention, has just been received. It was a Report made to the United States Entomologist, and is published by the United States Department of Agriculture. We shall give it in the BEE JOURNAL as soon as it is possible to find room for it.

Transferring Bees should be done while the fruit trees are blooming. The honey obtained from the fruit blossoms will stimulate the bees to repair the damaged and mutilated combs.

Bees and Grapes .-- C. M. Clay, in the Southern Planter, gives this testimony :

If the bees could puncture the grapes, one being found, as the grape is much richer in sugar than the melon, it is logical to suppose that they would attack the grape in force; but no such action takes place; a few bees find the broken bulls and suck the juices, but hey a pergent seen any indication of a but I have never seen any indication of a perforation of whole-skinned grapes.

Weak Colonies in the Spring will need care and attention. Mr. F. L. Dougherty, in the Indiana Farmer, gives the following hints concerning them :

From various causes some colonies come out weak in the spring. Such will require much cure to build them up ready for the honey harvest when it comes, and nnless they are got into working condition by that time, they are worse than useless capital. In their weak condition they can increase out very slowly for lack of heat, and should be assisted as much as possible, by the closing up of all space whereby the heat may escape. Entrances should be made small, so that they may be able to protect themselves from the depredations of rob-bers. They will breed very slowly at first, but with plenty of stores casy of access, they will grow rapidly as the weather becomes warmer. Later in the seaso they brood from stronger colonles. From various causes some colonics come

Dr. Miller, in his new book, carefully describes in detail the work that should be done all through the year, beginning with the taking of the bees from their winter quarters, and carrying the aplarist on day by day until the bees are again safely placed into winter quarters. In his preface Dr. Miller says :

I have no expectation nor desire to write a complete treatise on bec-keeping. Many important matters connected with the art I do not mention at all, because they have not do not mention at all, because they have not come within my own experience. Others that have come within my experience 1 do not mention, because 1 suppose the reader to be familiar with them. I merely try to talk about such things as I think a brother bee-keeper would be most interested in if he should remain with me during the year.

Telling the Bees. - The Cincinnati Enquirer gave this item on the subject to the world in a late number of that paper :

cottager leaned whispering by her hives. Telling her bees some news as they lit down, And presently a bee, a great bee, golden bee, That appeared to be the wateb-dog of the treasury.

- Shet like a ball from out the waxen town, And on the nose of cottager screnely aut
- him down, hg, "Excuse this liberty, Oh, pretty
- Build divine, mald divine, But I have news to tell thee, in return for news of thine,"

- The midden didn't linger long a-whispering to the bees,
   But struck a frightful galopade, her hair upon the breeze,
   And the bowls that she emitted, as she danced, and praneed, and ran,
   Were heard, the neighbors tell me, clear from Beersheba to Dan.

But the Enquirer must be sadly imposed npon-

> For that poet, never saw it-; Not a bit, did he : Else he'd know it, failed to do it-Did that "golden" bee.

Honey Season in California.-Mr. D. Wood, of Santa Barbura, writes thus to the Indiana Farmer dated March 15 :

Indiana Farmer dated March 15: This has been the coldest winter here for many years. We had one genuine hail-storm, the first 1 have seen. It was very fine, but plenty of it, and the montain peaks were covered with snow. Nevertheless flowers bloom, and last year's tomato vines are still on the trees, while others have young apples as large as small hens' egga. My bees are storing honey rapidly. Some have a two-story hive full above and below -about the same us two Langstroth hives placed one above the other. To-day 1 trans-ferred three colonies, cutting and fitting comb and honey; in the middle of the apiary, with 100 colonies at work, and not a robber bee came near me. Hits of broken comb and honey have been in open air, not two rods from the bives, untouched for several days. Honey is plenty io the field, and transferring can be done in the yard.

The Ree-Sting Remedy for Rheumathem was lately tried by a man living in Georgia, which resulted as follows, says an exchange:

Divesting himself of his clothing, he got into bed and covered up, and told his attendant he was ready. A swarm of young bees was then put into the bed with him, and the remedy commenced. It took four men to bring him back to the house, and it would have required forty to have put him in the bed again. He still has the rheumatism.

Mr. T. F. Bingham, of Abronia, Mich., has just returned from Central America, where he accured a colony of stingless bees, and has brought them home with blin, to ascertain if they will thrive in this elimate. As they are of but little use as honey-gatherers in their tropical homes, they will probably not be of much value in this cold eilmate. On last Thursday Mr. B. wrote us the following item concerning them :

My Central American bees flew out to-day, and brought in pollen. They are in good condition; none worth mentioning having died on the trip. I am glad I brought them bome with me, and I believe I shall be able to learn their habits this summer.

Honey in Virginia .-- This is what the itlehmond Dispatch says about that "new industry" in the South :

industry" in the South : The production of honcy is becoming an important interest in Amherst. One of the citizens got from his hives, last year, 2,000 pounds, and mother (this a Northern man) about 3,000. The Italian bee is preferred, and these (the queens) are sent away or received by mail. What the becomen call "foundation" is made by hand, and this is put into the hives, and upon this the bees build. Honcy without the comb sells at 10 cents, with the comb 35 cents, and when 1 inquired the reason for this difference in price, I was told that the honey can, by a certain process, he forced from the comb, and that the combs thus compted are placed in the hives and again filled by the bees, and much thme and lahor is thus saved to them. Honey, say those who have given this new industry a fair trial, pays better than tobaeco. tobacco.

That is not such a bad description for one who knows nothing about honey-production.

Why is it Called the Honeymoon? asks an exchange. Honey, because it is full of s(e)ells; and moon, because it "comes bigh."

. . . . . . . New Price-Lists have been received from the following persons;

Bright Brothers, Mazeppa, Minn.—24 pagea Bee Keepers' Supplies, Bees and Queens.

W. G. Russell, Millbrook, Ont.-15 pages-Bee-Keepers' Supplies.

11. H. Brown, Light Street, Pa.-22 pages-Bces, Queens, and Bce-Keepers' Supplies.

A. Snyder, Indian Fields, N. Y .- 1 page-Bees and Queens.

Eureka Mower Company, Utica, N. Y .- 24 pages-Mowers.

Smith & Smith, Kenton, O.-24 pages-Im-plements in Be@Culture.

J. W. Eckman, Richmond, Texas-5 pages -Bees, Queens, and Comb Foundation.

Any one desiring a copy of either of them, can obtain it by sending a postal card to the address as given above. -----

We have Just Received from the publishers a copy of the poem "Ostler Joe," which is published in neat pamphlet form, with about forty other choice recitations. "Ostler Joe" is the poem, the reading of which by Mrs. Potter in Washington Society a few days ago, caused such a sensation. J. S. Ogilvie & Co., publishers, 31 Rose Street, New York. Price, 12 cents.

To any One sending us one new subscriber with their own renewal (with \$2.00), we will present a copy of the new " Convention History of America."

### **REPLIES by Prominent Apiarists.**

### **Reversing Brood-Combs.**

Query, No. 235.—When reversing a set of brood-combs will the bees leave the honey where it is if they have no surplus apartment on the hive ?—C.

I think not. but never tried it.—C. C. MILLER.

Bees, as a general rule, store their surplus above the brood, but it depends upon circumstances as to whether they will remove sealed honey, as you state the question. I have never known them to change the position of their sealed stores in the late fall or winter months. Bees are slow to remove sealed stores at any time, because it must be done at considerable loss. Our bees here will leave their sealed stores in " patches" all over the brood-nest, though it is the chief source of our winter losses, during severe winters.—G. W. DEM-AREE.

It will depend upon the season and the yield of honey. The claim is that reversing sends the honey into the sections in a hurry; the claim is incorrect. however, in so far as experience shows it not to be the case at all times, and we must have further tests to prove that it really has any effect at all in this direction.—J. E. POND, JR.

That depends upon what the bees are doing. If at a time when all colonies are inclined to till the broodcombs, they would leave the honey where it is; if, on the other hand, breeding is going on rapidly, the honey would be fed out to the brood. Before the advantages of inverting combs can be appreciated, the operator must learn when to do it.—JAMES ILEDDON.

### Using Old Combs.

Query, No. 236.-I have a lot of old combs from last year, some of them taken from hives where the bees had died; the latter contain dead brood and considerable bee-bread; would it be safe to give these combs to the bees again without extracting the brood therefrom? and would the old bee-bread be likely to work injury to the bees?-W, J. C.

It would be safe, but do not give too many at a time.—W. Z. HUTCH-INSON.

I think it would be safe to give the old combs as they are ; but I should prefer to melt them into wax and give foundation.—H. R. BOARDMAN.

To use these carefully one at a time would, I think. be entirely safe; especially in good, vigorous. strong polonies.—A. J. COOK. I should prefer to melt up such combs and use foundation. The old bee-bread would do no harm.—G. L. TINKER.

Give one at a time to strong colonies, and no injury will come therefrom; but, on the contrary, your combs will soon be as nice as ever.— G. M. DOOLITTLE.

Where there is much dead brood, we would object to using old combs. If the bee-bread is too old and spoiled, the combs had better be melted over. Try one comb in a populous colony and see what they do with it. If the bee-bread is spoiled, they will cut it out, and throw it away.—DADANT & SON.

Such combs as contain much dead brood, I should work into wax after cutting out and burying the portions containing the dead brood. The bees will quickly clear out the old beebread.—JAMES HEDDON.

### Likes and Dislikes of Bees.

Query, No. 237.—Can persons control bees that can control themselves? or do bees distinguish any one except by their actions and motions? Some people think that they are the special favorites of bees, while others must stand at a distance or suffer the consequence.—H.

I think that actions pretty much decide the matter, although odor and color may have something to do with it.—C. C. MILLER.

l have never been able to discover that bees had any personal preferences or prejudices; but they show a very decided aversion to some kinds of texture in clothing worn, such as fur or fuzzy woolens, and perhaps to some colors in clothing. — II. R. BOARDMAN.

Yes, with the assistance of a good smoker. 1 did think, years ago, that bees took especial pains to go across the street to sting me, but now I think differently.—H. D. CUTTING.

I think that "some people" are mistaken in this regard. The problem hinges on the how, and not by whom, bees are treated. To your first question I say yes.—JAMES<sup>\*</sup>HEDDON.

Yes. I have never seen any one of ordinary coolness but that could handle and control a colony of bees. The superstitions of the dark ages are fast dying out, and ere long we shall all learn that there is no mystery whatever in bee-management.—J. E. POND. JR.

To the first part of the question, my answer is no It requires several traits combined in the person, to make him a successful manipulator of bees. If I was going to point out the ground-work of a successful apiarist, it would be a *lasting interest in bees*. Everything else by close application can be acquired. Two-thirds of the people believe that bees "hate them," and the other third, that they can manage bees as they please. There is nothing in the whole thing except that the man who is unfit for the beebusiness, is unfit for it.—G. W. DEM-AREE.

### Prevention of all Increase.

Query, No. 238.—I have 22 colonies which I wish to work for comb honey and avoid all increase next summer; how may I do it ?—G.

This is a rather hard nut to crack. We would advise using large broodchambers, and attracting the bees into the sections early, by giving them, here and there, a section partly filled from last year.—DADANT & Son.

By using-reversible hives, possibly; otherwise it is difficult. Why not get one swarm from each colony ?-A. J. COOK.

It does not appear to be possible to prevent all increase in a good flow of nectar in working exclusively for comb honey; nor is it desirable.—G. L. TINKER.

I never could succeed in doing such a thing, nor do I think the most comb honey could be secured in that way even if successful.—G. M. DOOLITTLE.

I am not certain that it can profitably be accomplished; but I would suggest hiving a swarm in a new hive upon the old stand, putting on a queen-excluding honey-board, then the surplus-cases, and over this put the old brood-nest. Allow no queens to hatch in the old brood nest, and when the bees are all hatched shake them out in front of the hive. A hive with a loose bottom-board would be needed.—W. Z. HUTCHINSON.

The ways are varied, depending upon location, season, and varieties of bees. After all were known it would require 2 or 3 columns to describe one course of management, and then some one would say that the plan would fail.—JAMES HEDDON.

### Convention Notices.

A cordial invitation is extended to all to attend the 8th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No botch bills to pay. B. F. CARROLL, Sec.

The next annual meeting of the Western N. Y. and Northern Pa. Bee-Keepers' Association will be held at Randolph, N. Y. on May 4, 1886. A. D. JACOBS, Sec.

127 The DesMolnes Co. Bee-Keepera' Association will meet at the Court House in Burlington, lowa, on Tuesday, Apr. 27, 1886, at 10 a.m. Any articles sent to the President, Mr.Geo. Bischoff, at Burlington, for exhibition, will be well cared for and returned or soid, as the sender may direct. A cordial invitation is extended to all interested in bee-keeping. JOHN NAU, Scc.

bee-keeping. JOHN NAU, Sec. **137** The semi-annual meeting of the Western Ree-Keepere' Association will be held in Pythian Hail, N. W Corner of Main and lith Sts. (entrance con 1ith St), at Kansas City, Mo., on Apr. 29 and 30, 1886. The Cable Line can be taken from the Union Depot for 9th and Maio Sts. The following casays will be read: "The Honey Market," by Clemons, Cloon & Co.; "Bee-Keeping in lowa," by E. Kretchmer; "Best method of bandling beea for comb honey," by A. A. Baldwin; "Missouri Bee-Keeping," by J. D. Pearce; "Does bee-keeping pay as a pursuit?" by Jos. Nysewander; and "Invertible Frames and Hives," by J. M. Shuck. P. BALDWIN, Sec.

**Explanatory.**—The figures BEFORE the names indicate the number of years that tho person has kept bees. Those AFTER, show the number of eolonics the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark  $\bigcirc$  indicates that the apiarist is located near the centre of the State named:  $\eth$  north of the centre;  $\blacklozenge$  south;  $\circlearrowright$  east;  $\circlearrowright$  west; and this  $\circlearrowright$  northeast;  $\circlearrowright$  northwest;  $\circlearrowright$  southeast; and  $\blacklozenge$  southwest of the centre of the State mentioned.

For the American Bee Journal

### Bee-Keeping as a Business.

### WM. F. CLARKE.

From his well-known and oftenurged views on the subject, it was to be expected that Mr. Heddon's book would strongly advocate bee-keeping as a specialty, and deprecate all at tempts to make a side-show or mere appendage of it. We may well be-lieve that Mr. Heddon's most conclusive arguments in favor of apicultural specialism are marshalled in the chapter devoted to that topic. On examination, these will be found condensed into one-the great advantage of con-centration on a given pursuit. This is, no doubt, a forcible argument in all cases to which it is applicable, but we must not forget that it is only to those of a certain cast of mind that the argument applies at all. Those who, as phrenologists phrase it, have concentrativeness large, will, no doubt, accomplish most by bringing all their powers to bear on one focal-point; but there are many people who cannot do their best at one particular pursuit, and would feel themselves toilers in a treadmill, if tied to only one line of activity.

"Many men-many minds," You cannot make one rule apply to all. One man will run several different lines of business, and throw immense energy into every one of them; while another finds it all he can do to keep one a-going. One man finds it a re-freshment to turn to something different from what he has been at, and he switches off and on with perfect ease; another finds his thoughts confused and his fingers all thumbs if he makes a sudden change in what he is doing. Whether it is better for a man to be a whole man to some one pursuit, or to divide himself up among several, depends upon the man himself-whether he be an indivisible or a divisible man. So you cannot lay down castiron rules to govern everybody.

Very probably the proverb, "Jack of all trades and master of none," will be quoted here, but are there not many people who have only one trade or business, and do not master that very well? Men are like steam-engines—Some have seant power for the

task assigned them, while others have any amount of surplus power. It is like steam hissing at every joint and rivet. Is it not wise to turn it to some good use? Yes; make it run a crank of some kind, and do something more and better than merely make a noise in the world.

The question whether a few colonies of bees can be kept with pleasure and profit can only be decided by the testimony of those who have tried it, and I do not hesitate to say that is overwhelmingly in the affirmative.

Mr. Heddon certainly is badly mistaken when he says apiculture has little connection with farming. Why, it is a branch of farming. Bees are as much part of the live-stock of a farm as chickens, ducks or sheep. In Britain, no farm is considered properly stocked, unless there are on it from six to a dozen hives containing bees. On a farm you can keep bees without any danger of anuoying your neighbors, while in a town or village they are apt to become a nuisance in the confectioneries, groceries, and cook-sheds. If you own a farm, your bees mostly pasture in your own fields. and you can grow honey crops on purpose for them. The long noon rest-ing-spell could have no better or more pleasurable employment than that of watching the bees. It may be true that "less pleasure and profit has been derived from the few colonies of bees kept on the farm, than from any other branch of mixed husbandry, when taken all in all, one year with another," as Mr. Heddon asserts, but the proof is a a-wanting, and I do not think will be forthcoming. I will pit a hive of bees against a cow or pig any day, and if I cannot get more pleasure and profit out of the bees than out of either cow or pig, I will own myself wrong, and Mr. Heddon right.

It is very encouraging to have an experienced honey-producer like Mr. Heddon express confidence in beekeeping as a specialty, notwithstanding a downward tendency in the market. I believe that tendency will operate until honey becomes about the same price as sugar. When higher than sugar, it is a luxury; when the same price as sugar, it becomes a necessary. The demand for luxuries is always more or less limited, but the demand for necessaries is practically unlimited. It will take a good deal of tact and industry to produce honey as cheaply as sugar, but I believe we are on the eve of accomplishing this feat, and that Mr. Heddon's book will prove a mighty factor in achieving this result.

Mr. Heddon is wisely cautious in refraining from holding out fictitious inducements to people to embark in bee-keeping, but does he not fall into the other extreme of being too repressive? He says he would not advise those "who are failing in other lines of business to try ours." Well, now, I would. It is those parties who have not yet found out their mission, who should try something else. It is a great thing to find out what we cannot do, as well as what we can.

We make both these discoveries by trying. I know the ditty says.

" If at first you don't succeed,

Try, try again ;"

but sometimes fair trial proves want of adaptation so conclusively that it is the part of wisdom to try something else. Sometimes incapability is manifest enough without trying. A lady was once distributing religious tracts among the patients in a hospital. As she passed on after giving a man a tract, she was surprised to hear him burst out laughing. On asking the cause of the sudden fit of merriment, "Why, ma'am," said he. "you've given me a tract on 'The sin of dancing,' and I've had both my legs shot off !" Some people are as manifestly unfit for bee-keepers as a man without legs is unit for dancing, and all such had better give the business a good letting alone.

It is a great surprise to me that Mr. Heddon should say, "I do not consider bee-keeping adapted to the gentler sex." Why it is not adapted to them he does not state, except inferentially, when he says he does not want his daughter to compete with men in this labor. Now I believe that bee-keeping is just one of those pur-suits in which women can compete with man to advantage, and if there were any insuperable difficulty in the way before. Mr. Heddon himself has removed it by inventing a hive, and devising a system of manipulation which more than halves the labor needful in an apiary. The exertion required to lift full-sized hives, was the one objection I should have urged against women becoming bee-keepers. That objection exists no longer. There is only a half-hive to lift when lifting is only a han-live to firt when firtubg is required, and by wintering bees out-of-doors on my hibernating stand, the necessity of lifting or carrying hives, is almost wholly done away with With restrict on the new start With no strain on the muscles with. demanded now, in what particular cannot women compete with men as bee-keepers? Their perceptive powers are keener than those of men, their patience is greater, and their per-severance is proverbial—"If she will, SHE WILL, you may depend on't; and these are the prime qualities de-manded in an apiarist. It is said a good surgeon must have 'a lion's good surgeon must have heart. an eagle's eye, and a lady's hand." So must a good bee-keeper.

I predict that when Mr. Heddon's book and hive become more widely known, there will be a great rush of the gentler sex into bee-keeping. So many have succeeded under the old, clumsy, cumbrous methods, that with a hive no larger than a lady's workbox to handle, the temptation will be irresistible to many ladies who are on the look-out for some not over-laborious method of earning a livelihood. There is much in bee-keeping that suits woman's cast of mind, in fact the whole manipulation demanded is of that gentle, quiet kind which harmonizes with woman's nature, and I venture to predict, that, on the new method now before the public, the ladies will enter the lists of apicul-tural workers both as competitors and assistants to an extent as yet un-paralleled in the history of beekeeping. Guelph. Ont.

For the American Bee Journal. Comb Honey vs. Extracted Honey.

### CHAS. SOLVESON, (40-64).

As I am the propounder of Query, No. 153, I have been much pleased with the discussion it has brought forth. When I read Chas. Dadant & Son's article on page 759 of the AMERI-CAN BEE JOURNAL for 1885, where they try to prove that Mr. Doolittle was mistaken in his estimate, that with extracted honey at 8 cents per pound comb honey could be produced at 12 cents per pound, with equal profit to the apiarist. I felt certain we should sooner or later have an article from Mr. Doolittle on the subject; and on page 58 Mr. D. gives us facts and figures which tend to prove that comb honey can be produced for less than 12 cents per pound, with the extracted at 8 cents per pound. Although I am not ready to accept anything less than 12 cents as the comparative cost of a pound of comb honey, to 8 cents per pound for extracted honey. I feel certain it is nearer right than Messrs. Dadants' 20 cents per pound.

On June 10, 1884, I selected 20 colonies as nearly alike as possible, and worked 10 for comb honey, and 10 for worked to for comb honey, and to for extracted honey. Those worked for comb honey were in 8-frame Improved Langstroth hives, with section-cases similar to Mr. Heddon's, and they produced, on an average, 70 pounds of honey in one-pound sections. Those worked for extracted honey were in were all supplied with an upper story filled with combs, and they produced, on an average. 120 pounds of extracted honey each; which at 8 cents per pound, amounts to \$9,60. This divided by 70 pounds (the average amount of comb honey produced by each of the 10 colonies), gives about  $13_{34}^3$  cents as the comparative cost of comb honey. And in the fall each one of the 20 colonies had to be fed from 8 to 15 pounds for winter stores, although I had not extracted a pound from the brood-chambers of either.

Again, on June 15, 1885, I selected 20 colonies and worked one-half of them for comb honey, and the other half for extracted. Those worked for comb honey were in the same kind of a hive as those in the first experiment. but were contracted to 5 combs. at about swarming time. I obtained 24 pounds per colony on the average. from those worked for comb honey; while I got only 30 pounds from each of the colonies worked for extracted honey, and they were provided for as those of the year before. This at 8 cents per pound gives \$2,40; and if we divide this by the average number of pounds of comb honey produced by each colony, we have only 10 cents as

half to three-quarters of their winter stores. I will add that the season of 1884 gave only about two-thirds of an average crop; and the season of 1885 was the poorest of any that I have known since keeping bees.

Mr. Heddon's new book, "Success in Bee-Culture," is the most practical work of its kind that I have ever read. It is intended for those who keep bees for the money there is in them, and they cannot well afford to be without it. Nashotah, & Wis.

For the American Bee Journal.

## Have Bees a Language ?

### J. M. HICKS.

The bees doubtless possess a lan-guage at least peculiar to themselves. The inarticulate sounds of the bee, which are instinctively uttered, are very readily understood by its own species. The expression of ideas is but the acknowledging of those sounds as representatives of our ideas. Then, properly speaking, the conveyance of ideas from one to another, either by sounds or gestures, becomes a language as soon as those ideas are understood between two individuals. Were it not so, the mute would be as isolated from the associations of man, as the insect world. That man actu-ally holds converse with the bee, receiving and transmitting ideas, is as true as that these are received and transmitted to and from the mutes.

If I give a gentle rap on the side of the hive, every bee with a short, buz-zing noise answers from within. This idea they have conveyed to me. A little harder rap conveys the idea to them that something is wanted out-side, and immediately some of them make their appearance at the entrance of the hive and fly around. This actually conveys to me the idea, "Who is here?" They have simply taken this way to say, "Who is here, and what do you want?" "I want some honey." The bees, not fully uu-derstanding my remark, necessary to convey the idea to them, I attempt to approach the hive for this purpose; they immediately catch the idea and they immediately catch the idea and answer by a sharp, sprill sound, "You cant' have it Mr. II., stand back, we shall defend our home." I get a faint impression that the bees are becoming a little irritable, or a little too free with their threats, so I bring my hand up as though I said, "Don't get in my face." The bees immediately answer, "We have the same right to your face, that you have to our honey; and suiting the action to the ideas they wish to convey, they slip a dozen or two ideas into my face and eves from their business ends. I now fully understand; I have ex-changed thoughts with the bees by actions, and am very sure that if I cannot talk to been, their language is perfectly intelligible to me-just as much so as if words had been exchanged.

their home. In swarming time, if the queen cannot leave the hive with them, how soon the bees that have them, how soon the bees that fact, left become acquainted with the fact, Take and return to the parent hive. the queen from a colony, and you will soon see how soon the whole colony becomes acquainted with the loss. Give a queen to a colony that is queen-less, and how soon a manifestation of pleasure and activity will be seen about the hive. As if by common consent, they change their former course of conduct; whereas they were continually constructing queen-cells, they now as rapidly destroy them and commence to carry in pollen in antici-pation of the wants of the young bees that are soon to be added to their number.

From every appearance it is certain that the bees possess a language by which they very readily and quickly communicate with each other. They project and carry out certain parts of their labors, according to conditions, with a fidelity of a united action that would do credit to what we might term more intelligent and rational beings.

Battle Ground. +oInd.

### For the American Bee Journal. The Hibernation of Bees.

### C. W. DAYTON.

Since the friends to the theory that bees hibernate, have put in a disclaimer of the condition "quiet," and have accepted torpor instead as the prime constituent, it leaves the whole theory dependent upon temperature, and temperature only. By actual tests when the bees were not breeding, I have found the temperature in different sized colonies, and at different distances from the center of the cluster, to vary from  $52^{\circ}$  to  $72^{\circ}$  when the temperature outside the hives was 43° above zero; but this cannot be the temperature of the bodies of the bees. because when they are clustered in a high temperature the temperature at the center of the cluster is lower than it is when the bees are clustered in a lower temperature. The difference in temperature is caused by the difference in compactness of their clustering.

About a year ago 1 made tests on colonies that contained brood, and I found the temperature at the center of the clusters to be about 88°, and 71° at the sides of the cluster. The bees in these colonies appeared as still as death, and were as torpid as bees usually get; yet the temperature was high. A high temperature warrants respiration, and respiration shows that there is no hibernation about it if torpor must be a constituent. Is it a fact that a bee cannot breath the smallest breath without lengthening and shortening its abdomen to an extent as to be readily visible by the naked eye?

It has been said that 41° or 44° is the the cost of comb honey, with the ex-tracted at 8 cents. Again I had to feed every one of the 20 colonies from of the hive to assist in carrying it to

nothing more than the temperature in which bees will remain quiet in the event of a suddenly appearing light. If the temperature is raised, the bees will continue to be quiet the same as before, until the light appears; 41° or  $44^{\circ}$  is a temperature sufficiently warm for bees to be comfortable without activity, and yet be cold enough to hold them in the cluster in the pres-ence of the light; though a foul atmosphere, moisture in the hives or need of a cleansing flight, may sometimes have so strong an influence that it is impossible to find a quieting temit is impossible to find a quicting tem-perature. In a general sense,  $41^{\circ}$  or  $44^{\circ}$  is the turning point between the quietness of bees and the activity to which bees resort when exposed to low temperature. It is the lowest point at which bees may be quiet (hibernate), but not the highest, by any means. I do not doubt but that Mr. Ira. Barbar's hear maintained Mr. Ira Barber's bees maintained quiescence (mistaken hibernation), in a temperature of  $60^\circ$ , but remember that he did not show them the light. To an ordinary philosopher it may be seen that the hibernation theory. based upon torpor alone, must fail.

But this is not all. Without regard to temperature, and notwithstanding the greatest quiescence which live bees are able to enter into, when I hold my ear close to the tops of the hives, without an exception, there is a considerable buzzing, as of wings, to be heard at any and all times, that cannot be heard from the bottom of the hives. Now where there is noise there must be activity. It is absurd to consider a man to be more than quiet while he continues to be noisy. (The idea has been entertained that live bees may become more than what is understood by the terms " quiet " and " quietude.") How this buzzing sound is produced 1 am. as yet, unable to tell, but I am confident that it will not be met with very successful oppo-sition. I call it the snoring of the bees during their nap. and ask all interested bee keepers to direct their observations with the hope of ascertaining if this is not true. This last may well illustrate the fineness of the points on which the substantiation of the hibernation theory turns.

Bradford. & Iowa.

For the American Bee Journal. "Feeding Sugar—Reversible Hives."

### CHAS. DADANT.

The article of Mr. Hutchinson, under the above heading, on page 152, has greatly astonished me, especially where he says: "Mr. Heddon does not claim to have originated the idea of tiering up hives, but of tiering up brood-chambers. He does claim that, whether prior as an inventor of this process or not, he was the first to make it public." And further: "Everybody knows that whoever used, or did not use a two-story broodchamber. Mr. Heddon was the first to place the idea before the public."

If Mr. Hutchinson will turn to the BEE JOURNAL for 1861, page 149, and

the same for 1866, page 71, he will see that these horizontal sections, or cases, were described in this country 25 years ago. In his *Feminine Monarchy*, published in 1634, 252 years ago. Butler shows hives in 4 sections piled one above the other; Bevan, in his *Honey-Bee*, in London, 1838, says that *storijying* hives were described in England by John Geddes in 1675. I have a book, published in Paris in 1734, in which the author, after describing the horizontal, sectional hives, adds that these hives are commonly used in Poiton and Limousin, where sometimes these sections are piled 5 feet high. I have another book by J. Simon, printed in 1740, praising also the *ruches a hansses* (Eke hives).

I do not think that it would be difficult to find 100 bee-writers, English, French, Italian, German or Danish, describing such hives. Nearly all these bee-keepers of old used a wire drawn between the sections, to cut the combs. before separating the sections.

Palteau, in 1750, in his Nouvelles constructions de ruches utiles (new building of useful hives), advises the use of a perforated top for every section. Later, in 1821, Radouan, in his Manuel, advised the use of triangular bars, under which bees could build their combs.

But the bee-writer, who came the nearest to the Heddon dividing hive, was C. Soria, who, in 1845, published his Notice sur la ruche a espacements, (Notice on the space hive). In this hive every story, about  $5\frac{1}{2}$  inches high, had triangular bars at top and bottom. These bars were fixed so as to leave a small space between the stories which could be separated, reversed, etc., without any cutting of comb. What do yon think of the newness of the grandest of all the grand features of the Heddon hive, Mr. Hutchinson? This hive did not give as good results as was anticipated. the dividing of the brood hindering the laying of the queen. I tried these space hives 23 years ago.

The reversing of hives (culbutage) has been practiced in France, in the province of the Gatinais for an immemorial time. Now it is every year more and more abandoned on account of the necessity of feeding back to the bees, which are deprived of all their stores. Not only this feeding back decreases the profits, but, if made sparingly, the net result is a clear tors. Besides, if made during a dearth of honey, it incites robbing, and it takes time, and time is money.

#### FEEDING SUGAR TO BEES.

Messrs. Ilutchinson and Heddon will reply that sugar syrup is better than honey for winter. Is Mr.Heddon right in thinking that he was the first to proclaim that "practical success in wintering bees depends upon proper food and temperature ?" Perhaps this notion is as old as the one of the divisible brood-chamber. I have given my views on this subject, in an article read at the National Bee-Keepers' Convention held at Lexington, Ky., on Oct. 5, 1881, under the heading, "Influence of Honey on

Wintering." page 325 of the AMERI-CAN BEE JOURNAL for 1881. Mr. Newman would oblige me, and help the solving of the question of wintering, by reproducing it. Five years have elapsed since I wrote that article, and I think that the varied winters that we have experienced since 1881, have but proved the correctness or my views.\*

Had Messrs. Heddon and Hutchinson followed the rules which I gave in the above-mentioned article, their losses of last winter would not have been half so heavy. It is not when the winter stores are of first quality, as they were this year, that we need to use sugar syrup; but when the honey is unwholesome for bees. It is easy for the bee-keeper to foresee his chances of wintering without taking the unnecessary trouble of replacing, every year, the provisions of his bees. with sugar syrup; for such replacing costs time and money.

Hamilton,+o Ills.

[\*We will republish the article referred to, as soon as space will permit.—ED.]

> For the American Bee Journal Observations in Bee-Culture,

#### H. O. KRUSCHKE.

In reading the "Observations upon Drones," by Rev. L. L. Langstroth, on page 614 of the AMERICAN BEE JOURNAL for 1885, I was forcibly reminded of what I experienced in 1883. It was my desire to increase my stock of bees as much as possible, and I wanted drones as early as I could get them. On May 10 I inserted a frame of all-drone comb into the hive of my strongest colony. I fed the colony liberally, and two days afterward two-thirds of the frame was illed with eggs, the weather having been fine and warm. I congratulated myself upon my success. The weather soon changed to cold and cloudy. The eggs in the frame remained just as laid, and not until May 26 could I find any tarvæ, and then only a very few. The eggs were still there, and hatched gradually as circumstances became favorable, or not until the bees were furnished food. Now, I think with such facts before us, it is not proper to say that eggs will hatch in so many days after being laid, but rather in so many days after they are changed from eggs to larvæ, or have been furnished with food. I do not doubt but what scme eggs were there a month before they underwent any clange.

Another observation: On July 7, 1884, I found that my bees were without stores, and I feared that they would starve. A few of my choicest colonies I fed. In most of the hives not a cell full of honey could be found.' The bees flew quite freely, and from outward appearances they were doing well. Under these circumstances I expected that breeding would be light, if not suspended entirely. But such was not the case; the brood continued to spread, and

the hives became populous as fast in those whose colonies had not been fed as in those that were fed. This condition of things continued until the last days of July. Now, I pre-some that there was honey enough brought in to feed the brood; but I thought that during the day a little ought to accumulate for feed in the night, but in many of them I did not see a drop of honey for over two weeks. It made me nearly sick to look at them, still they seemed not to suffer.

Still another observation : Whenever a laying queen is removed from a colony, and I look them over a day or two after. I find that the eggs have been removed. I do not know as it is the case in every instance, but I have found it true so often that I take that as the rule. Is that in accord with the "doctors." Necedah. Wis.

For the American Bee Journal.

### Oneens Reared Artificially.

#### 10-J. C. MISHLER, (23-18).

Mr. G. M. Doolittle, on page 86, says: "My queens reared under the swarming impulse, and those so reared that are purchased of others. have lived to be 3, 4, and some even 5 years of age, doing good business all those years; while I have never pur-chased but one 'dollar' queen that lived 2 years, and three-fourths of

Inved 2 years, and three-fourns of them never lived over one year." I wish to say to Mr. D. that most of my queens are reared "artificially," but I have never reared any in small nuclei hives. My queen-cells are reared in full colonies that are strong in bees. I proceed as follows:

I take out the queen with a frame of brood, and place it in a nuclei hive with 2 other combs, and put it in a new location. Then I take a frame that is full of eggs and young larvæ (having prepared it for the bees to from which I wish to breed, and put it in the centre of the now queenless colony which was prepared for the new comb. My queens are 1 and 2 years old the coming season. except one imported Italian queen which is 3 years old. Last season my bees worked on red clover, and really de-

1 will make Mr. Doolittle the fol-lowing offer: I will send him one of my 1-year-old pure Italian queens in exchange for one of his 1-year-old pure Italian queens; and if the queen which I send him does not do good service for the next 3 years (unless she is killed by the bees or the colony dies in winter). I will send him two dollars for his queen ; and if the queen he sends me does not do the same for me as my queen is to do for him, he is to pay me two dollars; the exchange to be made in the month of May.

The first season I went into the bee-business I reared all my queens "artificially," and the colony of one years old, which absconded, and she three days, and theu introduces a

did good service all this while. I have examined my bees, and there are no signs of diarrhea whatever, though there is plenty of pollen in the hives.

Ligonier, & Ind.

For the American Bee Journal.

Hibernation—The Lamp Nursery.

### W. Z. HUTCHINSON.

Mr. Clarke says that starved and chilled bees do not hibernate, in his Starved and chilled ants. 'opinion.' thornets, flies, etc., do hibernate; they at least take no food, and are in a freezing temperature. When I was a boy I helped my father in splitting rails, and we frequently found cavities in the logs in which were large ants; these ants, especially in early spring, were dormant; sometimes there was frost in the crevices about them; and to all appearances the insects were dead; but they revived in the warmth of the sun. Now I know that bees never enter this state.

I visited Mr. R. L. Taylor, the past winter. Under his barn is a cellar; in one apartment are his cattle, in another, poultry, and in another, bees. All of these living creatures staid in the cellar all winter, they moved about the cattle in their stalls, the fowls in their coops, and the bevs in their hives; they all consumed food, and all enjoyed the warmth that is necessary for their existence. Did all hibernate? When an insect requires warmth and food, and indulges in motion. it does not hibernate in the sense in which that word is usually understood. Mr. Clarke, in speaking of the hibernation of bees. calls it their kind of hibernation. Their kind of hibernation" is simply the well-known winter quiet, which, in Mr. Clarke's opinion, is hibernation in a slight degree. The only way in which the only way in which even appear reasonable, is to take that view of it, viz : to call the well-known winter quiet, a slight degree of hibernation, and in so doing we discard a very appropriate term for a misleading one. and-gain what?

#### THE LAMP NURSERIES.

Mr. Alley. on page 183, asks how 1 manage my lamp nursery at night. 1 explained, in my former article, how I managed. I examined each queencell in the evening, by the light of a lamp, and put each cell (the occupant of which showed signs of soon hatching), into a little apartment by itself. When so carefully examined, but few queens will hatch inside of 10 or 12 hours. As soon as "up and dressed ' nours. As soon as "up and dressed" in the morning, the nursery is visited, and if any queens *have* hatched, they have not been out long enough to do much if any damage. No, *sir*, I do not sit up nights with my lamp nur-sery; and I do not here more theme. sery; and I do not lose more than a dozen queens in the course of the season by their hatching out when I am not around.

queen that is old enough to become fertile the same day. I introduce a queen a day or two old at the time of removing the old laying queen. It does not seem to me as though either had much the advantage over the other; possibly Mr. Alley gets a day or two the start of me, but he gets it in being successful in introducing older queens than I have succeeded in doing. Queens can be kept in the nursery and supplied with food until they are several days old—perhaps 5 or 6 days— but I have never been able to make a practical success of introducing them after they were more than 3 days old. Will Mr. Alley please tell us if, in his opinion, the keeping of young queens in a queen-nursery is the cause of his successful introduction of them at 6 days of age? Or is it his method of introduction? Or is it both? Does he use one of the methods of introduction that are given in his book. if so, which one? If it is not given in his book, will he please give it?

I have never tried the queen-nursery simply because I could see no advantages in its use over the lamp-nursery; if there are advantages I shall use it; and thank Mr. Alley for calling my attention to it. How does it answer late in the season?

Rogersville, & Mich.

## Have Bees the Sense of Hearing?

For the American Bee Jonrna

### 10-s. A. SHUCK, (64-43).

In reference to the above question, Mr. Fox, on page 171, says : 1 would like to hear from others on this sub-ject." I am very much surprised to recognize the fact that few if any of our prominent writers on apicultural subjects are able to give any proof that bees do hear.

On page 729 of the AMERICAN BEE JOURNAL for 1885, in some experi-ments by Sir John Lubbock, he says : "It is, however, remarkable that bees, contained as a second to be a second solution. certainly do seem to hear on some occasions." Again he says: "Bees will take no notice of a very loud noise, even quite close to the hive." and Mr. Fox, in his criticism of Mr. Osburn's article, says : "I would like to ask Mr. O. why bees do not notice a loud noise around their hives, which we all know they do not.

It appears from the above quotations, that because bees do not become enraged, when, perchance, some one should "halloo" across the way, or the children in their play, forget, and shout aloud, they do not notice even a very loud noise about their hives. I trust that Mr. Fox. or any one who may read this, will not smile aloud, if I say that all loud sounds, if of a musical nature, have a charming influence over bees; at least not until they have given the following a fair trial:

Remove one of the central combs from the hive of a colony of gentle bees, but do not disturb them. so as to anger or frighten them. Still, pleas-

ant weather is best. The bees will be found moving about quietly and in every direction on

the comb. Now, while holding the comb in your hands, (but do not let your breath strike the bees), whistle a prolonged, keen whistle with the lips, sing a familiar stanza in loud tones. blow a loud horn or give a prolonged loud tone in any way, and observe the death-like stillness of your little hearers, and notice how quickly they all resume business when the noise ceases, and how quickly all hands "let up' again when the music begins; and say not again that we all know they do not notice a loud noise about their hives.

These experiments can be made without removing the combs, if you have an observatory hive. I can pre-(knowing), that bees do hear; but perhaps the above are sufficient for the present.

Liverpool, OIII.

For the American Bee Journal.

Essentials to Success in Bee-Culture.

----

OSCAR F. BLEDSOE. .

A great many on a superficial view, are fascinated with bee-keeping as a pursuit, with the impression that the labor is light, the pleasures connected with it unalloyed, the remuneration great in proportion to labor, etc., etc., and raking up what spare cash is on hand, rush into it with all the zeal of a novice. I would say to all such, "Make haste slowly;" if you have a decided case of bee-fever and cannot rid yourself of it, I would say, pitch in, but don't go faster than your knowledge. Bee-keeping requires deep study and thought, nice me-chanical skill, great industry and careful attention to details, indomi-table perseverance, and at times, a bigh degree of faith—that fully which high degree of faith-that faith which is "the substance of things hoped for, the evidence of things not seen."

Bee-keeping will not do to depend on for a support until you have mastered it and know exactly what you are doing. It is better as a sideyou are doing. It is better as a sub-issue where one can look for his main support elsewhere. I would lay down the following rules as, in my expe-rience, the best for guidance in this pursuit:

1. In the beginning, do not spend too much money-be content with small things-supply yourself freely with bee-books and literature-do not be economical on this point; then get a few colonies of black bees to be Italianized afterwards, and read and observe. Make your own hives; beware at first of the enticing circulars of supply-dealers; make the bees pay their way-let them be creditors. not debtors, and you will find if you act on this rule, they will supply you with what you need in their management and give you a surplus besides.

2. Study the subject thoroughly. Bee-keeping is a highly intellectual pursuit. It brings you into close communion with the mysteries of Nature and with the God of Nature. There and with the God of Nature. There devised from necessity, is a frame-are many theories connected with it and much chaff given forth. The it being stronger for the size of pieces.

mind has to east off all this, and with nice discrimination arrive at the essential truth. You cannot read and observe too much; let your mind become fully saturated with the subject, and you will thus become "thor-oughly furnished," not only unto abundant success in the pursuit, but you will find that you will achieve great intellectual improvement generally. Bee-keeping is an educator, and this is one of its chief fascina-tions to me. I can approach other branches of knowledge more successfully from having thoroughly analyzed this.

3. Adopt Italian bees, for in their purity they are superior to any race yet discovered. In your hives, adopt a plain, movable-frame hive. Avoid any kind of hive or system calling for too much manipulation and manage-ment. The bees must be examined often enough with the simplest hive, and should for their good be let alone, except where it is absolutely necessary to manipulate; besides, it is economy not to interfere too much. Let " cheap Italian labor" do your work as far as possible; only on this principle can you conduct large apiaries.

In conclusion I will say that as to profit, bee-keeping will, if conducted cautiously, surely pay moderately, at least, and in many cases it will pay largely.

Grenada, & Miss.

Conveniences for the Aniary.

For the American Bee Journal.

W. M. CHAPEL.

I keep my bees away from home in two or more localities, and visit them daily, which necessitates moving twice a year-out in the spring and home in the fall. I use the Lewis'-Improved Langstroth-Simplicity hive with tight bottom-boards, or I make them so. To prepare the hives for moving the bees, I have originated a very cheap device which is made as follows:

Plain a lath on all sides, cut off a piece long enough to reach the full width of the hive-portico inside; cut a notch on one side 8 inches long and  $\frac{1}{2}$ -inch deep, and nail over it a piece of wire screen; and har over it a piece of wire screen; on the opposite side in the centre, cut.a notch  $\frac{3}{2}$  of an inch deep by  $\frac{1}{2}$  or  $\frac{3}{4}$  of an inch long and place it in the portico with screen down on the side next to the bins down on the side next to the hive. Drive in a small wedge at one end to tighten it and keep it in place, and the bees are ready for transportation, with plenty of ventilation. Take out the wedge at the end, turn it upside down, keeping the screen next to the hive, and the entrance is contracted any size desired. I have used these successfully in the spring and in the fall to retain heat and prevent rob-bing. I can, by the use of these, prepare a load of bees for transportation in a few minutes at any time.

Another implement which I have

I take two pieces 21 inches long by I take two pieces 21 inches long by  $1\frac{1}{3}x\frac{7}{6}$  inches, bore  $\frac{1}{2}$ -inch holes in both ends of each piece for side pieces; then take two more like pieces, 12 or 13 inches long, as desired, and bore them the same way. Now take four pieces 12 inches long, the same size, cut round tenons on one end of each to fit the holes snugly. Place the end-pieces on the top of the sides, run the tenon through the holes on each corner, and it makes a frame with four legs that will hold 8 or 10 frames. This can be made to fit any size of frame. Pull out the legs and it falls to pieces, which, being tied with a string, occupy very little space.

I found it a necessity to have some anipulating tools, which I con-structed of ½-inch boards, except the ends and cover which are made of %-inch lumber. The box is 9½x10x13 inch lumber. inches, in which I can carry a large smoker and fuel for it, hammer and nails of all sizes, some wire-screen, tin shears, veil, brush-broom, screwdriver to open covers and other pieces stuck down with propolis, a comb scraper which I had made of steel by drawing it out into a blade similar to a putty-knife, though much stronger and larger, being 6 inches long and 2 inches wide at the end of the blade. which is square and drawn to an edge. The other end is narrower on which is riveted a piece of wood on each side for a handle, similar to a butcher-knife. This implement will scrape off propolis or old comb, wax, etc. is the best of any I ever used. This tool-box I have found to be of

all the tools necessary at hand at all times and places, and can repair and put to right anything about the aplary on short notice, as I always carry it with me.

Kingston,⊙ Wis.

#### Convention Notices.

137 The anomal meeting of the Northern Ohio Bee-Keepers' Association will be held in the New Yown Hall at Wellogtee. O., on Friday, April 30, 1886. All are invited to come and help make the meeting both pleasant and profituble. A special invitation is extended to the ladies. The officers of the Association will be elected at this meeting. H. R. BOARDMAN, Sec.

177 The next meeting of the Linwood Bee-Keepers' Association will be held in Condit's Hall at Book Fim, Wis, on Saturday, May I, 1886, at i p.m. All interested in bee-keeping are cordially invited to attend and make this a profitable meet-lag. B. J. THOMPSON, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. M. HAMBAUGH, Sec.

#### System and Success.

2 All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are as follows :

| For | 50 eolonies  | (120) | pages)\$1 00 |  |
|-----|--------------|-------|--------------|--|
| **  | 100 eolonies | (220) | pages) 125   |  |
| **  | 200 eolonies | (420) | pages) 1 50  |  |

The larger ones can be used for a few colonies, give room for an increase of numbers and still keep the record all together in one book, and are therefore the most desirable.

### Local Convention Directory.

Time and place of Meeting. 1886.

Apr. 17.-Marshall Co., at Marshalltown, Iowa. J. W. Sanders, Sec., LeGrand, Iowa.

Apr. 27.-Des Molnes County, at Burlington, Iowa. Jno. Nau, Sec., Middletown, Iowa.

Apr. 29, 30.-Western, at Kansas City, Mo. P. Baldwin, Sec., Independence, Mo.

Apr. 30.-Northern Ohio, at Wellington, O. H. R. Boardman, Sec., E. Townsend, O

May 1.-Linwood, at Rock Elm, Wis. B. J. Thompson, Sec.

May 4,-W. N. Y. and N. Pa., at Randolph, N. Y. A. D. Jacobs, Sec., Jamestown, N. Y.

May 5, 6.—Texas State, at McKinney, Tex. B. F. Carroll, Sec., Dresden, Tex.

May 20.-Wis, Lake Shore Center, at Kiel, Wis. Ferd Zastrow, Sec., Millhome, Wis.

Oct. 19, 20.—Illinois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

17 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings .- ED.

Good Prospects. - J. S. Scoven, Kokomo. Ind., on April 1, 1886, writes:

I commenced in the spring of 1884 with one black colony of bees, in-creased it to two, and took no surplus honey. I commenced in the spring of 1885 with 2 colonies. increased them to 6, and took a surplus of 175 pounds of fine comb honey. I winter my bees in large store-boxes, well packed in forest leaves. My bees are all alive, and brought in the first pollen on March 18. Bees are wintering well in this county, and the prospects for the coming season are good.

Malaria from Bee-Cellars.-J. 11. Andre. Lockwood, 9 N. Y., writes:

I would like to hear, through the BEE JOURNAL, whether those who have made a practice of wintering bees in cellars under dwelling-houses for a number of years, consider that it makes the cellar unhealthful for those living in the house above it. Some here contend that wintering bees in a cellar creates a poison which will produce malaria. I hope that those who have had much experience will kindly give their opinion. The 3 winters that I have had my bees in the cellar we have had a great deal of sickness called "malaria." I do not know that the bees caused it, but if they do cause such diseases the sooner we find it out and provide some other place for wintering, the better it will be for us. I would also like to ask if in making hives it would be a good plan to cut the pieces for the body of the hive just the exact length that one wishes the size of the hive inside. and then put them together by nailing through one-quarter-round moulding both ways, and thus save mitering them, which is quite a job unless one is somewhat skilled with tools. A

lap-joint we all know is good for nothing in constructing bee-hives.

Fastening Frames in Hives.-J. M.Goodrich,South Frankfort. Mich., says:

To fasten frames in Langstroth hives. I have two iron rods of 14-inch iron made with a small ring on one end and a nut on the other that can be turned up by hand, and as long between the ring and nut as the hive is wide. I drive a headless nail into each end-bar, near the bottom of the frames, letting them project 1/4 of an inch. I now make four holes in the sides of the hive, so that when the frame are in, and the rods are pushed into the holes, they will come against the frames and rest on the nails in the end-bars. Screw it up tight, and the frames will be fastened. Make the holes in the sides of the hive large enough to give a little play, and cover them with washers. When you wish to take out the frames. remove the nut and take ont the rods.

Only 2 Colonies Lost. - Mexico Sperry, La Harpe.+o Ills., on April 3. 1886, says :

I wintered my bees on the summer stands, and lost only 2 colonies out of 28. The 26 are in good condition.

Are the Drones Pure ?- R. F. Holtermann, Brantford, Ont., writes:

The last reply to Query. No. 230, interested me. I will not attempt to answer the Query; I cannot. But we know that the sperm-sac in the queen is filled not only with myriads of ever moving bodies, one of which fertilizes each egg, but the fluid surrounding it—all from the drone. It is by many eareful students supposed that this is absorbed in the system, in part at least, who will say it is not so with the queen. We know that the queen after tertilization, and often before having undergone any apparent physieal change, at least to the naked eye, externally, will have a new and more graceful carriage, and these sperms in the sac kept alive year after year, who will say there is no exchange between the contents of the sac and the organs of the queen ? May the relationship not after all be more intimate than we might at first think, as great as in the higher animals? And may the drone not have a greater effect upon its male progeny than we might at first be led to suppose ?

Wintering Bees-Old Drones.-W. H. Tuttle, Creston, 9 Iowa, on March

in tightly between and all around with forest leaves. I use the Lang-stroth hive with 8 and 10 frames. I divided several colonies last summer, and all did well. I bought 2 colonies in the spring of 1884, but some how one of them I suppose lost their one of them I suppose lost their queen, at least the bees were all goue out of the hive before I knew any thing about it; they left plenty of honey. The hives were close side by side. I then got an Italian queen, and when the bees were busy at work I put the queen-cage into the empty hive with the queen in it, carried the old stand 4 or 5 rods away, put the other in the place of the old one, and the bees went in with the new queen, all seemingly satisfied. They then ate through and let the queen out of the cage on the third day. In about six weeks they sent out a large swarm. I want to learn the best method of wintering bees. I shall continue as I wintering bees. I shall continue as I have done if they continue to winter as well as they have the past two winters. My neighbors lost all they had; I lost one colony which I think was caused by the queen's dying. Having a few warm days the last of February, the bees came out quite thickly in front of the hives, and I then noticed two drones from two different lives. I had always heard that the drones were all killed off in August or September.

Working on Early Bloom. - C. Weeks, Clifton. 9 Tenn., on April 1, 1886, says :

My bees have wintered without loss, and are now working on peach aud other early blooms.

An Old Colony .- J. S. Barb, Bristolville. & O., on March 25, 1886, writes :

In the fall of 1884, I had 14 colonies of bees; in the spring of 1885, I had only 4, and one of those was very weak. I built up the weak colony to a good one, bonght a swarm on June 11, and got a large swarm from it on Aug. 12. I had a colony to keep on shares, and I got a good swarm from that, so in the fall I had 13 colonies, and had taken 200 pounds of comb honey. I have lost but 2 colonies so far this winter. An Italian colony which had a Southern queen that I obtained in 1883, gave me 4 good swarms, and nearly 45 pounds of honey besides. How is that? The old colony and all the swarms are alive and in good condition now. I gave the swarms frames of comb. which I had saved. I had 31 colonies last fall, and now I have 28. My father has a colony of bees that I call the "Old Veteran." It is in a large box-hive, holding as much as a salt barrel. far this winter. An Italian colony hive, holding as much as a salt barrel.

bive every year, and a year ago last summer we got over 30 pounds; last year only about 15 pounds, as it cast a large swarm on July 8, which pro-duced about 20 pounds of honey. This old colony is of a stock of bees that have been on the place for 50 years. Father got his bees first in 1837, his father having had bees in 1836.

Hard Weather for Bees.-I. R. Good, Nappanee, 5 Ind., on April 8, 1886, says:

On April 6 we had a terrible snowstorm. Snow fell to about the depth of 15 inches. The mercury was 17° below freezing this morning. Bees have come through the winter in fine condition, but this weather must be hard on them.

Cold Weather for April.-B. W. Peck, Richmond Centre, & O., on April 6, 1886, writes :

Reports from different localities are interesting. I have to report very cold weather for this time of the year. It has been cold, freezing weather for about a week, and it is now snowing hard with about 6 inches of snow on the ground. I took 5 colonies out of a clamp on March 15, and 2 were dead, 1 was weak, and the other 2 were fair. Twenty-five out-doors, packed in chaff and sawdust, have wintered well; so it will be seen that so far my loss is 2 out of 30. I think that I shall not lose any more, although this weather will give them a set-back. White clover looks well.

Honey-Dew for Winter Stores.-H. T. Hartman, Freeport, vo Ills., on March 30, 1886, writes :

From reports that I have read in the BEE JOURNAL, it seems as though bees have wintered well nearly all over the country; but through this part of the State they have wintered very poorly. half of them already being dead; some have lost all they had. The cause of the heavy loss of our bees was the honey-dew, of which they gathered a great deal last sum-mer, as honey was very scarce. They had most of this black stuff for win-ter stores. To prove that honey-dew was the cause of our loss, I would say that last fall 30 colonies ont of 82 were light in stores. They were fed 34 pounds of coffee A sugar about Sept. 20, and were all numbered. They were all taken into the cellar about Dec. 1. and about Feb. 1 those that had boney-dew became uneasy and diseased. On March 1 it was very warm, and the bees were all taken out of the cellar and placed on the summer stauds. The sugar-fed colonies were all in splendid condition, strong and healthy. Nearly all those having honey-dew had the diarrhea. As the weather was nice and warm for 3 days, I cleaned things up back into the hive, emptied the bees back into the honey-board, put warm feed under the frames, and closed the entrance, and soon they were all plied with honey. As the weather right. I fed them enough, and they back into the hive, emptied the bees back into the honey-board, put warm feed under the frames, and closed the entrance, and soon they were all right. I fed them enough, and they

became colder on the fourth day after they were out, they were all taken into the cellar again, where they shall remain until there is something for I have already lost 12 of them to do. the colonies having honey-dew stores, and a great many are too weak to pull through. It is snowing again to-day, and it does not look as though bees could come out of the cellar for some time yet. A good many bee-keepers here did not return their colonies to the cellar again. As most of them are weak it is very hard on them, considering the much snow and cold we have now had for over a week.

Division-Boards, Straight Combs, etc.-Cyrus G. Pugsley, Denver. Mo., asks the following questions :

1. What is the use and advantage of a division-board, and how is it they are made? 2. How can I cause my bees to build straight combs? I am often bothered a good deal by an orten bothered a good deal by crocked combs, and they being fast to two or more frames. (I use home-made Langstroth hives.) 3. Are the hives advertised by Mrs. Lizzie Cot-ton good, practical hives? 4. I win-tered my bees in the cellar, and they came through all wight with dealers. came through all right with plenty of stores. I put them on the stands about a month ago, fearing my cellar was too damp, and I found some moldy comb in one hive, and lots of brood in all stages in every hive.

[1. A division-board should be made just to fit the hive, and its use is to contract the brood-chamber in the spring, or to force the bees into the sections.

2. Use full sheets of comb foundation.

3. It is an ordinary frame hive, perhaps just as good, but certainly no better than the ordinary Langstroth hive which will cost less than onehalf the price asked for the "Controllable."

4. The bees will clean up the moldy combs as soon as the weather becomes dry and warm.-ED.]

Were they Hibernating ?-A. C. Fassett, Watson. 9 Mich., on April 4, 1886, writes :

Since reading so much of late on hibernation, and especially Mr. Clarke's article on page 197, I would like to relate a little circumstance. It is as follows: Last November, when I put my bees into the cellar, I found that one colony which I had neglected to feed, was in a dormant condition I thought they were dead, but I took them into a warm room and brushed all the bees off the combs into a large pan, when I saw some of them begin to move. I immediately put the combs

came through the winter all right. A few days ago one of my neighbors told me that one of his colonies had died, but upon examination I found that they were in the same torpid state as mine were. I then poured some warm syrup on their backs, and they inmediately came out of their sleep. What is this condition of the bees called? They were just as dormant as a waspever was. Were they hibernating, in a trance, or is there some wasp blood about them? How long would they live in this condition? My bees have wintered with no loss so far.

Cold and Windy .- C. W. Dayton, (116-116), Bradford. & Iowa, on April 8. 1886. says :

The snow is not all gone, and we are now having the eighth day of a cold north wind. Pollen will not appear for some time yet. I have not taken the bees out of their 148 days' confinement, and will not unless it gets warmer. I have colonies packed on the summer stands that have not had a flight for 140 days. It beats all how cold it is !

Italian Bees, etc.-W. M. Barnum, Angelica, 9 N. Y., says:

I would like to have the following questions answered in the BEE JOUR-1. Would you oblige me by NAL: What is the best food for bees through April ? 3: Which is considered the best best bird is considered the best bee-hive ?

[1. For a full description and history of Italian bees, we refer to any of bee-books. It would be too long for our columns.

2. Honey.

3. The Langstroth, or any movableframe hive, is good enough for general purposes.-ED.1

Disagreeable Weather.-J. Nebel & Son, High Hill, & Mo., on April 3, 1886, writes :

The time has now come, in Missouri, to take bees from their cellar confinement and place them on the summer stands; but the weather has been so bad all this week that we could not do it. We have worse weather now than we had all winter, only it is not so cold, the temperature heing 24<sup>o</sup> above It has been snowing some zero. nearly every day and night. We have now 4 inches of snow, and it continues to snow. Our bees are all apparently in good condition so far. We have in good condition so far. We have lost only one colony out of 189. We hear that our farmer bee-keepers have lost heavily.

Anticipating a Good Harvest .--

come through the winter nicely, excome through the winter intery, ex-cept one colony, and on examination I found that to be entirely destitute of bees, with the brood-chamber full of drone comb. They are all strong now, have plenty of honey in store, lots of brood, and are in every way in lociting condition. We are expect a healthy condition. We are expect-ing a grand ingathering of honey this summer. Bees all over Northeastern Ohio, that were properly cared for in the fall, are getting along well. We are now passing through a severe snow-storm from the northeast, and now the snow is about one foot in depth, and still it is snowing. What effect it will have on the bees, time will tell.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., April 12, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

CHICAGO.

HONEY.-Comb is coming forward more freely and prices now are 15±016c, for 1-lb. sections. Ex-tracted is 10 light demand at 5@7c. Comb honey. in 25. sections. 9%12c. BEESWAX.-23@24c, per lb. Not much offered. R. A. BURNETT, 161 South Water St.

NEW YORK.

NEW YORK. HONEY.- We now quote: Eancy white comb in 1-ib. sections, 12@13c.; in 2-ib. sections, 9@10c. Fancy buckwheat honey in 1-ib. sections, 90:(; in 2-ib. sections, 70%c. Off grades 1@2c. per lb. less. Extracted, white,46%7c; buckwheat, 5%5%c. Cali-fornia, 5%6c; Southern, as to color and flavor, per gallon, 5%640c. - HEESW AX.-27%28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

### BOSTON.

HONEY.—One-lb, sections, white clover, 13@15c; 2-pound sections, 11@13c. Extracted, 6@\*c. BEESWAX.—25 cts, per lb. BLAKE & KIPLEY, 57 Cbatham Street.

### SAN FRANCISCO.

HONEY.-White and ex. white comb, 11%@13c.; dark comb, 8%@sc. White extracted, 514@3%c.; amber, 4@4%c.; dark and candled, 334@4c. BEESWAX.-Qaotable at 20@23c., wholesale. O. B. SMITH & Co., 423 Front Street.

### DETROIT.

110NEY.-Stocks are being slowly reduced, some sales reported at 13 and 14 cts., the latter being for best honey in 1-b. sections. BEESWAX.-Scarce at 25c. M. H. UNN., Bell Branch, Mich. Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form.

### ST. LOUIS.

HONEY.-Choice comb, 10@12c. Strained, in barrels, 4%5c. Extra facey of brikht color and in No. 1 packages, 14 povance on above prices. Ex-tracted in barrels, 5%5%. BEESWAX.-Pirm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

### CINCINNATI.

HONEY.-Extracted honey brings 4@8c., and holee comb honey brings 12@15c. in a jobblug way. BEKS WAX.-In demand at 22@25c. for yellow. C. F. Mortn & Son, Freeman & Central Ave. oh

#### CLEVELAND.

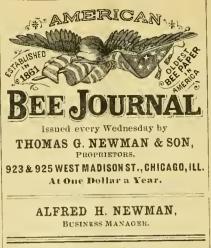

110NEY.—One pound sections, 14@15c.; 2-lb. 13e Extracted, 7@8c. BEESWAX.—Scarce at 25c. A. C. KENDEL, 115 Ontario Street.

#### KANSAS CITY.

HONEY.—Sales of comb are good, while extrac-ted is very dull and low. One-pound sections are scarce; stocks of all other grades are well supplied. Callf, 2-los. bring 11@12c.; Eastern 2-los., 12@13c.; 1-los., white, 14@15c.; dark, 12@13c. Extracted, 5@6c.; Southern, 3%@4c. BEESWAX.—23c. Chemons, CLeon & Co., cor, 4th & Walnut.

#### MILWAUKEE.

IIONEY.--This market is very poorly supplied with boney of any kind just oow, and comb boney in 1-th. sections, and extracted in barrels or kers, is not equal to the demand. We quote: Choice white 1-th. sections. 16@ Nev. White extracted in persor barrels, 7% a %cc.; dark, in same, 6@7c. \_\_\_\_\_ BEESWAX.-Scence at 25@ Sec. \_\_\_\_\_ K. V. BISHOP, 142 W. Water St.

Special Notices.

To Correspondents. - It would save

us much trouble, if all would be particular

to give their P. O. address and name, when

writing to this office. We have several letters

(some inclosing money) that have no name;

many others having no Post-Office, County

or State. Also, if you live near one post-

office and get your mail at another, be sure to give the address we have on our list.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent

to any one desiring a copy. Send name and

address, plainly written, on a Postal Card

Wire Nails have advanced in price, as

The Western World Guide and Hand-

printing, paper, and binding are excellent,

and the book is well worth a dollar. To any

one sending us two new subscribers besides

their own, with \$3, for one year, we will

Perforated-Zinc .- We have laid in a

stock of perforated zinc, for excluding

drones and queens, and can fill orders for

any size of pieces or quantity at 15 cents

per square foot, or in full sheets 3x8 feet at

\$2.75 per sheet. We also have pieces out to

fit the Langstroth hive-19%x14½-Price 25

present a copy of this valuable book.

### \_\_\_\_ Honey as Food and Medicine.

127 To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remnnerative prices. "Honey as Food and Medicine " are sold at the following prices :

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Fire hundred will be sent postpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Golden Hules for successful advertising, are these : 1. Attractive display. 2. Salient points clearly stated. 3. Repetition. Don't spend all your money in one insertion. 4. Choice of the Paper which reaches the people you want to reach. These rules never fail.

Kendall's Horse Book -- No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 25c., in either English or German.

Alsike Clover Seed .- We can furnish Alsike Clover Seed at \$8.50 per bushel-or \$2.25 per peck. These prices will take the place of those published in our Catalogue, until further notice.

ET Our rates for two or more copies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

Preserve your papers for reference. If you have no HINDER we will mail you one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

There will be a Rush for supplies needed in the apiary after uwhile, and we cannot do better than to urge all to look over their stock, ascertain what will be needed, and get it on hand before it is necessary for use-thus avoiding the perplexity consequent upon its possible delay in reaching them in time.

Frank Cheshire's new book on Bees and Bee-Keeping, can be had at this office .-Vol. I, bound in cloth, \$2.00, postpaid.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one Intending to get up a elub ean have sample copies sent to the persons they desire to interview by sending the names to this office, or we will send them all to the agent.

Vol. XXII. April 21, 1886. No.16. DITORIA MITTIN 

Could I Write, with ink unfading, One brief code for youths and men : Could I show its all-pervading Power in progress, I would pen-Try it.

Thus it was, will be forever ; If "to be " man has in vlew, Men must live with firm endeavor Well to think, then plan, then do ;-Try it.

-The Current.

Frank Cheshire's New Book will cost \$5.00 for the 2 Volumes. They are beautifully bound. Vol. I is now ready, and we are filling orders at \$2.50 per Volume. The duty and expressage is so high that they cannot be sold for less. Our offer to take orders at a less price is now recalled.

Another New Ree-Paper is on our desk. It is called "The Bee-Hive," and is to be published bi-monthly by E. H. Cook. Andover, Conn. It contains 8 pages, and 6 numbers will make a yearly volume, and the price is 20 cents. It is nicely printed and well edited.

A Downward Tendency in the prices of bee-keepers' supplies is quite apparent in our advertising columns. The bee-keepers who read the AMERICAN BEE JOURNAL will always be sure to learn where to buy and what the market prices are. It pays to keep posted.

"Ah! There !" Were you just writing something to send to the AMERICAN BEE JOURNAL, for publication? If it was on "hibernation" or "reversible hives"-please put it into the fire, or send it to some other paper 1 We shall publish those communications now on hand, as soon as convenient, but cannot accept any more, unless It be aimple explanations called for by previoua articles published. Give the "hibernation theory" and "reversible hives" a rest for a year or two, and write about something else I

Those Who Claim that Bees Injure Fruit, should earefully read the article on page 245, being a Report of Experimenta by Mr. N. W. McLain, at the United States Apicultural Station, at Aurora, Ills., made at the Department at Washington, and published in the Official Reports of the United States Eutomologist. These experiments show most conclusively that the bees never injure sound grapes, even when on the verge of starvation. Many similar experimenta we have heretofore published, but this adds another proof by carefully conducted and thoroughly guarded experiments under the fostering care of the United States Government. To California grape and raisin growers, who are now prosecuting a beekeeper there for injury said to be done to their grapes, should make a note of this and stop their jealous and foolish persecutions of bee-keepers.

The Academy of Natural Sciences, of Davenport, lowa, has our thanks for a pamphleton "Elephant Pipes," by the late president of that institution.

New Subscribers are being enrolled on our books very lively during the present year. In addition to all the renewals of old subscribers, the new ones will average hundreds every week since January. "Wideawake" supply dealers are not slow to diseern this, and are crowding the advertising columna of the AMERICAN BEE JOURNAL with their announcements Where the carcass is, there will the eagles congregate," is a trite but truthful remark.

Simmins' Non-Swarming System is the title of a new English bee-hook. It contains 64 pages; is well printed and illustrated. The author claims that it will inaugurate a "new era in modern beekeeping," and states that " it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result-a total absence of any desire to swarm." Published by S. Simmins, Ruttingdean, Brighton, England.

The Illustrated Graphic News of Cincinnati, O., of April 17, is a marvellous exhibition of enterprise, containing 11 pages of original illustrations, including scenes from the riot in St. Louis; and the floods in the South. The Graphic News contains altogether 24 pages, includiog a double supplement and cover. Bill Nye and Nym Crinkle begin their contributions this week.

"Socialistic Movements in England and the United States," which opens the May number of Frank Leslie's Popular Monthly, is a most timely and well written article. It reviews all the ideal schemes put forward to bring about a state where all shall have equal enjoyment with the least possible labor, where there shall be no wealth, no crime. The stories by Florence Marryat, Charles L. Hildreth, W. H. Waitt, Ellinor Brooke and others, are all capital, and the other articles are full of interest.

The Prospect is Good, saya Mr. C. H. Dibbern, in the Plowman. He gives this very seusible advice :

The prospects for the coming aeason are very good. It is true that the prices of honey are very low; but what is not low? The prospects of a good honey crop are now very encouraging. The ground has been well covered with snow, thus ensuring an abundant bloom of white clover, which is our best honey-plant; without it, I have never known a good year for honey. After all, everything depends on the abundance of honey-producing plants, and seasonable weather. weather

No matter how many hives of bees we may No matter now many nives of bees we may have, or what their condition, if the blossoma fail or do not secrete boney, the bees can get nothing, and the failure should be laid to the plants and weather rather than the bees. Honey is gathered, and not made, by the bees beea

bees. All material needed should be ordered now. Hives and sections should be made up, and everything possible be done before the busy times come. Plan now just what to do, aud how to do it. In the "bee-busi-ness" more than anywhere else, we must drive the business, or it will drive us.

For Spring Feeding, Mrs. Harrison, in the Prairie Farmer, suggests the following :

the Prairie Farmer, suggests the following : The late cold storms, no doubt, caused the death of many a colony by starvation, and a vigilaut eye must be kept on all remaining, lest they follow suit. In some winters bees consume much more honey than in others, so it is difficult to tell just how much is needed. I intended to feed those with insufficient stores last fall, enough to last until the return of nectar, but fearing that some might bo lacking during the past inclement weather, I laid pieces of comb honey over the cluster upoo the frames. Honey is the natural food for bees, and should be given them whenever obtainable, but when this is not to be had, a substitute is to be sought. Cakes of maple sugar put over the cluster will prevent starvation, and a syrup made of sugar the consistency of thin honey, such as the bees bring from the fields, should be supplied them, in vessels filled with straw eut up fine to prevent drowning. If the syrup is too thick, the bees will get aticky, and be unable to reach the cluster until their comrades elean it off. When bees are able to fly, food of inferior quality will not injure them, which would prove fatal, when they are closely confined to the hive.

A \$5 Bill paid a debt of one hundred dollars in this way : A owed B \$25; B owed C \$25; Cowed D \$25; and D owed A \$25. They met and paid each other in full with a \$5 bill, which A took from his pocket and handed to B; B to C; C to D; and D to A. That left each one in debt but \$20. They repeated 4 times more and A pocketed the hill ; their debts of just \$100 having all been paid with it. This illustrates how a small amount of money kept in constant circulation may cancel thousands of obligations. Do not therefore "hoard up" any money. As soon as you have it on hand pay a debt with it, and thus help others to pay their debts. This is good, honest and square advice to everybody.

The 11th Annual Meeting of the Association of Nurserymeu, Florists and Seedsmen will be held in the Department of Agriculture Buildings, Washington, D. C., commencing Wednesday, June 16, 1886, and continuing three days. The Association is the largest body of Horticulturists in the country. An outline programme, hotel and railroad arrangements and other information may be obtained by addressing the Secretary, D. Wilmot Scott, Galena, Ills.

### **REPLIES by Prominent Aplarists.**

### Queen-Excluders.

Query, No. 239.-When hiving swarms, what kind of queen-excluders are best for preventing queens from entering supers, and how are they constructed ?-Iowa.

The most perfect are probably the zinc queen-excluders as sold by supply dealers.-C. C. MILLER.

The best I have found are those made of perforated-zinc, and I have found them to answer the purpose most admirably.-J. E. POND, JR.

Perforated-zinc is good, but a cheaper one can be made by using a thin board with slots cut in it to allow the bees to pass through, but will prevent the queen and drones.-H. D. CUTTING.

In my opinion, based on some extight bee-quilt between the apart-ments till the queen has commenced to lay in the brood-combs, which will be in two or three days after the swarm is hived. After this the queen is not apt to go above as long as she has room below. The best queen-excluder to be used over the narrow-top frames is a plate of perforated-zinc fixed in a frame like a school-slate in its frame, and used as honey-boards are used.—G. W. DEMAREE.

I always hive swarms on full sheets of foundation, not on combs, and I need no queen-excluders to keep the queen out of the sections, even if I put them on, full of foundation, at the time of hiving. If I did, I should use either an all metal, or part metal and part wood queen-excluding honey-board.-JAMES HEDDON.

### Do Queens Lay Drone Eggs?

Query, No. 240.-Does any one know that queens lay drone eggs? Or is it not the food that does the business? If with queens, why not with drones ?-Pa.

It is quite evident that virgin queens lay drone eggs.-H. R. BOARD-MAN.

I have many good reasons for believing that queens lay drone eggs, that would be too lengthy to give here. I also have reasons for believ-ing that food cannot make an egg laid for a drone produce aught but a drone.—G. M. DOOLITTLE.

Everybody knows that queens lay drone eggs, and that the food has nothing to do with the sex. Drones are males, and queens and workers are females, though the workers are imperfect females.-DADANT & SON.

Because it is not Nature's way to have food perfect the female, and lack of fecundation of egg, result in male. There is no possible doubt. The same is true of wasps and ants.-A. J. Соок.

Yes. Workers are partially devel-oped females; food and abundant room develop into a queen, what would have been a worker. There are really only two sexes in the bee-hive, male and female, the workers not being sufficiently developed to perform the maternal office.-W. Z. HUTCH-INSON.

I have never seen a queen laying in drone-cells, but I have often seen one on drone-comb when there were freshly laid eggs, and her presence did not seem to be a coincidence. Food can have nothing to do with changing the sex of eggs.-G. L. TINKER.

### The Most Honey and Increase, etc.

Query, No. 241.-From which colonies can the most honey and increase bo obtained-those worked for comh honey or for extracted honey? At what distance from the ground should the hives set ?-R. L.

Extracted. 2. Four to 6 inches. -C. C. MILLER.

The 1. Usually extracted honey. most money and increase can be ob-tained from the production of comb honey. 2. I place mine about 6 inches from the ground .- JAMES HEDDON.

1. Extracted honey. 2. From 6 to 12 inches; in this locality with clean culture I prefer 6 inches.—H. D. CUT-TING.

1. It would depend upon the man-agement. If the honey is not ex-tracted till after it is all sealed, as I believe is the proper way, and "tier-ing-up" is practiced in both cases, there will be but little difference as to return linerase while the weight to natural increase, while the weight of honey will be in favor of extracted. 2. I prefer hives to be about 6 inches from the ground.—G. W. DEMAREE.

1. It will depend somewhat upon the locality, but as a rule from those worked for extracted honey. 2. I prefer to place my hives down on the ground, as then the bees have no trouble in finding their way into the entrance, as they sometimes do, when the hives are placed upon a high stand.—J. E. POND, JR.

### System and Success.

27 All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are as follows :

For

The larger ones can be used for a fow colonies, give room for an increase of numbers and still keep the record all together in one book, and are therefore the most desirable.

### **Convention Notices.**

137 The annual meeting of the Northern Ohio Bee-Keepers' Association will be held in the New Yown Hall at Weilington. O., on Friday, April 30, 1886. All are invited to come and help make the meeting both pleasant and profitable. A special invitation is extended to the ladies. The officera of the Association will be elected at this meeting. H. R. BOARDMAN, Sec.

137 The next meeting of the Linwood Bee-Keepers' Association will be held in Condit's Hall at Rock Elm, Wis., on Saturday, May I, 188-6, at 1 p.m., All interested in hee-keeping are cordially invited to attend and make this a profitable meet-ing. B. J. THOMPSON, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. N. HAMBAUGH, Sec.

A cordial invitation is extended to all to attend the 5th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indicationa for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No hotel hills to pay. B. F. CARROLL, Sec.

The next annual meeting of the Western N. Y. and Northern Pa. Bee-Keepera' Association will he held at Randolph, N. Y. on Msy 4, 1886. A. D. JACODS, Scc.

(B) The DesMoines Co. Bee-Keepers' Association will meet at the Court Honse in Burlington, Iowa, on Tuesday, Apr. 27, 1886, at 10 a.m. Any articles sent to the President, Mr. Geo. Bischoff, at Burlington, for exhibition, will be well cared for and returned or sold, as the sender may direct. A cordial invitation is extended to all interested in bee-keeping. JOHN NAU, Scc.

The semi-annual meeting of the Western Bee-Keepers' Association will be held in Pythian Hall, N. W Corner of Main and lith Sts., (entrance on 1th St.), at Kansas City, Mo., on Apr. 29 and 30, 1886. The Cable Line can be taken from the Union Depot for 9th and Main Sts. The following essays will be read: "The Honey Market," by Clemons, Cloon & Co.; "Bee-Keeping in lowa." by F. Kretchmer; "Best method of handling hees for comb honey," by A. A. Baldwin; "Missouri Bee Keeping," by J. D. Pearce; "Does bee-keep-ing pay as a pursuit?" by Jos. Nysewander; and "Invertible Frames and Hives," by J. M. Shuck. P. BALDWIN, Sec.

The next meeting of the Cortland Union Bee-Keepera Association will be held at Cortland, N. Y., on May 11, 1886, at 10 a.m. D. F. SHATTUCK, Sec.

to The next annual meeting of the Michigan State Bee-Keepers' Association will be held in Ypsilanti, Mich., on Dec. 1 and 2, 1886. H. D. CUTTING, Sec.

The Central Michigan Bee-Keepera' Associ-ation will meet on May 18,1886, with Capital Grange at their Hall in North Lansing, Mich., to bold 3 sessiona, viz : Forenoon, afternoon and erening, All interested In bee-culture are invited to attend and bring articles of the apiary for exhibition. For any special information address the Secretary, E. W. WOOD, N. Lansing, Mich.

### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

Explanatory.-The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark O indicates that the apiarist is located near the centre of the State named: **5** north of the centre; **9** south; **9** east; •O west; and this & northeast; ~ northwest; ◦ southeast; and 9 southwest of the centre of the State mentioned.

Official Report of U.S. Entomologist. Bees vs. Fruit—Experiments. N. W. M'LAIN.

For the purpose of testing the capacity of bees, under exceptional cir-cumstances, to injure fruit, I built a bouse 16 feet long by 10 feet wide, and 8 feet high at the corners. Large doors were hung in each end, and a part of the siding on each side was adapted to be raised up on hinges. Screen doors were hung on the inside of the outer doors, and wire cloth covered the openings on the side where the siding was raised. The house is entirely bee-proof. When the sides are raised up, and the outer doors opened, the temperature and light in the house is substantially the same as outside. Along the sides of the house I built shelves upon which fruit was placed so that the rays of the sun might strike the different varieties in different stages of ripeness from green to dead ripe. Plates of ripe peaches, pears, plums, grapes, &c., were placed on the shelves; clusters of different kinds of grapes, green and ripe, sound and imperfect, and such as had been stung by insects. were suspended from the rafters and cross-ties of the house.

On September 1, I removed three colonies of bees from their hives, carefully and quickly, so that they would earry very little honey with them when transferred from one hive to another. Two of the colonies were hybrid bees, and one Italian. These colonies were hived on empty combs, and placed in the house with the fruit. A wood-stove was put in the house, and for a number of hours each day a high temperature was maintained. The physical conditions which would ordinarily prevail in nature during a protracted and severe drought were artificially produced and

The bees were brought to the stages of hunger, thirst and starvation. The house was kept locked, and I carried the key.

Every inducement and opportunity was afforded the bees to satisfy their hunger and thirst by attacking the fruit exposed. They daily visited the fruit in great numbers, and labored diligently to improve the only remain-ing source of subsistence. They if the film is unbroken the pulp 1 successful a darning-the epidermis, or it may be removed, and in successful a darning-the epidermis of it may be removed, and is successful a darning-the epidermis of it may be removed, and is successful a darning-the epidermis of it may be removed, and is successful a darning-the epidermis of the pulp a darning-the epidermis of the epidermis of the pulp a darning-the epidermis of the epidermis of the pulp a darning-the epidermis of the epidermis of the

inspected and took what advantage they could of every opening at the stem or crack in the epidermis or puncture made by insects which deposit their eggs in the skin of grapes. They regarded the epidergrapes. They regarded the epider-mis of the peaches, pears, plums and other fruits having a thick covering, simply as subjects for inquiry and investigation, and not objects for attack. If the skin be broken or removed they will, in case of need, lap and suck the juices exposed. The same was also true of the grapes if the skin was broken by violence or burst on account of the fruit becoming overripe; the bees lapped and sucked the juices from the exposed parts of grapes and stored it in the cells for food. They made no attempt to grasp the euticle of grapes with their mandibles or with their claws. If the grapes were cut open or burst from overripeness the bees would lap and suck the juice from the exposed segments of the grape until they came to the film separating the exposed and broken segments from the unbroken segments. Through and beyond the film separating the segments they appear to be unable to penetrate. removed the outer skin from many grapes of different kinds, taking care not to rupture the film surrounding the pulp. When these were exposed to the bees they continued to lap and suck the juices from the outer film until it was dry and smooth as was the film between broken and unbrok-They showed no dispoen segments. They showed no dispo-sition to use their jaws or claws, and the outer film as well as the film between broken segments remained whole until the pulp decayed and dried up.

After continuing the test for thirty days, using such varieties of fruit as could be obtained, I sent to Michigan for varieties not obtainable here. Through the kindness and favor of the president of the Michigan Horticultural Society, Mr. T. T. Lyon, of South Haven, Mich., I secured twenty varieties of grapes, which arrived in excellent condition. Another colony of Italian bees was then placed in the house with those already confined for forty days, and the twenty varieties of grapes were exposed upon plates and suspended from the rafters as before. The conditions naturally prevalent during a severe and protracted drought were again produced, and the test again continued for twenty-five days. The result was simply a repetition of the former test. The bees showed no more capacity or disposition to offer violence to one variety of grapes than another. No more attention was given the thin-skinned varieties than the thick-skinned. As long as the skin remained whole they did not harm the grapes. When the skins were broken by violence, such as by cutting or squeezing, the juices exposed were appropriated. The extent of damage the bees could do to grapes burst from overripeness cutting or squeezing, exposed were appropri depended on the extent of the rupture

remained whole. The film seldom bursts until the grape is about to decay, or has begun to decay, and then the grape is of little value.

In order to determine the size of the opening necessary to be made in order that bees might injure grapes, I punctured the cuticle of the grapes in several bunches with eambric nee lies of various sizes. The puncture made with the point of medium-sized needles produced no effect. Neither does the puncture made by the sting of insects, when ovipositing, until the blister appears and decay progresses with the development of insect larvæ. I found that I might pass a medium sized needle through a grape, from side to side, and bees could obtain no juice except that oozing from the puncture. Many erroneously suppose that bees sting the grapes. Bees never sting except in self-defense or in defense of their homes from real or imaginary danger.

At times when bees could gather nothing in the fields I saturated clusters of grapes with honey and sus-pended them in front of the hives in the apiary, and from branches of trees and grape-vines near by. Other elusters dipped in honey and syrup were hung in the house. The bees thronged upon the grapes until the clusters looked like little swarms hanging to the vines and limbs. They lapped the grapes until the skins were polished perfectly smooth and shining like the inside skin of an onion, and no taste of sweet could be detected by touching the tongue to the grape. The skins of the grapes were left intaet.

Bees, like some animals of a higher order, seem to enjoy stolen sweets better than any other. Taking ad-vantage of their propensity to steal and despoil, I placed combs containing honey in an unoccupied hive and permitted the bees in the apiary to steal the honey and such portions of the comb as they could appropriate. I then suspended instead of the despoiled combs clusters of grapes dipped in honey. The bees attacked with desperate earnestness, apparently determined to literally go through those grapes. The clusters were left hanging for a day or two, until the bees had entirely deserted the hive, and examination showed the grapes to be as sound as when placed there, and the skins polished smooth and elean as before.

1 then punctured the grapes of several clusters by passing a darning-needle through the berries from side to side, and hung them in the house near the hungry bees. They sucked near the hungry bees. They sucked the juices from the broken segments as far as they could insert their tongues into the wound, leaving a depression near the puncture, and the remainder of the pulp was left whole. The instinct of hees impels them to

remove everything useless or strange from their hive. They will labor harder to remove any object which is useless or offensive than for any other purpose. After passing a darning-needle through some of the grapes in top of comb frames by using fine wire and placed them in the center of strong colonies of both hybrids and Italians. The juice was extracted from the punctured segments as before, and the perfect grapes hung undisturbed for fifteen days. They appeared to have kept better hanging in the hive than they would have kept on the vines.

The evidence then shows that bees do not injure perfect fruit. I have observed that they give no attention to the puncture and blight caused by the ovipositing of other insects, until after the larvæ is hatched and decay has set in, and then only in cases of extremity. The circumstances under which bees appear to be able to injure grapes are very exceptional. That they will not molest or even visit grapes when it is possible to secure forage elsewhere is certain. It also appears certain that they never attempt violence to the skin of grapes. The capacity of bees to injure over-ripe grapes is limited by the extent to which the juice and pulp are exposed by the bursting of the film. If the film is only slightly burst the bees can do but little injury. If the progress of decay has caused a wide rupture in the film the bees more readily appro-priate the juice. If overripeness and decay have exposed the pulp of grapes to such an extent that bees can dam-age them seriously, the bees should be confined to the hive (unless the weather be excessively hot), and the grapes should at once be gathered, for from this stage the progress of decay is rapid. Confinement to the hive for a short time, while the overripe grapes are being gathered, would result in no loss and the bees would be prevented from gathering the grape-juice and storing it in the hive. Bees confined to their hives in warm weather must always have ample top ventilation, and should be liberated and allowed to fly half an hour before sunset each day during the term of their confinement. The excessive use of grape juice often produces inebri-ety. In the case of the bees it produces diarrhea. After grapes have arrived at the stage of overripeness and decay in which it is possible for bees to injure them, and the circumstances are so exceptional as to cause the bees to seek such food, it would be advantageous to the grape-grower to secure his grapes from the ravages of decay, and advantageous to the bee-keeper to secure his bees from the ravages of disease.

The following named varieties of grapes were used in making these tests: The Niagara, Delaware, Roger's No. 10, Roger's No. 14, Roger's No. 15, Roger's No. -, Taylor, Ives, Lady, Hartford, Martha, Concord, Northern Muscadine, Vergennes, Brighton, Pocklington, Worden, Isabella, Diana, and Syriansfrom California, and three other varieties the names of which I did not learn.

Mr. Richard Rees, a florist and horticulturist of many years' experience in the Eastern and Western States, informs me that he has very carefully observed the effect of bees upon flowers and fruits in the orchard,

garden, and greenhouse. He regards their presence as wholly desirable and altogether beneficial. During a term of four years he had charge of a large conservatory and garden in this city. At times he had as many as fourteen different varieties of exotic grapes in bearing in the conservatory, and from 2 to 3 tons of ripe grapes hanging on the vines at once. A large apiary was located near by, and late in the fall and early in spring the flowers and fruits in the conservatory were visited by the bees in great numbers. The grapes were unmolested, and the bees aided in fertilizing the flowers. He says that he has had large experience in grape-growing in vineyards, and that he has never known any damage or loss resulting from bees, and that when grapes are burst from by the hatching of insect larvæ, to such an extent that bees can appropriate their juices, they are of little, if any, value. He has never kept any bees, but he regards them as being of great service to floriculturists and horticulturists on account of the service rendered in fertilizing blossoms.

# "Kindly Criticism."

### WM. F. CLARKE.

Mr. J. E. Pond, Jr., has an article in the last issue of the *Bee-keeper's Guide* on the new Heddon hive, which he prefaces with a plea for free discussion, in the course of which he complains that bee-keepers are apt to regard adverse criticism as being actuated by a wish to injure the person or object criticized. This he disclaims, and avers that the opinions he is about to express, though adverse to the new hive, are of the nature of "kindly criticism." He concludes the article by saying that he has written "with malice toward none, and justice toward all."

In the course of his remarks Mr. Pond says of the new hive: "Mr. Heddon is very enthusiastic in regard to it; 'my friend' deems it the greatest output of the age; 'Bro. Clarke' sounds its praises with a big blast of his 'ministerial trumpet.'" I beg to ask if this reference to myself can be fairly called "kindly criticism," and if it is entirely harmonious with the principle of "justice to all." I go farther, and inquire if it is in strict harmony with truth? For in what sense have I sounded a "ministerial trumpet" in praise of the new Ileddon hive? Did I quote Scripture in support of its claims? Did I bring any religious arguments to bear in its favor? As a *literatew*, I am somewhat versatile. I write on agriculture, apiculture, and even on politics as well as religion. It was well said once by a member of the military profession that the worst thing about the army was that a soldier cannot be a man. The same is 'true about the ministerial calling. No one is better aware than Mr Bond that when I

write on general topics, I write as a man, and he would be one of the first to object if I claimed that any special weight attached to my utterances because I am a minister. Does Mr. Pond sound the trumpet of a lawyer when he discusses bee-keeping ? Only when he deals with patent rights. Then he manages to advertise his extensive knowledge and large experience as a patent lawyer.

It may be asked why not send this critique on Mr. Pond to the Bee-keeper's Guide? "Thereon hangs a tale," which is a pat illustration of the heading to this article. The March number of the bee-periodical just named contained an editorial paragraph, part of which reads as follows:

"It appears that James Heddon has organized a band. He is to play first fiddle. W. Z. Hutchinson, the second fiddle, while Rev. Clarke is to blow the horn. Prof. Cook is learning to play in hopes of getting in. The necessity of this band is to operate a new hive, etc., etc." I wrote the editor complaining of the injustice done to myself and the other gentlemen mentioned, by this style of remark. No notice of this communication is taken in the April number, nor has it been even acknowledged by private letter. The idea of my being hired as a member of the Heddon band to "blow the horn," seems to have struck Mr. Pond's fancy. Hence he produces it second-hand by speaking of my sounding "a big blast" with the "ministerial trumpet."

The phrase "kindly criticism" reads well, but there is an old proverb which suggests that we should be *just* before we are *generous*, and another which truly declares that "consistency is a jewel." It is "the unkindest cut of all" to say or to insinuate that what a man writes with protestations of honesty and impartiality is prompted by self-interest, or part of the set policy of a ring or clique banded together "to operate a new hive." If you consider me in error, say so freely and manfully; produce your strong reasons in support of the statement, and I shall think the better of you for so doing. But unjust reflections are not changed in character by calling them "kindly criticism," any more than a jar of glucose compound is redeemed by labelling it "pure honey."

Guelph, Ontario.

For the American Bee Journal Mr. Frank Cheshire's New Book.

### DR. C. C. MILLER.

"<sup>6</sup> Bees and Bee-Keeping; Scientific any religious arguments to bear in its favor? As a *literateur*, I am somewhat versatile. I write on agriculture, apiculture, and even on politics as well as religion. It was well said once by a member of the military profession that the worst thing about the army was that a soldier cannot be a man. The same is true about the ministerial calling. No one is better aware than Mr. Pond that when I

excellent, but on turning over the leaves, that which most excites attention is the large number of illustrations. There are eight full page plates, beside 71 figures scattered throughout the book. No one is likely to imagine the exquisite delicacy of these illustrations without seeing them. They are, for the most part, to show the anatomy of different parts of the here more interviewed to the the of the bee magnified 5 to 400 times. Mr. Cheshire gives in these pages the result of much painstaking labor as a microscopist. But ninety-nine out of every hundred bee-keepers will, like myself, find much beyond the range I think there will arise some desire to know more of it.

One cannot help a feeling of regret that such beautiful pages should be marred by the unkindly spirit shown toward Prof. Cook. Surely, the in-terests of science do not demand the least resemblance of any thing like an exhibition of personal dislike.

After speaking of the position of the hive-bee in the animal world, and giving its classification in the first chapter, the second chapter gives the economy of the hive-bee, including development from the egg, larva and papa. Speaking of this development the author says (page 24) " in some-thing more than 12 days from the time of sealing, the transformations are complete." Has this been verified by others? On the same page, speaking of the just-hatching bee, he says, it "bites at the door of its prison-house, into which it soon carves a long, curved slit... and then, by a push, it makes way for its emergency, the head is advanced as at N, and a pale but perfect bee walks into view." In the many cases which have come under my observation, it is not a simple cutting a slit then a single pnsh and out it comes, but after cutting a slit the bee gives a push, finds more room needed, cuts again, then pushes again, and this may be repeated sev-eral times before the bee emerges. It may be said I am engaged in hair splitting, and in an ordinary work I should not notice this, but Mr. Cheshire is very severe upon others who are not strictly accurate in matters apparently more difficult of exact observation than this.

Chapter III treats of general struc-ture, and Chapter IV of the nerve system. After speaking of the brain as showing intelligence superior to other insects, he says, "As we pro-ceed, I shall have more than once to point out a misconception, which would appear to be all but universal amongst bee-keepers, and to show that the queen is not superior to, but greatly the inferior of the worker; and the brain bears evidence to this position, as that of the queen is relatively small, as is also that of the drone."

Chapter V treats of the digestive system, and Chapter VI of glands.

Chapter VII tells about the tongue chapter vil tells about the tongue hound of the torgenerate and mouth parts, the wonderful it may be of more practical value than mechanism by which "the bee is I suspect), a full understanding of the equipped to take advantage of all wonderful mechanism of the different sources of supply. She can gulp down parts of the bee, and the beautiful big draughts, or sip a stream of nec-

tar so fine that 600 miles of it will, when evaporated, store but a 1-pound section-box."

The next chapter treats of the antennæ, the organs of touch, smell-ing and hearing. Think of 37,800 dis-tinct organs in two antennæ of the drone l This chapter treats also of the eye with its thousands of facets.

The thorax and legs form the sub-ject of Chapter IX. Since reading this book I think I can never again look upon a bee climbing a smooth surface without a feeling of profound admiration. Imagine that a person is trying to climb a wall by means of his inger uails, and that whenever the wall becomes so smooth that the nails lose their hold, the resulting closing of the ingers causing the instantaneous pressing of the flat of the knuckle against the wall, the knuckles being furnished with a substance so adhesive as to sustain the weight, and idea which Mr. Cheshire so clearly brings out by the aid of his illustrations.

Chapter X has for its subject wings and flight, buzzing and humming. Four hundred and forty is given as the number of vibrations of the wings per second. The beat of the wings makes the buzzing, but the humming is a true voice. In Chapter XI (secretion of wax,

and bee architecture), we are told that in a square inch on one side of a comb there are 28 13-15 worker-cells, and 18 178-375 drone-cells.

Here, surely, is heresy, for every one knows that worker-cells measure 5 to the inch and 5x5=25. A moment's thought, however, will show that 25 is correct only on the supposition that the cell is a square, and a little figur-ing upon the surface of the hexagon will show 28 13-15 correct to within one-thousandth. The only wonder, after one's attention is called to it, is that so palpable an error should have passed unchallenged so long. As it makes the difference of 1,114 cells in a square foot of comb it is a matter of some consequence. The scaling of honey-cells is described as not absolutely impervious to air, although the author himself speaks of it in a former

chapter (page 18) as air-tight. The structure of the sting and its action is minutely described in Chapter XII, and the organs of the drone and queen in the next two chapters. and queen in the next two chapters. The ground is taken that the queen never mates the second time, that drones reared from drone laying queens are fully virile, and that dwarf drones reared in worker-cells are probably virile, and that drones have no other use than to fertilize queens. Two interesting chapters, one on bees and flowers mutually complementary, and one on bees as fertilizers, florists, and fruit producers, close the volume.

I would give many times the price of this book to have its contents clearly in my head. Suppose there is nothing of direct practical value (and

one a thrill of delight that cannot but cause a greater enjoyment in his daily intercourse with these tiny creatures. Although not well posted in such matters, I have no idea that there is in the English language (or indeed in any language) anything approaching this volume in fullness of information and completeness of detail as to the subjects of which it treats. Marengo, & Ills.

## Honey for Bees in Winter.

For the American Bee Journal.

### J. E. POND, JR.

Mr. Heddon says: "I no longer doubt that practical success in wintering depends upon proper food and temperature." Why he should ever have had such doubts is a mystery, as the proposition, so far as it goes, has been a well established axiom for years. Under right conditions any colony will winter safely, is another axiom, and both of these propositions are of one and the same effect, the first being the lesser, and that contained in the last the greater.

What are right conditions? is the real question at issue : in other words, what combination of circumstances and things is necessary to produce the desired result? Winter losses do occur with all kinds of food, and in all temperatures; this is a significant fact, and shows conclusively that the conditions are not right; that some thing is lacking. As yet we have no really satisfactory proofs that sugar is a safer winter food than pure honey; and we have the strongest possible evidence that with other conditions right, pure honey is abso-lutely safe; and we have not as yet such proofs in regard to sugar. This being the case, and I have ventured the assertion on historical grounds solely, we have a strong argument against the use of sugar as winter food for hees when pure honey can be obtained. I will say nothing now in regard to honey being a natural food, as the argument is strong enough without such aid, but will confine myself to established proofs rather than to theoretical notions.

The idea of adulteration obtains to a large extent in regard to honey; that this is so will not be denied; the glucose idea did prevail, but now the fact that sugar is being extensively recommended and used as food for bees has great weight with would-be consumers, and they do not become consumers simply from fear they will consumers simply from fear they will not get pure honey. It is not at all strange that the general public do not understand the matter. Why should they? They simply know that *honey* is, or ought to be, the product of the hees; they have been told by the "Cottons" and others, that hone will store sure the same as that bees will store sugar the same as they do honey, and when they find bee-keepers feeding sugar, it is diffi-cult—I might say impossible—to convince them that it is not so fed to be stored and sold as or for honey. The above is a natural and a logical conclusion, and as such, is to the consumer a fact that will admit of no denial. The remedy is with us. We must learn-what right conditions for wintering consist of and in; then we will use pure honey as bee-food, and show the world both by precept and example that our honey is purely gathered nectar, and that it cannot possibly contain any adulterants.

Foxboro, O+ Mass.

For the American Bee Journal. Care in Making Progress.

### REV. L. JOHNSON.

Much harm has been committed in the past among bee-keepers by a too rapid reception of new things, and unless great care is taken a like evil may result from the injudicious use of new things now coming forward. Before using anything we should know for what it is designed, and then how best to attain that end in view.

The new reversible hive may be a a good thing, and in the hands of those who understand bee-culture and have clearly defined ideas of what it is intended for, may accomplish good results. But may there not be some danger of many persons without proper knowledge or experience, taking hold of it and after much expense and trouble, having the sad report to make that they have been humbugged? Yet this may not be the fault of the hive, but entirely for want of proper handling.

To illustrate: Some ten years ago a great deal was said in many sections of the country about "Dividing," "Artificial Swarming," etc., and one enthusiast on the subject went so far as to state that as many as 32 colonies could be made from one in a single without proper knowledge began to rapidly divide their colonies, and divided them to death. One old gentleman with whom I was acquainted, was given 4 colonies in box-hives in the spring of 1876. He got a friend to transfer them for him; when he began dividing and by the first of August he had 21. The next spring he had 21 empty hives—the only bees lost in the neighborhood that winter.

When the honey extractor first when the honey extractor inst came into use, many persons who knew nothing of honey in an un-ripened state, purchased one, and began throwing out the stores of the same colonies every 3 days. The result was that a lot of unripe, sour honey was placed upon the market, which was uttory undiffere outbing which was utterly unit for anything. An injury was done to extracted honey that it will take years to over-come. The same mistakes have been made in comb foundation, and introducing the new races of bees. Espe-cially is this true in regard to handling the Cyprian bees. In the hands of those who understand them, 1 have no doubt they are an acquisition. but so many have taken hold of them without proper knowledge, that their

attention for any number of years can call to mind other instances where some actual benefit to our craft has been much injured by its too rapid introduction.

The reversible hive has only been tried by its inventor and one or two others for two seasons. These men are practical apiarists; and in their hands it has done well; but when others with less knowledge and without properly understanding what is intended by this hive, undertake its use, it may receive a backset from which it may not recover in years.

I am in favor of making every progressive step in bee-keeping that is possible; but so much enthusiasm often ushers in a new thing as to do it harm. I would urge bee keepers to carefully ponder before doing away with the old, tried and profitable standard hives which we now have. and adopting something we do not yet understand. Take hold cautious-ly, and let those who have time and money with which to experiment, enjoy the benefits for a time. Better lose a little, than through haste and ignorance permanently injure a good thing. Walton & Ky.

For the American Bee Journal. Feeding Sugar—The Weather.

### JOSHUA BULL.

I have read with much satisfaction the caution that was given on page 195, about feeding sugar to bees; also other articles which have appeared in the BEE JOURNAL upon the same subject. I am heartily glad that this matter is being considered in its true character in relation to the effect it has upon the honey market. What-ever the motive may be on the part of those who feed it, the fact that sugar is fed to the bees has created a suspicion of fraud in the minds of consumers, which has, no doubt, very materially affected the market, by curtailing the demand for honey, through a want of confidence on the part of purchasers as to the purity of the article; and I can see no better way to allay such suspicion, and restore confidence between producer and consumer, than to discontinue the practice of feeding sugar altogether.

We have had a long winter up here in Wisconsin, most of the time quite mild for this latitude, although we had some extremely cold weather. On the morning of Feb. 3, the mercury made a plunge down to 40° below zero; on March 17 we had sharp lightning with heavy thunder and rain. During the first week in April the mercury was down to zero four times. It almost makes one nervous to read in the BEE JOURNAL about bees gathering pollen, drones flying, etc., in other localities, whilst with us the air is chilled and vegetation held in check by large banks of snow and ice, which, however, are now rapidly disappearing.

wintered well in this vicinity; yet considerable losses have occurred where conditions were not right, We are hoping for a good and prosperous

This afternoon the clouds have broken away, the sun shines down brightly and warm—mercury up to 58° in northern shade—and the bees are having a great jubilee.

Now winter may go, With its ice and its snow. Without any further delay; For summer is coming, The bees are out humming, And the apiarist's heart is gay.

Seymour, 0+ Wis., April 12, 1886.

For the American Bee Journal.

Rearing and Introducing Queens.

### S. J. YOUNGMAN.

I desire to fully describe what I consider the best manner for rearing queens for home use, and their suc-cessful introduction to nuclei pre-pared for their reception in anticipa-

pared for their reception in anticipa-tion of their hatching. I think it can be said, and with well-founded reasons, that some of the best methods and essential de-tails of queen-rearing have been kept in the back-ground by queen-breeders who are rearing queens for the mar-ket, and who have selfishly been the means of materially hindering the progression of that noble art—beekeeping. In this climate queens may be reared, nuclei formed, and queens fertilized, earlier than natural swarm-The ing can be expected to occur. first essential to successful or early queen-rearing is, of course, in strong, Queens are more easily reared by Cyprian, Syrian, or hybrid bees than by pure Italians, and should be given the preference for such work. If the apiarist has any of the new races in his yard, I would also say that queens, hardy and strong upon emerging from the cell than are those of the Italians. I have repeatedly seen them take wing when first escaping from

the cell, and disappear, but return again in a short time. Of course every bee-keeper will have some colony in his yard that he prefers to the others, and may wish to breed from this exclusively, which is advisable, and easily done. The first step is to take out one of the central frames of the brood-nest and replace it with one selected that is not over one year old, and one that brood has not been reared in more than once. This comb will usually contain eggs at the end of 24 hours, which may be used at once; but when the eggs are used the average apiarist will usually meet with failure, con-sequently I would recommend that the eggs remain until they hatch and first reach the larval state. Queens reared from the young larvæ are fully as good as those reared from the eggs.

The colony that is to do the work should now be deprived of its queen, which may be removed with the best reputation is ruined forever. All of So far as I have learned, bees that which may be removed with the best us who have given apiculture much were in good condition last fall, have frame of brood and adhering bees to another hive in a distant part of the yard, and quickly be built up to a strong colony by the aid of old combs or frames filled with foundation. I usually remove the queen in the even-ing, and the next morning all the brood may be removed and distributed among other colonies. From 40 to 48 hours after the removal of the queen, a colony is in readiness to re-ceive the eggs or larvæ from which the queens are to be reared.

Now, to prepare the eggs or larvæ ready for the bees: Take a frame of comb (½ or ½ full is as good as any, or if it is all or part *drone comb* it will answer as well); heat a thin case-knife and cut this comb so that it will be about t inches from the lower side be about 4 inches from the lower side of the top-bar to the lower side of the comb, forming a semi-circle; the comb will be the shape of a crescent or half-moon, being about 4 inches deep in the middle. Being ready for the larvæ they are now removed from the hive of the favorite colony, and taken immediately to a warm place. I proceed to cut strips from a part where I am able to get cells in rows from 3 to 6 inches long. I leave one row of cells intact, but cut each row of cells at each side through the middle. One side of this strip should now be cut off with the aid of the hot knife, leaving the cells not over  $\frac{1}{4}$  of an inch in depth. The larvæ should now be removed or destroyed in every other cell, not leaving anything. The bees may utilize, in rearing a queen, any room except in the straight row of cells, and there only in every alternate one. Enough of these strips should be prepared to form a row on the under side of the crescent-shaped comb, which may be made to adhere by dipping the side which has the long cells, into a mixture of beeswax and resin—two parts wax and one of resin, heated quite hot in a small, square. shallow dish made of tin or sheet-iron,

The reason for having the comb in the shape of a half-circle, is so that the bees may have plenty of room on all sides of the cells, and give room to pass a sharp knife between the cells without destroying or injuring any of the cells. Under the old way several cells would sometimes be built together so that it would be impossible to remove and separate them without destroying some of them.

The colony is now in condition to put all its energies to cell-building, and will do so as they have no brood to attend to. Their whole attention will be given to the cells, and but a The prudent beckeeper will be gathered. The prudent beckeeper will there-fore see that they are well supplied with food, and if they should be uneasy and many bees die, some capped drone brood may be given them to advantage; in fact, I think it will be beneficial from the start. The queens will hatch on the 16th day from the day the egg was deposited in the cell. I usually remove them on the 14th day, as all they need after that until they hatch, is the necessary warmth, although the bees will help remove the young queen when she sometimes would not be able to emerge from the cell by her own efforts.

It will be found that the new races of bees, with this method, will average one dozen good cells, and what-ever bees are used it will be found that more cells will be built, and they will be larger, contain more of the royal jelly, and that the queens will be larger and more beautiful than when reared under the so-called swarming impulse.

The two most important matters in increase of colonies is to keep the colonies *strong* in bees; a prolific queen is also very important; second, to guard against the chilling and loss of the brood in the newly-formnd nuclei, by a change of temperature or the lack of the requisite number of bees to properly protect the brood from chilling. The cells, if left too long, must be carefully watched, for, the bees will quickly destroy the re-maining cells by biting into them and removing the young queens. I pro-ceed to form the nuclei the evening before I wish to remove the cells, by first taking a frame containing the greatest number of hatching bees, and between two empty combs. If there are not enough adhering bees upon the comb of brood, bees to the amount of from one-half to one pound may be shaken into the hive, according to the weather, being careful in all cases not to get the queen in. The bees should be shut in until morning before being liberated. Some small boards should be set up in front of the hive, so that the bees may mark their new location and not return to the old hive.

Remove all the queen-cells from the hive. The cells may be separated by using the warm knife, leaving a small piece of comb attached to each, To introduce them, all you need to do is to spread one end of the combs in the nucleus, and place the cell in between the bars in such a position that nothing will prevent the queen from emerging from the lower end of the cell. If the queens have hatched on your hands, and you have been fortunate to have saved them, all you need to do is to simply let one run in at the entrance of the hive. The bees will not harm or molest her in the least. No more bees need be added, but after the queen shall have hatched, and the most of the brood also, select another frame of the oldest brood that may be found, and place it in the centre of the nucleus which will serve to add strength to the immacure colony, and if for any reason the queen has not hatched or has been lost, you may soon know it, as queen-cells will soon be started if the frame contains any uncapped brood, which is an easier and surer test of queenlessness than not finding the queen.

Some of the advantages of this method of increase will plainly be seen; first, the bees do not waste any of their energies in the wrong direction, but are obliged to work on such eggs or larvæ as are given them; the queens are reared in strong colonies, and I think are superior to queens hatched in the natural way. The bee-keeper need not be without queens, as any one surely will be if they

depend upon the bees to rear them under the swarming impulse. I have known a colony of pure Italians to build but one queen-cell, and then it was of such thickness and solidity that the queen could not hatch. I have also known bees to swarm and not leave anything nearer a queen than newly-laid eggs, and without any queen-cells whatever.

This is also the safest manner of introducing queens, for but very few of the nuclei will fail to have a queen. Some may be lost on taking their bridal trip, if the hives are not placed in proper position, and the right distance apart. It will also be seen that it takes but few bees to start a nucleus, as we depend almost entirely upon brood to form them, and brood may be taken every week from a strong colony and not perceptibly weaken it if done judiciously, if the queens are prolitic, and none others should be allowed in the apiary of a modern and progressive bee-keeper. Bees in a Greenhouse in Winter.

### J. A. BALMER,

On Nov. 14, 1885, I was offered a colony of bees. Their owner intended (about 5 lbs). They were in a box-live, and as the man wanted to save his hive, I undertook to drive the bees. The day was cold, but not freezing. I turned the "gum" upside down and commenced knocking the hive and smoking them, but they would not drive, so I cut out the combs, brushed the bees into a sieve, and brought them home. I had placed my own bees, that

same day, in a sawdust-packed house, and did not care to disturb them; therefore I had to hive these few bees on 3 frames of drawn-out foundation, without a particle of honey or beegreenhouse 12x50 feet. The bees were very numb from cold, but soon recovered under the influence of the greenhouse temperature.

I made them some nice, thick, warm feed, using granulated sugar and water just brought to a boil; to this I added a pinch of tartaric acid. They took the feed readily, and soon made preparations for extending the comb. They flew well every day, and did not atrugging much to got out of did not struggle much to get out of their confinement: though a few would be lost every day. The point of interest in these bees lies in the fact that they were badly affected with diarrhea from the first day they were put into the greenhouse, and this without pollen. There were a few flowers in the greenhouse, but very few pollen-yielding ones. After they had been in-doors 5 days, there came a warm spell of weather, and I placed them in a sheltered position out-doors; they flew well, but still

laying freely, but of course no larvæ, as there was no bee-bread in the hive. Soon the weather changed and I again moved them in-doors. I kept them two weeks on pure sugar syrup. during which time they drew out and capped three sheets of foundation. And I never saw bees with the diarrhea as bad as they had it.

As I pack my bees without removing any frames, I had no bee-bread or honey to give them; so I went to a neighbor bee-man and got two frames well filled with bee-bread and some honey; one of these I placed in the hive, the other I hung up in the house, and uncapped a little of the honey. Soon the bees were working on the suspended frame, and eventuon the suspended frame, and eventu-ally they removed every particle of honey and bee-bread from it. They were now rearing young bees pretty well, and had a few inches of capped brood. Many of the bees had wax scales sticking to their bodies. They still had the diarrhea very badly, and many bees were dying daily; they would settle on a leaf and gradually stiffen and die.

The temperature of the house ranged from 55° to 65° at night, to 70° or SO<sup>C</sup> during the day.

This I think is not in accordance with the conclusions arrived at by correspondents of the BEE JOURNAL early last year while discussing the pollen theory. They agreed that cold, and cold alone, was the prime cause of diarrhea among bees. It certainly was not cold in this case. for the temperature was never below 55°, Fahr.

They used the two frames of bee-bread very quickly, in fact so quickly as to lead me to believe that not onehalf of it was used for feeding young bees. By Jan. 1st, the supply of beebread run out, and bee-rearing stopped; their supplies were now all capped and I then thought that the diarrhea was ended, for they had no pollen; but not so, however, for the same dirty splatches continued to be found on the white-painted sash-bars.

I kept them three weeks without bee-bread, but there was no improve-ment in their diarrhetic condition. Their number was fast being reduced, so I gave them some flour, and placed a frame of capped stores from their own hive in front of the hive. They then commenced to rear young bees.

My object in placing the frame of honey outside the hive, was to keep were able to do. On Feb. 1 the queen was laying freely, yet not one-third of her eggs were hatched; the bees, no doubt sto them doubt, ate them.

What was the cause of the incessant diarrhea? It could not have been the cold; and I do not think that eating the eggs would affect their health. Could it have been the excessive moisture in the greenhouse? Most of the bees up to Feb. 1 had been reared since Dec. 1; therefore they knew no other pasture than the greenhouse afforded; and not 5 per cent were lost on the glass by struggling to get out.

books, namely, that old bees can produce wax at will, and that without the aid of pollen or bee bread. I would like to have some of the experienced apiarists give their opinions on the above case. Paris, o+ Ills.

For the American Bee Journal

### The Wintering Problem.

### S. BITTENBENDER.

This problem seems to be the most important thing to be mastered by the apiarists of to-day. This problem once mastered means one-third less cost in the production of honey. More has been written upon this branch of our growing industry than upon any other. Hundreds of theories have been anyanced through the beeperiodicals, yet all have been found by experience to be only theories. The hibernation theory, as advanced

by Rev. W. F. Clarke, appeared plausible at first, but it is not a solution of the problem at all. Bees in a normal condition in winter have a quiet state of repose, but do not hibernate as some other insects do. My reasons for so believing are: 1. Strong colonies are perfectly quiet, (or hibernating?) in January and February while they are breeding and consuming honey, either in the cellar or out-of-doors. Can bees hibernate while breeding and consuming honey? 2. I care not what temperature the air outside of the hive is (when the hive is in the cellar or on the summer stands.) strong colonies are all the time humming? Can bees hibernate while humming? 3. The ants, while in the state of hibernation, are appar-ently frozen as hard as ice; pick them up and they will be found as motionless as a stone; here is true hibernation. Bees in this state will not live 48 hours, although I have known them to become seemingly dead for 12 hours (from cold) and yet survive when placed near a fire.

How may we winter our bees on their own combs with natural stores? Here is my theory, which you may call the "October theory" or whatever you please :

There is a law in all nature which requires living things to take periods of repose. Man and the higher orders of creation require a daily repose at night, while most insects, trees, and flowers, require a yearly repose. Violate these laws and you must suffer. Nature provides for all things. She bids our "pets" to discontinue breeding from Oct. 1, to midwinter. Common sense would teach us to suppose that this was the natural time for bees to hibernate or repose. Bees in their natural state in the woods keep themselves in the trunks of trees 4 to 6 inches thick, where the autumnal sun cannot disturb them in their October and November repose. We thwart nature's ways when we put our bees into a  $\frac{1}{8}$ -inch hive and let the sun beat upon it till cold weather comes, disturbing I have learned one lesson from these the bee in its natural repose. Bees bees that is not recorded in the text- should be put into the cellar, or packed

on their summer stands, as soon as they stop breeding; if they are packed it should be so effectually done that the warmth of the October and November sun cannot allure them out of their hives. Bees contract their well-known complaint in October and November as follows :

During the first cool weather in October, breeding having ceased, they October, breeding naving claster, inc. fill themselves with houey prepara-tory for their natural repose, but in a few days they are disturbed by the warmth of the October sun. They warmth of the October sun. They take a flight. The apiarist is happy. The bees unload themselves. I have known them to spot the ground con-The cool October nights cause them to fill themselves with honey again for nature's repose, but another warm day thwarts nature's plans once more. Things continue thus until a temperthe bee-keeper to carry them into the summer stands, "according to scientific prin-ciples." ciples. <sup>22</sup> Now in what condition do we find the

bees? 1. They are weakened by the loss of their natural repose the same as their owner would be were his quiet sleep to be disturbed every night for the half year. 2. They have already the germ of diarrhea within them. Their intestines are in an abnormal condition, being unnatur-ally exercised, and weakened by inflammation. 3. They have acquired an unnatural appetite for eating honey. They eat too much, and now being deprived of their natural flights. soon become distended beyond endurance, and with their intestines inflamed, they must have a flight every few weeks or perish. Is it any won-der that we lose our bees when we thus treat the laws of nature? Why do bees cease breeding October 1, if nature does not bid them repose at that time? It is not because they gather no honey, for in February and March they will breed without collecting honey.

In support of the theory of early reposing, I would remind the reader of the fact that a very mild fall, with a late beginning of winter, thus giv-ing bees frequent flights, is a certain bees. The fall of 1884 was very mild. Bees took a flight every week till December 10, and never was bee-diarrhea so prevalent in the Unite States as during the succeeding winter.

Last fall my brother and I put 87 colonies into caves; 53 were put in 3 weeks before the usual time—I think about Nov. 10. I never saw bees winter any better than these are wintering; they have no signs of disease whatever. Every flight that bees get after Oct. 1 is a detriment. I doubt whether breeding in this latitude (42°) is any advantage after Oct. 1.

There are other things to be consid-ered in the solution of this wintering problem, such as moisture, food, temperature, etc., but the most im-portant thing is to get the bees in their winter repositories early. Knoxville, Q Iowa.

Dec. 1, 2.-Michigan State, at Tpsilanti, Mich. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.-ED.

Gathering Pollen.—H. E. Hill, Titusville, ~ Pa., on April 9, 1886, says:

A warm spell of weather about March 25 opened the willow and soft maple. But on March 27 the temperature lowered to  $30^{\circ}$  above zero, which suspended work in the hives. We are having nice weather now, and the bees are carrying in pollen to-day.

**Only One Colony Lost.**—W. Stearns, Lima,  $\infty$  O., on April 12, 1886, says:

Here the last season was a very poor one for honey; consequently very many colonies died during the past winter for want of honey. I lost only one colony out of 50 put into the cellar, and that one the mice destroyed. I intend to unite them down to 38. The bees are bringing in pollen to-day for the first.

**Reversible Hives, etc.** — Edwin Wilby, Toronto, Ont., on April 4, 1886, writes:

I think that Mr. Heddon's new hive is just the thing. I have long thought that the brood-nest should not be disturbed any more than is necessary. I commenced to keep bees 26 years ago, making my own hives, as I was a carriage-maker by trade. I commenced with the box-hive, at which time I had not heard of Mr. Langstroth's book. I afterward bought Langstroth's book, and made his style of hives after that. My bees never were troubled with foul brood, and I never lost any bees by having pollen left in the hives in the winter. I notice on page 184 is an article by Charles F. Muth, and as far as my experience

goes I can endorse every word that he says. I wish to thank him for putting his experience in print. I always have kept bees for pleasure, but my son attends to them now. We have 26 colonies in the city, all in good condition, packed in sawdust 2 feet thick, back, front, and on each side of the hives. It has been 23° below zero the past winter here. We had very little surplus honey last snmmer. All my bees are wintered on the summer stands, 8 inches from the ground, under a water-proof shed. They stand on a platform, and all have 6 inches of sawdust under each hive on the platform. I never lose any except now and then one by a queen dying.

Success in Wintering.—Wm. B. McCormick, Uniontown, 9 Pa., on April 9, 1886, says :

I have wintered my 25 colonies of bees without any loss—9 colonies in the cellar and 16 packed on the summer stands; both did equally well. I think that my apiary is now entirely clear of foul brood, which destroyed my 40 colonies (save one) during the summer of 1883. I hope we may have a good honey season the coming summer.

Bees have Wintered Well, etc.—2 —J. L. Comstock, (36-35), Sac City,+0 Iowa, on April 12, 1886, writes :4

I started with 9 colonies in the spring of 1885, increased them to 36, and took off 500 pounds of surplus honey. On Nov. 28, 1885, I put 36 colonies into the cellar. I put them out on April 7, 1886, and found one colony queenless, so I inited it with another, which leaves me 35 good colonies to start with. We organized a bee-keepers' association here on March 27, known as the "Sac County Bee-Keepers' Association." The following officers were duly elected for the ensuing year : President, S. R. Culp; John Barlow, Vice-President; Wm. P. Drewry, Treasurer; J. L. Comstock, Secretary; Executive Committee, Wesley Cheney, Wm. P. Drewry, and Walter Harrison. The association is to meet on the last Saturday of each month at 10 a.m., at the Court House in Sac City, Iowa.

Experience in Wintering.—Thos. S. Wallace, Clayton,+o Ills., on March 31, 1886, writes :

I invariably put my bees into the cellar, which is about 16x36 feet with a partition in the centre, and with cemented floor. One room is used to store apples, potatoes, etc., and my bees; the other room is used for a kitchen and dining-room. I place the hives one on the other in rows just so I can pass between them. I close the entrances before I put them into the cellar. After they are all in I go through and let them all out. I have a ventilator in the bottom of each hive. I put about 50 colonies in the cellar about Dec. 1, and 50 more on Dec. 31, 1885. I left them in for about 3 months, when I put them out.

I found 5 colonies dead—1 was out of honey, the other 4 had honey but not enough bees to keep up the heat. They had used up the honey that was in reach, but could not spread ont to get more. Bees are in good condition up this date, but the weather is very poor for bees. It has been snowing every few days. I keep my bees on honey if they have it; if they have no honey I feed them sugar syrup. I think that pollen is certainly necessary for bees to eat, or nature would not have them gather so much of it. I think that more bees die from eating poor honey than from eating pollen. I do not think that pollen will hurt any healthy colony of bees in a proper place. I think that the moth will wholly subsist on pure wax. I have had them to hatch and breed in nice boxes of white clover honey, and almost destroy it before I would know it. They did not seem to eat the honey, but the wax.

No Dead Bees this Spring.—T. F. Bingham, Abronia, 9 Mich., on April 8, 1886, writes :

Bees had a nice flight to-day—only one colony dead from those that were wintered out-of-doors. Those in the cellar have been there for 5 months, and are as quiet as when put in. Shall put them out in a day or two. There are no dead bees around here this spring.

Bringing in Honey.— John Rey, East Saginaw,⊙ Mich., on April 8, 1886, says :

My bees have gone to work on the maples to-day, and are bringing in some honey. If the weather keeps warm the willows will be in bloom in a few days, and then the bees can get plenty of pollen. My bees "came through the winter in good condition; I did not lose a colony. I think that fully 80 per cent. of the bees in Northern Michigan have wintered.

**Bee-Keeping in Kentucky.**—G. W. Ashby, Valley Station, & Ky., on April 5, 1886, writes :

For the last 10 days we have had one continued series of rain, hail, and snow storms. During the few days of warm weather that we had in March, the bees brought in pollen plentifully, and some water. I have a few Northern willows that the bees literally covered in their eagerness to gather everything in bloom. I have made some inquiry, and find that there has been but little loss in wintering, except among my bees. I have lost  $\frac{1}{4}$ ; all by not feeding them early enough to give them time to cap their stores over, consequently it soured, and the capped honey was so scattered that they died, with plenty of honey, but they could not get at it. Some have lost 1 or 2 in 30 colonies; some none in 15 to 20. We have some "bee-gum" men here yet; one has 11, and lost one. He has 2 colonies in patent hives that wintered all right. Working on Oats and Corn.-Dr. C. C. Miller, Marengo, & Ills., on April 14, 1886, says:

We have had very little weather for bees to fly, but they worked up about 2 bushels of ground corn and oats vesterday.

Sectional Hives .- II. M. Noble, Swedesburgh, Iowa, writes :

Are not bee-keepers deceived by discarding the Langstroth Hive for the different traps that are being manufactured now? I am about as old a bee-keeper as there is in the United States; I have kept bees over 50 years, and I find that the less fixtures you have the less profit. Why, I saw a bee hive 40 years ago that was in sectional parts so that one part of it could be taken off by cutting the combs with a wire. Any part could be reversed except the top section.

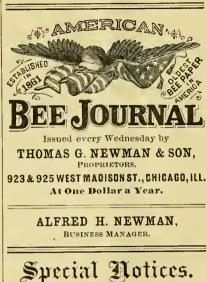

Bee-Keeping in Texas.-J. W. Eckman, Richmond, Texas, on April 6, 1886, writes :

On Jan. 28 bees commenced carrying in pollen. We have had a good deal of cold weather since that time. I had my first swarms on March 31. It is now nearly cold enough for frost, which stopped swarming to-day. From 190 I increased my apiary to 270 last season, and took 23,000 pounds of extracted honey. I have taken out about 1,000 pounds this spring that was left in the hives last tall on proceeding and there is a state of the season of the se of sickness, and there is account about 3,000 or 4,000 pounds more in the hives that should be taken out, but I cannot on account of starting robbing. Our bees do all their swarming in April and the first of May, and gather no surplus honey until the middle or latter part of May, when basswood and horse-mint come into bloom.

Fine Prospect for White Clover.-Geo. W. Morris, Cornishville, Ky., on April 7, 1886, writes :

My bees have wintered well, con-sidering the small amount of attention given them. I lost only one colony out of 20, and found another one that was queenless, which I gave to another weak colony. On March 14, 15, 16, 17, and 18, bees had good flights, and brought in some pollen; since then they have not had much chance to fly on account of cold, rainy weather. In looking over 108 colonies of my neighbors base. colonies of my neighbor's bees, I found 15 dead colonies. They were, in the most part, black bees that suc-

cumbed. We have a fine prospect for white clover this season. I have already seen young bees on the wing. Snow has been falling for two days and nights here; it is now about 4 inches deep.

To Correspondents. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

Our New Catalogue of Bec-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Pestal Card for it.

----

Preserve your papers for reference. If you have no BINDER we will mail you one tor 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

Frank Leslie's Sunday Magazine is redolent of Spring both in text and illustration. The Easter Festival, which comes this year on Apr. 25, its latest possible date, is largely dealt with. The "Ancient Customs of Easter Day," is a very interesting article, and Dr. Talmage's sermon, "The Queen of Festivals," is a powerful presentation of Easter lessons. "The Flight of the Bells," with its pretty picture, is a quaint Freoch Easter legend. Full installments of the several serials, and many appropriate and enjoyable short articles and poems are in it. Altogether this May number is an exceptionally interesting one.

### Honey and Beeswax. Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a.m., April 19, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

\* HONEY.-Comb is coming forward more freely and prices now are 15<sup>a</sup>/a16c, for 1-lb. sections. Ex-tracted is in light demand at 5@7c. California comb honey, in 22b, sections, 9@12c. BEESWAX,-23@24c, per lb. Not much offered. R. A. BURNETT, 161 South Water St.

### NEW YORK.

NEW YORK. HONEY.- We now quote : Fancy white comb In 1-1b. sections, 12@13c.; In 2-1b. sections, 9@10c. Fancy buckwheat honey in 1-1b. sections, 9c.; in 2-1b. sections, 7@8c. Of grades 1@2c. per lb. less. Extracted, white,6@7c; buckwbeat, 5@5%c. Cali-fornta, 5@6c.; Southern, as to color and flavor, per gallon, 50@64c. BEESWAX.-=27@28c. McCAUL & HILDRETH BROS., 34 Hudson St.

#### BOSTON.

HONEY.-One-b. sections, white clover, 13@15c; 2-pound sections, 11@13c. Extracted, 6@8c. BEESWAX.-25 cts. per lb. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.-White and ex. white comb, 114@13c.; dark comb, 84@8c. White extracted, 84@54c.; amber, 404/c.; dark and candled, 34/4c. BEESWAX.-Quotable at 20/23c., wholesale. O. B. SMITH & Co., 423 Front Street.

#### DETROIT.

HONEY.—The supply of comb honey is consid-erably decreased and prices a trifle firmer. Best white in 1-lb. sections 13:0;14 cts. BEESWAX.—Scarce at 23:0;25c. M. H. HUNT. Bell Branch, Mich.

### ST. LOUIS.

HONEY.—Choice comb, 10@12c. Strained, in barrels, 465c. Extra fancy of brikht color and in No. 1 packages, ½ apvance on above prices. Ex-tracted in barrels, 5@5½. BEESWAX.—Firm at 22%c. for prime. D. G. TUTT & CO., Commercial St.

### CINCINNATI.

HONEY.-Extracted boney brings 4@8c., and choice comb honey brings 12@15c. in a jobbing way. BEES WAX.-In demand at 22@25c. for yellow. C. F. MUTH & SON, Freeman & Central Ave.

#### CLEVELAND.

HONEY.—One pound sections, 14@15c.; 2-lb. 13c [xtracted, 7@8c. BEESWAX.—Scarce at 25c. A. C. KENDEL, 115 Ontario Street. Еż

### KANSAS CITY.

HANSAS CITT. HONEY.—Sales of comb are good, while extrac-ted is very duil and low. One-pound sections are scarce; stocks of all other grades are well supplied. Calif. 2-lbs. bring 11@12c.; Eastern 2-lbs., 12@13c.; 1-lbs., white, 14@15c.; dark, 12@13c. Extracted, 5@66.; Southern, 33@4c. BEESWAX.—23c. ().EMONS&LOON & Co., cor. 4th & Walnut.

#### MILWAUKEE.

HONEY.—This market is very poorly supplied with boney of any kind just now, and comb boney In 1-b, sectons, and extracted in barrels or kegs, is not equal to the demand. We quote: Choice white 1-b, sections, 16@18c. White extracted in kegs or barrels, 7½ 8½c.; dark, in same, 6@7c. BEESWAX.—Scarce at 25@26c. A. V. BISHOP, 142 W. Water St.

Perforated-Zinc .- We have laid in a stock of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, er in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive-19%x14½-Price 25 eents each.

Kendall's Horse Book .-- No beek can be more useful to borse owners. It has 35 engravings, illustrating positions of siek horses, and treats all diseases in a plain and compregensive manner. It has many good recipes, etc. Price, 25c., in either English or German.

There will be a Rush for supplies needed in the apiary after awhile, and we cannot do better than to urge all to look over their stock, ascertain what will be needed, and get it on hand before it is necessary for nse-thus avoiding the perplexity consequent upon its possible delay in reaching them in time.

Alsike Clover Seed,-We can furnish Alsike Clover Sced at \$8.50 per bushel-or \$2.25 per peck. These prices will take the place of those published in our Catalogue, nntil further notice.

Our rates for two or more copies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

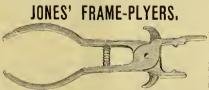

Wire Nails have advanced in price, as will be seen by quotations on page 159, last column.

128 Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to iutervicw by sending the names to this office. or we will send them all to the agent.

FOR SALE, IN 9 and 10 frame hives, all strong and healthy, I wintered in the cellar. Will deliver them aboard of cars-for Italians \$8,50 ; Hybrids at \$7,50. Will guarantee as represented, or money refunded. Italian Queen-Untested, \$1,00 ; Tested, \$2,50. Send money by P. 0. Order or Registered Letter.

16W8t L. J. DIEHL, BUTLER, IND.

FOR taking frames out of hives, or moving them in any way desired. It is H moving them in any way desired. It is made of galvanized iron, and can be utilized in many ways. It has a long claw for loos-ening frames, and a book which may be used for carrying other frames besides the onc held by the Piyers. Price, 40 cts., by mail.

Sprout Brook, Mont. Co., N. Y.

**Those who Plant** potatoes should read the "A B C of Potato Culture" before planting.

Mr. Boar, one of the prominent citizens of Gordon, Ga., met with a most singular death lately. On his return from a trip over his field he noticed bees swarming. He undertook to hive them, when they turned upon him, settling upon his face, hands and neck, and stung him to death.

The Vineyard Men are Speaking Out.—Mr. E. Baxter, one of the proprietors of the "Golden Hills Vineyards," at Nauvoo, Ills., writes as follows concerning the article by Mr. N. W. McLain, in the last issue of the BEE JOURNAL:

I have just read the article on "Bees vs-Fruit," on page 245 of the AMERICAN BEE JOURNAD, which coincides with my personal observations for years past; as I have seen the bees wild and eager for food, on clusters that could yield nothing to them, being sound in the berry.

The evidence is accumulating that bees do not injure sound grapes—and comes from the careful and successful grape-growers themselves.

The Great Enemy of knowledge is not error, but inertness. All that we want is discussion, and then we are sure to do well, no matter what our blunders may be. One error conflicts with another; each destroys its opponent, and the truth is evolved. This is the course of the buman mind, and it is from this point of view that the authors of new ideas, the proposers of new contrivances and the originators of new heresies are benefactors of their species; whether they are right or wrong is the least part of the question. They tend to excite the mind; they disturb the public sloth.—Buckle.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

The Alternating Hive, mentioped by Mr. Kretchmer, on page 264, came duly, and has been examined carefully. This matter reminds us of a story-one that greatly impressed us during our school-days, over 40 years ago. It was this: Two men were coming towards each other from different directions, and both saw a lizard-like reptile on a low branch of a tree. Both men admired its color. One declared that it was bloodred; the other, astonished at the colorblindness of his friend, said he was a foolthat the color was hottle-green. Both men became excited, and quarreled vigorously. They rushed at each other to decide by blows the controversy-when, taking a look at the reptile, each was astonished to find that both were right 1 It was a chameleon. and its color in the sunlight, but reflected the hues of the surrounding objects. Being disturbed by its visitors it became mottled. the colors varying in different parts of the body, as it is capable of doing very rapidly. It was blood-red or bottle-green by turns, and both of the disputants were right !

Just so, in this old hive matter, both are right and both are wrong. Mr. Heddon, no doubt, relied upon what he read in the Patent Specifications; in the last paragraph of the first page it is distinctly stated that "the bottom-board, G, of the box is permanently attached to the sides."

In the hive sent by Mr. Kretchmer the bottom-board is attached to one side only, and in a peculiar manner. It is attached to one end of the alighting-board by a piece of sheet-iron, and also to a piece at the rear of the hive in the same manner. Both the alighting-board and the piece at the rear of the hive, swing horizontally on screws near one corner, by which they are attached to the box.

Mr. Heddon judged by what he read in the Patent Specifications, and Mr. Kretchmer had in mind the peculiar bottom of a hive, as shown in the model—and the story of the ehameleon is a good illustration; fuller light reveals the true situation.

But why discuss these minor matters any further? Mr. Kretchmer says on page 264, that he has "earefully examined Mr. Heddon's hive and special system for which it was constructed," and adds the following as his conclusions :

I most cheerfully admit, with all due honor to Mr. Heddon, that many of the various combinations are new, when applied to that system of management and manipulations laid down in his book; and since reading his patent, I believe that the claims and combinations in it are valid.

We did not intend to have anything to say on this controversy, but now being appealed to by both parties, we have given the foregoing, and hope it will end the discussion now too long drawn out.

L. Reed, Orono, Mich., has sent us a sample of the louse neetar which the bees gathered last fall for winter stores. Of course it cost him a loss of abont 20 per cent. of his bees. Fortunately for Mr. Reed's bees, the winter has been a short and mild one, and he adds:

My bees are now in splendid condition; young bees are playing to-day. We have lately had warm June weather; and no frosts for the last ten days. Bees are working on the soft maples and willows. The prospect is good for a large yield of honey.

In Testing Heeswax, says an exchange, when it is chewed it should have no disagreeable taste, and must not stick to the teeth. In the adulterated wax the nature of the foreign material can generally be detected by the taste; the addition of fat can generally be readily detected. If it sticks to the teeth, the presence of resin may be assumed. A simple method of detecting the presence of fat in wax consists in melting it and placing a drop on a piece of woolen cloth ; after it is perfectly cold and solidified, pour on a few drops of 90 per cent. alcohol, and rub the cloth between the hands. The wax will be converted into dust. and will easily separate from the cloth if it contains no fat, and will leave no stain; when it contains fat it will leave grease spots.

The Hees are Swarming.—This spring is the earliest for many years in this latitude. Mr. John C. Gilliland, of Bloomfield, Ind., writes ns as follows, just as the forms for this JOURNAL are being closed up. It is dated April 22, 1886 :

My Italians cast the first swarm to-day; earlier by three weeks than any previous year. They are working with a rush on rock maple and fruit bloom; with prospect of the best honey season for several years.

New Price-Lists bave been received from the following persons :

F. Boomhower, Gallupville, N. Y.-11 pages-Bees and Queens.

A. Cox, White Lick, Ind.-1 page-Bees and Queens.

A. F. Stauffer & Co., Sterling, Ills.-8 pages -Queens, Bees, and Bee-Keepers' Supplies.

Catonsville Manufacturing Co., Catonsville, Md.-11 pages-Bee-Keepers' Supplies. A. B. Johnson, Clarkton, N. C.-1 page-

Bees and Queens. C. Weckesser. Marshallville, O.—4 pages— Bees, Queens, Plants, etc.

A. I. Root, Medina, Ohio – 40 pages – Bee-Keepers' Supplies.

Thomas Horn, Sherburne, N. Y.-1 page-Bees and Queens. This was accompanied with a queen shipping-cage containing a few living bees, which came in excellent condition.

Any one desiring a copy of either of them, can obtain it by sending a postal card to the address as given above.

Bright, Beautiful and Charming as . May Blossoms comes the American Agriculturist for May. With this number appears the first of the series of engravings of the homes of our farmer presidents-23 inches long, 17 inches wide, executed in the best style of art, and presenting a complete view of Monticello. The engraving likewise embraces front and back views of the residence, the tomb of Jefferson, and also neighboring objects of interest. The long and complete description of the engraving by James Parton, the American historian, will be read with surprising interest. The engravings are presented to all subscribers to the American Agriculturist as they appear. The price of the American Agriculturist, English or German, is \$1.50 a year. We will elnb it with the AMERICAN BEE JOURNAL for \$2.25 a year, each subscriber to receive both papers and the special engraving and descriptions by American authors as they appear.

### **REPLIES by Prominent Apiarists.**

### Taking off Surplus Honey.

Query, No. 242.—The greatest trouble I have is in taking off the surplus honey from the hives. Which is the best way of doing It and save the most bees ?—N. Y.

I do not understand what you are "driving at." All the bees should be saved by any method.-G. M. Doo-LITTLE.

Smoke the bees down in the case of Then remove it quickly to houey. the honey-house, having a bee-escape window.—G. L. TINKER.

Place the cases in a box or room, and the bees will soon leave the combs and fly back to the hive. Of course in a room there must be holes at the tops of the windows, or else windows that open out easily.—A. J. COOK.

The best way to do it is to have light, shallow surplus-cases, and shake out nearly all the bees, and put the cases where the remainder will leave, yet where robbers will not enter. I use a screen-house. I never heard of destroying bees to get them out of the supers.—JAMES HEDDON.

Wintering Bees in a House-Apiary.

Query, No. 243.—A friend of mine has a house apiary. The bees enter by large chutes which are flush with the weather-bearling on the outside : on the inside end of these chutes are placed the hives, which are tall box-hives. The heuse is double-walled, with two large veutilators in the bottem 2 feet square, and one overhead of the same size. Also, on the back end of the chutes, and underneath the hives, arc holes covered with wire-loth. His bees wintered very poorly with plenty of good stores. What was the cause? There is a strong current of air passing continually in at the entrance and eut of the holes at the back end of the chute. Was this a detriment? Each hive is surmounted by a cap packed with hay, and there was not the least bit of glass and combs were often frosted ever. Why was this? Would it be ageed plan to close the outside entrances altogether, open the air heles in the hives on the inside or the house, and keep thereom warm, say 45°, all winter? If not, how should they be pre-pared to winter wel?—D. B. U., Ohie.

I think that house-I do not know. apiaries have failed in most cases to give satisfaction.—A. J. Cook.

I should say that the room was too cold, and the bees had too much ven-tilation also. Forty-five degrees with little ventilation, seems to do the best with me.—G. M. DOOLITTLE.

How do you know that the stores were good? Did other bees in the immediate vicinity winter well, when prepared in a different manner? I cannot say that the current of air was a detriment; it might have lowered the temperature, otherwise I cannot see what harm it could do. The heat arising from the bees probably kept chaff. I should remove the damp HEDDON.

the hay above them dry. I would do as suggested.-W.Z. HUTCHINSON.

I believe that winter losses are caused by low temperature and bad food. I should close np the "chutes" and give the bees ventilation from the inside, and keep the temperature of the room up to 40° to 50°.—JAMES Heddon.

All currents of air are disturbing to bees in winter confinement, especially when entering that condition I am when entering that condition 1 and pleased to call hibernation. The fact that there was frost in the hives is evidence enough why the bees did not winter well. Raise the temperature in the bee-house by all means, closing the outside entrances. If the room be heated the ventilation will take care of itself, and the air be made pure and dry-two of the conditions of success. -G. L. TINKER.

If we were to advise, we would say take the bees out of that house altogether, or open the side so the bees can have sunshine when there is any ; or else keep them at 45° during cold weather. This last way would be the hardest to put into practice.-DADANT & SON.

### Cellar Wintering of Bees.

Query, No. 244.—Weuld a cellar under a residence be a good place to winter bees? It never freezes vegetables.—T. J.

Most likely it would.—C.C.MILLER.

"Yes," if the bees will not be affected by the jar from the closing of doors.—II. D. CUTTINO.

It might be a very good place, and it might be a very poor place. I have used two such cellars this winter. The place I thought the most perfect gave the poorest result. A trial of such repositories is the best test of their fitness for such a purpose.-H. R. BOARDMAN.

Yes, if the temperature can be regulated so as to be uniform the whole season, and be kept about 45°, Fahr., above zero. Unless a uniform temperature can be maintained, it will be found far safer to winter bees on the summer stands. This question of wintering, however, is the bugbear of the business, and as yet it is not well understood, even by the most expert. -J. E. POND, JR.

Yes.—JAMES HEDDON.

### Bees Packed on the Summer Stands.

Query, No. 245.—My bees are in hives packed on the summer stands with the brood-chambers contracted, hay chaff all around and above, and burlap over the trames, with ne top ventilation. Above the burlap is a half-story filled with hay chaff, which is very damp, and in some cases meldy, but the burlap is dry. Would you have recommended taking eff the borlap by Varch 1 and putting in its place enameled March 1, and putting in its place enameled cloth, also replacing a dry chaff cushion? Would it have forwarded breeding and less-ened the chances of spring dwindling?-Rhede Island.

packing and replace with dry. I am not certain that it would forward breeding or lessen the chances of spring dwindling.—W. Z. HUTCHIN-SON.

No, I should have left them without any disturbance.-A. J. COOK.

A better plan would be to remove the damp, moldy chaff and substitute dry chaff. I prefer burlap to enameled cloth until settled warm weather comes.-G. M. DOOLITTLE.

I think that I should have put in dry chaff, leaving on the burlap.—C. C. MILLER.

We do not know that it would have made any material difference with the breeding, but we would always recommend the removing of the packing in March, and using a tight-fitting cloth and a straw-mat over it.-DA-DANT & SON.

On warm, pleasant days the covers of hives should be taken off, and the cushions exposed to the sun. In no case would I recommend enameled cloth over the brood-frames either in winter or spring. It rapidly conducts away the heat of the bees and pre-vents all moisture from arising. When laid upon frames closed up tight with wooden strips in winter, the frames will be found soaking wet. On other hives prepared the same, but without the cloth, all would be dry, showing that <sup>1</sup>/<sub>2</sub>-inch of solid wood is no hindit is, in my opinion, the best winter covering next to the bees that can be used, as it confines the heat and permits the free upward escape of mois-ture.—G. L. TINKER.

My rule is to clean out hives and put on enameled cloth as early as it is safe to examine the colonies. Two points are thus gained, viz: 1. The heat generated is all retained in the hive. 2. This I consider of importance, the moisture is retained also, and the bees enabled to get water therefrom for the brood, when, per-haps, they could not get it outside.— J. E. POND, JR.

If the burlap is all right leave it for the present. Throw out the damp hay and replace with dry, or open the tops of the bives and let in the sun, and it will be all right. It is a benefit to open up the tops of hives to let in the sun and warm it up and dry it out. U.D. CUTTING out.-H. D. CUTTING.

If the bees were dry and healthy I would have left them just as they were. But if there was evidence of were. But if there was evidence of dampness inside of the apartment occupied by the bees, I would have removed the damp chaff and let the sunshine dry out the upper story of the hive, and repacked it with dry material. I methe it a rule to remove material. I make it a rule to remove dampness in the early spring, and let in the sunshine for a few hours. It puts new life into the bees.—G. W. DEMAREE.

I should have made the change you mention, but I should have put on a good board, and discarded the emameled cloth once and forever.-JAMES

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is located near the centre of the State named: δ north of the centre; 9 south; • east; •O west; and this o northeast; `O northwest; A southeast; and 9 southwest of the centre of the State mentioned.

For the American Bee Journal.

The Medicinal Properties of Honey.

### G. P. HACHENBERG, M. D.

The physiological effects of honey are singularly effective, though mild and passive in their character. It occupies a broad line between alimentation and therapeutics, being both food and medicine; therefore it belongs to that class of medicinal remedies that cure indirectly, that is, by putting the vital forces in such a condition as to enable them to overcome diseased action. Mineral waters, cod-liver oil, glycerine, malt, etc., all belong to this class of remedies.

Before speaking of the curative properties of honey we will note its physical properties.

In the first place, where is honey from? Some assert that it is a secre-tion of the bee, others that it is a natural product in plants. If it is a natural vegetable product, the labor-atory would have furnished us, long ago, with genuine honey. It must be remembered that the sugar and glu-cose in the flowers and fruit that bees resort to, is never honey until it has passed through the stomach of the bee, and please do not call this organ a bladder, as some do. It is virtually a stomach and performs the functions of that organ. The bee gathers into it a saccharine material. After its reception, a gastric element is mixed with it for two purposes, one to give it the character of honey, and the other to make it assimulative for the formation of an oil, that is, perfect wax.

It is generally supposed that after a bee returns to its hive with its treasure, that it hurriedly dumps it into a cell and goes out for another, and so on. This is not the case; when the bee returns, from fatigue and under the stupefying influence of digestion, it has to abide its time, both to recuperate, and to get rid of its burden of honey and wax. We have reason to believe that even after the honey is deposited into the cells, it has yet to receive the finishing touch of perfec-tion by the bees, in all probability by here of the hive. The young bees are active house-keepers in the hive; they live on the honey imported, and this rich, concentrated food demands an excess of gastric apply them, changing frequently.

secretion: when coming to a certain point, it creates a regurgitation something akin to vomiting. This the young bee economically puts back into the cells, thus completing the Another process of honey making. Another point as to the character of the bee's stomach: As soon as it is unloaded, an insatiable sense of hunger and restlessness ensues, which at once forces the old bee to work abroad and the young at home. We all know how to respect the buzz of the hungry bee, and admire the sweet disposition of the one that has just finished a sumptions repast. And how rare are family jars when the pantry is ever full. It is Nature's law, in all the same.

We go more especially into these details, to point out the medical properties of honey. It has two physical elements that make it particularly a medicine, viz. 1. An aromatic irri-tant imparted to it by the stomach of the bee. 2. Its ready transformation into fat; without those complicated physiological operations necessary to transfer other saccharine elements into this material.

These make it at once both a local and constitutional remedy. Locally, it is an irritant, sedative, emoluent, detergent, antiseptic, resolvent, rubefacient and a parasiticide. Constitutionally it is nutrient, demulcent, laxative, deobstruent, alterative, tonic, expectorant, restorative, febrifuge, diuretic, diaphoretic, vermifuge and antaphrodisiac, as well as containing certain poisonous properties manifested under peculiar circumstances.

When we say that honey is both an irritant and a sedative we mean that its first effects may irritate. followed with a sedative effect. All liniments work beneficially on this princi-ple, the same with the most of eyewaters, etc. The solution of honey as an eye-water, proves particularly beneficial on account of its antisep-tic, absorbent or resolvent properties. It cures inflammation of the eye, in the way a solution of borac acid does, that is, mainly by reason of its antiseptic and sedative properties.

The irritant properties of honey are. in a great measure, destroyed by dilution. Therefore as a topical irritant, where we wish to favor resolution, by counteraction, it is used in a pure state or in conjunction with other more active irritants. It is its irritant or rubefacient effect joined with its emoluent nature, that precipitate local inflammation into suppuration, and is, therefore, a suitable remedy for abcesses, boils, whitlows, carbuncles, etc. Therefore, wee to the one that applies a honey-plaster over an inflamed eye, in place of the solution! As a rubefacient and ab-sorbent it makes an excellent local application in glandular swelling, and in chronic tumefaction, in particular when joined with iodine, iodoform or mercury.

On account of the temperature of the body, it is difficult to keep pure, undiluted honey on the surface; this can in a measure be remedied by satnrating layers of Canton flannel, and

I speak of it as a parasiticide not only in connection with the theory of the pathagenesis of diseases as advocated by Pasteur, Cohn, Koch, Klebs, and others who have investigated the bacteria, but even those who created several skin diseases, well known by almost every one. Take honey for almost every one. Take honey for the destruction of the bacteria, because of its antiseptic, tonic and laxa-tive effects, its daily use would disarm every dire and malignant disease of its destructive force. Cholera, yellow fever, small-pox, scarlatina and diphtheria may run their course as before, but comparatively in such a mild form as to afford but little anxiety. I only speak of honey as a preventive of malignancy in these diseases, and not as a curative agent.

I have reason to think that it may even serve as a prophylaxis in epi-demic diseases. Last year, Austin and vicinity were afflicted with an epidemic of dengue, prostrating nine-tenths of its inhabitants! My resitenths of its inhabitants! My resi-dence and apiary is two miles south from the city; and I suppose almost every one in our neighborhood had the disease; however my family and servants never took it, although we kept a daily communication with the city, and with persons having the disease. I cannot account for this exemption, which created a great surprise among our friends, unless it was the honey we ate almost at every meal.

The constitutional effects of honey cannot be fully understood and appreciated, except to study it from its medical properties, as represented above. All scientific investigation of remedies are made in like manner. It is the text to a long and complicated sermon. Every physician will read in it such a multiplicity of appli-cations, that would astonish the uninitiated.

As a nutrient I will not speak of it as food but in connection with its properties that serve to arrest the waste of certain diseases, in particu-lar in consumption. The important features of the medical properties of honey lie in the nutrient, expector-ant, deobstruent and restorative effects in the management of consumption, and its alfied diseases. Now let us go back to a fact that exists in the process of making honey. No honey could be had, if it were not for its ready metamorphosis into oil, or in other words in the making of wax, as stated. The great object in the treatment of consumption is to arrest waste. Therefore we resort to the use of oils or remedies that will readily make fat in the system. But the great difficulty in the way, is to get the system to accept these rem-edies and effect their assimilation. Under Leibig's authority we give sugar freely to make fat, but the system often refuses it, as it does the oil, for before it can be assimilated it has to he changed into a glucose, or really into pretty much what honey itself is. This alone gives us a great advantage in giving honey to stay the waste caused by disease, tha have in no other remedy.

Honey in being assimilated is disposed of in three ways: what is not deposited in the cellular tissue as fat, is consumed by the liver, and its volatile principle is eliminated by the lnngs. This elimination is a matter of the greatest importance as a remedy in all pulmonary disorders. But the most remarkable feature of honey as a pulmonary sedative is its administration by atomization and inhalation. The spray arising in extracting, has been proved to exert a very beneficial effect upon cough and dyspnæa, thus revealing its curative tendency. Austin,  $\odot$  Tex.

For the American Bee Journal. "Feeding Sugar—Reversible Hives."

### W. Z. HUTCHINSON.

In my article under the above head-In my article under the above head-ing, I thought I was sufficiently ex-plicit in regard to the difference between *hives* and *brood-chambers*. The hive (not brood-chamber), referred to by Mr. Dadant, and des-cribed on page 149, Vol. I, of AMERI-CAN BEE JOURNAL, was constructed of straw rings or sections 4 or 5 inches high. There were no frames, the combs being built solidly from the top to the bottom of the hive, and when it was necessary to separate the sections a wire was drawn between them, thus cutting the combs apart. In the spring, or if a colouy were weak, only one section was used. As the colony increased in strength another section was added, etc., but the sections were all alike, and there was no point below which the hive was brood-chamber, and above which it was surplus apartment, any more than there is in an ordinary box-hive.

All the other references given by Mr. Dadant refer to sectional hives, not brood-chambers; the purposes and functions of which are altogether different.

If the tiering up of hives is to be considered the same as Mr. Heddon's sectional brood-chamber, then I must sectional brood-chamber, then I must admit that I used too strong language when speaking of the "newness of the grandest of all the grand features of the Heddon hive." I am aware that hives have been formed by tier-ing up several stories; that these stories have been made both shallow and deen; and that brood has been and deep; and that brood has been reared in more than one of these stories, at the same time and in the same hive; but I did not suppose that these hives were made and used in these nives were made and used in this manner in order that the brood-chamber might be divided horizontally in sections; I supposed that other objects were in view in making hives in this manner, and that the result of having brood in more than one section came about incidentally, was considered of no value in itself, and no advantage was taken of the fact. It is, 1 believe, to Mr. Heddon that belongs the honor of discovering that there is an advantage in being able to divide the brood-chamber horizontally, into sectional, interchangeable parts.

All those old hives mentioned by Mr. Dadant, are, I suppose, now dead, and laid aside for something that is adapted to the needs of bee-keepers under the light of the advanced state of the art. I know, by actual test, that the Heddon hive is *practical* and gives the best of results. I said some gives the best of results. I sold some of the "results" last fall, and at a paying price, too, considering how much easier I produced it with the new hive and system of management.

Mr. Dadant says that the reversing of hives has been practiced in France a long time, but is now being aban-doned. Reversing is either a damage or a benefit, according to the propri-ety of doing it. Neither the revers-ing of combs nor the use of sectional brood-chambers necessitates feeding for winter, as I have explained in a previous article, but allows the choice of natural stores in exactly the best shape for winter,

### FEEDING SUGAR TO BEES.

I had never supposed that Mr. Heddon claimed to be original or prior in advocating that the cause of bee-diarrhea was in the food. I think that he never made such a claim. If I am correct, he has simply been a strenuous advocate of the theory.

I have just read Mr. Dadant's able essay on page 325 of the BEE JOURNAL for 1881, and I am pleased to note such able support of the food and pollen theory. I also notice the same doctheory. trine advocated by Mr. Heddon on pages 137, 275 and 283 of the same volume, and all published *previous* to Mr. Dadant's article. Mr. Dadant says that the replacing

of natural stores with sugar costs time and money. If by the use of proper hives and management we get all the honey stored in sections where it can be sold for three times what sugar would cost, and we have simply to make the syrup and feed it to the bees, it appears to me as though it was time and money well spent.

Rogersville, & Mich.

### For the American Bee Journal.

### Opposition to Bee-Keeping.

### C. G. BEITEL.

This is a subject which sooner or later will become a serious matter, if not promptly attended to. While we do not object to an association for the mutual protection of bee-keepers, and for the accumulation of a fund for their defense against the attacks of men, who, in their ignorance, may honestly feel themselves aggrieved by the bees of their neighbors, yet there are two old "saws," namety, "An ounce of prevention is worth more than a pound of cure," and "A stitch in time, saves nine," which may be very forcibly applied to this subject.

By the first I mean, that by education we may teach the ignorant their errors; let them once understand that the bee, so far from being their enemy, is one of their best friends, and we will hear of no more lawsuits about them. This can be accomplished by the diffusion of all the knowledge

upon the subject, collected in pamphlet or book form, and disseminated broad-cast among the fruit-growers; let them once comprehend that it is money in their pockets as well as in that of the bee-keeper, and fruit-growing and bee-keeping will go hand in hand, all over our broad land, as it does now among the more intelligent.

It is true the bee may sometimes be a tresspasser, as for instance, in the drying of fruit, raisins, etc., but this is only in common with wasps, hornets, and the common fly, and here I think the owner is much to blame; he should not dry fruit in the open air without screens; it is a filthy practice and should be condemned practice, and should be condemned.

Again: "A stitch in time," etc.: By this I mean that by prompt action in the matter of education, much litigation may be prevented. The trial of cases before ignorant juries, may, even before ignorant juries, nay, even before judges ignorant on this subject, carried away by the testimony of interested witnesses, may establish precedents in the lower courts, which, if not reversed, will be looked upon by courts of co-ordinate jurisdiction in sister States as guides jurisdiction in sister States, as guides, and in the course of time establish a line of decisions, which now the higher courts would hesitate to shake. Judges do not like to reverse each other—they prefer a uniform system of jurisprudence, and often adopt a ruling inconsistent with their own opiuions, rather than disturb the symmetry of the law; therefore, let these decisions start out right, and soon all will be lovely for the beekeeper.

As a sample of the literature that would recommend for dissemination, I append an abstract from the reports of the State Board of Agri-culture of Pennsylvania, for 1884, by M. W. Oliver, chairman: "To obtain such information as your com-mittee thought desirable to embody in this report, they prepared and sent to a number of prominent apiarists within the State, the following list of questions, viz. [I select but two]: 'Are bees destructive to fruit? Are bees of importance in the fertilization of flowers?" To these questions we have received answers, from which I condense as follows :

To the first we answer : In no sense whatever. We hold to the opinion that so long as fruit is in a sound condition the bees will never harm it; nor have they the power to do so. It is only when fruit is injured by other insects, by over-ripeness, or other causes, that the bees step in to fill their place as nature's scavengers. Many bee-keepers plant grape-vines in their apiaries, and so trellis them as to give shade to the bees. From these vines as perfect clusters of fruit are plucked as from vines not visited by the bees. Our experience has been that while the rose-bugs have destroyed all the fruit on vines just outside, that non the vines in-side the apiary has been found un-molested; so that we count them guardians, rather than destroyers, of fruit.

As to the second: "We hold strongly to the affirmative side of this

question. We hold, with others, that plants only secrete nectar that they plants only secrete nectal that they may attract insects. And why, we imagine you are ready to ask, this need of insect visits? It is that they may serve as 'marriage priests' in the great work of fertilizing the flowers. It is well know that many plants, such as willows and chestnuts, are directions. The male element, the pollen, and the female element, the ovules, are on different plants; and so the plants are absolutely dependent upon insects for fertilization. The pollen attracts the insect to the staminate flowers, while the nectar entices them to visit the pistillate bloom. In the case of the strawberry-of which good old Isaac Walton wrote, 'Doubt-less God might have made a better fruit than the strawberry; but doubt-less God never did '-some varieties would remain barren but for these kindly ministrations of bees and other insects. In some plants, we find the stamens and pistils are on the same flower, but so peculiar are their struc-tural peculiarities that unless insects were wooed by the coveted nectar, fertilization would be impossible."

Here follow a number of experi-Here follow a number of experi-ments to prove what has been stated, many of them having appeared in the BEE JOURNAL before; it is not necessary to repeat them, with one exception, namely: "A member of this committee cites a case which came under his observation, where the yield of an orange grove fell off when, upon the death of the owner, the bees were sold off: and when upon the bees were sold off; and when, upon the establishment of a new apiary, the yield was substantially increased."

The fruit-growers of California might learn a lesson from the fore-going, and if they persist in their suicidal course against the bee-keepers they will ere long find that they were playing with a double-edged sword.

Easton, o+ Pa.

For the American Bee Journal. Management for the Most Honey.

### G. M. ALVES.

How may I manage my bees so as to obtain the greatest amount of honey?

At this season of the year we frequently hear such questions as the above. Now the great difficulty in properly answering them lies in the fact that conditions differ—an answer that would be coad for my lawly would not be good for another locality ity. No man is well litted for beekeeping who does not study the conditions of his locality. To blindly follow a guide-book in all cases is folly. Such books are of great value, but after all we must do our own work in order to succeed.

I propose to answer the above question here in as short a space as possible My answer is based upon repeated tests of different methods, and also upon what I think is a careful study of my conditions. Remember, I am speaking now for my own location stricted nature!" I have found by

and conditions. The directions might or might not hold good for another location. I know they would not for many conditions that I could describe. Readers versed in current literature and opinions, may be surprised at some of my directions, but, fellow-bee-keepers, I have been all along there in practice.

But first let me tell how my bees do But first let me tell now my bees do when left in "unrestricted nature." Eliminating exceptionable years, I have found that the apple, pear, etc., bloom here about April 20. This the bees use to build np on. About May 15, the locust, raspberry, tulip-tree and white clover bloom. The bees use the first three also to build up on, though sometimes they will store tulip-tree honey in the surplus department, but not often. After these are all gone the bees commence on the white clover. For a while they work briskly, and if it is well filled up below, they will carry the honey up-stairs, but as a rule, a lazy spell soon comes over them, and if permitted they will hang listlessly on the shady side of the hive. If driven in, they hang idly in the sections brooding upon "going west." In the meantime the queen has well nigh suspended work, and trims herself-but in no hurry,-for emigration.

All of this idleness goes on when the bive is over-flowing with should-be-workers, and at a time when the white clover is secreting its maximum necclover is secreting its maximum nec-tar. The bees are in no hurry to work or leave. They seem to look around lazily and say, "We've done enough for posterity and now propose to take a good rest before we start out for ourselves." But finally the time does come for leave-taking. Then there is activity in the comb indeed! Out they rush pell-mell, and the queen among them in almost virgin propor-Mind you, now, this hive is right here—not in New York—not in Michigan—not in Ohio—not in northern Illinois, where those bee-books were written; but right here, here in south-western Kentucky. Now what do we find? Those books tell us that we will find " much brood in all stages of development," but we do not at all; and let me say confidentially, that I have always found just what we now find—a great deal of sealed brood, but wery little unsealed brood. See how many empty cells there are. The queen has been too much occupied with her corsets to lay in them, and her daughters have been too lazy to put honey in them.

But for the sequel: The new colony works mightily, but alas! if they can fill their brood-chamber before our dry weather cuts off the clover, they do full average well. We may, how-ever, count on getting some goldenrod honey from them after the Autumu rains begin. The parent colony, if it casts no further swarms, will give, on an average, from 15 to 20 pounds of clover honey before the dry weather comes; and likewise a sur-

repeated tests, that art can improve on nature here.

After trying all the methods of the books, I have found the following one much the best; and it is one that does not require the rearing of a queen: First, as early as practicable, stimu-late by feeding; afterward supplement this by uncapping sealed honey. I have never tried inverting, but I will. I do not like spreading the brood on account of the risk. If the weather is favorable afterward, you have done a good thing; if it is not, you have spoilt your colony for the season.

Now with all stimulating methods we must carefully watch that the bees do not get short in stores, as in such a case we would much better have let them alone. If we have carefully done our work, our hives, by the time the tulip-tree blossoms fail, will be running over with bees. Now we go to each hive in this condition and place on its stand a very contracted brood-chamber (one of Mr. Heddon's cases would be excellent), filled with foundation. Shake every bee in front. Empty frames or frames with only starters will not answer well for the reason that the queen at this time usually begins her resting spell, and at such times the bees are prone to build drone-comb in the brood-chamber. I have tested this sufficiently to accept it with me as a general fact.

Now, on the same day, or the day after, place on a case of sections, and after the bees have filled it about onethird full, put between it and the brood-chamber another case of sections, and so on until the clover sea-son is over. The reason I use a contracted brood-chamber is because I have found by tests that more honey will be gathered than with a larger brood-chamber. I rest on the fact, but I presume the reason is that bees, like people, are inclined to slacken work when they see enough around them; whereas with the contracted brood-chamber they do not see enough around them, and in the necessity of the case must go up-stairs for storage room; and as they continually find a void between the brood-chamber and the honey above, they strive desperately to fill the gap, thus acquiring a momentum of work that stops only with the failing of nectar in the fields.

By this time I presume the readers are curious to know what I am going to do with the old hive which has

to do with the old hive which has honey and brood, but no bees. To every 4 or 5 of such hives I divide out among them a forced swarm procured at a distance of a mile or more, or I do the same with a natural swarm if I have one. They are thus left to rear their own queens on new stands, and I do not expect to get any honey from them until the fall flowers bloom. I find that it does not pay to do more with them.

In conclusion I will state that I have not made my experiments on an extensive scale, as I do not keep many colonies, but I have experi-mented sufficiently to convince me that the method given above is the best in this locality for honey. Henderson, & Ky.

For the American Bee Journal.

## Methods of Wintering Bees.

### C. W. DAYTON.

On page 151, Mr. Heddon renders a "Our great enemy is decision thus : conquered, and the wintering problem is practically solved." I would change it somewhat; it is proved that our great enemy may be avoided, but in so doing the wintering problem is impractically solved. Should Mr. Heddon succeed in wintering quite all of his colonies he will be no more successful than many of his neighbors in apiculture who winter their bees on natural stores. The winter problem has been solved to such extents as that, hundreds of times, but in a general sense it has not been very universal. It is considerably known, however, that a colony without pollen or brood and with stores of sugar syrup is not always subject to the usual amount of disease of ordinary wintering; but that that method would be safer and practical with more than a few, is another momentous question.

That cellarfuls of bees do winter well and without loss on natural stores, one winter after another, ought to be sufficient evidence to show that there must be other solutions of the winter problem, and for all we know there may be several of them. That Mr. H. has, or will, winter his bees successfully this time, probably settles the winter problem with him, so long as he can afford large expense; but the greater share of bee-keepers, will go on trying again and again with natural stores, as they will be obliged to do, and some will discover, as many already have done, a safe and really practical method of wintering bees.

As I understand it, for fear the bees will freeze, Mr. Heddon maintains an even temperature of no less than 45°. That is the temperature required to winter on natural stores, but to leave the hives tightly covered, as he does, fixes the difference between life and death. Simply remove the covers and the pure natural stores are as good as syrup. There seems to be a fancied, (though ever so idle) consolation in leaving the brood-chambers tightly sealed above. If Mr. H. has conducted a thoroughly logical test in wintering bees on natural stores, I believe it has not appeared in the bee-papers.

That bees void substances of a solid nature is not an unfortunate occurrence so long as it is the effects of the watery part that kills the bees; if the cause of the liquid portion is removed there will be no liquid ; consequently no disease or disorder. Where the evacuations are moderate and of a solid nature the bees do well; in fact it is nature and health themselves.

Good authority says that it is harder to sell anything after we get it than it is to produce it in the first place. If this is as true everywhere as it is If this is as true everywhere as it is in my locality it brings the cost of the said-to-be-cheap syrup up to 15 cts. per pound, if honey in the hive is worth 6 or 7 cents. It will be a fine (?) has to quanty of our honey: That his patent I believand from penny-royal is light-colored and but it has too much of the penny-royal flavor to suit my taste. The honey from on page 259.—ED.]

state of affairs, indeed, when every bee-keeper will be rushing his honey on glutted and "hibernating" markets early in the season, and all at once, in order to purchase, with the proceeds, winter feed for his bees; and, as will be the case, not one bee-keeper in 10 is so "fore-handed" as to be able to

while it is desirable to know how to winter bees with the least expense, we must winter them cheaply as well as successfully, because it is so easy for expense to overbalance profit. Bradford, & Iowa.

For the American Bee Journal.

### South Florida for Bee-Keeping.

### HARRY G. BURNET.

In answer to many who are continually writing for information. I will set forth as briefly as possible, the honey-flora of this section of Florida. By South Florida, I mean that portion By South Florida, I mean that portion of the State south of a line drawn eastward from Tampa. Monroe county is the southernmost county in Florida. Alva is situated in the northern part of the county, on the lovely Caloosahatchee river, 35 miles in an air-line from the Gulf-coast. This as to location.

As to the honey-flow: We call about Dec. 1st the opening of the "season," as that is the time when the penny-royal, (Saturia Rigida), not the penny-royal of the North, opensits diminutive blossoms to the impatient bees. This plant is found growing on the second-class pine and "scrub" lands. All through the Manatee, Brevard and Monroe counties, and dur-ing the season of bloom, the whole country is scented with its minty odor. There are thousands and tens of thousands of acres of this bloom going to waste in South Florida every year. The period of bloom extends from about Dec. 1 to Apr. 1, or a little later; but about that time the sawpalmetto opens its creamy blossoms in countless millions, and the bees desert the stronger flavored pennyroyal, for the milder flavored, goldentinted nectar it affords so bountifully.

The bees work on the saw-palmetto, (Sabal Serrulata) until about June 1 to June 15, when they take a vaca-tion until the advent of the bloom among the broad leaves of the tall cabbage palms (Sabal Palmetto), about July 15. Very little surplus is gathered from this source as a general thing, on account of its blooming in the rainy season; but if the weather is propitious, they will do well. This bloom lasts only about two weeks.

There are many other dowers that yield honey here, but not enough to afford surplus. Feeding is unknown. On the coast they have the muchtalked-of black mangrove, but mosquitoes and sand-flies are such pests as to make life a burden.

As to quality of our honey: That

light golden in color, and fully as heavy as the penny-royal honey. That from the cabbage palm is also of

fine flavor, color and weight. As to quantity: I will "draw it mild" and say that we get about 200 lbs. per colony per year, and an in-crease of one. This will seem—and is—a large yield. I cannot be very definite, as I have not kept weight before, but will do so this season and report accordingly. Comb howev does report accordingly. Comb honey does not pay and is not produced. There is room for many bee-keepers here, but to those desiring to come, I would say, come first, look around, and see how you like it—do not decide hastily. Alva, 9 Fla.

For the American Bee Journal.

### The Kretchmer Alternating Hive.

### E. KRETCHMER.

DEAR EDITOR :-- I send you one of my alternating brood-chamber sec-tions for bee-hives (half-width), with bottom and honey-board all made as described in the patent. with letters of reference from the drawings marked thereon. Please examine it and compare it with the patent, and you will find that Mr. Heddon errs in some of his assertions made on page 213. You will find that it has not and never had a "fast bottom," and that it is "capable of heing inverted," although it never was made with that purpose in view; and in justice to Mr. Heddon I will say that I do not know of its being used in an inverted position.

By referring to my article on page 185, it will be seen that I gave it as a scrap of history, and with no desire to wrong Mr. Heddon; it will further be found that I described the sectional brood-chamber idea as *old* and not as patented by me. I simply arranged such sectional brood-chambers with a series of frames clamped within such a chamber with a wedge; standing on a metal strip, the brood-chambers standing on cleats raised above the face of the bottom, as described in my catalogue issued in January, 1884; and above the brood-frames a honey-board with bars arranged for intermediate passage-ways described in the specification of my patent. Then who would not say, when a hive is named with the same arrangements, that such arrangements are not new? Since then I have carefully ex-amined Mr. Heddon's hive, and the

special system for which it was constructed; and since Mr. Heddon admits as old the "double brood-cham-ber" device, unless made in the particular manner in which he makes them, I most cheerfully admit, with all due honor to Mr. Heddon, that many of the various combinations are new, when applied to that system of management and manipulations laid down in his book; and since reading his patent I believe that the *claims* and combinations in it are valid.

[See Editorlal remarks on the above,

# Honey-Plants for Bees.

### J. H. ANDRE.

The honey-producing plants here in a good season are so various that they furnish honey the entire season; consequently, when I first began to read the BEE JOURNAL, it seemed strange to me to see mention of a honey-drouth in some localities in mid-summer

The first to furnish food for the bees here are the common creek willow. alder, skunk cabbage, and poplar, all of which blossom at about the same time. Next is soft maple, then trailing arbutus, which I think furnishes the first honey, and although it is not very plentiful, and its tiny blossoms can secrete but little honey, its extra good quality, and closeness to the ground enables bees to work upon it in windy weather; and according to its size, etc., it is a valuable plant. Dandelion comes next. Last season it furnished food for the bees for over one month continuously. I do not see how it could very well be spared. White clover is next and in a good season it lasts from May 20 until late in October, but if a drouth comes in the last of May, and the season continues dry, it secretes but little honey. The wild red-raspberry then blooms and is far the best of all honey-plants known. It never fails to secrete honey wherever we have plants, but as yet none are cultivated here, and our main dependence is upon the forest fires to start a new crop of plants. There is sometimes a scarcity, but never a complete failure of this plant. I believe that if cultivated plants furnish the same amount of honey accordingly as wild ones, it would pay to plant 1/4 of an acre for each 10 col-onies of bees, even if it did not fruit at all.

Honey-locust secretes well, but only a few trees are grown. Red clover, (the large variety), sometimes fur-nishes an abundance, but it is only once in a great many years that the bees can reach it to gather any amount. The season must be a continuously wet one to make it of any profit. The year 1865 was a season of plentiful The showers, so much so that few plants furnished any honey except white and red clover and buckwheat, and yet it was a first-class honey season. The latter is somewhat uncertain; it seems to do best if there is scarcely while in blossom with heavy dews. Old field balsam, or moonlight, as it is sometimes called, is one of our hest fall pollen plants. Fireweed is one of our late honey-plants. Some seasons I have known surplus stored from it nearly through October. Another plant called Indian pink, (I suppose that is only a local name), sometimes late and sometimes early, is a plant that secretes much honey. I believe that bees will go farther to work upon this plant than any other plant known here. I cannot speak positively in regard to the quality of honey gath-ered from it, but from the very offen-both bc sent for \$1.30.

sive odor of the plant I would not care to take that kind of honey as a choice. Sumac honey I do not fancy either, at least that which is gathered here, but as it blossoms just about the right time for young swarms of bees to get pollen with which to rear brood, and in great plenty at a time of the season when other sources are scarce, it is a great help in that particular. In addition we have corn, heart'sease, goldenrod and dozens of others of minor importance.

In regard to the nearness that apiaries may be to each other with profit, I would say that in all of my bee-hunting experience I have never caught bees at work on the flowers but little if any over 1 mile from the colony. As this is the only way to get anything like facts in regard to the matter, it would seem safe to locate apiaries within 2½ miles of each other. Bees that are forced to go a distance of 2 miles for honey will be of very little profit to their owners as it takes so much time to go and come, and they are more apt to be caught in heavy showers, during which, and if towards evening the weather turns cold, many die on the way, thus keeping the colony thinly populated in spite of brood-rearing. I have timed bees many a time when working on syrup, and it takes them from 10 to 15 minutes to make a trip of half a mile; add to this 5 minutes more when working on the flowers, and 20 more for a distance of 5 miles, (for no heavily laden bee can fly 2 miles without stopping to rest on the way), and it is self-evident that not much surplus will be stored if the bees have to go a distance of 2 miles for honey. I have known of hundreds of bee-trees being found and not one in twenty were "lined" <sup>3</sup>/<sub>4</sub> of a mile. In all of my experience I have only once "lined" bees a distance of a mile.

Lockwood, 9 N. Y.

### **OUR CLUBBING LIST.**

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

Price of both. Club The American Bee Journal ...... 100..

### Convention Notices.

The annual meeting of the Northern Ohlo Bee-Keepers' Association will be held in the New Town Hail at Weilington. O., on Friday, April 30, 1886. All sre invited to come and help make the meeting both pleasant and profitable. A special invitation is extended to the indice. The officers of the Association will be elected at this meeting. H. R. BOARDMAN, Sec.

187 The next meeting of the Linwood Bee-Keepers' Association will be held in Condit's Hall at Rock Eim, Wis., on Saturday, May I, 1886, at 1 p.m. All interested in bee-keeping are cordially invited to attend and make this a profitable meet-ing. B. J. THOMPSON, Sec. ;

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oct. 19 and 20, 1886. J. N. HANBAUGH, Sec.

A cordial invitation is extended to all to attend the 5th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No hotel bills to pay.

B. F. CARROLL, Sec.

TF The next annual meeting of the Western N. Y. and Northern Pa. Bee-Keepers' Association will he held at Randolph, N. Y , on May 4, 1886. A. D. JACOBS, Sec.

**137** The DesMoines Co. Bee-Keepers' Associa-tion will meet at the Court House io Burlington, Iowa, on Tuesday, Apr. 27, 1886, at 10 a.m. Any articles sent to the President, Mr. Geo. Bischoff, at Burlington, for exhibition, will be well cared for and returned or sold, as the sender may direct. A cordial invitation is extended to all interested in bee-keeping. JOHN NAU, Sec. bee-keeping.

The semi-annual meeting of the Western Bee-Keepers' Association will be held in Pythian Hall, N. W Corner of Main and ith Sts. (entrance en 11th SL), at Kansas City, Mo., on Apr. 29 and 30, 1886. The Cable Line can be taken from the Union Depot for 9th and Main Sts. The following essays will be read: "The Honey Market," by Clemens, Cloon & Co.; "Bee-Keeping in Iowa," by E. Kretchmer; "Best method of handling bees for comb honey," by A. A. Baldwin; "Missouri Bee-Keeping," by J. D. Pearce; "Does bee-keep-ing pay as a pursuit ?" by Jos. Nysewander; and "Invertible Frames and Hives," by J. M. Shuck. P. BathuyN. Sec.

P BALDWIN, Sec.

The next meeting of the Cortland Union ee-Keepers' Association will be held at Cortland, . Y., on May 11, 1886, at 10 a.m. 12

D. F. SHATTUCK, Sec.

The next annual meeting of the Micbigan State Bee-Keepers' Association will be held in Ypsilanti, Mich., on Dec. 1 and 2, 1886. H. D. CUTTING, Sec.

The Central Michigan Bee-Keepers' Associ-ation will meet on May 18,1886, with Capital Grange at their Hall in North Lansing, Mich., to hold 3 sessiona, viz: Forenoon, afternoon and evening. All interested in bee-culture are invited to attend and bring articles of the apiary for exhibition. For any special information address the Secretary,

E. W. WOOD, N. Lansing, Mich.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a Binder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few hours, to get subscribers.

Kendall's Horse Book .-- No book ean be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 25e., in either English or German.

### Local Convention Directory.

1 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetinga.-ED.

Clean and Healthy Bees.-Wm. G. Gosney, De Mossville, & Ky., on April 10, 1886, says:

In November, 1884, I packed 75 colonies of bees in fine condition. In the spring of 1885 I sold one colony, burned one, and had 50 left. In burned one, and had 50 left. In November, 1885, I packed 59 colonies, and I now have 52 in moderate con-dition. I took 40 pounds of comb honey last year, and now I will have to feed about 20 colonies. My bees are clean and healthy, and I hope never to meet another year like the lost last.

Good Results.-L. J. Diehl, Butler, 6 Ind., on April 15, 1886, writes :

I have some of the strongest colonies that I ever had come through the winter, after being housed up in the cellar for over 4 months. I com-menced the season of 1885 with 61 and hives well filled up with honey; besides, they gave me over 2,600 pounds of surplus all in one-pound sections—the finest lot of honey I have ever taken. I do think I can realize more profit on bees than I can on the same amount of capital invested in any other pursuit that I ever have tried.

Encouraging Prospects.-Mr. E. Henkle, Washington, C. H., Q O., on April 20, 1886, writes:

doubled up last fall. I have never had bees come through the winter so strong and bright as they have the past winter. There are no signs of diarrhea. Last spring I lost 18 colo-nies out of 52 with the diarrhea. I feel very much encouraged for the prospect this season. The cherry and plum trees are now in full bloom, and apple bloom will be out in a few days. The weather is fine, and the bees are working from daylight till dark, and young brood is hatching very fast. I do not see that the snow-storm that we had the first six days of April in-jured the bees any. I feel now that we are going to have early swarms this year, and I look for a good crop of honey, as white clover looks very fine. I have 11 acres of Alsike clover close to my apiary. If I only can do as well as that man who reported in the BEE JOURNAL, 2 or 3 months ago, about getting 15 barrels of honey, last year, from 31 colonies, I would surely feel myself able to take the BEE JOURNAL another year! I have exactly the number, so now look out for the result l

Stark Co., O., Convention.-Mark Thomson, Sec., Canton, & O., on April 15, 1886, writes:

The bee-keepers of Stark and adjoining counties met in Grange Hall at Canton, O., on April 13, 1886, and organized the "Stark County Bee-Keepers' Society." A very pleasant Reepers' Society. A very preasure and profitable meeting was held, and there are prospects of great good being done to our pursuit through the instrumentality of this Society. The next meeting occurs on the last Tuesday in August, 1886.

Late and Cold Spring.-J. C. Wilson, Ridgeland, 9 S. C., on April 10, 1886, says :

My bees are a month behind. Last year I had my first swarm on March 8; this year my first swarm is recorded "April 9." Unprecedented cold winter and a late spring has reduced strong colonies almost to nothing. feel very much disappointed at my prospect being blighted. Last year I produced 825 pounds of honey from 12 colonies, and as I was this year one year older, and therefore the better prepared both in knowledge and apiarian appliances, I had hoped to do much better. But nothing daunted by the bad prospect, I shall push for-ward with the hope of a reasonable success.

### Bee-Keeping in Ontario. - R. F. Holtermann, Brantford, Ont., writes:

Having delightful weather for bees, and noticing to-day that maple is in bloom, it will not be considered altogether premature or valueless to give a brief report of the general condition of our bees. I have the reports of at least 10 bee-men possessing over 100 colonies, in different parts of Ontario, I started in the winter with 35 colo-nies, all packed on the summer stands with chaff and leaf cushions. I now have 31 colonies, having lost 4 weak colonies that ought to have been

great many possessing from a few colonies up to 100, and the percentage of loss is very small, and the general condition excellent. The mercury has fallen fully as low as last year, although if I mistake not the duration of severe weather was shorter. In parts of Ontario bees wintered outside have had one or two cleansing flights. I should very much like to see a report of the relative degree of humidity for a number of years, and this report connected with the general condition of bees in the spring. I should be yery much surprised if Mr. W. H. Tuttle's 2 colonies, mentioned on page 234, as having drones, mentioned on page 234, as having drones, were not queen-less; that is, if they were at home when seen, which is probable. In reply to Mr. A. C. Fassett's question on page 235, 1 would say that every one would be inclined to come to the conclusion that they were starving conclusion that they were starving. I have seen colonies starved for foul brood act in that dormant manner and revived by such feeding. It is the very last stage before death, and although a higher temperature may in a measure temporarily revive them, -food only can save them from death.

Successful Wintering.-J. P. Henslev, Grand Island, O Nebr., on April 15, 1886, writes :

I began in 1885 with 1 colony, in-creased it to 4 last season, and last fall contracted them to 6 frames each. I contracted them to 6 frames each. They were partly filled with natural stores, and I gave them the balance in sugar syrup, and all was nicely capped by Dec. 26. I then packed them on the summer stands in dry oats chaff, 6 inches deep all around, bottom, sides and ends. I unpacked them to-day, when, lo and behold, I found them with over half the stores that they began the winter with and that they began the winter with, and I think as strong as most of the colo-nies usually are. I think that I hit upon the right way to winter bees. Take care that they are properly packed, and have plenty to live on, notwithstanding the pollen theory, and I see no reason why we should have very heavy losses. It has been very cold here, and raining almost every night this month, but to-day it seems as if spring had come to stav. that they began the winter with, and seems as if spring had come to stay.

Expecting Early Swarms.-6-J. W. Buchanan & Bro., (25-16), Eldora, ⊙ Iowa, on April 20, 1886, write:

Bees in this locality have wintered very well, where they were in good cellars. Those wintered outside, or in cold cellars, have not done so well. Out of 20 colonies in the cellar we lost 7, and 2 out of 5 on the summer stands, packed in chaff. Our cellar was divided into two apartments-one for the bees and the other for vegetables. Part of the bee-cellar was un-der the sitting-room, and part under a bed-room. The end of the cellarunder the bed-room was too cold. The

leaving plenty of honey in the hive. We have 14 splendid colonies, and 2 weak ones. They are very busy now carrying in honey and pollen. Soft maple is in bloom, and is the best we have ever seen it. Box-elder will be in bloom in a few days. Colonies are very strong, and we look for early swarms.

**Strong Colonies.** — Esau Russell, Tiffin, •+ Iowa, on April 18, 1886, writes :

I put my 40 colonies of bees into the cellar on Dec. 5, and took them out on April 8 and 9. Every colony was living and was extra strong. They commenced to carry in pollen immediately, but would not take to meal. They seem to have plenty of natural pollen. The colonies are stronger than I ever saw any in the spring. My cellar is not walled, and I have never found but one dead colony in it since I have kept bees.

House Wintering of Bees. – W. Mason, Fillmore. + O Ind., on April 16, 1886, says:

My bees had a few days about March 18 for a flight, and took in some pol-len and stores fed them. I carried my bees to their summer stands on March 10. I have rather weak colonies, 2 being queenless. I had lost 3 before my last report, but I have 26 that are very strong in bees and brood. I like the house-wintering, but there is something to be learned from experience to make it a success. Being at Greencastle, on April 14, I visited Mr. A. O. White's apiary; we examined his White's apiary; we examined his bees, and found them in fine condition, 4 being a little short of stores and being fed; one we noticed in particular was very full of brood, with a fine lot of young drones, and almost ready to swarm. The most of his bees were wintered in the cellar. He will try it again.

**Profitable Experience with Bees.**— Mrs. J. F. Upton, Bath, Q Maine, on April 18, 1886, writes :

I had 3 colonies of bees a year ago in March, which I had wintered in the cellar. I moved 3 miles on March 10, so the bees had to be put out at that time after going so far. I lost a good many in the light snow on their first flight, still they did well, and each colony swarmed in June. I gave away one swarm, leaving five from which I got 175 pounds of honey; 95 pounds I sold at the house at 25 cents a pound; 40 pounds I gave to friends, and I have now on hand 40 pounds more. All of it was in twopound boxes, but as nearly every one wanted one-pound boxes. I wintered 4 coloniessafely, as the fifth, being in very poor condition in the fall, died; but as they were nearly all drones, and were in a "Cotton" hive I was glad of it, as I wished to get rid of that kind of hive. My cellar was so warm, and the bees so uneasy, that I put them on the summer stands

early in March. On April 16 I sold a colony for \$10, and have two more engaged as soon as they swarm. I like to keep bees, though they sting me often and poison me very badly. I think they have paid their way though; but of course I am not making a fortune at the business. My expenses have been light, so there has been some profit.

Good Prospects.-W. Frank Storm, Lexington,⊙ Ky., on April 18, 1886, says:

The loss of bees in this part of Kentucky is fully one-half. There has been almost a clean sweep among the bees of box-hive bee-keepers, but our propects for a crop of clover honey is good.

**Bees in their Glory.**—S. L. Sherman, Oskaloosa, Q Iowa, on April 20, 1886, writes :

The weather here for the past two weeks has been warm, and the bees are in their glory. I have now S4 colonies out of S6, fall count. The last 2 or 3 mornings the bees have just been a-booming from before sunup till about 9 a.m.; then again from about sundown till darkness puts a stop to operations. Can they be working on honey-dew? They come in heavily laden, but have no pollen on their legs. The blossoms on the boxelder are the only bloom I can see the bees at work on. Currant and gooseberry are just beginning to bloom. Everything is favorable for a good honey-season.

honey-season. P. S.—I have just been out examining the bees, and I find them at work on the soft maple and cotton-wood, which are just coming into leaf, the blossoms having fallen off. I expected to have to feed some, but if this flow continues a few days more I will have to extract.

When to Put a Section-Case On.— John W. Brockenbrough, Coffee,⊙ Va., on April 14, 1886, asks :

I had much trouble with my bees sticking the top of the hive to the frames, when I took the section-case off for the winter; and now, when should I put the section-case on ? They also stick the section-case to the frames. Please let me know what I can do to keep them from doing so. I use the Langstroth hive with the Heddon section-case.

[Put on the cases when't the honeyflow begins. To prevent the bracecomb trouble you mention, nse the skeleton, zinc, break-joint honeyboard, and proper bee-spaces, a scant  $\frac{3}{6}$  inch.—JAMES HEDDON.]

Bees and Grapes.—H. Sontag, Cucamonga, Calif., writes :

rid of that kind of hive. My cellar I have a vineyard about one mile features. "Honor to whom honor is was so warm, and the bees so uneasy, distant from my apiary, sustaining due," should be the motto of every-that I put them on the summer stands much loss by ground-squirrels and body.

quails, but i had a notable experience last year about the damage it is said that bees do to the grapes. I usually dry my raisin-grapes in the apiary or by the side of it. I expected a leavy loss of raisins by the bees last season, as it was a dry one; but I saw less bees working on the grapes than any previous year. The reason was, that I do not remember of seeing one yellow jacket. These and the quails puncture the berries first, and then the bees of course suck them after that, but not before, as bees are not able to cut the skin of grapes, because their mandibles work like scissors, not like a gimlet or a knife. That is the reason that they are able to cut paper, cloth, etc.

Killing the Young Bees.—Thos. J. Bell, Opelousas, La., on April 26, 1886, writes:

I have one colony of bees that I cannot tell what is the matter with them. The old bees are killing the young bees, or pulling them out of the hive. They drop on the ground and are unable to fly. The bees of the colony are pure yellow Italians, with a large, beantiful, and very prolific Italian queen. There is plenty of pollen, and the bees are storing honey, and as it is the only colony so affected in the apiary of 100 colonies, I do not know what to make of it. Does any one know why they should kill the young bees?

Not One Colony Lost.—D. D. Herrick, Libertyville, & Ills., on April 18, 1886, writes :

I carried my 13 colonies of bees into the cellar on Dec. 15, 1885, and left them until March 15, when I took them out for 3 days, and then put them back until April 15. When put ont again they carried in pollen in less than an hour. I never have seen colonies stronger or better, and I did not lose one.

Half Bee-Spaces.-M. M. Baldridge, St. Charles, & Ills., writes as follows:

It is said by some that there is nothing new about the Heddon hive. This may be true, but as yet I have seen nothing *in print* to convince me that Mr. Heddon is not the first and original inventor of the half bee-space over and under the brood-frames, or over and under the wide-frames for sections; or the full bee-space over and under the brood-frames, and wideframes for sections, when secured at will, as described by Mr. H., and when used for the purposes set forth by him. As Mr. H. does not claim a hive made simply of two or more stories, nnless provided with a half bee-space over and under the frames, or with a full bee-space over or nnder the same at will, bee-writers are surely wasting time and space in describing old hives, having two or more stories, that never had these *new* features. "Honor to whom honor is due," should be the motto of everybody.

Issued every Wednesday by THOMAS G. NEWMAN & SON,

PROPRIETORS. 923 & 925 WEST MADISON ST., CHICAGO, ILL.

At One Dollar a Year.

ALFRED H. NEWMAN. BUSINESS MANAGER.

# Special Notices.

To Correspondents. - It would save ns much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending ns two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

Perforated-Zinc,-We have laid in a steck of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces ent to fit the Langstroth hive-1934x141/2-Price 25 cents each.

There will be a Rush for supplies needed in the apiary after awhile, and we cannot do better than to urge all to look over their stock, ascertain what will be needed, and get it on hand before it is necessary for nse-thus avoiding the perplexity consequent upon its possible delay in reaching them in time.

Alsike Clover Seed .- We can furnish Alsike Clover Seed at \$8.50 per bushel-or \$2.25 per peck. These prices will take the place of those published in our Catalogue, until further notice.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a.m., April 26, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.-Comb is coming forward more freely and prices now are 15±016c. for 1-ib. sections. Ex-tracted is in light demand at 5@7c. California comb honey, in 2b. sections, 9@12c. BEESWAX.-23@24c. per lb. Not much offered. R. A. BURNETT, 161 South Water St.

NEW YORK.

NEW YORK. HONEY.- We now quote : Fancy wblte comb in 1-b. sections, 12@13c, in 2-b. sections, 9@10c. Fancy buckwheat honev in 1-b. sections, 9c; in 2-b. sections, 7@8c. Off grades 1@2c, per b. less. Extracted, wblte #@7c; buckwheat, 5@5%c. Cali-fornia, 5@6c; Sonthern, as to color and flavor, per gallon, 51@6/c. BEESWAX.-DUCYDERT BUDG 24 Hudson St

MCCAUL & HILDRETH BROS., 34 Hudson St.

### BOSTON.

HONEY.-One-b. sections, white clover, 13@15c; -pound sections, 11@13c. Extracted, 6@8c. BEESWAX.-25 cts. per lb. BLAKE & RIPLEY, 57 Chatbam Street.

### SAN FRANCISCO.

HONEY.-White and ex. white comb, 114@13c.; dark comb, 64@8c. White extracted, 54@634c.; amber, 464%c.; dark and candled, 34@4c. BEESWAX.-Quotable at 20@23c., wholesale. O. B. SMITH & Co., 423 Front Street.

#### DETROIT

HONEY.-The market is almost bare of comb honey, and very little is wanted. Best while in 1-b, sections 14 cts. BEESWAX.-Scarce at 25c. M. II. IIUNT., Bell Branch, Mich.

#### ST. LOUIS.

HONEY.—Choice comb, 10@12c. Strained, in barrels, 4&5c. Extra fancy of brikbt color and in No, 1 packares, ½ apvance on above prices. Ex-tracted in barrels, 5x65%. BEESWAX.—Firm at 21½c. for prime. D, G. TUTT & CO., Commercial St.

### CINCINNATI.

HONEY,—Trade is periaps dulier than usual. We quote : Extracted honey brings 4@8c., and choice comb honey brings 12@15c. ha globbing way. BEESWAX.—In demand at 20@25c.for yellow. C. F. MUTH & SON. Freeman & Central Ave.

#### CLEVELAND.

HONEY.-- One possi-Extracted, 7@8c. BEESWAX.-Scarce at 25c. A. C. KENDEL, 115 Octarlo Street. HONEY .- One pound sections, 14@15c.; 2-lb. 13c

HONEY.—Sales of comb are good, while extrac-ted is very dull and low. One-pound sections are scarce; stocks of all other grades are well supplied. (ailf. 2-bs. bring 11@12c.; Eastern 2-bs., 12@13c.; 1-bs., wbite. 14@15c.; dark, 12@13c. Extracted, 5@66c.; Southern, 3%@4c. . BEESWAX.—32c. CLEMONS, CLOON & Co., cor. 4th & Wainut.

### MILWAUKEE.

MILWAUKEE. HONEY.-This market is very poorly supplied with honey of any kind just now, and comb boney in 1-b, sectons, and extracted in barrels or kegs, is not equal to the demand. We quote: Choice white 1-b, sections, 16@18c. White extracted in kegs or barrels, 7%28%c.; dark, in same, 6@7c. BEESWAX.-Searce at 25@26c. A. V. BISUOP, 142 W. Water St.

E Our rates for two or more copies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

Wire Nails have advanced in price, as will be seen by quotations on page 159, last column.

To any One sending us one new subseriber with their own renewal (with \$2.00), we will present a copy of the new "Convention History of America."

### System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are as follows :

For 50 colonies (120 pages)......\$1 00 100 colonics (220 pages)..... 1 25
 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few col-

onies, give room for an increase of numbers and still keep the record all together in one book, and are therefore the most desirable.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview by sending the names to this office, or we will send them all to the agent.

Preserve your papers for reference. If you have no BINDER we will mail you one for 75 cents, or you can have one FREE if you will send us 4 new yearly subscriptions for the BEE JOURNAL.

nn

We have Received a copy of the "Report on Agricultural Colleges and Experimental Farm Stations, with suggestions relating to experimental agriculture in Canada, by Prot. Wm. Saunders, F.R.S.C." It is quite an exhaustive report, and shows that Canada is alive to the proper means of education, in the department of agriculture.

Dr. Miller's New Bee-Book is now published, and all orders already received will be filled before this paper is in the hands of its readers. A glance at the index, which covers six pages, will reveal the great number of subjects which the Doctor discusses. The book is printed on nice paper, and is bound in eloth, and makes a nice volume. It can be obtained at this office for 75 cents, postpaid.

**Dakota.**—The second annual Territorial Fair will be held under the auspices of the Dakota Board of Agriculture, at Huron, Sept. 6 tn 10, 1886. Fifteen thousand dollars in preminms will be offered ; \$350 in cash for the best county exhibits. Reduced railroad rates on all railroads. Free transpertation for stock and exhibits. Premium list will be ready Jane 1. It can be obtained of W. F. T. Bushnell, Secretary, Huron, Dak.

A Success at Last, says Mrs. L. Harrison, in the Prairie Farmer, is the heading of a circular now upon my desk, describing a "simple device, which is a complete protection to bees against the ravages of the beemoth. It is a simple attachment to the platforms upon which the hives rest."...I cannot recommend this wonderful piece of mechaoism, which is furnished with a tank of water to drown the millers in, but 1 can put in a word for a trap that I have used for years with success, and is not patented. It is called the Italian Bee. A tea-cupful of them will protect the combs in a hive. The honey produced by these bees seldom becomes infested with their moth, after it is removed from the hive. I should forget these pests entirely if I was not reminded of their presence by the patent eatchers.

| The First of MayMr. W. J. Cullis           |
|--------------------------------------------|
| ft. Sterling, Ills., send us the following |
| he ''May Day '' :                          |
| The oriole is carroling                    |
| Its sweetest songs to-day,                 |
| The blue-bird in the elm-tree              |
| Now trills its softest lay.                |
|                                            |

The partridge drums, perched on the fence, In solemn cadence low :

The BEES are busy 'mong the flow'rs, A-humming to and fro.

The lambs are sporting merrily On yonder hill-slope there, While flights of songsters, cheerily Sing, gamb'ling through the air !

- Sounds like these one loves to hear, They fill the soul with mirth ; They drive away dull thoughts of care— Their glory is their worth.
- But the sweetest sound with pleasure fraught,
  - That I have heard to-day,

**Mr. Bohn**, who has been sned by the raisin growers of California, has met with another calamity. Concerning it Mr. M. Segars, of San Bernardino, writes as follows:

Mr. B. has recently lost one of his aplaries —abont 200 colonies—by fire. The insurance agent informed me that it was purely a case of incendiarism, as rain fell the night before, and green grass was growing between the rows of hives. It is generally believed to be a new method adopted by one or more fruit-men to decide the case of bees vs. fruit. An effort by fruit-men is being made to convey the impression that Mr. Bohn burned his bees to obtain the insurance money. This cannot be considered for a moment in view of the fact that we are on the threshold of a bountiful crop, having had timely and abundant rains, and that the bees were insured for only \$3 per bive. No bee-keeper having such grade of bees, and in such condition, would think of selling at this price. It is hard to predict to what extent the bee-industry will suffer by want of zeal in the defense of this case.

The case is to come on this month, and though the bee-kcepers of California do not seem to be alive to their interests, we have aided them to vigorously prosecute the case.

The Hlustrated Australian Bee-Manual, and complete guide to modern bee-culture in the Southern Hemisphere, by Isaae Hopkins, Matamata, Auekland, New Zealand, is the title of a book on our desk. It contains 336 pages, and covers the entire ground of modern bee-keeping. We have had no time to examine the contents of the book, but will publish a review in a future number.

Through Mr. Hopkins we learn that the past season has been a very fair one throughout New Zealand, for bee-keepers. He estimates the honey erop of that island at over 300 tons. With such a prospect it is no wonder that Mr. Hopkins has issued such a good bee-manual.

Let No One be Deceived by supposing that the bees are gathering "lots of honey," becanse they have noticed a few of "the flowers that bloom in the spring." The "perfect sea of bloom," with "the genial sunshine," will entice the bees and tell a better story !

A Good Place to Stop.—Mauy of our subscribers complain of the tiresome discussions on the Reversible Hive that have been given a place in the BEE JOURNAL during the past three mouths.

As a "new system of management" in bee-keeping, it was perfectly proper and desirable to discuss it thoroughly in our columns, but it has now come to a discussion about the hive, the validity of the patent, and matters only appropriate in the advertising columns of bee-papers. Here are two samples of many letters which we have received. A subscriber from Louislana sends us this question :

Do you not think that the columns of the AMERICAN BEE JOURNAL are getting pretty well used up for advertising Heddon's hive? We have no objection to Heddon's new ideas, but give us something else than those long discussions of no interest to the majority.

Another, from Michigan, sends us this query:

query: Is the Heddon hive controversy the best thing with which to occupy so much space in the BEE JOUNNAL? While I do not object to the new hive, I am quite well satisfied with the Langstroth, and want to read in the BEE JOURNAL something besides discussions concerning the validity of somebody's patent. If Mr. Heddon wants to advertise his hive, let bim do so in the advertising columns; and if any one wishes to oppose him, let him advertise a better hive in the same department, and relegate all questions on the validity of the patent to the United States conrts. At all events, give us something else in the reading columns of the BEE JOURNAL.

We have now arrived at a good place to stop. Mr. II. is entitled to reply to questions and criticisms, and in this week's issue, he has replied to them, and now we will dismiss the subject.

We have a lot of articles on hand discussing different points of the hive controversy —but to publish them will but prolong the unprofitable discussion, and disgust our readers. If the writers of these articles desire it, we will return them—if not, we will dump them into the convenient wastebasket.

We have endeavored to control the controversy—to pour oil on "the trenbled waters" of contontion, but when men become excited and engaged in "heated controversy" they are not easily controlled or soothed. Enough has been said to give bee-keepers a good idea of the invention and "new system of management," and now we may safely talk of other and more important matters.

New Price-Lists have been received from the following persons :

J. B. Hains, Bedford, O.-8 pages-Apiarian Supplies, Bees and Queens.

A. J. & E. Hatfield, South Bend, Ind.-6 pages-Bees and Supplies for the Apiary.

Ihring & Fahreuholtz, Berlin. Germany.— 12 pages—Mannfacturers of Comb Foundation Presses, etc.

Any one desiring a copy of either of them, can obtain it by sending a postal card to the address as given above.

**Do Not Divide Colonies** until after they are strong in numbers and have commenced preparations for swarming, and then only with caution. Too many colonies are *divided* to death.

**REPLIES by Prominent Apiarists.** 

## When to Unite Weak Colonies.

Query, No. 246 .- Is it better to unite weak colonies early in the season, or just before the white clover blooms ?-W. S.

Early in the season.-H. D. CUT-TING.

Just before white clover, according to my experience.-G. M. DOOLITTLE.

Here, where we have basswood and autumn flowers, it is best *never* to unite them.—JAMES HEDDON.

would unite them early. Two weak colonies united will sometimes "pull through;" if left alone they may die.—W. Z. HUTCHINSON.

Generally I should not unite them, but if I did, the earlier the better.--C. C. MILLER.

The spring uniting of weak colonies is a mistake, unless they are entirely worthless or queenless, or unless there are already too many in the apiary.-DADANT & SON.

It is better to unite weak colonies just at the beginning of the honey season—unless they are too weak to build up, and are likely to perish, in which case unite early to avoid rob-bing.—H. R. BOARDMAN.

I think by stimulation, close packing on few frames, and giving capped brood from the strong to the weak colones, we may succeed without uniting them. If we have more colo-nies than we wish, we may unite them, which I should do at once.—A. J. COOK.

It is better to unite early. Be sure to cage one of the queens, but if one of the colonies is queenless it is not necessary. Place them near each other, and shake off all the bees from the combs of the queenless colony, and take away with the hive. They will unite without trouble, but it is best to look after the queen, if not caged, in a half hour.—G. L. TINKER.

It does not pay me to unite weak colonies in the spring. I prefer to build them up, even though they are mere nuclei. I can build up nuclei and got a fair group of honcy from and get a fair crop of honey from them if they only fill one space be-tween the combs the first of April. I now have a few such nuclei, and every night the hives are wrapped up with user which is removed in the with burlap, which is removed in the daytime. If I united colonies at all, it would be about 10 days before white clover bloomed.—G. W. DEM-AREE.

I do not believe in uniting weak colonies at all, unless one is queen-less. It is far better to build them up to full strength by drawing on other colonies that can spare a frame of

brood occasionally. Of course if you have but 2 colonies, and both very weak, they may be united in order to save them. In such case use the best queen.—J. E. POND, JR.

## Stimulative Feeding of Bees.

Query, No. 247 .- 1. Will it do to feed bees in order to stimulate them, if the weather is too cold for them to fly? 2. Will feeding amount to anything if they have an abundance in their hives? 3. Will it stimulate the bees to uncap honey already in the hive.-G. W. M.

1. No. 2. It will do some good, if fed very sparingly, but we would not advise it. 3. Yes, beyond a doubt, this is the best spring stimulant.— DADANT & SON.

1. I should not approve of the course. 2. Feeding is a greater stim-ulus to breeding than an abundance of stores in the hive. 3. Yes.-W.Z. HUTCHINSON.

1. Yes, certainly. 2. It certainly will, or does, in our apiary. 3. Yes, and it is as well as feeding, I think.— A. J. COOK.

1. Yes, if they have no stores; otherwise it is not advisable. 2. Not in my experience. 3. Yes, and I deem it the very best method that can he adopted.—J. E. POND, JR.

1. Such feeding is not necessary, in my opinion. 2. I think not. 3. To a certain extent, but one warm day with new pollen is better than a week of all other kinds of stimulation .-- G. M. DOOLITTLE.

1. I would rather not feed them unless there was danger of starving. 2. In case the queen does not lay well, feeding may urge her, but I do not generally find it necessary. 3. It is probably as good as feeding.—C. C. MILLER.

1. They may be fed if it is done judiciously, and with the right kind of feed, without serious results even if the weather is too cold for them to fly out. 2. It increases brood-rearing. 3. If fed in small quantities only to stimulate—yes.—II. R. BOARDMAN.

1. It will not do for me. 2. I am sure it is unprofitable to feed bees that have an abundance of stores. 3. Yes. I discovered this many years ago when transferring bees. Still my bees breed up as fast as they ought to, if they have plenty of sealed stores. -G. W. DEMAREE.

1. No. 2. Not with healtby colo-nies in fair numbers. 3. It will save their nncapping it, and aid them in their work of removal to a point near the brood, but if there are plenty of bees to do it, they will get the honey as fast as they can use it—if it is only there to get, or in the flowers .-- G. L. TINKER.

tion let them alone and you will be just as far ahead when the proper time arrives.-H. D. CUTTING.

My queens will, without any feed-ing, always breed as fast in the spring as the temperature will admit of. Heat is where the lack is, and after many trials I have abandoned stimulative feeding.—JAMES HED-DON.

### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, I0 a. m., May 3, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

### CHICAGO.

"HONEY.-Comb is coming forward more freely and prices now are 15±16c. for 1-lb. sections. Ex-tracted is in light demand at 5@7c. California comb boney. In 2D. sections. 9%12c. BEESWAX.-23@24c. per ib. Not much offered. R. A. BURNETT, 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY.- We now qnote: Fancy white comb in 1-lb. aectiona, 12@13c.; in 2-lb. sectiona, 9@10c. Fancy buckwheat honey in 1-lb. sectiona, 9c.; in 2-lb. aectiona, 7@8c. Of grades 1@2c. per lb. leaa. Extracted, white,6@7c; buckwheat, 5@5%c. Cali-fornia, 5@6c.; Soutbern, as to color and flavor, per gallon, 50@60c. BEEEWAX.-27@28c. MCCAUL & HILDRETH BROS., 34 Hudson St.

### BOSTON.

**Explanatory.**—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark  $\bigcirc$  indicates that the apiarist is located near the centre of the State named:  $\eth$  north of the centre;  $\blacklozenge$  south;  $\circlearrowright$  east;  $\circlearrowright$  west; and this  $\flat$  northeast;  $\circlearrowright$  northwest;  $\circlearrowright$  southeast; and  $\rarphi$  southwest of the centre of the State mentioned.

## For the American Bee Journal. Sections—Difference in Colonies.

### G. M. DOOLITTLE.

Not long since I chanced to see these words in one of the bee-papers: "In the fall, after extracting sections when re-casing the sections of empty combs, (as we use no separators), the combs are not always perfect in the frames; when we find one side a little fuller than the other, we put the two full sides together, and the hollowing sides together. No matter if the tull sides of the comb should touch each other, when the bees begin operations the following season they will cut right through, building out the other sides equally, and the occasional crooked ones are thus made straight."

Upon reading the above I began to wonder if the writer had ever practiced the plan given, and, if so, how it could be that his experience was so much different than mine had been when trying the same plan. In every case where I ever put two combs in sections, or brood-combs even, so that they touched each other, I have found that the bees always left little bridges of comb from one comb to the other, so that when the combs were pulled apart the capping to one or both combs was broken, thus setting the honey to running and making the sections unsalable, unless put back on the hive for the bees to re-cap the cells. In so doing the bees nearly always remove all the honey out of these damaged cells, so that the whole process requires nearly 1/2 as long as it does to fill a section from the start. This causes a great waste of time to the colony, for they are thus kept fussing over a bad job instead of doing new work.

Ing new work. My plan has been to place such crooked combs at the top of a warm room on a piece of canvas until thoroughly warmed through, when the combs can be bent and straightened to the perfect satisfaction of the operator. If any of the cells jut out too far they are shaved off with the uncapping knife. In this way I have a surer thing of it, and as the work is performed in the winter it is much more cheaply done than in having the bees make a "botch job" of it in the summer.

In another paper I find these words: "Colonies are exactly alike, so near as we can discover, and yet one colony yields an excellent surplus, another none. Why is it ?" Here is a question that used to greatly bother me, for I formerly was troubled in the same way, but of late years I have succeeded in making each colony produce nearly like results; *i. e.*, if one colony contains 40,000 bees and produces 100 lbs. of honey, I get about that amount from every colony containing that number of bees ; while one having but 20,000 bees gives a yield of 50 lbs.

After careful study I found that colonies which I pronounced "exactly alike" on June 1, would not be so at the time the honey harvest was at its best. The trouble was that I did not have a thorough knowledge regarding the working-force of my bees at all times, nor of the interior of the hive. For instance, the colony which I called my best on June 1, might become one of the poorest by July 10, at which time the boney harvest arrived. This, as a rule, would be owing to a failing queen, as I have often noticed that a colony which wintered extremely well and goes to breeding rapidly in early spring, does not equal one that wintered rather poorly, but commences brood-rearing in earnest about May 25. The reason is that by about June 10th the queen in the stronger one ceases to be as prolific as the other, and this allows the bees to put the first honey coming in into the brood-combs, rather than forcing it into the sections, as does the other through her extra prolificness later on.

I have often noticed if the bees are allowed to get the start of the queen so as to store much honey in the brood-chamber during the first of the honey harvest, that colony will be an unprofitable one. The remedy is to give each colony only as many combs as the queen will keep occupied with brood, and when a colony is found having a failing queen, either give another queen or remove a part of the brood-combs.

Again, the giving of a colony a large amount of surplus room to start with has a tendency to make the colony an unprofitable one, which has not a force of bees large enough to occupy the whole of the surplus department at once. They seem to become discouraged, and instead of taking possession of a part of it, they will often cluster outside, and crowd the brood out with honey, never entering the sections at all. I usually give only surplus room to the amount of 15 to 20 lbs., and a part of this space has combs in it left over from the season previous, thereby coaxing the bees into the sections with the first load of new honey. In a week, more room is given, and so I continue to give surplus room as needed. In this way I always receive a good yield from all. It is the attending to the little items in bee-culture that gives success.

Official Report of U.S. Entomologist.

Artificial Fertilization of Queen-Bees.

### N. W. M'LAIN.

Since I began this work I have given much thought and labor to experiments in methods of artificial fertilization. No other branch of apicultural experiment possesses the same scientific interest or practical value to the industry of bee-keeping.

Ever since the art of hee-keeping began to be practiced upon scientific principles, the value of exact knowl-edge and perfect control of the process of fecundation has been recog-nized. In 1846 an able German apia-rist wrote: "If it were possible to ascertain the reproductive process of bees with as much certainty as that of our domestic animals, bee-culture might unquestionably be pursued might unquestionably with positive assurance of profit, and would assume a high rank among the various branches of rural economy. And in a current number of one of the most progressive bee-periodicals, a prominent writer on apiculture says : "The apiarist who finds out a sure, safe, and certain method of controlling fecundation as it is controlled in the animal kingdom, will confer a great and lasting blessing upon beekeepers, and be the means of advancing the profession a long way toward perfection." Realizing the difficulties to be overcome, there was little encouragement to expect success. However, all progress " is usually the slow out-growth of repeated trials," and "failures precede successes." Various methods and expedients have been adopted for securing the fertilization of queens in continement, none of which have proved satisfactory.

During the past two years reference has occasionally been made in api-cultural papers to a process of fecundating queens while in the larva and pupa or nymph stage of development, by crushing a drone larva upon the queen larva, or by opening the cell and introducing crushed drone larva upon the nymph queen. In a few instances experimenters have reported that the practice has been success-ful, and that queens thus treated have begun laying fecundated eggs in from one to two days after leaving the cell. In each of the reported cases some important fact in the evidence tending to establish the genuineness of the claim to success seems to have been wanting or doubtful. In consequence, these reports have been received with reserve and often with ridicule.

For putting these claims to the test, I caused a number of queen-cells to be built, and just before the cells were capped I squeezed the contents of the generative organs of nymph drones upon the larval queens. The bees removed the larvæ and destroyed the cells. After other queen-cells were capped I opened them by making a horizontal incision at the base of the cells, and another at right angles down the side of the cell, and laid back a part of the side, exposing the queen pupa. Through the opening in the cell I squeezed the liquid

contents of the generative organs of imago drones upon the pupa queens. The sides of the cells were then replaced and sealed with melted beeswax and resin. These cells were placed in nursery cages and hatched in queenless nuclei colonies. These queens were liberated in nuclei colonies after their wings were clipped. Upon being hatched they resembled fecundated laying queens more than virgin queens. The treatment they received from the bees and their action upon the combs was that of fecundated rather than that of virgin queens. Repeated experiments, however, failed to produce a queen capable of laying fecundated eggs. Still, the fact that the treatment given the embryo queens had to such an extent changed their physiological characteristics was suggestive. From the analogy between the animal and vegetable kingdom, where ripe seed is known to grow better than unripe, it seemed more than probable that the contents of the generative organs of a mature drone would have more virility than those of a drone larva or pupa.

That the active principle in the fluid contained in the procreative organs of the drones attains a degree of activity at a very early stage in their development, is evident from the effect produced by exposing the larval queens to its influence. Con-tinuing the experiment I caused more queen cells to be built. Removing the testes and seminal sac from mature drones with a pair of pliers, the contents were pressed upon the larval queens. The bees removed the uncapped larvæ as before. Most of the pupa queens so treated and placed in nursery cages for hatching died in the cell after assuming the imago state and after being partly colored. I hope to be able yet to discover what principles and practice are essential to success, which seems possible, for many possible opportunities remain untried. While possessing possibil-ities of the greatest interest and value to the embryologist and entomologist, it is doubtful whether a demonstrated method of what may be called par-thenogenetical fecundation would possess the essentials of certainty and permanence in such a degree as to make the method serviceable to beekeepers. It remains to be tried whether a sufficient number of active spermatozoa may be received into the spermatheca of queens while in the larva, pupa or imago state to render them serviceable for any practicable purpose, even if some of the reported successes were true. Failing to succeed by these methods it appears more reasonable that the best time to fecundate a queen is when she wants to be fecundated, or when orgasm appears. Orgasm takes place in from five to seven days, usually in five days after the queen leaves the cell, and continues for eight or ten days, and a few instances are reported where queens have been fertilized as late as twenty-three days after leaving the cell.

When orgasm takes place the generative organs of the queen are highly

excited and much distended. I confined a queenless colony in their hive and gave them a queen-cell which had not been disturbed while maturing, and allowed the queen to hatch. When the virgin queen was six days old orgasm occurred, and on the evening of the seventh day I removed her from the hive and placed drops of the male sperm upon the open vulva as she was held, back downwards, by gently grasping the thorax between the thumb and forefinger. The instant the male sperm was pressed from the testes and seminal sac of a mature drone upon the excited and distended vulva, it was curious to observe the effect. The action of the abdomen and vulva resembled that of young birds while being fed. There was the reaching up after the seminal fluid, and an action of the parts resembling the opening of the mouth and swal-lowing food. As much seminal fluid as could be obtained, by the imperfect method employed, from three or four drones, was utilized and readily absorbed by the queen, after which her wing was clipped and she was dropped on a frame covered with bees returned to the hive and the and bees were liberated. Up to this time her appearance and action was that of a virgin queen. The next morning, 12 hours after exposure to the seminal fluid, her abdomen was distended and her appearance and action in all respects was that common to fertile, laying queens. She was moving about slowly over the combs and peering into the cells, and 24 hours afterward she had 400 or 500 eggs in weeken cells. worker cells. I watched the development of larvæ from those eggs. In due time worker larvæ appeared, and at this date, November 13, worker bees in considerable numbers are being hatched. I then reared two queens from the eggs laid by this artificially fecundated queen, in queenless colonies, and as soon as they were hatched I clipped their wings, and when orgasm appeared they were treated as before described, and in three days one laid a few eggs in worker cells. The other has the appearance and action of a fertile queen, but has laid no eggs, and the lateness of the season forbids advantageous continuance of the experiments.

Fully realizing the necessity for exactness and certainty in all details, before tabulating the results of any method so revolutionary. I have endeavored to effectually guard against all possibility of the test being abortive. Instances have been reported where fecundation had taken place in the hive; but as many examinations proved that there were no drones in these hives, and judging from the lateness of the season and severity of the weather, probably none in the country, except a few which had been preserved in a queenless nucleus colony by frequently feeding the bees and confining them in the hive, and from the further fact that the experiments were conducted when few bees at any time attempted to leave the hive, and from the fact that these queens' wings were clipped

when they were removed from the nursery cage, we can confidently assert that fecundation by the natural method did not take place. These experiments in fecundation been conducted through months of October and later have the months of October and November, during the prevalence of most unpropitious weather, and those acquainted with the habits and instinct of bees will understand the difficulties under which I have had to labor. With the return of spring and the advantageous conditions attending the normal season for breeding, and after discovering and adopting better methods and devices for appropriating and depositing the seminal fluid, I am hopeful that the fecundation of queen bees may be controlled with the same ease and certainty as fecundation is regulated among all domestic animals, and that the pedigree of the breeding stock in the apiary will be as readily traced and as highly valued as is the recorded pedigree of the illustrious scions of the turf, and the aristocratic families of the American Herd Book.

I regret that the lateness of the season prevents the further continuance of these tests now, as I fully appreciate the necessity of placing the evidence in support of the facts set forth on the incontestable basis of continued and often repeated successes, and not upon the success obtained in two individual cases. However, the fact that I have succeeded in producing queen bees of two generations which have by artificial means been made to perform the normal functions of naturally fecundated queens, seems to furnish ground to hope that this subject has passed from the plane of experiment to the position of practicability. Other methods for controlling fecundation also remain to be tested.

Experiments in Wintering Bees.

### MAHALA B. CHADDOCK.

I examined my bees yesterday, took off the chaff boxes and cleaned out the Gallup hives, and unpacked the Simplicities. I stated last autumn that I was going to experiment a little. I filled one Simplicity hive with oats chaff packed in solid, put another hive on it with five frames of brood in the middle and divisionboards on each side; then another hive on top of that with 5 frames filled solid with honey in the center just over the brood-nest, and divisionboards on each side corresponding with those below. I covered the top with Indian-head muslin, and filled in at the sides and on top with chaff. I told them to hibernate, and din not touch them again until now.

I built up four of these monuments. Of course the middle hive—the one containing the brood-nest—had an entrance cut for the bees to go out. When I opened them I found the brood in the upper story of three of

them, and they had built large pieces of comb between the combs and all was full of sealed brood, except the everything was booming. If I had no other hives, I would say fix them just so other hives, I would say sides next to the division-boards, and

fix them just so every time. My colonies in Gallup hives (that I fixed with no fussing, but nailed a piece of muslin on an empty honey-box filled it with chaff loosely thrown in, and laid four cobs under it, a la Porter), are booming just as much, so what is the use ?

Neighbor Phillips' bees, with not a spear of chaff in the honey-boxes, are rushing and roaring just the same. He had the honey boxes, with no honey, on them, and left them on all winter, and he is now ready for the honey harvest without any lifting and lugging around. After the cold weather had set in for good, and everything was snapping and cracking with the cold, he carried a few armfuls of straw and piled on the hives. I want a hive that can be fixed for winter without doing anything to the brood-nest; take off the honey and put on the feather-beds, and no fussing nor backache about it. Who will invent the hive I want?

I clip all my queens' wings when I clean out the hives in the spring, and then let them alone unless they need feeding. I go round between apple bloom and white clover every few days, and lift the hives, and if they feel light I feed at the entrance at dusk, in some feeders that I made out of tin separ-ators that I once used between sections.

Vermont, +o Ill.

For the American Bee Journal.

### Using Comb Foundation.

C. W. DAYTON, (116-115.)

There are two different times when the bees will work upon foundationone of them is when there is a large amount of honey being stored, and the other is where there is not very much honey to be found-about enough to supply the daily wants of a colony. If we give the foundation when there is a heavy yield of honey, the cells will be drawn out so as to be about 14 of an inch deep, or deep enough to hold honey, and as combs are not so plentiful as honey at such times, the unfinished cells will be filled nearly to the brim with honey which will prevent the bees using the surplus wax in the lower part of the cells. Thus if there is enough wax to construct combs t inchin thickness but little more than  $\frac{1}{2}$  of it will be economically used.

In working foundation where there is not much honey to be found there is nothing in the way, but if there is more wax than is absolutely required to produce the cells to the depth for brood, it goes to make thick side-walls or "fish-bone," and of course is wasted. I believe it to be the case that when combs are produced to a certain thickness, which thickness

may be varied by conditions, the bees use their own wax. It takes about 7½ square feet of straight, natural to comb to contain a pound of wax, and it should require but a trifle more than a pound of foundation to pro-duce  $7\frac{1}{2}$  square feet of comb.

That weight of foundation seems to be about right when the bees are not getting much honey, but if the honeyflow is heavy it might be economy in money saved to have it much thinner than that, if it can be kept from falling down

After using several of the different kinds of comb foundation in the frames at a time, I can see no difference in its acceptance by the bees. Sheets of wax barely showing the prints of the press will often be worked into the nicest of comb, if it does not contain too much wax for the occasion, and then cell-bases could be no advantage. If there is any choice it would be in favor of the molded kind, and then only in regard to strength. This choice would be thestrength. This choretical, however.

Last season I used in the broodchamber, 120 pounds of foundation running 8 square feet to the pound, and there was less than 3 pounds to be made over again from being pulled down by the bees, and I did not use wires. Perhaps the best way to fasten unwired foundation in the frames is to place one edge under a thin strip of wood tacked to the under-side of the top-bar. In hiving the swarms upon these frames of foundation, for obvious reasons it is advisable to place the frames as close together as possible or alternate them with combs, which should be placed near together. When a swarm has been hived 5 or 6 hours, the frames may be placed the right distances apart, as the foundation will have reached a comb-like aspect. All things consid-ered, I think that this management is easy, and saves valuable time over that of using wires. Bradford, & Iowa.

### Replies to Various Criticisms.

### JAMES HEDDON.

I ask to be excused for compelled procrastination in replying to Mr. Caldwell. Referring to his first question on page 217, I will say that I have wintered, and propose to winter my colonies in one case of the brood-chamber of my hive. I used under a part, two-inch rims. This experiment was made with but 5 colonies. and it presented favorable results. I am aware that the idea is old. One case of the brood-chamber presents all the comb capacity needed for every purpose for wintering, one of which being to hold sufficient stores to always last from gathering to gathering.

If Mr. Caldwell will carefully read the chapter on the new hive, in my book, he will see that my bees are not in both cases of the brood-chamber,

the cool weather he speaks of. If Mr. C. has read my articles carefully, as he states in his second paragraph. he must have overlooked my words of caution on page 73, at the bottom of the last column, where I advise not to make haste to cast aside a good hive for a better one.

He also wants to know how much more honey can be taken on an aver-age, from these hives than from the old ones. To this I answer, not a drop more. It is bees, not hives that produce honey. I can get as much honey from a nail-keg, or half-barrel, as from any hive. To do it, I should have to devote my entire attention to one keg, or at least not many kegs, or the attention would not go around. When the keg is nearly full, I would cut out some of the honey-combs, thus giving more room, and so on. But if Mr. Caldwell would ask from what hive I believe I can get the best-filled sections of nicest comb honey, with the least amount of friction and labor, I am prepared to say, from the new invertible, double-brood-chamber hive. As far as the quantity of honey is concerned, that depends upon the secretion of nectar, and number of bees to gather it.

The new hive with complete broodchamber, has the same brood-comb capacity of 10 standard Langstroth frames, and by interchanging and inverting, we can develop one-half more brood than we get from the same brood-comb capacity in non-

invertible frames. I have read Mr. Dadant's article on page 231. As the term "original" is used in patent parlance, it refers to something not borrowed, whether prior or not. I trust that no one im-agines that I had any knowledge of these old, dead tiering-hives, laid aside by our French and German brether I base met failed brethren. I have yet failed to see an account of any hive containing two distinct apartments (surplus and brood), where the brood-apartment was divided into two horizontal sections. If Mr. Dadant's article was written for the purpose of showing that past experiments have proven my new hive and system inferior, I will only say that the construction was so ill, that they could not work successfully, and did not contain the functions of my hive, which fact I am willing to rest with future experiments. If, on the other hand, the article is supposed to anticipate my invention. I have only to refer the reader to Section V, page 213, which reads as follows:

"Patent law declares that the fact of abandon-ment and subsequent adoption of things claimed to be alike, is evidence sufficient to negative that claim."

On page 219 we are again treated to a transfer out of a brood-chamber made in sectional parts. I do not know why these statements are written. Are the writers now auxious to transfer back into the double brood-chamber hives? If they are, will it be true that the hives they then transferred out of (abandoned), will be just like those they will now trans-fer into (adopt)? What has been fer into (adopt)? going on to produce such inconsistent changes ? "Whatever can be shown in but only one case, at the approach of print, that anticipates my claims

(either patent or honorary), let us see it by all means; but claims that rest with any one's veracity, are not safe guides outside of United Stats\_courts, and not then, in many cases. Let him who claims it is in print, turnish it.

I was, some weeks ago, made aware of what Mr. Dadant cites, but that cannot and does not in any sense anticipate any of my claims. My patent claims are outside of it, and my honorary claims to the invention are based upon the fact that I knew no more of these old discarded de-vices than did Prof. Cook and others, and a dead past can in no way anticipate a living present.

But some may inquire, "Will your new hive live ?" I reply—I am willing to leave that to the bee-keepers of to-day. They are testing it. Let us await their decision. "Let the dead bury the dead," and the present test the living.

I have read Mr. Kretchmer's reply on page 265, and I still affirm that I made no mistake in my report of Mr. Kretchmer's patent. The 28th line Kretchmer's patent. The 28th line of his specifications reads thus, as or his specifications reads thus, as you say, Mr. Editor: "The bottom-board G of the box is permanently attached to the sides." There is nothing double about the brood-chamber. There is no "honey-board," nor "metal strips" with frames resting thereon. Mr.K.says that it is "capable of being inverted." In one sense this is true, and in another it is sense this is true, and in another it is not. Any hive *might* be inverted, even by the wind. This hive is by no means practically invertible. Wedges will not support frames when inverted, and the bee-spaces would be thrown all out of position. Mr. K's patent plainly states the purpose of these wedges, as follows:

"I insert a wedge-shaped piece of lath for the Insert a wedge singled piece of numfor the purpose of closing the crevices between the frames, so as to prevent the bees from depositing lbdir bee-glue between the frames, and to leave no crevice for heat to escape, or where moth might obtain a lodging-place."

The objects sought to gain by the invention are plainly set forth in the specifications, and not one word is said about inverting or interchanging any of the parts of the hive, and no such action is practically possible. The drawings also show that the bottomboard is "permanently attached to the sides"—not to the side ! Again I assert that in this patent

cited by Mr. Kretchmer, there is not a single feature in any way anticipating my invention. There is no double broodchamber, but one deep one. I would willingly leave the matter to Mr. R. L. Taylor, who is a lawyer, and also a large and expert bee-keeper. I mention him because he is in every way fitted to judge, and was mentioned by Prof. Cook in Gleanings.

On page 259, Mr. Editor, I think you do us injustice. I see no just comparison in your "chameleon story." The hive that Mr. K. has just sent you is not evidence in this case. What we demand is some sort of proof that is self-evident, and that is no doubt what is demanded by Messrs. Alves and Cook.

patent. He should have done this before he wrote. There is hardly a bee-keeper in the country who yet thoroughly and entirely understands all the functions of the bive in ques-tion. Mr. K. says "special system" and "particular construction." Let me say to Mr. K. and all, that my invention cover yeastly more ground invention covers vastly more ground than a single "particular construc-tion" or "special" line of manage-ment. A thousand hives might be constructed, all characteristically different, every one of which might infringe my invention.

Two-thirds of all that has been written with a view to uprooting my invention, has really had no bearing upon the subject whatever. In the United States courts we should be compelled to give more or less weight to the sworn statements of witnesses against the novelty of the hive, and that testimony would weigh accord-ing to its reasonableness and the integrity of the witness, as can be shown from what he has said and written before; and even then perjury may do injustice; but here, in a bee-paper, nothing amounts to evidence worthy of consideration, except what can be shown in public print. Dowagiac, 9 Mich.

### For the American Bee Journal.

### Fertilization of Flowers.

### J. F. LATHAM.

As a farewell to the subject I wish the indulgence to inform Mr. S. D. Webster that, in my opinion, his quotation, on page 203, from my arti-cle on page 153, embodied an allusion to a living principle in the economy of Nature—a molecular affinity or co-relation of organic entites—a con-necting-link between the animal and vegetable species, and the lower the descent in the scale of existence the more prominent it becomes, as evidence of the—beginning.

I believe that is a settled conclusion among geologists, that the vegetable species commenced their rounds of development prior to the animal species; and, at the compatible grade of their development, furnished the entites from which the animal races have evolved. But the precise point in the development of cosmic matter at which evolution commenced, is beyond the reach of human investiga-The Great First Cause, like the tion. symbolical fruit of Paradise, is guarded from man's irreverent touch; he can find out the Universal Life-Giver—the Fructifying Power, but not unto perfection. He can see in the phosphorescent glow of the steamer's path, as it dashes through the briny waves, evidence of the existence of the molecules of future entites. He can see in the "jelly-" as it floats in the calm waters of tish. the land-locked estuary, maintaining in its movements the impetus imparted to it by the waves of the open Messrs. Alves and Cook. In Mr. Kretchmer's last paragraph, he says that since then he has care-fully examined my hive, system and it originated, its organism but a

degree in advance of the vegetable, and its animal functions being but the power of volition, imparting to it but the impetus to maintain existence where the strictly veget-able entity would perish. Divide it into pieces, and each fragment becomes a distinct entity in the sphere of its progenitor. Will not this process of organic growth hold good when applied to the method of development of all the species of animate life which inhabit the great deep?

But, we are not compelled to search the ocean for a manifestation of the Life-power; it is all around us. It permeates the rivers and rills, lakes and ponds as well; and there is scarcely if at all, a vegetable which springs from the earth, but that furnishes support to the infant entites of living, moving forms-future animals and insects. So it is plainly evident that we are not wholly indebted to the testimony of the rocks when seeking to unveil the affinity of animal and vegetable existence-the co-habitation, so to speak, of the positive and negative, or active and passive forces, which represent the propagating agencies, as displayed in the attributes of the universal-spiritual, and universal-material principles; cosmologically unfolded in the vivifying expanding impulses of nature, in endless evolution.

The bees and the breeze may convey the fecundating element from flower to flower, but fructification can be accomplished only when the elemental conditions are susceptible of molecular assimilation. This-as I believe it to be-bottom fact from the occult store-house of Nature, the connection of animal and vegetable lifeseems to exercise a more subtile influence in matters pertaining to some of the vital elements of bee-keeping than at first thought it may be supposed to exercise; for had it been properly understood, the "pollen theory" would never have been, and the disciples of the " hibernation theory" would have sought elsewhere than a hollow-tree, for the basic principle evinced in the winter repose of the hive-bee.

I see nothing in Prof. Cook's kindly notice of my article, page 188, original with the Professor, that appears to substantially conflict with my state-ments. Both tend to the same point. In short, I feel gratified in being sustained by so eminent an authority. But 1 am not prepared to believe with "all botanists," that gaily variegated, or showy uni-colored petals are assumed by the floral species for the purpose of inducing insects to their banquets of sweets, or stores of pollen for the purpose of accomplishing their fecundation. Chemical constituents produce showy uni-colored petals in the floral species, and hybridizing, or cross-fertilization, will result in variegation. Showy flowers may be more prominent in attractiveness, than plain ones, and thereby "fool" the plain ones, and thereby bees at times, as I think I have observed; but nectar and pollen are the substantial allurements, and the appetite and habits of the insects the prompters of their visits, thereby

### Feeding Sugar to Bees.

### H. E. HILL.

"I have seen sugar taken there by the barrel." I think that almost any of those who practice sugar-feeding have heard this remark, and if they have ever attempted to give an ex-planation as to why and the wherefore of it, they will understand what a task this is, and generally to no purpose.

The teachings of such men as Messrs. Hutchinson, Heddon, Doo-little and others are carefully followed by many. Their writings are eagerly sought after and their suggestions are put into practice at the first available opportunity, and many seem to think, "All I have to do is to follow their plans, and the result will be abundant success." The writer has been no exception to this class, for such writers as these are our teachers. I am sure that any bee-keeper cannot too highly estimate the value of their articles, that contain the results of their experience and practice. But do they not make mistakes sometimes?

For instance : Has Mr. Hutchinson on page 152, given a lesson that will prove beneficial both to bee-keepers and the honey market, or otherwise? Mr. II. says: "If no more sugar should be used for winter stores, or fed for any purpose for 20 years, these same stories would live and be repeat-I do not wish to contradict this "those stories" would die out entirely in that length of time, I have no more to prove that such would be the case than Mr. Hutchinson has to prove his assertion. But certainly people could not say as they do now, "I have seen, etc.," which seems to be the backbone of the falsehoods in circulation at present.

Farther on in his article, Mr. II. says: "The sugar fed to bees is not a drop in the bucket, so far as the sugar market is concerned." I do not think that anybody has intimated that the sugar market would be built up simply by the sugar consumed by the bees, although the hundreds of barrels used annually certainly assists sugar manufacturers more or less. But it builds the sugar market up by laying the foundation for such conversation as we hear oftener than we would if we left sugar out of the apiary; something similar to the following: A lady asks the price of honey and adds: "Is this the pure, or the manufactured?" The dealer replies, "That is pure honey from Mr. Brown." "Omy, I can buy sugar for 7 cents per lb., and if you want to know what Mr. Brown makes his honey out of, ask his neighbors." Such stories lose nothing by traveling and soon nearly everybody in when they can get it for 7. This reported drones at their apiaries. The

enhancing the increase of useful seems too bad just because some people think that bees cannot be wintered just as successfully on honey as with something that gives grounds for suspicion, thereby destroying the market for the genuine article.

Many of our most successful apiarists do not use sugar for winter feeding, nor any other purpose about the apiary. One for example, is Mr. J. B. Hall of Ontario, whose colonies number several hundred. His annual crop of honey (principally comb) is counted by tens of thousands of lbs. His average loss in winter does not exceed 3 per cent, and I am quite sure if any of the bee-keepers that seem to think success hinges on feeding sugar were to offer sugar gratis, to be used in Mr. Hall's apiary, it would be refused.

Of the many thousand pounds neat-ly stored in Mr. Hall's honey-room last September, he says in a private letter, "I have just two one-pound sections left. I have had to refuse many orders." Mr. Hall has learned by experience that feeding sugar does who says in a recent number of the American Apiculturist: "I am now convinced that sugar syrup is inferior to honey for winter stores in this climate, and I want to enter my protest here against the wholesale sugarfeeding going on in the apiaries of the country." This agrees with Mr. Hall and the Editor of the BEE JOURNAL, when he says: "This sugar-feeding is is undermining the honey-trade." Mr. Newman, in an editorial on page 195, says : "To avoid the appearance of evil, use honey for feeding bees."

The above shows that some of our best men are awake to the dangers of feeding sugar to bees; and let us all hope that all men of influence, may realize that fact, and use their influ-ence in the way that is best for our pursuit.

Titusville, ~ Pa.

### For the American Bee Journal.

Des Moines Co., Iowa, Convention.

The Des Moines County Bee-Keep-ers' Association met at the Court House in Burlington, Iowa, at 10 a. m. on April 27, 1886. The subject of wintering was discussed. Mr. Breder has a bee-house built expressly for wintering. The Secretary also has such a building. Many others winter their bees on the summer stands, and some in cellars. Some prefer to have a hive slope forward, and others to have them stand level, the latter method seeming to have the most followers.

"Which race of bees winter the best?" The general answer was, "No difference." Mr. Landeck favors the blacks because they work earlier in the morning. Mr. S. J. McKinney favors the Italians because the queen is more easily found. A vote was taken as to which bee was the best worker, and the hybrid was preferred by the majority.

subject of swarming was discussed, and the majority favored natural swarming; also some claimed that there was no difference between natural swarming and dividing colonies. Mr. Bischoff had a Shuck's invertible hive on exhibition, which attracted much attention. Winter losses were about 10 per cent. according to the reports of members.

JOHN NAU, Sec.

### For the American Bee Journal. Extensive Brood Rearing, etc.

### ALLEN LATHAM.

I wintered 5 colonies of bees, and

I wintered 5 colonies of bees, and they came through the winter in fine condition; each had brood by March 1. I fed them several pounds of rye meal. We have had two weeks of nice weather here, and since Sunday, with the exception of Tuesday, the mercury has risen to 80° above zero; to-day going to 84°. This weather is the weather for bees. They have carried in a large amount of honey for this time of the year, and I believe for this time of the year, and I believe I never saw pollen go in so fast and in such loads. I examined my bees to day; and I found that every hive is nearly full of brood. The weak colonies have nearly the same quantity of brood as the strong; one hive, which has not more than a pint or so of bees, has about one thousand square inches of brood, or four full frames. If this weather continues they will do well, weather continues they will do well, but if it does not, and a cold spell comes, there will be some chilled brood, I fear. I have not yet taken the packing from the hives (I packed my bees for the winter with shavings), and I shall leave it till May. Last March, as I examined one hive, I found a sealed queen-cell in it with a larval queen inside. The hive had a fertile queen which I saw, and also eggs and brood. What is the reason for their rearing a queen at that time of the year? Apple trees are nearly ready to bloom. ready to bloom.

Lancaster, & Mass., April 23, 1886.

### Convention Notices.

13 A cordial invitation is extended to all to attend the 8th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., an May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will her made to render this meeting the best and largest ever held in the State. No hotel bills thr pay. B. F. CARROLL, Sec.

The next meeting of the Cortland Union Bee-Keepers' Association will be held at Cortland, N. Y., on May 11, 1886, at 10 a.m. D. F. SHATTUCK, Sec.

177 The next annual meeting of the Michigan State Bee-Keepers' Association will be held in Ypsilanti, Mich., on Dec. 1 and 2, 1886. H. D. CUTTING, Sec.

The Central Michigan Bee-Keepers' Associ-ation will meet on May 18,1886, with Capital Grange at their Hall in North Lansing, Mich., to hold as All interested in bee-culture are invited to attend and bring articles of the apart for exbibition. For any special information address the Secretary, E. W. WOOD, N. Lansing, Mich.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day, Oet. 19 and 20, 1886. J. M. HAMBAUGH, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.-ED.

Strong Nuclei.-J. F. Latham, (29-29), Cumberland, 9 Maine, on April 26, 1886, says:

My bees have wintered finely. I never had them winter better. Three nuclei colonies, with not more than a quart of bees in each, are as strong as last fall, and are building up vigor-ously, having been favored for a week with very warm weather, for the season.

Good Season Expected. -W.V.Whitney, Waucoma, & Iowa, on April 23, 1886, says :

Bees are a-booming. I put 99 colo-nies into the cellar on Nov. 14, 1885, and on April 9, 1886, I took 94 colonies were queenless, and those I doubled up with others. The weather is warm and nice. We have not had a frost since April 8. I think that my bees have flown every day since they were taken from the cellar. Every thing bids fair for a good honey season. One colony that is on scales gained 4½ pounds yesterday.

Italianizing Bees.-W. J. Cullinan, Mt. Sterling, +o Ills., on April 23, 1886, writes:

Having commenced the work of Italianizing my apiary, I will give my success thus tar. First, I purchased a choice Italian queen. and introduced her to a full colony with success, as follows: I caught and caged the queen in the colony to which I wished to give her, leaving her caged 9 hours; at the end of that time I took her out and put my new queen in the same cage, leaving her there 24 hours. I then liberated her about 6 o'clock in the evening. On examination the next morning, I found her attending quietly to business, and apparently in

fully harmony with her large family. She has since been doing good work. Yesterday (it being the 6th day after her introduction) I took out three frames containing eggs and young larvæ, and placed them in a strong colony after depriving them of their queen; crowding the bees into six Langstroth frames. I receive the  $\Delta$ MERICAN BEE JOURNAL regularly every Wednesday, and though my subscription is not half expired, I consider I have already received more than my dollar's worth.

Beautiful Weather for Bees.-Thos. Stokes, Minesing, Ont., on April 20, 1886, writes:

We are having most beautiful weather here now, the mercury the weather here now, the mercury the last few days ranging from  $70^{\circ}$  to  $80^{\circ}$ in the shade. Bees have been carry-ing in pollen, and now they are bringing in some honey. My colonies are very healthy, and most of them are strong, after being wintered in a clamp packed with sawdust. 1 put the first of them away on Nov. 1. 1885, and put them out the last of Marchrather early, but I was afraid of their being short of stores, as the last fall was very poor for honey. Three colo-nies had died from starvation, and I since have found some that were queenless, thus leaving 23 colonies from 32 put away. These are the increase from 3 colonies in the spring two years ago.

Fine Weather for Bees.-C. W. Dayton, Bradford, & Iowa, on April 20, 1886, says :

Since the cold weather, which ended on April 8, we have had the warmest weather (from  $65^{\circ}$  to  $85^{\circ}$ above) of any which I can remember at this time of the year. It appears like midsummer, and the bees are rolling in the pollen from morning till night. What I am afraid of is, that it will cause them to extend the brood so much that if we get a cold snap there will be a great deal that may be destroyed. may be destroyed.

An Apology.-J. E. Pond, Jr., Foxboro, o+ Mass., writes :

Rev.Mr.Clarke arraigns myself-and justly so—on page 246. I am always desirous of keeping within the bounds of courtesy in discussion, but in the case to which Bro. Clarke refers, I frankly admit that I overstepped them. I trust that Bro. Clarke will accept my apology in the same spirit it is made, when I say to him that the words he alludes to were penned upon the impulse of the moment, as a figure of speech, without any basis therefor so far as any articles of his are concerned, and without thinking of the inference that might be drawn. All I meant to say was, that a clergyman had, without a chance to test the matter, made a very favorable criti-cism in favor of a theoretical question. I own up to the error, and will endeavor not to repeat it; and in this long. They have just bee case I will say, that I have never seen since warm weather came.

anything in Bro. Clarke's articles that does in any way show that he presumes upon the fact that he is a clergyman, to give strength to the point he argues. I might have apolo-gized in a private letter, but I deem that an apology to be of value should be made as publicly as the offense.

Clover Mainly Killed, etc.-Ira Barber, De Kalb Junction, 5 N. Y., on April 21, 1886, writes :

The bees in this locality have wintered nicely, as a rule, and are having a lively time on the willow and soft maple, which the last few days of hot weather have rushed into bloom. The bees have no time for plundering, but go directly to work, and have all they can attend to. I finished putting out bees to-day, and I found a loss of 121/2 per cent.—all my own fault, by care-lessness in leaving two cellar-windows out when the bees were put in, and the cellar was closed. I have known all winter that the temperature was too low, and what the trouble was I did not know, until I took the bees out and found the windows lying on the wall. The outlook for a crop of honey is far from favorable in North-ern New York. We have had but little snow here all winter, and the fields have been bare, or nearly so, all killed out; and that is our main de-pendence for a large crop of honey.

The "October Theory."-W. Z. Hutchinson, Rogersville, & Mich., says:

Mr. Bittenbender seems to possess the happy faculty of drawing apparently correct conclusions from false premises. At least some of his premises appear to be false. He says: "Bees in their natural state in the woods keep themselves in the trunks of trees 4 to 6 inches thick, where the autumnal sun cannot disturb them in their October and November repose. We thwart nature's ways when we put our bees into a %-inch hive, and let the sun beat upon it till cold weather comes, disturbing the bee in its natural repose." This is the sec-ond theory that has been built upon the false assumption that bees in beetrees, "in a state of nature," winter better than in the modern apiary or cellar. The "hibernation theory" may be true in the sense in which its author now uses the word; and I certainly agree with the author of the "October theory" in thinking it im-portant that bees be packed early, or else put into the cellar early; but, bee-keepers, do not build your theories upon bee-trees.

Getting Ready to Swarm.-2-J. L. Haworth, (1-7), Georgetown, 0+Ill., on April 26, 1886, says:

I have 7 colonies of Italian bees in Langstroth hives. One colony has had drones flying for several days, and upon examination to-day I found new queen-cells about ½ of an inch long. They have just been booming

Bees Wintered Well. - Geo. W. Homer, Dubuque, - Iowa, on April 22, 1886, says:

My bees wintered well out-doors, the loss being 4 colonies out of 75, fall count. Their condition is fair to firstcount. Their condition is fair to first-class. The weather here could not well be better than it has been for the past week, being as balmy as in June, and the bees are merry.

Nice Weather for Bees.-F. M. Taintor, Coleraine, \* Mass., on April 24, 1886, says :

I placed my bees on the summer stands on April 14, after a confine-ment of 5 months in the cellar. They wintered well, but are light in bees, owing, I think, to flying so much last fall. We have had very warm weather since I carried them out, so at present they have a fine lot of brood for this time of the year; and if this weather continues they will be all right.

Bees in nice Condition .-- Wm. H. Graves, Duncan, OIlls., April 24, 1886. writes:

My bees have wintered in fine condition. I had 59 colonies last fail, and now I have 58. Never since I have kept bees have I had them in as nice condition at this time of the year. They began carrying in pollen on March 16. I wintered them on the summer stands, except 4 that were in the cellar-the first that I ever win-tered in a cellar, and they came through nicely. I could not help but wonder at the small amount of honey consumed. Last season was the poorest for honey I ever saw; I had only about 500 pounds from 60 colonies. We have every prospect now for a good honey season. My bees are building up rapidly.

Upward Ventilation, etc.-J. W. Johnson, McFall, Mo., on April 21, 1885. writes :

I think that I have the winter problem settled, at least to suit me. Ventilation is necessary, and upward ventilation at that, for we must keep from the bees the hot air that rises in bitter cold weather. In the fall of 1884 I put my bees up for winter-50 colonies in all-and when the next May came I had 7 colonies, and only I out of the 7 was very strong. When I examined them I noticed an open space in the honey-board. The upper story was just set on. and no straw nor anything else was in it. Last fail I had some 40 colonies, and when I put them in for the winter this hive was left in really a worse condition than it was the previous winter, and the colony in it came out strong again this spring; while lots of my colonies that were put up in good condition, as I thought, were dead. I now have 27 colonies of bees. I took a frame from this strong, colony yesterday to build up a weak one, and it had brood Upward ventilation is the best in it. in winter, I think.

Feeding Maple Syrup, etc.-Freeman Chute, Port Burwell, Ont., on April 19, 1886. writes :

Although I have been a bee-keeper for about 30 years, yet I find that I know nothing as I ought. I com-menced the winter of 1885 with 24 good colonies, and the next spring I had 1 colony. The winter just past I tried to winter 11, and came through with 8. The cause of my loss of the 3 colonies I attribute to too many frames in the hive, which did not allow the bees to cluster enough to keep up the natural warmth. The cellar I keep them in is wet, but roomy, and has not much ventilation. 1. Does the presence of vegetables injure the wintering of bees in the same room? 2. Is maple syrup good to feed bees when they are short of honey? 3. What is the occasion of bees swarming out in the spring and alighting, and if put back will come out again and act so till they perish?

[1. If the cellar is kept sweet, the presence of vegetables will not be detrimental.

2. Yes; maple syrup will answer when the bees have occasional flights.

3. They are disgusted with their quarters, short of food, or something of that kind. The causes are numerous.-ED.]

Strengthening Colonies.-D. S. Goff, Ridgefield, & Ills., on April 28, 1886, says :

I have I weak colony of bees, and a neighbor about 10 rods away has 3 colonies. 2 of them being pretty strong ones. The 2 strong colonies have commenced to rob mine a little, and I thought it would be a good plan to strengthen them with a pound of Italians. What is the best thing I Italians. can do?

Yes; if the queen is good. Buy a pound of hees and give them to the weak colony.-ED.]

No Loss in Wintering. -D. R. Rosebrough, Casey, O+ Ills., on April 24, 1886, writes:

It perhaps will be remembered that last fall I stated if it was a detriment to have too many bees in the hives to winter, it would affect the wintering of my bees, for my hives were then full of young bees; but the winter is ended, spring is here, and my bees are all right. I wintered 55 colonies without loss. Here, the that here the without loss. How is that for out-door wintering, and in thin hives? All except one of my queens are living, and all had brood but one colony, and that was strong in bees, so I exchanged some of its frames with those of other colonies. This has been the finest week for bees that I have ever known at this time of the year. Apple, cherry, and plum trees are in full bloom. It is assafe to work with the bees now as it is in the middle of white clover bloom. I have vention History of America."

drones flying, and a few colonies are working in the surplus apartments. I have no weak colonies. The past is my second winter without loss.

Early Queens, etc.-N. H. Rowland, Keene. O Ky., on April 26, 1886, writes:

Bees are booming. I never saw them breed up faster. Apples are in full bloom, and the weather is just right. I have already reared one lot right. I have already reared one lot of early queens to supply some colo-nies that had lost their queens through the winter. The queens were laying on April 20, and have had drones flying since March. This is the earliest I have ever reared queens. Our old friend, the AMERICAN BEE JOURNAL, still makes its weekly visits, as it has been doing for years; and though an old visitor, it is always and though an old visitor, it is always a welcome one, for, in my opinion, it is still ahead of all others.

Breeding in the Cellar. - S. J. Youngman, Cato, Mich., April 17, 1886. writes :

Bees have wintered fairly well. I removed my own from the cellar on April 9, after a confinement of 126 days. Several of the colonies were very heavy, one having several frames of brood in all stages, from the newly laid egg to hatching bees, and no diarrhea. How does this agree with the pollen theory? One of my neigh-bors also had a colony wintered in a cellar, with brood in all stages, and it had drones flying on the next day after being put out. Is it common for bees to breed in dark cellars ?

Bees Wintered Fairly Well.-F. H. McFarland, Charlotte, Vt., on April 26, 1886, says :

Bees have wintered fairly well here, although some have lost quite heavily. Mr. A. E. Manum called a few days since, and informed me that his bees never wintered better, having lost less than 2 per cent. of the colonies which I prepared for winter for him lost foil. last fall. He has, this spring, about 700 colonies. The past week has been quite warm, and considerable pollen and some honey has been gathered. Our early honey-plants, before fruit bloom, are the willow, elm and maple.

Bees Wintered Splendidly.-Jno. Haskins, Empire Prairie, ~ Mo., on April 27, 1886, says:

All of my bees have wintered splendidly but one colony that was queen-less, I think. I wintered all of them ess, I think. I wintered all of them except 2 on the summer stands with-out any protection, but snow that I shoveled around them, except in the fronts of the hives. The fruit trees and red-bud are in bloom.

To any One sending us one new subscriber with their own renewal (with \$2.00), we will present a copy of the new " Con-

923 & 925 WEST MADISON ST., CHICAGD, ILL, At One Dollar a Year.

## Bee-Hives, Honey-Boxes, Sections,

Largest Bee-Hive Factory in the World.

Capacity, one car-load per day. Beat of goods at lowest prices. Write for price-list.

**DO YOU EAT CANDY**? SEND f1.25 and 1 will express 5 lb. Todd's Honey O'Candies, same as made a sensation at last Penn-sylvania Etate Fair. Remember, every pound sold helps the honey trude. Special rates for quantities for Fairs. Dadant Fonndation always in stock at market prices. Bees, Queens, Hives, Smokers. Vol. 1 of Frank Cheshire's New Book mniled free for \$2.50. **ARTHUR TODD**, 1910 Germantown Ave., PHILADELPHIA, PA. 17Ast 17A9t

The engraving gives a good idea of the hive. The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or mverted at will. The cover, bottom-bourd, and top and bottom of each sectional case has one-half of a regular bee-space, so that the surplue cased with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangreable. The brood-frames will ALL be bored for wires.

ALL be bored for wires. A SAMPLE HIVE includes the hottom-board and stand; a slatted honey-board, and cover; two 6-inch brood-chambers, each containing 8 frames; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separa-tors, and the other without separators. This latter chamber can be interchanged with the other storles, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

It is absolutely essential to order one nailed hive as a pattern for putting thase in the flat together correctly.

IN the null together correctly. HIVES READY TO NAIL-ID filling orders for these hives, in the flat, we make 6 different com-binations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers :

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 frames, and the slatted honey-board. Price, \$1.55 each. No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—interchangeable, but not reversible,— Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus sto-ries as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-cnambers. Price, \$2.10 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00. No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each.

Those desiring the bives without the stand, honey-board or sections, may make the following deduc-tions from the above prices : Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at \$4 cent acch, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hires, 5 per cent. discount; for 25 or more hires, 7 1-2 per cent.; for 50 or more, 10 per cent.

The World is a looking-glass Wherein ourselves are shown, Kindness for kindness, eheer for cheer, Coldness for gloom, repulse for fear, To every soul its own; We cannot change the world a whit, Only ourselves which look in it.

The Winter Losses of Hees were very small indeed in the Northern States. In the Middle States the losses were heavy—probably on account of the poor quality of the hency they had for winter use.

Get all the Colonies Strong, so as to be ready for the honey harvest when it comes. They should "build up" nicely with the fruit-bloom, new se abundant. After that there will be a dearth until white clover comes. During that time the bees should be developing, so as to have multitudes to gather the white clover harvest.

**Go Slow!** We would advise beginners to go slow at first, and not invest too largely in the business. We had a visitor a few days ago who contemplated investing several thousands of dollars in an aplary. He will, in all probability, "go home and *think* about it" before investing very much money in a business about which he knows nothing.

New Price-Lists have been received from the following persons :

J. Van Deusen & Sens, Sprout Brook, N. Y.— pages—Flat-Bottom Comb Foundation O. H. Townsend, Alamo, Mich.—1 page— Comb Foundation and Bees, accompanied by very nice specimens of foundation.

E. T. Jerdan, Harmony, Ind.,-4 pages-Bees and Bee-Keepers' Supplies.

Thos. L. Thornton, Dividing Ridge, Ky.-6 pagea-Heney, Bees, Queens and Supplies. A. O. Crawford, South Weymouth, Mass

A. O. Crawford, South Weymouth, Mass.-16 pages-Honey-Labels, etc.

M. E. Mason, Andover, O.-1 page-Hives and Foundation, with good samples of the latter.

Any one desiring a copy of either of them, can obtain it by sending a postal card to the address as given above.

**Mr. J. E. Pond, Jr.**, writes us that it has been intimated by some that he has endeavored to get himself engaged as counsel for the "National Bee-Keepers' Union." As the Editor of the AMERICAN BEE JOURNAL is the Manager of the "Union," he desires us, as that officer, to say publicly, if such is the case, and we cheerfully give the facts as tollows :

Last fall, while preparing to defend the sheep-bees case, we wrote to Messrs. Demaree and Pond, as both were lawyers as well as bee-keepers, to know upon what terms they would undertake the defense of the case. Mr. Demarce responded that it would be difficult for him to leave his home at the time mentioned, but if it was deemed essential, he would do se; but suggested that the case might be studied by Mr. Pond and others, and "points of law" might be written out for use by the local attorneys, and it would be less expensive and de just as well as to take the more expensive method.

Mr. Pond replied that if it was deemed necessary he would go to Wiscensiu and conduct the ease, but that he did not think the Union could afford to employ him, and pay the necessary traveling expenses. He said that he could not afford to do it for less than day-pay for the time occupied in coming and going, etc.

After consulting with the Executive Conmittee, we concluded to employ local attorneys, and have Messrs. Demarce and Pond review the case, examine the authoritics, and write out "points of law" for use at the trial.

This was done, the "briefs" were sent to us, and, together with several ethers furnished by other lawyers, were sent to Mr. Freebern for use by his counsel. We paid \$25 each for the "briefs," and \$100 to the local attorneys, besides some other expenses. If such a report as Mr. Pond intimates is being circulated, it must have been eaused by a misunderstanding of the facts in the case. As to who are intimating anything of of the kind, we are not advised, but the facts we have recited, which will also be published in the annual official report next June, will set at rest any such false rumors. Mr. Pond offered to gratuitously advise with the local attorneys, but never intimated to us such a thing as desiring to be employed as counsel for the Union.

Sensible Words are those of Mr. C. H. Dibbern, in the *Plowman*, which read thus :

The successful bec-keeper must be ever on the alert, and do things at the right time. Some weak colonies may still need feeding or uniting with others; remembering that instead of a great many colonies we want all strong in numbers. Everything possible should be done this month to induce the queens to fill the hives with brood and bees, as they are the ones that will gather the boney. De not give the bees too much room till warm weather comes to stay.

In most localities it is no use to put on the surplus honey arrangements until the white elaver commences to bleem, towards the last of the month. The entrances should be contracted till the bees show signs of laying out, then more honey-sections should be put on, rather than enlarging the entrances. Under no circumstances allow the bees to lay out idly on the hives during the honey harvest.

The apiary should be a model of neatness and beauty. All bives, caps, etc., not containing bees, or in use, should be stored elsewhere. A few trees, evergreens and

flowering shrubs, planted among the hives help to relieve the sameness of the scene, and in summer give a grateful shade to the bees and their keeper. Everything about yeur shep and honey house should be kept scrupulously clean and neat. No friend or customer should ever be allowed to leave your place feeling any doubt as to the cleanliness or purity of the boney yeu may wish to sell him.

**Kiot.**—While the steam press was rattling off last week's AMERICAN BEE JOURNAL, a bloody riot was in progress at the Me-Cormick Factory, about three miles south of our office; but it was promptly quelled by the police. This seemed to exasperate the rioters, and they held a meeting on the Haymarket Square on Tuesday evening, hurling denunciations at the police, and all constituted authority. The police were ordered to break up the meeting and disperse the crowd. A bomb of dynamite was then thrown in the midst of the police officers, which exploded with terrible effect -then there was a general firing of pistols on both sides, but the mob scattered, running into the alleys and adjoining streets, leaving the dying and injured ones to be cared for by the police. Five of the policemen are dead and several others will die very soon. Some 40 or 50 more are injured, but are expected to recover. Of the rioters, many are killed and wounded - nearly all are being cared for at the Hospital.

The instigators of the riot as well as many of the participants are arrested, and will be tried for their lives.

We give these facts to correct the erroueous opinions held in the country concerning the condition of affairs in Chicago. We have heard of some who imagine that the city is in the hands of the anarchists, that business is practically suspended, that citizens are being assaulted and murdered in the public streets, and that in fact a "reign of terror" exists in this city. In consequence, considerable trade has been diverted from this city, under the false impression concerning the status of things here. It is true that some of the railroads have been embarrassed by the strike of the freight-bandlers, but they are now in operation, and are doing all they can to catch up with the business that has accumulated. Shipments have only been delayed a few days at most, but new even that will be remedied.

There has been no danger of personal violence at any time, if persons keep away from the crowds, and attend to their regular business—except, of course, to the policemen. "Law and order" are in the ascendency; and the anarchists are quailing before the tempest of pepular indignation, which their murderous deeds have invoked.

LATER.—On Monday morning we open this page to say that the freight-handlers have declared the strike "off," and have gone to work again. This ends all the trouble so far as shipping goods is concerned, and business now will go on with its usual promptness.

The Outlook for a large honey crop is very promising. White clover looks well, and there is an abundance of fruit bloom. Bees are building up rapidly in numbers. Unless we get a very pronounced "setback" there will be a large honey crop this seeason.

WITH

#### **REPLIES by Prominent Apiarists.**

## In-and-In Breeding of Bees.

Query, No. 248.-Among 40 colonies I have 2 that build comb of wondrous purity and beauty, but as the queens of these colonies are of the same age, and daughters of the same mother, will it do to rear queens from one of these, and drones from the other? Or are they too nearly related to do well ?-Subseriber.

I think I would risk it for the first year .-- C. C. MILLER.

I should prefer it otherwise; how-ever, you might try it.-G. M. Doo-LITTLE.

Do not be afraid to rear queens and drones from either colony. Your bees will get a change of blood only too soon.-II. D. CUTTING.

such in-breeding often, no Just doubt, takes place in all of our large apiaries with no serious result for one generation, but continued in-breeding deteriorates, and is not apt to occur where the queens can have a choice.-G. L. TINKER.

I should use my best if they were closely related. Close in-breeding has made our magnificent short-horns. With care it may do as much for our bees.-A. J. Cook.

Among 40 colonies, the chances of Among 40 colonies, the chances of securing the mating of queens of one particular colony with the drones of another, are small indeed. I think that no harm would result from the course that is mentioned, even if the desired mating were secured .- W. Z. HUTCHINSON.

I think it most probable that there is no peculiarity about those 2 colo-The time and circumstances nies. under which they build that beauti-ful comb, may have had more to do with it than the bees. All things being equal, I would prefer to breed from queens which show excellent traits. I should not fear the results of in-breeding. You can do as you say, but it will be like a lottery ticket say, but it will be nice a lottery ticket as to the mating. I want at least 20 colonies to rear drones of the stock I want to breed from. I commenced with 2 Italian colonies, both had drones plentifully, and I got just one out of twelve of my queens mated at home.-G. W. DEMAREE.

I should most certainly try the ex-eriment. There is less danger than periment. is supposed from in-and-in breeding. Some of our very best varieties of stock have been produced by so doing; all that is necessary being, when weakness is found to exist, to breed strength back again. The matter requires care, however.—J. E. POND, JR.

## Enameled-Cloth or Oil-Cloth Covering.

Query, No. 249 .- Have you used enameled cloth or oil-cloth on top of the frames, and under the chaff cushion, during the past winter? If so, with what success ? -J. S.

No; nor would we use it in the winter.-DADANT & SON.

On a few; and as a result I had wet hives and moldy combs, but the bees wintered fairly.—G. M. DOOLITTLE.

Yes, I have, and I must condemn its use over bees in winter. A plate of cast-iron over them would not be more effectual in rapidly radiating the heat, nor be more impervious to moisture.—G. L. TINKER.

I have used some painted cloths on the frames for several years, and they have done good service, but I de-cidedly prefer bee-quilts made from carpeting.—G. W. DEMAREE.

No. The enameled cloth not being porous, will prevent moisture from evaporating. If the colony is warm enough to prevent this moisture from freezing, all may go right; otherwise the colony will probably be lost.-J. E. POND, JR.

I have need it in just this way for I have used it in just this way for about ten years with the best of suc-cess. Enameled cloth is the best thing I have found to cover frames and sections. When put up for win-ter put plenty of dry, warm covering on top of the enameled cloth. I use a chaff anglian in the cover of the section. chaff-cushion.-H. D. CUTTING.

I have not. I tried it once and did not like the result. I now think that it was because it was not warm enough over the cloth. I think that it is just as well to use wood or oil-cloth, but we must keep this so warm that water will not condense below.— A. J. COOK.

## Storing Comb Honey.

Query, No. 250 .- Does comb honey in sections lose in weight in being stored away, alter being taken off from the hives ?-S.B.

Not perceptibly, unless it leaks .-DADANT & SON.

I presume it does a very little, if in a place favorable for drying .-- C. C. MILLER.

It probably does if it is in an atmosphere conducive to evaporation .- W. Z. HUTCHINSON.

I have never found it to do so, and I do not think that it will to any per-ceptible degree.—J. E. POND, JR.

Possibly a little in warm, dry rooms. In damp rooms it may gain in weight. -A, J. COOK.

Slightly if stored in a warm, dry room. If in a damp, cool room it gains slightly and deteriorates fast.— G. M. DOOLITTLE.

If exposed to currents of air prob-ably it would lose in weight. The

nicest way to keep comb honey is in white poplar shipping-crates, warm, dry rooms.—G. L. TINKER. in

If kept in a dry, warm place it will lose slightly in weight; but if stored in a damp place it will gain slightly in weight by absorbing moisture from the atmosphere, to the injury of the honey.-G. W. DEMAREE.

It may lose or gain according to its chance to "ripen" or absorb mois-ture. I should prefer to have mine where it would lose in weight. We cannot be too particular about the really good quality of our honey. It will pay us well to look to this point. -JAMES HEDDON.

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., May 10, 1886.

The following are the latest quotations for honey and beeswax received up to this honr:

#### CHICAGO.

<sup>10</sup> HONEY.-Comb is coming forward more freely and prices now are 15∞16c. for 1-lb. sections. Ex-tracted is in light demand at 5@7c. Californis comb honey. in 2b. sections, 9@12c. BEESWAX.-23@24c. per lb. Not much offered. K. A. BURNETT. 161 South Water St.

#### NEW YORK.

NEW YORK. HONEY.- We now quote: Fancy white comb in 1-lb. sections, 12@13c.; in 2-lb. sections, 9@10c. Fancy buckwheat honey in 1-lb. sections, 9c.; in 2-lb. sections, 7@8cc. Off grades 1@2c. per lb. less. Extracted, white, 6@57c; buckwheat, 5@554c. Call-fornia, 5@6cc; Southern, as to color and flavor, per galloo, 50@60c. BEEEWAX.-27@29c. MCCAUL & HILDRETH BROS., 34 Hudson St.

#### BOSTON.

HONEY.—One-lb. sections, white clover, 13@15c; 2-poind sections, 11@13c. Extracted, 6@8c. BEESWAX.—25 cts, per lb. BLAKE & RIPLEY, 57 Chatham Street.

#### SAN FRANCISCO.

HONEY.-White and ex. white comb, 11%@13c.; dark comb, 6%cokc. White extracted, 5%co%c.; amber, 46%c; dark and candled, 3%de4c. BEESWAX.-Quotable at 20@23c., wholesale, O. B. SMITH & Co., 423 Front Street.

DETROIT. HONEY.-The market is almost bare of comb honey, and very little is wanted. Best white in 1-ib, sections 14 cts. BEESWAX.-Scarce at 25c. M. H. HUNT., Bell Branch, Mich.

#### ST. LOUIS.

HONEY.—Choice comb, 10@12c. Strained, in barrels, 4@5c. Extra fancy of brikbt color and in No. 1 packages, ¼ apvance on ahove prices. Ex-tracted in barrels, 5@5%. BEESWAX.—Firm at 21½c. for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEY.-Trade is perhaps duller than usual. We quote : Extracted honey brings 4@8c., and choice comb honey brings 12@15c. in a jobbing way. BEESW AX.-In demand at 20@25c for yellow. C. F. MUTH & SON. Freeman & Central Ave.

#### CLEVELAND.

HONEY.—One pound sections, 14@15c.; 2-lb. 13c Extracted, 7@8c. BEESWAX.—Scarce at 25c. A. C. KENDEL, 115 Oniario Street.

#### KANSAS CITY.

HONEX.-Sales of comb are good, while extrac-ted is very dull and low. One-pound sections are scarce: stocks of all other grades are well supplied. Calif. 2-bs. bring 11@12c.; Eastern 2-bs. 12@13c.; 1-bs., while, 14@15c.; dark, 12@13c. Extracted 5@6c.; Southern, 3%@4c. BEESWAX.-23c. CLEMONS, CLOON & Co., cor. 4th & Walnut.

#### MILWAUKEE.

HONEY.—The receipts of hooey have been more liberal of late, and the supply is now very fair. We quote: Choice comb, in 1-1b, sections, 17@18c.; in 2-1bs., 16@17c. Extracted, white, in kees or tin, 75@kc.; dark, in the same, %60%c. BEESWAX.—Demand moderate at 25c. A. V. BISMOP, 142 W. Water St.

Explanatory.-The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist ls located near the centre of the State named:  $\delta$  north of the centre;  $\varphi$  south;  $\Theta$  east; •O west; and this o northeast; ~ northwest; ∞ southeast; and 9 southwest of the eentre of the State mentioned.

For the American Bee Journal.

## Hum, Sweet Hum.

#### EUGENE SECOR.

The'soft strains of music from palace may come, Be it ever so charming, there's no sound like "hum."

"hum." The bees are so busy this bright, sunny day, There's joy in the air—so happy are they. Hum, hum—sweet, sweet hum, In all be bright spring-time, there's no sound like "hnm."

When prisoned at home during Winter's long reign, How joyous to bask in the sunshine again ! The birds singing gally, the frog's cheery call— Give me them-and the "becnote," sweeter than all.

Hum, hum—sweet, sweet hum. e "bee-man" can never dispense with their hum. The

To me there is nothing so sweet to the ear, As the nusic that comes from the apiary near. No allurements abroad can entice me away From the spot where the bees, tho' at work, seem to say, "Hum, hum-sweet, sweet hum, No labor is irksome to us when we hum."

Toil on, little workers-evangels are ye Of the sweets in this world to be garnered by me-The sweets that from cheerful activity come; Then cease not to labor, continue to hum. Ilum, hum-sweet, sweet hum, There's no earthly music like *Industry's* hum.

Forest City, Iowa.

For the American Bee Journal.

Large Honey-Yields, Wintering, etc.

#### WM. F. CLARKE.

I have been strongly importuned to write out in full the remarks 1 made Convention, which will be always memorable to bee-keepers as the one on which the winter problem was forever solved, and the main difficulty in the way of successful bee-keeping removed. It is not easy to satisfy this request, because what was said was almost wholly spoken on the spur of the moment, and under the in-fluence of exciting circumstances that cannot now be recalled. The AMERI-CAN BEE JOURNAL gave a very correct report of my remarks as follows :

"Rev. W. F. Clarke said there were three matters of great importance to him which had transpired to-day. First, Mr. Hall had explained his method of bee-keeping, and he was much obliged to him for it. Second, Mr. Barber and Mr. Hall had sup-plied confirmation of the hibernation

theory. A year ago he did not un-derstand Mr. Barber's method. Mr. B. said at the Rochester Convention that he (Mr. C's) method was a cold system of wintering, and his (Mr. B's) a warm one. This was a mistake. Our systems are alike, only Mr. Barber secured the right temperature in the whole cellar, and I secured it in the single hive. But Mr. Barber's hees quiesce in the fall; if the hive is too full of bees, a cluster will hang outside; they remain in torpor until the breeding instinct awakes, and then they arouse to activity. Third, then they arouse to activity. Third, the pollen theory has got its quietus from Prof. Cook. He has told us in scientific terms the nature of beefood, and the process of assimilation. He has maintained that bees cannot breed without pollen, and that they cannot stand work without taking nitrogenous food. If they take that food it must be digested, and the feces excreted. Well, Mr. Barber and Mr. Hall have proved that bees breed barrely is a work hard and therefore largely, i. e., work hard, and therefore must eat and digest strong food. The inferences are plain. The bees, if they excrete, do it in dry feces. They must excrete, that is clear. Therefore, there is no danger in having pollen in the hive. On the contrary, it is necessary."

Taking the above as a text, 1 will endeavor to explain and amplify upon it for the information of those who were not present. First, as to Mr. Hall's method of bee-keeping: I had long known that Mr. H. had been in the habit of obtaining prodigious yields of comb honey, one season averaging as high as 250 pounds per colony. Naturally, I had been trying to find out how this was accomplished. I will not say that Mr. Hall had wil-fully tried to conceal his art, but confess that I had been stupid enough host to discover where the sceret of his success lay. The apparently sim-ple questions of Mr. Muth made the mystery clear. They were as follows:

"C. F. Muth asked if he understood Mr. Hall correctly yesterday, that his honey harvest closed about July 20, and that last year he did not put his bees out until May 2. If so, how did he obtain a sufficient force of bees to get in the honey during so short a harvest?

"Mr. Hall replied that the secret lay in the bees being kept so warm that they bred early. He expected his bives to have several combs with brood in them by the time he put them out in the spring. By May 20, there would be not only brood in 6 or 7 combs, but that number full of brood. Ile could not winter without pollen, because if he did, he would not have his bees bred early enough in the spring to gather in the honey. If they started without brood they would not build up to strong colonies until near winter.

It was no new thing to be told that we must have a numerous force of workers in readiness to gather the honey harvest. We have known that from time immemorial. How to do it, was the question; how to multiply bees in time for the brief season of

ingathering. If they did not breed until they came out of winter quar-ters, there would not be time to rear ters, there would not be time to Mr. the force of workers needed. Mr. Barber and Mr. Hall winter their bees in such a way that they begin to breed long before spring opens. They house them in a temperature which enables them to hibernate in early winter, and then when the breeding instinct rouses up, to generate warmth sufficient to hatch out young brood.

Messrs. Barber and Hall treat a cellar as if it were one vast hive, and regulate the temperature so that the bees can control it at will. It is kept at a point which favors hibernation so long as the bees remain inactive, but becomes warm enough for broodhatching whenever the bees begin to bestir themselves, as they do about mid-winter. The same phenomenon happens in a hive so packed out-ofdoors that the temperature inside can be regulated by the bees. They sink be regulated by the bees. into the hibernating condition on the approach of "winter, and they arouse to the work of brood-rearing on the approach of spring. It is all a question of temperature.

The third point is in reality anticipated. Bees cannot breed without pollen. If there be none in the hive, they must await the advent of spring to start brood-rearing. That is too late to provide the requisite working force to gather in the honey harvest. So the presence of pollen in a hive, instead of being a source of danger is absolutely necessary to the welfare of a colony. In proving the indis-pensableness of pollen on the resumption of activities in a hive, Prof. Cook extinguished the theory which makes the absence of pollen a condition of successful wintering.

The light on these three points shone so clearly and blended so harmoniously that, to me, it was like a new revelation. I seemed to see all at a glance. It was like sunrise when you are standing on the mountaintop. The standpoint is such that every object is illuminated at once. Every one did not share my feeling of ecstasy, because all had not climbed by the same dark, rugged road as I had to the mountain-top, or if they had, they had fallen asleep with the toil of the ascent, while I was wide awake, and eager for the expected vision. So I beheld the sun-burst, they did not; I was enthused, and they were not.

I see that Mr. Demaree, since the convention, resolves the large yields of honey gotten by Mr. Hall, into "locality." This, I think, is a mis-take. I do not doubt that Mr. Hall get a much larger honey crop than he does at Woodstock, Ont., for the very reason that he would obtain it from a slow, steady yield of nectar, instead of having to prepare his bees for a single brief "dash" at the honey flow. If we can get our hives brimful and running over with bees by the time the first bloom comes in the spring, we shall secure large yields of honey in any average locality, be the season a brief or a protracted one,

Guelph. Ont.

## My Report for 1885.

#### B. F. WOODCOCK.

As I have kept a strict account of the expenses and receipts of my apiary during the season of 1885, it may not be uninteresting should I present it for inspection.

My number of colonies in the fall of 1884 was 37; in the spring of 1885, 34; 1 then doubled them, down to 30. I credited my apiary with the following:

| 1345 lbs. comb honey at 15c\$201     |    |
|--------------------------------------|----|
| 1710 lbs. extracted honey at 10e 171 | 00 |
| 4 Italian colonies sold              |    |
| 1 hybrid colony sold                 | 00 |

Total.....\$404 75

In addition to the above I think I should be safe in counting my in-crease, as I had them out for a flight a few days ago, and every colony was alive, and in fine condition. I had 36 swarms, but I sold some and doubled down the rest to 28. This would, at \$5 per colony, add \$140, making \$544.75. Our good friend, Dr. Miller, can count the swarms or not, but if he does not, we will make them count next summer.

It may be asked, "But did yon pay out no money?" Yes, and here are the figures:

| 30 lbs. of foundation\$            | 9        | 75 |
|------------------------------------|----------|----|
| 650 1-lb. sections                 |          | 25 |
| 300 2-lb. sections                 | <b>2</b> | 00 |
| Glass, nails, tacks, etc           | 2        | 00 |
| I keg of white lead & 2 gals. oil. | 3        | 00 |
| Oil-cloth                          |          | 00 |
| 20 Langstroth hives in the flat. 1 | 2        | 50 |
| Honey-pails not returned to        |          |    |
| stores                             | 2        | 45 |
|                                    |          |    |

Total.....\$35 95

I do not charge up the remaining 8 they were kept over from the previous year, and had been charged up to that year's honey account.

Some may inquire, "How about your honey-crates and kegs?" The bees were charged with and paid for when I sell a keg of honey I charge the purchaser with the keg.

"How do you get 10 cents per pound for all your extracted honey, when we are glad to get S cents, and throw the keg in ?" I do it by having worked hard for seven years to create a home market. I hever have shipped a pound of comb honey, and very little extracted. I sell most of the ex-tracted honey at my door in 3 to 5 gallon jars, the customer in almost every case buying the jar along with the honey, and that at a profit to me, as I buy them by the wholesale. The honey is all sold except about 250 pounds, and I could sell that in half a day by hitching up the ponies and "How do you get 10 cents per pound day by hitching up the ponies and going out with it; but it is not neces-sary as it will all be taken away from

I am not permitted to count my increase, \$368.80 I have kept bees for nine years, and there has been but one year out of the nine in which the bees did not give me 50 per cent. better results than anything on the farm. If any one wishes to know bow I managed my bees to get over 100 penude per cent. 100 pounds per colony, spring count, in an average season, the information will be freely given. Pleasantville, § Iowa.

Johnson Co., Ind., Convention.

The Johnson County, Ind., Bee-Keepers' Association met at Franklin, Ind., on April 3, 1886, with Pres. Hall in the chair. About 60 bee-keepers were present, and the con-Pres. Hall delivered his annual ad-dress, on "The Bible Bee."

The following officers were elected: The following officers were elected: President, C. H. Hall, of Franklin; Vice-President, W. W. McCaslen, of Franklin; Secretary, L. R. Jackson, of Urmeyville; and Treasurer, Phebe J. Kelly, of Franklin. Prof. D. A. Owen then read an interesting essay on "The Benefits of Bee-Keepers' Associations." The fol-lowing experiences were given:

Bee-Keepers' Associations." The fol-lowing experiences were given: H. H. Luyster—I first commenced bee-keeping with the box-hive. I made a failure of it, and in a few years lost all my bees. In 3 or 4 years I tried it again with the Langstroth bive out here since been mederately hive, and I have since been moderately successful.

A. T. Kelly—I have 27 colonies in Langstroth hives. Bees have wintered well.

L. R. Jackson-I have lost 5 out of 6 colonies of my Syrians. The Ital-ians have wintered without loss.

G. Kerlin—I had 30 colonies last fall, and I think they are all alive now. I give no protection to them, and lose but few bees.

H. Williams-I protect my bees by a tight fence on the west side of the apiary, and a shed over the hives. filling the upper stories with leaves to absorb the moisture. W. W. McCaslen—I give my bees no

protection. I wintered them in a house one winter and lost all of my bees, and now I prefer to leave them on the summer stands.

H. II. Luyster—I winter my bees without protection. This winter I left the boxes on a part of them, and the hive-covers of 2 colonies were so warped that they had strong upward ventilation, yet they are in good condition.

John Tilson-I put part of my bees into the cellar, and they have used less than half as much honey as the ones left on the summer stands. They are all living and in good condition. I do not believe that bees will freeze. They may chill so that they cannot

cellar and out-doors, and I prefer leaving them on the summer stands. During my father's life we built a large cellar for our bees, and the first winter we did not lose a colony. The next winter we placed the bees in the cellar and lost all; since that I have tried every way that I have heard of, and I find nothing that suits me as well as to lay sticks across the frames to hold the quilts up, and cover with forest leaves. I do not believe that bees will freeze as long as they can get to the honey. They may become chilled, and to all appearance be dead, and remain in this condition for 24 hours, and then if they are warmed and fed they will live.

Prof. Owen—I would like to know if our bee-keepers generally keep a record of their bees, and know the condition and the work of each colony. I believe it very essential that this should be done. If we wish to suc-ceed in any business we must know what we are doing.

F. L. Dougherty-I keep a record of my bees.

L. R. Jackson-I also keep a record of my bees, the age of the queens, and the amount of honey taken from each colony.

#### Adjourned till 2 p.m.

#### AFTERNOON SESSION.

The convention was called to order

at 2 p.m., Pres. Hall in the chair. On the subject of "Spring feeding of bees," Mr. F. L. Dougherty said-I would not feed to stimulate breeding. If the bees are short of stores, feed enough at once to last them.

L. R. Jackson-Do bees hibernate? Prof. Owen says that they do not; some others say positively that they do. I have never found them in a do. condition that I would call hibernating.

Pres. Hatl — That depends upon what is meant by "hibernating." More than % of the discussions of this subject come from not understanding the true definition of the term used. If it is meant exactly what the word really means, they do not hibernate.

F. L. Dougherty—A few—only a few—claim that bees hibernate; but they have been downed at every point of their argument. It seems to me an easy thing for any one to settle this question in his own mind. I have opened a hive of bees every day in the year, and have never found them in a condition to be called hibernat-ing. The least jar will cause the bees to move, which they would not do if they were hibernating.

#### PREPARING FOR THE HONEY-FLOW.

Pres. Hall-I put the boxes on and let the bees get ready themselves. I do not pretend to know how it should

be done. A. T. Kelly—I put the boxes on when the bees begin to whiten the combs in the brood-chamber.

going out with it; but it is not neces-sary as it will all be taken away from the honey is on the market. The way I figure it, my bees have given me \$508.80 for my pains; or, if

one time. When bees begin to get a surplus of honey, they will come in heavily laden and fall in front of the hive, many of them before they reach the hive. To get bees ready for this, remove all the combs that the bees do not need, and when they get these well filled with brood, give them another comb by spreading the brood, and add frames in this way as fast as they will use them. Do not give them combs too fast, or the bees can-not use them, and the brood will become chilled. At the beginning of the honey-flow give them two empty combs in the brood-chamber, and put on the boxes. This gives the queen room in the brood-chamber and the bees in the boxes, and .if you have managed rightly all the other frames will be filled with brood from top to bottom, and the bees will usually go to work in the boxes at once.

#### FOUL BROOD.

F. L. Dougherty-I have seen but F. L. Dougherty—I have seen but two cases of foul brood, and know but little about it. If I had a case I would burn both bees and hive at once. If I had a large apiary affected with it, I do not know what I would do with it.

L. R. Jackson—I have had no experience with it. I found several cases of it at and near Vevay, Ind.. last spring. I learn that there is some of the Vevay honey in our market now, and I would caution all bee-keepers against buying any honey to feed their bees, as some are talking of doing. Do not buy honey to feed your bees unless you know where it comes from.

Pres. Hall-I once had a colony of bees that was nearly all drones. Was it queenless?

F. L. Dougherty-I think that it was, and had what is called a laying worker.

W. W. McCaslen—I once had such a colony. I do not believe that they were perfect drones. They were small and not fully developed. I put a swarm in with them and they killed all the drones in a few hours.

F. L. Dougherty-The drones were perfect, and were only small because they were reared in worker cells. If they had been reared in drone cells, they would have been as large as any drones.

PROTECTION AGAINST BEE-MOTH.

Pres. Hall-I know of no protection

as good as a strong colony. F. L. Dongherty—There is no protection except strong colonies. It is natural for moth to eat beeswax, and they are the only thing that can digest it. A strong colony is never bothered with moth. To see what a strong colony could do with moth. I gave such a colony a comb literally alive with them, and before night they had carried every moth out and torn down the comb and carried the web and all away.

#### DIVIDING COLONIES.

L. Dougherty - Many persons divide their colonies until all are so weak that none of them are of much stay in the ground longer.

value. One strong colony can rear more brood than three or four weak ones. Colonies should not be divided until they are nearly ready to swarm.

Pres. Hall-What are the indica-tions of bees swarming?

F. L. Dougherty-Building queencells.

A. T. Kelly—Can you keep back a swarm by cutting out the queen-cells?

F. L. Dougherty—It is a disadvan-tage to cut out the queen-cells to prevent swarming. If they have commenced to build queen-cells it is best to but they group or divide best to let them swarm, or divide them. The bees may be hived on empty frames for a few days and then returned to the old hive and be satisfied.

Pres. Hall-Is it an advantage to clip the queen's wing? F. L. Dougherty—It is. If you are

there when the bees swarm, to catch the queen as the bees come out, and put an empty hive in the place of the old one, the bees will return and go in it. If you are not there, the bees will return to the old hive and may be divided.

T. Kelly-Are the bees not Α. liable to go into some other hive ?

F. L. Dougherty – They may at times, if there is anything to attract their attention to some other hive.

A. T. Kelly-That is the trouble with my bees, and the reason I object to it.

F. L. Dougherty-There is no more danger from this than any other way. Anything that would attract their attention to another hive in this way would attract them in any other way.

W. T. Hougham-Is it the old or young queen that comes out with a lirst swarm ?

F. L. Dougherty-The old queen always goes with a first swarm, unless she has been superseded. John Tilson—Bees will always sting

me when I go near them.

F. L. Dougherty-It is usually our own fault if we get stung. Many persons use too much smoke, and drive the bees from the combs before they fill themselves with honey. Every bee thus treated becomes an

enemy. W. W. McCaslen-Why are some

F. L. Dougherty-It is usually second swarms that have come from hives that are short of stores.

H. H. Luyster-How far will bees go for honey?

F. L. Dougherty-Usually 2 miles; sometimes 5 miles. When they have to go over 2 miles they cannot work to much advantage.

W. W. McCaslen-Has Alsike clover any advantage over white clover, for bee-pasturage ?

F. L. Dougherty - It has more bloom, and by cutting it may be made to bloom almost the entire season. It is superior to red clover as a feed or for pasture for stock, and is better as a fertilizer. W. W. McCaslen—Is it as hardy as

red clover ?

L. R. Jackson-I think that it is a hardier clover than the red, and will

John Tilson—I have a field of it that has stood 3 years, and is good yet. I never had red clover to stand 3 years. The convention then adjourned.

L. R. JACKSON, Sec.

For the American Bee Journal

## Bees Swarming Out.

J. C. WILSON.

On April 17, I had 2 colonies of bees swarm out within a few minutes of each other, and settle near together. As I was too busy to give them attention, my brother-in-law undertook to put each swarm into a separate hive, but not being accus-tomed to handling bees, he soon suc-conduct were used to reacting beth ceeded very nicely in getting both swarms into one hive, and thinking all would go on well, except the combat between the queens, he placed the hive where it was to stand. About noon the following day I found the portico still filled with bees—I think about four quarts—and I determined to see if I could not tickle the sulks out of them, put them into the hive, and they would then go to work.

During the process of tickling, which was done with a small limb from a bush, with a leaf or two on it. I found one of the queens "balled." I washed the bees off in a basin of water and caged the queen and took her to my piazza steps, about 50 yards from the bee-yard. As she dried off I offered her honey, which she took ravenously, and I determined to pass her to another cage, which I thought better for introducing, and in so doing I let her get away. She made one circle to mark the location, and then flew away. Giving her up as lost, I returned to the hive to go on with the tickling, when, to my astonishment, I found the other queen "balled" also. After washing the bees from and caging her. I again repaired to the steps to take care of her. A moment after I reached the steps, the first queen, which had flown away about 25 minutes previously, returned. I knocked her down with my hand, then picked her up and again caged her, and introduced her to the colony, and all is going on well.

This may be no new thing to veteran bee-keepers, but to me it teaches some important lessons, viz: First, I believe the bees "balled" both queens whilst fighting, in order to save themselves from total destruction; and second, how quickly and precisely bees mark their location.

Ridgeland, 9 S. C.

For the American Bee Journal. Granulated and Thin Honey.

20-J. O. SHEARMAN, (136-116).

Query, No. 229.mentions granulated honey. I would say that this fact is not given due prominence by bee-keepers generally, that granulated boney is a very serious cause of loss of bees in winter and spring. Mr. H.

D. Burrell wrote me that a number of his colonies had died by reason of their stores of sugar becoming granulated. I find that the thin honey is more apt to granulate than thick, well-ripened honey, and the bees cannot live on it in cold weather. The granulated particles are of no use to them, and the remainder is so thin as to be unwholesome food for them in cold weather. Besides, any little warm spell will cause the thin liquid to sour, causing bee-diarrhea even after the brunt of winter has passed. I lose more bees in March and April from these causes than from all other causes combined

Last week I found a rather small colony that actually had starved with plenty of comb honey in the hive, and only one comb removed from the cluster. They had a patch of brood as large as my hand in two combs, and I had taken out extra combs and and r had taken out extra combs and put the combs with honey close to the brood-nest, but I did not notice that it was granulated; then a few days of cold weather came, and they could not get enough out of it to keep them and their brood warm. I have noticed others dwindling and leaving their brood nest to store the would their brood-nest to starve (they would even cluster in some other part of the hive); and in every case when I cut into their honey I found it granulated.

I find that all of my colonies that wintered in good condition, and are strong, have thick, waxy honey in their hives—with no grain in it. I claim that this thin honey was gath-ered late in the fall, or too late to ripen well. We had a long, cool fall last year. My loss would have been greater than at present (20 colonies), but my bees had a sort of half flight in February that enabled them to get rid of some of the thin honey juice. The remedy for it is extracted honey, fed warm.

Tipping the brood over will not injure it, as Mr. H. Clark mentions on page 220. I fed a nucleus frame of comb honey last spring, by laying it flat on top of the frames of a strong colony, before unpacking them ; they filled it with brood head downward.

New Richmond, 9 Mich.

For the American Bee Journal.

Marion Co., Iowa, Convention.

The Marion County Bee-Keepers' Association met at the residence of Dr. H. J. Scoles, in Knoxville, Iowa, on April 15, 1886, President B. F. Woodcock in the chair. The attend-ance was large, and an increased interest was manifested by all.

The reports of those present gave great encouragement for a grand harvest from the labors of the blessed bees. The majority had wintered their basis of the second their bees in cellars or caves. The temperature was kept at from  $40^{\circ}$  to  $45^{\circ}$ , Fahr. A few wintered their bees on the summer stands. Of 292 colonies put into winter quarters 288 were reported in good condition and very strong. Several reported drones fly-ing, and brood in frames from side to side.

Mr. Heddon's new hive was ex-hibited by Mr. J. W. Bittenbender, and its merits discussed. All were and its merits discussed. All were favorably impressed with the hive, and were unanimous in the opinion that Mr. Heddon's patent was good, and should be respected. Some en-thusiastically declared that it would work a revolution in bee-keeping.

The one question of importance and interest asked and discussed was, "How shall we prevent or control swarming and yet obtain the best yield of surplus honey?"

Bees were never in better condition. The season is nearly two weeks early. Prospect for bloom of honeyplants is excellent-never was better. Count on 100 pounds of surplus honey to the colony for Marion county, for 1886. · ALBERT M. BROBST, Sec.

Official Report of U.S. Entomologist. Production of Wax, Feeding, etc.

#### N. W. M'LAIN.

Experience has taught me, in common with all progressive apiarists, that in the production of wax for honey-comb building, there is serious prodigality. Much valuable time is lost and much energy is expended, which, in view of the shortness of the honey-producing season in nearly all parts of the United States, results in a serious reduction of the possible efficiency and honey-producing capacity of bees, and a corresponding curtailment of the profits possible to be realized from the industry. To overcome this waste of time and prevent the large consumption of honey required for producing wax for comb-building, the comb foundation ma-chine and the honey extractor have been almost universally adopted by progressive bee-keepers.

As another step in economic methods for securing the best results from the cultivation of bees, I have made some experiments in what may be called wax-feeding or furnishing

The price of beeswax in the open market ranges from 20 to 35 cents per pound, according to quality, and varying with the supply and demand. Estimates can easily be furnished to prove that the production of every pound of wax costs the bee-keeper ten times the sum realized from its sale. If account be taken of the loss resulting from having the time and energies of the bees expended in wax production, instead of honey-production, at a season of the year when there is most imperative need for uninterrupted and diligent activity in honey-gathering, and of the value of the honey consumed in producing wax, and of the labor required in wax, and of the labor required in preserving and preparing the wax for market, it will readily be seen that the production of a pound of wax, costs the producer many times the current prices realized. About 20 pounds of honey are consumed in producing one pound of wax. If a ing, in order that the colonies may be method of management can be de- strong in numbers when the blossoms vised and introduced by which the appear. I use this device also for

loss sustained in wax-production and comb-building can be still further reduced, a corresponding percentage will be added to the profits of those engaged in the industry.

I observed that if pieces of new comb were exposed on a warm day, the bees would tear off pieces of the wax and carry them to their hives for use in comb-building. I then put pieces of new comb in a shallow, square tin-pan having a close-fitting cover, and having holes in the bottom. This pan being placed on the cloth covering the comb frames in the hive, holes were cut in the cloth registering with the holes in the bottom of the pan, thus affording a passage for the bees into the pan. The heat arising from the bees produced a high temperature in the closely-covered pan, keeping the wax plastic and easily worked. When such auxiliary re-sources were furnished, comb foundation was drawn out and completed with great rapidity, and this work appeared to be performed largely by the young bees, aided by the field bees at night, as the comb-building pro-gressed more rapidly by night than by day. There being no necessity for wax producing, the working force labored without hindrance during the day in the fields, and with equal energy by night in the hive. Whenever the space above the frames is not being used for superstorage, this method of furnishing wax may be employed without inconvenience.

#### DEVICE FOR FEEDING SUGAR SYRUP.

I have also devised a fixture for use in the brood-chamber in the body of the bive, which serves a variety of uses, and proves well adapted for the purposes for which it is designed. It consists of a wooden frame of the size of those used for brood-frames, the strips of which it is made being 3/8 of an inch thick and 2 inches wide. Parallel with the top-bar of the frame I suspend three tin troughs, one above another. These troughs are 134 inches wide and 2 inches deep, and the length corresponds with the inside measure of the frame. Beginning 11% inches below the top-bar, the troughs are suspended, 1 inch apart, by means of a small screw from the inside of the end of the trough entering the side-bar of the frame. The first trough next to the top-bar has a partition, one-fifth being intended to contain water, and the remainder is used to supply honey or syrup. The second trough is used to syrup. The second trough is used to supply pure wax shavings, and the third is used for supplying flour or meal as a substitute for pollen. These inside and out, as bees do not readily get a foothold on the smooth tin. The trough for food and water is supplied with floats to prevent the bees from drowning.

This fixture, supplied with food, salty water, shavings of pure, bleached wax, and flour, I place in the centre of the colony as early in the spring as it is desired to stimulate brood-rear-

supplying wax shavings in the body of the hive when surplus honey is being stored above the frames, and if floats are supplied for each trough it makes an excellent inside feeder when feeding syrup preparatory to winter. The wax used is clarified and bleached in the usual manner and shaved with a sharp knife. If very thin comb foundation with shallow walls be used in the sections, a superior quality of

The second secon syrup. A rim of tin reaching within half an inch of the cover is soldered in the holes, through which the bees enter the feeder, and a raft or float made of thin strips of wood supports the bees when taking their food. The advantages to be gained by using such a device when building up colonies in the spring, or during the working season, when time is honey, will be appreciated by those who give it a trial.

#### WINTERING BEES.

Each of the different methods of wintering bees, whether in cellars, in bouses, or upon the summer stands, has its advocates among experienced and progressive apiarists. Success by any method depends largely upon the proper observance of a variety of conditions. Failure to comply with essential conditions brings failure by any method.

The lack of water during long confinement has been accredited with due consideration as a prime cause of the frequent severe losses in winter. Observation and experience suggests the inquiry as to whether as many bees do not perish each winter from the lack of water as from the lack of food. In the northern half of the United States bees are often confined to the hive continually from 100 to 150 days. Frequently the suffering from thirst is intense, as is evidenced by the bees going from frame to frame, visiting every comb and uncapping the honey in search of water.

I have frequently observed these chips of cell capping distributed all the way through the pile of dead bees in the bottom of the hive, and on the bottom-board, showing that the bees were suffering for water when they began to die. Perishing from thirst day by day the cluster dwindles until, a mere handful being left, they succumb to the cold.

Excessive thirst and prolonged low temperature cause what is called "roaring in the hive." Disquietude from any cause induces excessive consumption; diarrhea follows: death usually results. I have frequently quieted roaring in the hive and restored the bees to their normal condi-

stored the bees to their normal condi-tion of quietude by supplying water. For furnishing the bees water in winter without disturbing the clus-ter, across the tops of two comb frames, and above the intervening space between, I place a block 3 inches sont inches songe and 2 inches inches or 4 inches square and 2 inches thick, through which is a 2-inch auger hole. In the bole in the block is placed a sponge dipped in water and

the water from dropping on the bees below. The blanket being replaced, the heat from the bees prevents freezing, and usually the sponge will be sucked dry in 24 hours.

The sponge should be thoroughly rinsed before refilling. The water given the bees should be lukewarm and brackish. The salt is relished by the bees and acts as a corrective. - I f cushions are used above the frames, the sponge may be suspended between the frames above the cluster by means of a fine wire. A mild day should be selected for watering the bees. If after the bees have been confined 50 days a sponge full of water be given every 30 or 40 days during their stay in winter quarters, in many cases valuable colonies will be saved which would otherwise be lost. Whether the bees are to be wintered indoors or on summer stands, the arrangement of the hives should contemplate the practicability of giving water.

#### IMPORTANCE OF APICULTURE.

As the economic importance of this industry is more generally realized, a wide-spread and growing interest is manifested in this much-neglected branch of rural husbandry. The lack of practical knowledge is the main hindrance now existing in the way of the very general adoption of this pursuit among agriculturists, as nearly all parts of the United States are well adapted to profitable bee-keeping.

An idea of the present importance of this industry can be gained from the following figures, taken from the report of the statistician of the Northwestern Bee-Keepers' Society for 1884. He says : "According to conservative estimates we have now a total of three millions of colonies of bees, which annually yield 120,000,000 pounds of honey. The value of the annual product, at an average of 15 cents per pound, would be \$18,000,000."

The estimated annual product ranges from \$15,000,000 to \$20,000,000, and the annual product of wax is about \$1,000,000 in value. Not more than 8 or 10 per cent. of those favorably situated for the cultivation of bees are engaged in the pursuit. If even one-half of those favorably situated were so engaged, the annual product would not fall below \$75,000.-000 or \$\$0,000,000 in value. The United states imported 2,400,000,000 pounds of sugar, at a cost of \$94,923,500, in the year 1884.

A large percentage of these imports do not bring with them a character above suspicion. Instead of being importers we should be exborners of sweets, with the balance largely in our favor. Instead of pay-ing their money for the vile adulterations of foreign importations, our agriculturists should gather the pure wholesome nectar annually and wasted in their own fields.

The degree of skill necessary to engage successfully in the cultivation of bees and the production of honey is not greater than that required in keeping a dairy and producing good dairy products. The difference is in squeezed out sufficiently to prevent kind, not in degree, of skill, and one

is as easily acquired as the other. That reliable reports concerning this industry may be furnished in the bulletins and annual reports of the Department of Agriculture is earnestly wished for by all progressive bee-keepers. Reports giving the number of colonies in the several States and Territories on the first day of June, and crop reports of apiarian products the first day of August and the first day of October of each year, would be of very great value. The facilities possessed by the Depart-of Agriculture, through their correspondents, furnishes the best means for obtaining reliable statistics and crop reports. That such facts and statistics may be furnished in the bulletins and reports of the Department is earnestly desired.

## Feeding Sugar to Bees.

#### R. F. HOLTERMANN.

The question of feeding sugar has been brought up in many lights. I do not think the apiarist can take 25 or 50 colonies in his apiary and feed them sufficient honey for winter stores to advantage, assuming that he can realize 16 cents per pound for his honey, and obtain sugar at 8 cents per pound. I have had large and somewhat extensive experience in feeding syrup, and not by any guess-work, and I am satisfied that however rapidly (rapidly it should be done to obtain the best results) the syrup is fed after the honey season has closed, the difference between the weight fed and the quantity left in the combs after the bees have quieted down, and the syrup is ripe, is astonishing. I have never attempted to feed syrup directly; at the close of the honeyflow it might be less then. I have generally fed it before frost, however. Then the idea advanced that to feed sugar syrup means so much more honey thrown upon the market, is decidedly practical, and no theory.

Again, the fact that many look with suspicion upon such quantities of sugar going to the apiary is also a sound, indisputable fact. If I were to theorize, I would account for the loss of weight as partly owing to the undue excitement of the bees when storing the syrup, the increased consumption necessary to perform the work, evaporation, etc. I should say that this revival of activity debilitated the bees and decreased their powers of coping with the coming winter. I also believe that we will yet learn that in order to enable the system of the bee to excrete and add certain constituents to the honey or syrup, they require conditions other than confinement to the hive-cool nights, perhaps, or cool days. Who will answer this question? Why does honey extracted, then fed to the bees and sealed by them, granulate in the comb, when honey in the same comb not so re-fed will not granulate? Brantford, Ont.

For the American Bee Journal

## Cause of Loss in Winter,

#### L. REED.

I have kept bees for 33 years, first in the old box-hive, next in the crossbar hive (as it was called), and then in the Langstroth hive. When I kept bees in the box-hive I had no losses to speak of. I wintered them on the summer stands without any protec-tion, in the southern part of this State; but since I adopted movable frames I have had more or less losses in wintering.

My experience in bee-keeping in this country commenced with 4 colonies of Itatlian bees in Langstroth hives. 1 got them in August, 10 or 12 years ago, and put them into an outdoor cellar or cave for the winter. They had plenty of good honey, and the hives had on honey-boards 1-inch thick, glued down tight. The hive-bottoms were nailed on, and there bottoms were nailed on, and there was no ventilation whatever. The cellar was 10x12 feet, and not venti-lated. I took them out on April 1, and they were in extra good condi-tion, full of bees, and young bees hatching. They commenced swarm-ing on June I, and swarmed twice each in June. One of the old colo-nies cast the third swarm on Aug. 6, something yery unnsul. I put them something very unusual. I put them into a large box-bive and they filled it in two weeks. I put on a 10-pound box and they filled that. The 13 colo-nies averaged a surplus of 75 pounds each.

I put them into the same cellar in the same way, and they came out the next spring in good condition; with no loss. They all cast two swarms each, and averaged about 65 pounds per colony. I then had 39 colonies, so per colony. I then had 39 colonies, so I had to build my cellar larger. I put them into it in about the same man-ner as before, and lost 2 out of 39, by starvation. The rest were in good condition.

During the third season I let them swarm as much as they would, and in the fall I had 104 colonies. I doubled some of them up so that I had about 84 colonies. I did not get as much surplus that season as before. We had a frost on Sept. 1, and 1 had a great many water-melons. The first thing I knew the boys were cutting them up and putting them on stumps for the bees to work on. The bees took in quite a quantity of this melon juice. I put my bees up for winter with this in the hives, took off the honey-boards and put quilts on and the next spring I was minus 50 colo-nies—all died with the diarrhea; cause, water-melon juice.

The next season my bees gathered about 4½ pounds to the colony, of honey-dew or "bug-jnice." The next winter I lost 33 colonies with diar-rhea; cause, "bug-juice," not pollen. One year ago I wintered my bees

in a warm cellar with small loss. Last summer my bees did well, On Sept. 1 I noticed that the bees were work-

lice; they were also curled up, and the bees were taking the liquid in at a fearful rate. My bees had to go 3 miles for this stuff. My son had 2 colonies within one-half of a mile of this blackberry region, and his bees took in 30 pounds to the colony, of this "bug-juice," in about ten days. His hives were the Mitchell, with 12 frames, and they filled the frames one-third full of basswood honey, the rest with the honey-dew, to the bot-tom. His bees died before the first of January. They were packed in chaff. I sent some of this plant-louse nectar to Prof. Cook, and he pronounced it safe to winter bees on. He had some of it at the Detroit Convention. I sent Mr. Newman some of it, and he mentioned it on page 259. It is fermented, and can be smelled for 40 rods !

Last fall I pnt up for winter 51 colonies-40 in the cellar and 11 on the summer stands, packed in chaff. of which 6 died, 1 starved, and 5 had the diarrhea. The loss in the cellar was 6—1 starved and 5 had the diar-rhea, caused by the "bug-juice." I have 39 colonies in good condition, except 3 or 4 that are very weak in bees. I took them out of the cellar to stay on April 15 and 16, and they brought in the first natural pollen yesterday (April 15). It has been the warmest weather for the last week that I ever have known for this time of the year. Bees were robbing badly to-day, and I had my hands full.

As far as my experience goes, I have found that "bug-juice" or late, frost-bitten honey is the sole cause of bee-diarrhea. I do not care how much pollen or bee-bread the bees have. for if they have plenty of good honey they will come out all right. Prospects are good for a large crop of honey in this locality.

Orono, O Mich.

## New Jersey and Eastern Convention.

#### A. WYE.

The New Jersey and Eastern Asso-ciation met at New York, on March 10. 1886. Officers for the ensuing year were elected as follows—all of New Jersey : President, J. V. Hutch-inson; Vice-President, J. T. Tucker; Secretary, F. E. Johnson; and Treas-urer, C. F. Kroch.

Prof. Kroch delivered an address on spring management, saying : The first point to be determined by the novice, is the time when his principal honey-flow will probably begin; I say probably, because it will vary from year to year. Then he must know that, as a bee will become an active worker about 30 days from the time the egg is laid, he must begin operations about five or six weeks before to induce breeding. <sup>a</sup> For this purpose he must feed each colony about a gill of sweetened water per day in such a way as will least disturb them. Dur-ing the time, the bees must be coning very strong. I found that they fined to the least possible space by they wandered, by were working on blackberry bushes. means of divison-boards. It is of no about so treating The leaves were covered with plant- advantage to make the bees breed too desire to wander.

fast. If the colony is weak, they cannot take care of much brood. During cold snaps they contract their clusters, and any brood left uncovered will die. It is considered best not to unite weak colonies in the spring, but to wait until some of the stronger colonies can spare frames of hatching brood later in the season.

Mrs. Dr. E. H. Mason advocated destroying the brood-combs every second year. She thinks that her bees have by this means become larger than any she has ever seen elsewhere. She also waxes the inside of her hives to save the labor of her bees, and prevents propolization by the use of

palm-soap. Mr. J. H. M. Cook, who had passed the months of January and February upon the estates of Senor Cassanova, in Cuba, gave an account of the same.

A practical bee-keeper in Cuba, or elsewhere, will follow, as his highest guide, the forms and methods of nature in caring for and managing them properly. It was a singular them properly. It was a singular experience for him to see bees gathering honey in mid-winter; but he had proved that bees do not cease labor for any cause other than is derived from the climate. In Cuba they gather honey every day. The prin-cipal honey-plant there is the morn-ing-glory, and its honey is good. On Samer Casesanoval's center there were Senor Cassanova's estate there were 300 colonies employed at the time of Mr. Cook's visit, and their production was 18 tierces. equivalent to 1.320 pounds of honey each, or an aggregate out-put in January and February of 23,760 pounds. In his own business, which involved 100 colonies, near Montclair, N. J., Mr. Cook used the method of reversing frames; and for the protection of his bees, he believed in the enameled cloth next to them, and chaff upon that; for thus the condensation of the air is prevented, the bees are dry, and their hives continue warm.

Prof. Kroch was in accord with Mr. Cook, and said : The water from the air will condense only on cold surfaces; if you have no cold surface, there will be no condensation. The cushion—be it of chaff or other material over the enameled cloth, keeps the heat from escaping. If an aplarist puts porous cloth, instead of enameled, next to the bees, he will find that he has gone contrary to the law of nature, because they will make it impervious to air by varnishing its entire surface; while to the enameled cloth they will do nothing except about the edges. This would seem to indicate that the air-tight covering in the engenthing is the proper thing.

Mrs. Dr. Mason gave her 25 years' experience. She started out with brown bees, but had so changed the character of her colonies that now they were Italian, or what might be called grades, produced by crossing pure Italians with the Germans. She did not believe in disturbing bees by noises or alarms, or by opening their hives unnecessarily. She had no difficulty in bringing them back when She had no they wandered, but she was particular about so treating them as to leave no

#### For the American Bee Jonrnal.

## Importance of Upward Ventilation, etc.

5-CHAS. WALKER, (48).

In the fall of 1880 I bought 19 colonies of bees, and I had I colony that I had taken from a tree. I put them all into a good, dry cellar, leaving the hive-covers on. The bees and lives became damp, the combs moldy, and all of the 19 colonies died, leaving the solitary one, and the hive of that one had the cover off, as I was feeding it; consequently it had upward ventila-tion. The colony was weak and did not swarm at all, so in the fall I hardly knew what to do with it, for I was afraid that it would die if I put it into the cellar, as I did with the 19.

When cold weather came on I took the hive down cellar again, but I first packed the body of the hive with dry chaff. Imagine my surprise the next spring, when I put them out, to find that they were dry and warm. I at one time put my hand down in the chaff and I could feel the warmth from the cluster. I came to the con-clusion that that was the way to win-fer hees and I have not since changed ter bees, and I have not since changed my mind. I have increased that one colony to

48, in 4 years, and I have not lost a colony. On the last day of last October I packed the hives of those 48 colonies well with chaff, and carried them down cellar, taking all the covers to the barn. Our heater is in the front room right over the bees, and it hears over the bees. and it keeps every part of the cellar dry and warm. When the mercury was at 22<sup>°</sup> below zero outside, my thermometer indicated 40° above zero in the cellar.

From my experience I would not try to winter my bees without upward ventilation, as I feel sure they would all die. I simply spread a cloth over the frames and bees, and fill right over that, about 6 or 8 inches, with chaff. I would never close the hiveentrances while in the cellar. While carrying the bees down cellar last fall, through mistake I left some rags in one, and a few days later, on going down cellar, I found that the bees of this hive making a very loud noise. They were very restless, and I pulled the rags from the entrance, and on going down an hour later I found them quiet. My experience in my cellar teaches me that I must give the bees plenty of upward ventilation.

I read, on page 54, Mr. Hewitt's article on "Infallible Queen Intro-duction." It sounds new to me, and I shall try it and report my success or failure, as requested. I like to read such articles of information, and if they are only as practicable as they appear on paper, we can all succeed

with the introduction of queens. Our honey crop was rather light here last season, but we are hoping for a better crop this year. I in-creased my apiary from 24 colonies to 48, and had about 1,500 pounds of comb honey in 1-pound sections. In 1884 I increased from 10 to 24, and had 1,000 pounds of comb honey. Bravo, 9 Mich.

Robber Bees. - Wm. Anderson, Sherman, O+Mo., on May 3, 1886, writes thus:

My bees are doing well now, although I had quite a time in getting robbing stopped. A little careless feeding caused all the trouble, and the loss of 2 colonies. I fed a weak colony, but they did not clean up all the feed, and I thought no more about it until it seemed that nearly every bee in the apiary was heard. 1 at once cleared up every thing, but the robbing had started, and it was two weeks' work to get it stopped. A lesson was learned, and will not soon be forgotten.

Best Spring for Bees.-E. T. Jordan, Harmony,+o Ind., on May 3, 1886, says:

I put 42 colonies in my bee-house on Nov. 27, and took them out on March 17, all in splendid condition. This has been the best spring for bees for the sections. I shall work 25 colonies for extracted honey, and the balance for comb honey.

Bees vs. Fruit.-D. A. Dimitry, Morgan City, Q La., writes :

The question "Whether or not bees injure fruit," is one of great interest to the majority of bee-keepers. It seems to me that the plain and highly interesting report of Prof. N. W. McLain, on page 245, should remove all doubt, and set at rest this vexa-tions subject. Most of my colonies are beneath the shade of orange trees, some under peach and mulberry trees, and all within 500 feet of my vineyard. I have two varieties of grapes, one ordinary small red, the other a large, white, thin-skinned variety, very juicy and easily punctured. If I for one moment thought that my bees injured the fruit, my personal inter-

est would compel me to discard the bees, and my 100 colonies would have to go. My experience has been, that my oranges and peaches have im-proved steadily, since the bringing of the first colony to my orchard. The fruit not only "holds" better, but it has improved in size as well as flavor; and brings a much better price, which is proof enough to me. As to the grapes: While I cannot say that they have improved any, still I do assert, and that decidedly, that so far not a single grape has been injured by the bees.

White Clover in Bloom.-S. J. Youngman, Cato, Mich., on April 29, 1886, writes :

Never in the recollection of the traditional oldest inhabitant have we in Michigan had such a warm April as the one now passing into historyboney and building new comb, al-though the fruit-trees are not in bloom yet, but the buds are about to burst forth in great profusion. The bees are booming, hatching workers and drones very fast. The honey gathered must be from the forest trees, although wild flowers are blooming some. I saw dandelions, and plucked a white clover blossom to-day, which I send you as a sample of what Michigan can do on a pinch.

[Yes; the spring weather has come early, and seems to be "here to stay." The white clover blossom is the first we have seen, and promises early honey gathering. All should prepare for a good, early honey harvest.-Ep.1

Prospects Good in Kentucky.-E. Drane, Eminence, 9 Ky., on May 4, 1886, writes:

Everything is lovely now for a honey crop from white clover, though our bees lost 3 weeks in March in which the queens totally quit laying, and the ate all unsealed larve. The weather opened nice on April 5, and sugar maples commenced to bloom immediately, and the bees have made the most of it and fruit bloom. Locust bloom will be here in a few days; then white clover, and honey. I have one of Mr. Heddon's new hives, and I think that I will like it—especially for comb honey.

Bees Doing Finely .-- W. H. Tuttle, Creston, 9 Iowa, on May 5, 1886, says:

Bees are all right, and are doing finely. I have added 11 more colonies to my small apiary, making a total of 26. In reply to Mr. R. F. Holter-mann, on page 266, saying that he "would be very much surprised if the 2 colonies mentioned on page 234 as having drones, were not queenless, that is, if they were at home when seen:" They were at home, and both the colonies have good, prolific queens and are doing finely, but the drones disappeared in a few days after I first

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

> ALFRED H. NEWMAN. BUSINESS MANAGER.

## Special Notices.

To Correspondents, - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

Our New Catalogue of Bee-Keepers' Supplies for 1886 is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it.

Perforated-Zinc .- We have laid in a stock of perforated zinc, for excluding drones and queens, and can fill orders for any size of pieces or quantity at 15 cents per square foot, or in full sheets 3x8 feet at \$2.75 per sheet. We also have pieces cut to fit the Langstroth hive-19%x14%-Price 25 cents each.

There will be a Rush for supplies needed in the apiary after awhile, and we cannot do better than to urge all to look over their stock, ascertain what will be needed, and get it on hand before it is necessary for use-thus avoiding the perplexity consequent upon its possible delay in reaching them in time.

Wire Nails have advanced in price, as will be seen by quotations on page 159, last column.

IT Our rates for two or more copies of the book, "Bees and Honey," may be found on the Book List on the second page of this paper. Also wholesale rates on all books where they are purchased "to sell again."

\*\*\*

Alsike Clover Seed.-We can furnish Alsike Clover Seed at \$8.50 per bushel-or \$2.25 per peck. These prices will take the place of those published in our Catalogue, until further notice.

#### **Convention Notices.**

A cordial Invitation is extended to all to attend the 8th annual meeting of the Texas State Bee-Keepers' Association, to be held at Judge W. H. Andrews' bee-farm, at McKinney, Tex., on May 5 and 6, 1886. Indications for a grand meeting grow brighter every day, and every effort will be made to render this meeting the best and largest ever held in the State. No hotel bills to pay. B. F. CARROLL, Sec.

17 The next meeting of the Cortland Union Bee-Keepers' Association will be held at Cortland, N. Y., on May 11, 1886, at 10 a.m. D. F. SHATTUCK, Sec.

17 The next annual meeting of the Micbigan State Bee-Keepers' Association will be held in Ypsilauti, Mich., on Dec. 1 and 2, 1886. H. D. CUTTINO, Sec.

The Central Michigan Bee-Keepers' Association will meet on May 18,1886, with Capital Grange at their Hall in North Lansing, Mich., to hold 3 sessions, viz : Forenoon, afternoon and evening. All interested in bee-culture are invited to attend and bring articles of the apisry for exhibition. For any special information address the Secretary, E. W. Wood, N. Lansing, Mich.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers'Association will hold their next meeting at Mr. Ed Whitlesey's, 256 miles south of Pecatonica, Ilis., on May 25, 1886. J. STEWART, Sec.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tnesday and Wednes-Mt. Sterning, ins., on Thesday and Wedne day, Oct. 19 and 20, 1886. J. M. HAMBAUGH, Sec.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

When Renewing your subscription please try to get your neighbor who keeps hees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a Rinder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few honrs, to get subscribers,

"Don't Stop "-that is what many write to us about their papers, when their time is nearly ont. One subscriber says ; "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It runs out with this month ; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

Cash in Advance is the rule, but no longer than six months of grace can be allowed on the small snni of \$1.00. Subscriptions may commence at any time, and discontinuances may be ordered at any time, when arrearages are paid up.

Preserve your papers for reference. If you have no **BINDER** we will mail you one for 75 cents, or you can have one FREE If you will send us 4 new yearly subscriptions for the BEE JOURNAL.

Kendall's Horse Book .-- No book can be more useful to horse owners. It has 35 engravings, Illustrating positions of sick horses, and treats all diseases in a plain and comprenensive manner. It has many good recipes, etc. Price, 25e., in either English or German.

The Illustrated Graphic News of this week will give exciting scenes from the terrible Chicago Riots, exhibiting the fearful Bomb Explosion, together with portraits of the Sheriff. Mayor, Prominent Police Officials and Murdered Officers, and other interesting illustrations besides an abundance of the choicest reading matter.

Frank Cheshire's new book on Bees and Bee-Keeping, can be had at this office.-Vol. I, bound in cloth, \$2,50, postpaid.

THOMAS G. NEWMAN, EDITOR.

May 19, 1886. No.20. Vol. XXII. NITOR/A ma name maan

Artificial Honey .- The late falsehoods about the "manufacture" of "artificial honey," by the religious and secular press, has led many to offer to sell recipes for making such. A correspondent sends us a eircular offering recipes for sale, with the following lefter:

I enclose an advertisement of artificial Among them is one for making "artificial honey." It is claimed that this stuff can scareely be distinguished from the genuine article. This advertisement is from a firm article. This advertisement is from a firm by the name of Ellis, in Chicago. If there is any law for prohibiting the manufacture of such stuff, it should be put in force imme-diately, and this company be prosecuted.— R L. C.

Here is what is said about the recipe in the eirculars :

ARTIFICIAL HONEY .- Equal to bee's honey. and often mistaken by the best of judges to be genuine. It is palatable and inxurious and often mistaken by the best of judges to be genuine. It is palatable and Invarious : costs 8 cents per pound, to make, and will sell for 16 cents per pound, while bee's honey sells for 25 to 35 cents. Agents make money fast selling the recipe to bearding-houses, stores, and private families at \$1 each. In an average territory you can easily sell ten recipes a day, for \$1 each. Ten dollars clear profit. One agent writes : "I average a recipe at every sixth house."

As Ellis only offers to sell the recipe for making "artificial honey," and get his agents to do the same, there seems to be no law to prevent him from doing so. He sells it for what it is-making a begus article; an imitation 11

What fools people must be to buy a recipe to make a bogus article, an imitation, when the genuine article can be purchased for about the same price !

What a liar Ellis is to say that "bees' honey sells for 25 to 35 cents" per pound ! Many bee-keepers would be glad to get 10 cents per pound for their crop of extracted honey in bulk.

But-just as long as people will allow the netarious traffic of selling food which is adulterated (such as bogus butter and the like), there will be no law to prohibit its manufacture and sale 1 When "the people " demand that such a law be enacted and rigidly enforced, then it will be done-ns it is in Great Britain and other older countries. How long it will take the people of America to "screw up their courage to the sticking without any dearth. Then, too, raspberries, Vol. I, bound in cloth, \$2.50, postpaid.

point." and demand legislation to protect them from such depraved and infamous scoundrels, we know not 1 Meanwhile millions are being poisoned daily; byslow but sure steps, hopelessly driven to their graves by the cupidity and avarice of villainous adulterators !

Outlook for the Honey Crop.-On page 314, Mr. S. F. Newman, of Norwalk, Ohio, asserts that the present season has been the hest, so far, for bees, that he has "ever known," and adds : "We have had a constant flow of honey for about five weeks from maples and fruit trees, and the weather has been very pleasant. We already have about 1,000 pounds of honey, and our bees are in fine condition to take advantage of the white clover when it blossoms-the lower stories of the hives being packed full of bees and honey. We expect a very prosperous season."

Mrs. J. N. Heater, of Columbus, Nebr., says that her bees nre "all beeming on fruit bloom now, and some are preparing to swarm."

Alex Rose, of Sullivan, Ills., reports that his "bees are storing honey in the sections new," and that the prespect is fine for an early honey-harvest."

C. W. Dayton, Bradford, Iowa, reports the first natural swarm on May 8, and that the bees are gathering honey freely from fruit blenm.

Dr. H. R. Dorr, of Worden, Ills., reports that his first swarm came out on Sunday, April 18.

Geo. E. Hilton, of Fremont, Mich., writes thus of the good prospect : "Never in the history of my keeping bees has there been se favorable a spring as this. The weather has been of the very best. Ever since the first willow bloom there has been honey enough coming in to stimulate brood-rearing, and now we are in the midst of fruit bloom, and my strongest colonies have been at work in the surplus eases. My first swarm eame out on May 11, which is 10 days earlier than I ever had one before. The prospects for a good yield were never better."

C. H. Dibbern, of Milan, Ills., adds his testimony as follows : "I have never known a season so favorable to bees as the present. They have worked almost every day since they were put out, about the middle of April. There has been no cold storms to chill the bread, and they have built up nicely. The weather is now just right for houey gathering, and the bees are improving the "shining hours" from daylight until dark ; some even returning so late that they cannot find their bives; others drop exhausted at the entrances. If we have suitable weather for the next two months, we will have the finest and largest crop of honey this country has ever produced. The statement that after fruit bloom there will be a dearth of honey till white clover comes, does not apply to my locality. Bees just now are fairly bonming on honey locusts, which is yielding honey abundantly. Our fruit bloom, apples, plums, cherries, etc., is immediately succeeded by the wild erab and hawthorne, of which we have an abundance. The honey locusts are only just commencing to bloom, and as we have hundreds of trees within reach, they will carry us into the white elover harvest

blackberries, etc., any just opening, and that with the locusts will give the bees all they can attend to."

Other testimony is equally, encouraging. Take the country all through, we think Mr. Dibbern is quite correct in saying that if the weather shall continue favorable for the next 7 or 8 weeks, we shall have "the finest and largest crop of honey this country has ever produced."

Home-Made Binders for the BEE JOURNAL. - Mr. Gardner H. Perkins, of Cazenovia, N. Y., has sent us a sample of one he uses, and we will attempt to describe it.

He has a cover of eard-hoard large enough to wrap around the JOURNALS to be bound. Then runs a long pin through each end of a whalebone spring (2 inches long), and then through the cover and JOURNALS-the point of the pin is then turned up something like a meat book. The spring holds them tight. and other JOURNALS can be added by hitching them on this hook, inside the last cover. Of course to use such a binder is better than to let the numbers be lost or soiled, but an Emerson Binder, made expressly for it, is vastly superior, and with care will last for 8 or 10 years-making the real cost only about 10 cents a year. Every one should ebtain an Emersen Binder if pessible; if not, then make such as is described above.

Punctuality in sending the BEE JOUR-NAL results in its being received punctually by its readers. They always know when it will come, and do not have to make a number of trips to the Post-office for it, and sometimes be bitterly disappointed in its non-arrival. Mr. C. W. Dayton, of Bradford, Iowa, writes thus on this subject :

I take and read seven papers, four of them I take and read seven papers, four of them bee-periodicals, but among them all, there is none so punctual as the AMERICAN BEE JOURNAL. Every Thursday morning at 9 o'clock I take it out of the office, year in and year out, and that punctuality alone is in itself a gratification worth many times the subscription price. If \$5 instead of \$1 was required to get it, I should take it all the

"System" and "order" are necessary to satisfy our patrons, and we are glad to knew that our efforts are appreciated. The forms of type are closed up every Saturday afternoon. On Monday they are placed on a fast-running steam press, and even while its readers are asleep on Monday night, the presses are still rattling away for their comfort and edification. On Tuesday morning 50 girls fold up the sheets, and then they are stitched by steam wiring machines. While this is being done the addresses are printed and pasted on the wrappers by machinery, and at 4 p.m. the JOURNALS are wrapped up, put in sacks and taken away in a wagen to the General Post-Office, 3 miles away. This programme does not vary au hour searcely once a year.

Bives for increase will be needed soon. Order them at once if not already done. Also sections for the surplus honey crop, which will soon be on hand.

-----Frank Cheshire's new book on Bees and Bee-Keeping, can be had at this office .--

#### Replies by Prominent Apiarists.

## The Mating of Queens.

Query, No. 251.-In answer to Query, No. 224, about the distance a queen will fly to meet the drone, is not the distance given too great? Do not the drones go part way? -J. S. B.

Very likely they meet half way .- A. J. COOK.

We said one mile. The drones probably go over half way.-DADANT & SON.

We are gradually learning a little about the subject, but I do not be-lieve that much is known positively. -C. C. MILLER.

I think you are correct in suggest-ing that the drones go part of the way, and I should not be surprised to learn that their part is the greater part .-- JAMES HEDDON.

I do not believe that anyone knows which does the most of the traveling. All I know is that I have had queens mate with drones reared five or more miles from my apiary.-G. M. Doo-LITTLE.

In all probability they do. If you will throw fine flour on some drones, after noon, you will find that they will be absent from one to two hours, giving an opportunity to go a long distance. But this is all guess-work. —II. D. CUTTING.

This is a subject of which I know but little, except that queens have mated with drones from hives at the distance mentioned.—W. Z. HUTCH-INSON.

To the first part of your question 1 think 1 should say yes. I have good reasons to believe that virgin queens rarely, if ever, go out of the range of vision from their homes. I feel sure that this is the case as a general rule. The case is different with the drones. I could not find room to discuss the matter here, but nature has evidently imposed the greatest risk upon the drones.-G. W. DEMAREE.

Yes, queens never fly very far from the hives, probably never more than one-half of a mile. The drones not only have powerful wings, but are able to maintain for two hours at a time, without rest, their wonderfully rapid flight, and traverse over miles of country. The wing-power of the worker bees will never fail with such matchless winged sires; especially since the male is prepotent over the female offspring.-G. L. TINKER.

Answers to this query are all theo-retical. It is assumed with some show of proof, however, that drones have a particular place of congregation, and the queens are met by them there. In the present state of knowledge this idea is as good as any. The facts can only be determined by thorough tests.—J. E. POND. JR.

## Room for Surplus Honey.

Query, No. 252 .- In using the Falconer ehaff hive, how many sections would it be best to use on top of the brood-frames-a rackful holding five rows of nine each, one holding four rows of 8 each, or four rows of 9 each ?-Ohio.

Thirty-six sections above the broodchamber is the number most gener-ally in use.-W. T. FALCONER.

I never have used the hive named, hut I suppose it would depend on the strength of the colony and the size of the sections. A good, strong colony ought to take five rows of nine each, if 1-pound sections are used.-C. C. MILLER.

I never have used the Falconer chaff hive, hut I have had the best success with 3 rows of 8, making 24 sections to the rack, and tiering up 2 and 3 racks high.—H. D. CUTTING.

I should cover the entire brood-nest with sections .- W. Z. HUTCHINSON.

Either would do, but I prefer a surplus arrangement which would allow of putting on 2 rows of 8 each, and in a week another 8, and so on until all the room is utilized. The putting on of the whole surplus-room at the start often discourages the bees.-G. M. DOOLITTLE.

I prefer to tier up the sections, and I object very decidedly to such large section-cases. For the ordinary pound section, four sows of 5 or 6 each are enough under all circumstances.-G. L. TINKER,

I do not know the size of the top of the brood-nest of the Falconer hive. I prefer a section-case made just the size of the top of the brood-chamber, and made so that the broat chamber, and made so that the sections will run parallel with the frames. The length of the case can be regulated to suit the length of the hive by nailing cleats on the ends, if necessary. A case holding 32 sections suits me best for tiering up.-G. W. DEMAREE.

I have never used the Falconer hive, but it will depend upon the honey flow. When honey is being gathered in large quantities give am-ple room; when in less degree, give less; in fact, proportion the room given to size of colony and amount of honey being gathered, and you cannot go far wrong .- J. E. POND, JR.

## Reversing Frames.

Query, No. 253 .- In reversing frames, do the bees not have a great amount of extra work to do in changing the cells? Most of the combs of brood that I have noticed, on the upper side, have a strip of houey. and the cells dip towards the centre. would think that in reversing the combs, if the honey was very thin, it would run out. Do the bees change the the angle of the cells ?-Oregon.

I do not believe that the bees change the angle.-C. C. MILLER.

All the experience I have had was in reversing sections. This causes book, and are therefore the most desirable.

the bees extra work, for the reasons given in the query.-G. M. DOOLIT-TLE.

I do not think that any such change is made, and certainly the honey does not run out. I find that I get more honey, and such facts are worth oceans of theory.—A. J. COOK.

I think not. No nectar is thinner than that gathered from fruit-bloom, and it will not run out of the combs until they are held nearly horizontal. Even when water is poured into a comh it is pretty hard to shake it all out.-G. L. TINKER.

In transferring combs I frequently put the top side of the combs down and the bees seem to fix the cells all right. The thin honey will sometimes run out when handling the combs. Inverting combs will never give a great deal of trouble, for the simple reason that practical bee-men will soon learn that it does not pay to reverse combs or hives for practical purposes.-G. W. DEMAREE,

All the work the bees are induced to perform by reversing, is profitable work for the bee-keeper. No, the bees do not change the pitch of the cells, nor does the honey run out.—JAMES Heddon.

1. Yes, most certainly, and also in conveying the stores to the upper story, as it all must be moved a sec-ond time. 2. Yes, at times, but the idea of the reversionists is, that the frames will be re-reversed in a short time. The whole theory of reversing J. E. POND, JR.

I have never noticed that the bees changed the angle or "dip" of the cells, and the thin honey does not run out. But let us suppose that the bees did change it, and that it caused them a great deal of work, what would we care if better results were secured ? It is the "results" that we are working for, and not to save the bees from labor.-W. Z. HUTCHINSON.

#### Convention Notices.

17 The Northwestern Illinois and Southwes-tern Wisconsin Bee-Keepers' Association will hold their next meeting at Mr. Ed Whitteser's, 24 miles south of Pecstonica, llis. on May 25, 1886. J. STEWART, Scc.

The Illinois Central Bee-Keepers' Association will hold its next meeting at Mt. Sterling, Ills., on Tuesday and Wednes-day Oct. 19 and 20, 1886. J. M. HAMBAUGH, Sec.

The next annual meeting of the Michigan State Bee-Keepers' Association will be held in Ypsilanti, Mich., on Dec. 1 and 2, 1886. 11. D. CUTTING, Sec.

#### -----System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. the prices are reduced, as follows :

 For
 50 colonies (120 pages).
 \$1 00

 "
 100 enlonies (220 pages)
 1 25

 "
 200 colonies (420 pages)
 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is located near the center of the State named;  $\delta$  north of the center;  $\hat{\varphi}$  south;  $\Theta$ + east; \*O west; and this o northeast;  $\infty$  northwest:  $\infty$  southeast; and 9 southwest of the center of the State mentioned.

## For the American Bee Journal. Superseding of Queens, etc.

#### G. M. DOOLITTLE.

The question is asked, "How do bees know when to supersede a queen?" and as the time of such superseding of queens is near at hand, perhaps a few words on the subject may not be uninteresting.

After a careful watching of all cases of supersedure of queens which have come under my notice, I am led to believe that the bees, as a rule, supersede a queen on account of her ceasing to be as prolific as she has been heretofore, and especially is this the case where the attempt is made to replace the old queen previous to swarming, or immediately after the prime swarm has sought a new abode. say during the first two weeks after the swarm has been hived.

In all of the cases of supersedure which happened at the times above mentioned, the queens were failing, and soon died, nearly always before the young queen began laying, so that I had positive evidence that the fewhas of eggs laid by the queen was the real cause of her being replaced by another from her brood. Later in the season, however, the evidence that the bees know at all times what they are about, is not so great; thus we have exceptions to some of the rules regarding the workings of our pets.

During the latter part of August, in 1872, I found that the bees were bent on superseding one of my very choicest queens; so as fast as they got the queen-cells capped I removed them. While cutting out these cells one day, having a friend with me who kept bees, we found a nice young queen which had hatched from an unobserved cell, at the sight of which be said he would give me \$2 for the old queen and take his chances on her. As he was an apiarist of considerable experience, I thought he knew what he was about, especially as I had explained the whole matter to him; so I let him have her. He took her home, succeeded in safely introducing her, and to the surprise of both of us, she lived and did good work for two years, he rearing scores

of queens from her. This proved to me that the bees made mistakes sometimes.

Another case coming under my observation, showed a still worse blander on the part of the bees. In the fall of 1880, as I was preparing my bees for winter, I found two queens in a hive, the mother having her wing clipped. They were left to see what the result would be. In the spring both were there and soon had the hive full of brood. One day Prof. Boyn-ton (who exposed the "Cardiff giant" fraud), called on me and I showed him the two queens, both on the same comb, which seemed to be a great curiosity to him. After he returned home he sent me a high price for the colony, as he wished to study into the matter, but when I went to prepare them for shipment, I could find only the old queen in the hive. After a short search in front of the hive I found the young one where the bees had drawn her out. The old one failed fast, and was only able to lead out a swarm (from the brood of the two) before she died. These are the only two exceptions to the rule, which I have found.

#### BEES DYING ON THE SNOW.

Another asks, "Is there any way to prevent bees from coming out of their hives and dying by the hundreds on the snow?" In answer to this I will give my plan to prevent such loss, but first I wish to say that there are two causes for bees acting thus; one of which is bee-diarrhea, and the other the direct rays of the sun in and about the entrance. If the former is the canse, the bees might as well die on the snow as anywhere, for die they will; but if the latter, the cause should be removed by shading the hive.

As the sunshine is apt to entice all bees out more or less, I always, at the beginning of winter, lean up a wide board, nearly as long as the hive is wide, in front of the entrance, which not only keeps the sun from enticing the bees out when it is too cold for them to fly, but shields the bees from the cold winds which would otherwise blow directly in at the entrance. Whenever a light snow falls I sweep the snow up over this board and still higher up on the hive, which gives additional protection. As this takes but a few moments I consider that I am well paid for doing it.

There is one point whercin some are deceived regarding dead bees on the snow. Bees can rise as safely from melting snow as from bare ground, if the air is only warm enough. The degree of warmth required I find to be 45° in the shade, providing it is still, with the sun shining; yet with even a warmer temperature the snow will often appear covered with dead bees. A little careful watching will show that these dead bees are those brought from the hive and dropped by the other bees while they are "house-cleaning;" this house-clean-ing is always going on when the weather will permit of a flight. Again, 100 bees will make more show on the snow than as many thousand right angle; then I cut a 1/2-inch hole

would on bare ground. For this reason we are often alarmed when there is no occasion for it. Borodino, ON. Y.

For the American Ree Journal.

## Are Bees Taxable Property ?

#### T. B. BLAIR.

I should like the above query answered in the columns of the BEE JOURNAL. So far as I know, bees have never been taxed in this locality, but I have been informed by an officer of the town in which I reside that my bees will be assessed this year. I am willing to concede the right to tax hives and other fixtures of that kind, as well as merchantable honey on hand at the time the assessment was made; but in my judgment colonies of bees are not taxable any more than are dogs. They might put bees on the same plane as dogs, and require bee-keepers to take out licenses (when the legislature enacts such a low) but it comes to work the such a law), but it seems to me that our tenure of property in bees is so uncertain that it would be difficult to assess them. I may have 50 colonies on May 1, when the assessment is made, and lose half of them before clover comes; I may put them in in the fall and lose  $\frac{34}{4}$  of them before spring (as I did two years ago); or my colonies may come out so light as to be valueless, while my neighbor may have his in good condition, but the average assessor would value all alike.

I should like to know the practice in other States in this matter, and if there is a lawyer among our brother-hood I should like a legal opinion upon the matter as early as can be convenient. I believe it to be a mat-

ter of interest to all bee-keepers. From what I hear at this date beekeepers have lost heavily in this and adjoining counties the past winter. My bees came out in good condition. I lost 6 colonies out of 60 put into the cellar.

Neenah, O+ Wis.

[Your query will be duly submitted and answered in the Query Department in due course,-ED.]

Temperature Inside of the Hives.

#### WM. F. KANZLER.

In preparing my bees for winter last autumn, I arranged an average colony so that every day I could read on a thermometer placed at the inside of the hive, the degrees of either heat or cold; for I do not believe in guessing, and I am not so full of vanity as to and I am not so full of vanity as to think that I know the temperature or dampness of the inside without the use of a thermometer or hygrometer. To do this so that I should not jar the hive and molest the bees in cold weather, I procured an elbow-shaped thermometer the shorter part of

thermometer, the shorter part of which is 5 inches long and bent in a

in the sheet of burlap lying over the frames, and bored with a ½-inch hole right over the winter cluster, and plunged the short end of the thermometer through this hole into the hive about 5 inches deep, so that the longer end would lie flat over the frames. Over the thermometer I laid 4 sheets of wadding to keep the bees warm, and then placed the cap on the hive.

The cap is roof-shaped, 6 inches high on the sides, and moves very easily. My hives are like Mr. Da-dant's, holding 13 or 14 of American frames 12 inches deep, and standing in a shed on the east side of my smoke-house, so that the hives can be worked from the rear; in the front I place bundles of corn-stalks to keep rain and snow off, and between the bives I pack dry wheat-straw, the ends of the shed being closed with boards.

When I want to know if my bees are comfortable or not, I enter the shed by a door on one end, take off the cap without a knock or jar, lift the wadding, and the thermometer lies before me and shows, to my great joy, without opening the hive or molesting the bees, that the bees are in better circumstances than the birds in the open air. On Jan, 12—the coldest day—the thermometer showed  $+70^{\circ}$  in the inside of the hive, and  $-22^{\circ}$  in the open air; on Feb. 5, inside,  $+41^\circ$ , and outside,  $-4^\circ$ . I live in latitude  $38^\circ 8'$  north, and I shall not take it as a personal insult if the thermometer of another observer in biober latitude above another observer. a higher latitude shows another number of degrees, or if some one else makes other conclusions than I do. Until to day the mercury never was lower in the inside of the hive than 32°, and that only for two days, on Feb. 16 and 17; and to find out if the bees were sleeping or awake, in closing the cap one day, I let it down not very carefully, and it gave a light jar, and one hour after the thermometer showed 2° more. In finding that the temperature changes almost every day, and sometimes in opposition with the outside air, *i.e.*, when the outside temperature lowered the inside temperature advanced, I con-cluded that the bees must be in motion to create this warmth; and besides this, old naturalists and close observers in the old and new worlds told us long ago (see Langstroth's Hive and Honey-Bee, page 335) that they marked their bees in an ob-servatory hive with different colors, and in watching closely, they found that the bees were moving in the coldest weetboard that the bees more moving in the coldest weather; that those which were on the outside of the cluster could be seen in a few days on the inside. I never doubted these statements, and therefore I did not open my bive, and made no glass doors to it. I desired only to find out the temperature of the inside of the hive for my own information and to satisfy my curiosity.

As given in the Bienen-Zeitung of Nordlingen, for 1885, page 245, at the forms, become equally prominent as a last meeting of the German-Austrian sweet. Bee - Keepers' Society, at Liegnitz, in Silesia, the Rev. Schemfeld—the many purposes honey is found to be solution to be solution to be solution. Solution in the support of the general bee-keeping public, which

greatest scientific bee-keeper in Ger-many-said: "We know as a certainty that bees in their winter cluster are in a constant rotation, so that bees which are to day on the right or left side, may be to-morrow in the comfortable warmth in the centre; and others which hang to-day on the lower part of the cluster, may be tomorrow close by the honey-cells; here they fill their honey-sacs, then go down and hide in a cell and have a store for days; it is not necessary for them to go up very soon, and they are so sheltered against hunger and cold."

Perhaps the climate in Germany is different from ours, but the advocates of hibernation should make the same experiments; mark their bees, plunge one or more thermometers into their observatory hives, and then they can see if the bees are moving, asleep or hibernating. To give all of my observations would require too great a space, therefore I will give only the highest and the lowest temperature of the inside of the hive for each month, commencing with Oct. 23, 1885, and taken at 8 a.m. It is as follows :

#### Inside Outside

|                | temp. cemp.                          |
|----------------|--------------------------------------|
| Oct. 23, 1885, | $+87^{\circ}+44^{\circ}$ highest.    |
|                | $+64^{\circ} +40^{\circ}$ lowest.    |

Read at the New York Convention.

## The Apicultural Outlook.

#### L. C. ROOT.

In my address at the last meeting of the North American Bee-Keepers' Society, held at Detroit, Mich., in December last, I gave what seemed to me to be some facts, and offered some suggestions as to the future of bee-keeping.

Very close observation during the sessions of that convention, as well as careful study since that time, have conlirmed me in the conclusion that many points in that essay were well taken. I think that I may safely say that no one point is more thoroughly established by the experiences of all, than that we need to bend our best energies to the consideration of the disposition of our products. We must have'a firmer, more certain, and a larger demand for our honey.

Iarger demand for our honey. It seems to me that if any country should represent the "Promised Land," and "flow with milk and honey," it is this land of ours; and I believe, that as milk and its products are among the best and most desir-able—yes, indispensable articles of food so sincely will honey in various food, so surely will honey, in various

the cheapest sweet that can be used. Mr. C. F. Muth, of Cincinnati, Ohio, tells us that pork-packers, and others who have been using cheap molasses very largely, find that though honey costs more per pound, it contains a greater sweetening capacity and is cheaper for their use. I am thoroughly convinced that the value of honey as a pure, wholesome, and natural article of food is yet to become more fully appreciated and understood. It is purely a natural product, as entirely so as milk, with which it has been associated since Bible times, and the day will come when manufactured sweets cannot compete with it, as a common article of food, and for medicinal and manufacturing purposes.

The great question for us to consider at this time is, in regard to the best methods of securing as substan-tial a market for our productions as for other essential commodities. We have stern facts before us, and we must meet them fairly. Many are looking to us as authority, as to the desirability of engaging in bee-keep-ing, and we should not fail to respond to this inquiry. Is it not a fact has yond dispute that with the present limited demand for honey, there is already an over-production? The outlook from all directions leads me to the conclusion that bee-keepers must at present be governed largely by the demand for their products, in their own locality. If you have no home market at prices which will pay you to produce honey, do not expect to ship it to distant markets with better results, while they are already overstocked.

While there will always be a de-mand for comb honey for table use, the great bulk of our honey in the future will be taken with the extractor, and be used for a greater variety of purposes. We must reasonably expect to compete with other sweets in this direction. To do this we must resort to methods which will enable us to produce our honey much more cheaply than we have yet been able to do. We must be able to winter our bees more successfully. In this item alone, the saving would be very great. If the present losses in wintering could be avoided, and our colonies all be populous at the beginning of spring operations, we should reduce our expenses one-half, and treble the quantity of honey obtained. But upon the demands which are created for our honey, will depend the future of beekeeping; and to further this end, we should bestow the most thorough study and application.

One great lack in our present One great lack in our present methods of marketing, is that those who handle our honey are not thor-oughly enough versed in bee-keeping in all its branches. From careful ob-servation I am satisfied that no one thing contribute more to the successful of the succe thing contributes more to the success of honey-dealers than the fact that they have an extended knowledge of bee-keeping, and are entirely alive to its best interests. We need specialists

they could only do by working faithfully for their mutual interest. Shall prove ourselves equal to the we emergencies of the time, and by massing our forces upon these important points, prove by our success that "in union there is strength ?"

## Wintering Bees in Warm Cellars.

#### C. THEILMANN.

In Mr. Barber's essay on "Winter-ing Bees in Cellars," page 809 of the AMERICAN BEE JOURNAL for 1885, some interesting as well as very queer ideas are mentioned. How Mr. Barber can winter his bees in a cellar at a temperature from 65° to 90° above zero, is surely a marvel to many of our best and most experienced bee-masters. I would be much araid that any one would make a complete failure of it, in trying to winter his bees in a cellar with so high a temperature. One of our most practical beek keepers tried the experiment a year ago last winter, and thereby lost nearly all the bees he experimented with. Now if Mr. Doolittle could not winter his bees in a high temperature what could we expect of the inexperienced ?

Would not Mr. Barber's essay miswould not Mr. harber's essay mis-lead many bee-keepers, if we did not have Mr. Doolittle's sad experiment in the winter of 1883-84? What did we learn from Mr. D.? Turning to page 356, of the AMERICAN BEE JOURNAL for 1884, we find that he had heave losses in wintering his beca had heavy losses in wintering his bees in a temperature from 50° to 60°, and Heretofore, and after trying higher. outside wintering awhile, he built an under-ground bee-cellar in which the temperature was kept at  $42^\circ$ , and therewith he wintered his bees successfully, until the above-mentioned winter, when he put faith in Mr. B's ideas; but he durst not go the whole about the middle of the month we had air," as formerly, many tons are an- $65^{\circ}$  to  $90^{\circ}$ , and tried it first with  $50^{\circ}$  a warm spell. On the last and warm- nually harvested, which finds a ready

above zero, with the above-stated result.

When Mr. D. saw what was coming, he wrote to Mr. Barber for information on temperature, etc., during the winter. He replied that he could not tell him anything about it, as he had no thermometer in his cellar. I do not want to criticise Mr. B's statements, and yet I do like to get at facts and not have so an important a point (in fact it is the one of success or tailure in our pursuit) handled so carelessly or ignorantly. How could Mr. Barber know the temperature in his cellar if he did not have a thermometer there through the winter? Mr. Barber says on page 11 of the AMERICAN BEE JOURNAL for 1884: Hundreds of bee-keepers will raise their hands in horror when told that my bees were wintered in a tempera-ture of from  $65^{\circ}$  to  $90^{\circ}$  of heat!" How is that? Why could he not state the temperature to Mr. Doolittle? Because he had no thermometer in the cellar, though he still says on page 292, of the same volume, that his bees that were so heated, separated all right, etc. They were surely smart bees, when before they were in a cluster 5 feet in height, as he tells us on page 408 of the same volume; and on page 264 he says, and very reason-ably too, that he does not think it necessary to keep the temperature at 65° to 90° above zero in bee-cellars, but finds after the winter's experiments, that with ventilation at the top of the hive the bees were in much better condition, and came out in as good condition, and came out in as good condition as when put in for winter. By thus wintering he has had no trouble since. But Mr. B. did not stick very long to the ventilation on top of the hive, as he speaks in his essay of " no upward ventilation," but adheres to 60° to 90°-perhaps without a thermometer.

On page 235 of the AMERICAN BEE JOURNAL for 1885, we find that Mr. B. really made tests during the winter of 1884-85, which showed 47° on Dec. 20, 1884; 45° on Jan. 20, 1885, and 4S° above zero on March 30, with 200 colonies in the cellar. Now where does the great difference in his cellar come in? I will let the readers answer this question. I would also like Mr. B. to explain it.

On page 316 of the AMERICAN BEE JOURNAL for 1885, Mr. B. comes down one-half of the 90° above zero, and one-han of the solution above zero, and says: "In a cellar as good as mine has been— $45^{\circ}$  to  $48^{\circ}$ —bees should be placed one foot or more above the cellar bottom;" and he tells us on page 422, of the same volume, that every colony is alive and in a flourishing condition. I have no reason to doubt it in the least, as we have a number of writers who winter their bees in a temperature from  $45^{\circ}$  to  $50^{\circ}$ ; but when we come up to 60° and more above, the bees become restless and lose that quiet state which is so much desired by experienced bee-keepers, and which Mr. Clarke calls hibernation.

1 will now describe the experiment that I made in February, 1883, when about the middle of the month we had

est day I went away in the morning. and did not return until about 4 p.m. Hastening to the bee-yard I could hear the bees roaring in my double-walled bee-house 3 to 4 rods distant; and when 1 tried to enter the house, the bees came rushing out as if it was swarming time. I immediately shut the door, but I had a look at the the door, but 1 had a look at the thermometer which indicated a temperature of  $65^\circ$  above zero. There was a little door in the gable end of the house through which I went in on the upper floor, and lifted up the boards by which a clear space of 17 inches was made, and the entire length of the house, to let the heat escape under the roof. I then waited for the night to come to open the doors. The upper and lower ventilators had been open, but the outside air was too warm to cool off the inside air much. When night approached I opened the doors. The sight and my feelings I can hardly describe. When I got into the house, the hives, walls, floor, and everything in the house was covered with bees, crawling one over the other, apparently suffoca-ting, and thousands of dead ones all over. The air in the house had a very disagreeable gassy smell, with the thermometer at 63°. These 130 colonies were all quiet at 42° three days before this, but from this on they were restless until I put them out, about four weeks afterward. The house was 16x18 feet, by 7 feet high.

I have no desire for another such experiment, and on account of it I have read Mr. Barber's articles with suspicion, I must acknowledge. On account of my experiment I have written this article; also because my bees winter best in an under-ground bee-house in a temperature of 420 above zero; and to warn bee-keepers to be cautious about wintering their bees in a temperature of 65° to 90°.

Thielmanton, Minn.

## An Apiary in New Zealand.

The following is from the New Zealand Herald of March 6, 1886:

Amongst the several rural industries now being carried on at Matamata, there is none more generally interesting to visitors than that of apiculture. Bee-farming has now become an established industry in England, America, on the Continent England, America, on the Continent of Europe, and in Australasia, and deservedly so, for very few industries connected with rural pursuits have made greater progress during the last few years, or shown better results when systematically carried out. The importance of apiculture as an indus-try attracted the attention of Mr. J. C. Firth, who, with his characteristic enterprise, started the nucleus of a hee-farm some 3½ years ago, with Mr. Hopkins, the well known apiarist, as manager. The result has proved the good judgment of Mr. Firth, for instead of the whole of the honey that is secreted in the clover blossom now "wasting its sweetness on the desert

market, at a remunerative price. There is one thing worthy of mention, viz: The honey produced at Mata-mata is, without doubt, equal to the best produced in any part of the world

Connected with the management of the apiaries, of which there are two at present, there are two substantial buildings-one containing a large workshop, in which the hives, frames, and other appliances are made, a honey-room for storage of honey, a funigating room, and an office. The first thing that attracted our attention on entering, was the large stacks of 2-pound tins of honey-nearly 10,000. These thad been brought from the principal apiary, and were ready for soldering, preparatory to being labelled and cased for market. At the time of our visit the season's crop of honey was nearly all in, and this will amount to about 10 tons—the product of 200 hives-an average of 100 pounds per hive. In the fumigating room, which for the nonce had been turned into a wine room, we were shown a number of casks containing shown a number of casks containing fruit wines, mead, cider, and vinegar in a state of preparation. These had been made principally with honey, and gave promise of turning out excellent in quality. The honey used in their manufacture had all been before extracting the honey from them, and which is useless for market.

Mr. Hopkins, the manager, is of the opinion that were mead, honey and fruit wines, honey-vinegar, and other such-like products obtainable, an immense demand would soon spring up for them. We have no doult that this might be made a very profitable branch of bee-keeping if bee-keepers would but turn their attention to it. It would not only be the means of utilizing a vast amount of surplus honey, but a great benefit would be conferred on humanity by placing within reach some wholesome, healthgiving beverages in place of the vile compounds now sometimes sold as wines. There is no reason why we should not again revive some of those metheglin, miodomel, so highly prized when honey was considered as an indispensable article of food for man, before sugar took its place.

The other building is used for manufacturing comb foundation. Four of the latest and most improved machines for making it are in use at Matamata, and, in fact, everything that can be devised for purifying the wax and manufacturing a first-class article.

The home apiary, situated near to the manager's house, is a small one of about 30 colonies, principally devoted to queen rearing. Here we saw a large number of miniature or nucleus hives, in which the young queens are reared and kept until they are required. Until quite lately none but pure Italian bees were kept and bred queens reared from them mated by Italian drones, as the progeny from this cross are now considered to be the best working bees cultivated.

The "Burwood Apiary," situated some 2½ miles from the "Home Apiary," is devoted to honey produc-tion. The hives—about 200 in number-are in long rows in an enclosure of about an acre, surrounded by pine trees, and are well sheltered. The extracting house, where the honey is extracted from the combs, stands nearly in the centre of the apiary. At the time of our visit extracting was going on. From the extractor—which stands on a platform about 4 feet above the floor-the honey runs into a triple strainer and from there into the honey-tank, capable of holding 3,000 pounds. Here it is allowed to remain for a day or two to get thoroughly ripe, when it is skimmed and run off into tins for market.

One peculiarity about the Matamata honey is its rapid granulation and very fine grain. In the hottest weather it granulates in about three days from the time it is extracted, and in more than one instance this season it would not run from the tank 36 hours after being taken from the comb. When placed in a dish on the table its color and grain gives it the appearance of butter, from which it is sometimes difficult to distinguish it.

Mr. Hopkins informed us that the past season has been a fair one throughout New Zealand for bee-keepers, and that he estimates the season's crop at over 300 tons for this colony. He thinks the Auckland province alone will have produced nearly one-half of that quantity. Altogether, we look upon the industry of apiculture as one of much importance to the State, and well worthy of any indirect encouragement the State can give it. We congratulate Mr. Firth on his enterprise and the example he has set to other colonists to 'go and do likewise."

For the American Bee Jonrnal.

## "A Year Among the Bees." N. W. M'LAIN.

This is the title of a new book on bee-keeping, by Dr. C. C. Miller, of Marengo, Ills., published at the office of the American Bee Journal. In his introduction the author explains that he has no expectation or desire to write a complete treatise on beekeeping, but rather to speak of such things in detail as would come within the experience of one who, being in-terested in the industry of bee-keep-ing, should remain with him during a whole year.

The design of the author is that the book shall consist of "A talk about some of the implements, plans and practices of a bee-keeper of 25 years' experience, who has for 8 years made the production of honey his exclusive These for the purpose of having the young being just what it professes to be-

simply a plain "bee-talk, wherein I shall try to tell honestly just how I do, talking in a familiar manner about such things as have come within my own experience."

The talk begins with the spring of the year, when "the bees can get out on the lirst good day," when the red of the blossom on the soft maple actually begins to push forth, and progresses by seasonable stages throughout the year, telling all about spring management and preparation for the honey harvest; the methods practiced and devices used during the working season; the care of the product and its preparation for market; the prepartion for winter; the winter repository; placing the bees in winter quarters, and the attention given them during winter; not neglecting to speak of the work which should be done during the winter preparatory to the coming year.

Moreover, during the narrative the dramatis personæ are naturally in-troduced, and we are told of the division of labor, so that each of the assistants may become proficient in the parts to which they are assigned, or for which they have a preference; and both scene and incident are so clearly and faithfully presented that one may almost imagine himself seated under a tree near the apiary and shop, the long rows of hives standing in pairs to the right, the comfortable dwelling and the orchards to the left, and the genial Doctor in the foreground narrating his monologue, "A Year Among the Bees." (The writer has had the pleasure of a day among the bees, with Dr. Miller at his home.)

In bee-keeping frequent emergen-cies arise. There is "a world of comfort " in being equal to an emergency. If one does not feel entirely equal to an emergency, there is a feeling of satisfaction and security in knowing that you have an adviser at hand upon whose experience and counsel you can rely. The author of this book is a progressive bee-keeper whose methods and practice are safe and conservative. When a progressive bee-keeper of 25 years' experience, and one who makes bee-keeping his exclusive business, gives to the public his methods and practice, the service cannot fail of appreciation from all those engaged in the industry.

The bee-keeper of experience will find many valuable hints in this book, and it is noticeable that most of the devices recommended and used are simple and cheap, and mostly homemade, and well adapted for the pur-Beginners in bee-keeping will find that the adoption of the methods, devices and practices here recommended will save them from investing in much costly experience. Experi-ence is frequently worth what it costs, but more frequently the amount invested by original explorers in the field of bee-keeping fails to declare satisfactory dividends.

Bee-keepers of experience do not need to be told that it is prudent and wise to glean from the experience of others, and incorporate into their own methods and practice all that their Wisdom dicjudgment commends. Wisdom dic-tates to those lacking in experience, the adoption of methods, devices and practice which have been tried and approved, as the only safe course. Experiments with new devices or in new methods should form no part in the curriculum of those just matriculated.

This prescription written by the Doctor, for bee-keepers, he assures us he has tested in his "own experience," and surely he must be a good doctor who takes his own medicine.

U. S. Apicultural Sta., Aurora, Ills.

For the American Bee Journat. Quietude, Semi-Hibernation, etc.

#### WM. F. CLARKE.

I read somewhere lately about a certain family, old-fashioned enough to have a lot of children in it. The to have a lot of children in it. The children were making a great noise, when a big brother said: "Let there be peric silunks!" which was obeyed instanter! Our Editor has shut down "all of a suddint" on "hibernation" and "reversible hives." An exception is made in regard to explanations called for by previous articles published.

I have nothing written on either of these topics, but under the exception allowed, there is only one thing I wish I have to say about hibernation. said it before, but no attention seems to be paid to it by several writers on the subject. It is that hibernation is not one certain, fixed, unalterable state, but admits of and exists in various degrees. For the truth of this statement I have cited the greatest entomologist of the age, Prof. Kirby, and once more calling atten-tion to it, I am content to let the subject hibernate.

But I ask as a special favor the publication of the following letter. which is altogether too good to be condemned to hibernation in one of my pigeon-holes :

MR. W. F. CLARKE :- On page 232 of the AMERICAN BEE JOURNAL, Mr. W. Z. Hutch-inson appears to think that if bees biber-nate at all, it must be in a state identical with that of ants, etc.

We know that some insects may freeze We know that some insects may freeze solid and yet live, but if a bear, or Mr. Malone's ground-squirrel, should once freeze, I do not believe they would ever move again. If bees do really hibernate I think it must be another one of the many different kinds of hibernation. If bees are only quiet during the long periods, then they are the greatest exceptions known—entirely too great. If bees are only quiet, I think that either of the terms, quiet, quiescence, or quietude, is no name for it. It is neither usual onietness no ordinary hibernation. usual quietness no ordinary hibernation.

usual quietness no ordinary hibernation. Mr. Taylor's eattle and poultry under the barn were quiet; almost any thing may be quiet for a short time, *i. e.*, practice qui-escence, and it may properly be called quietnde; but it is very different from the quiet condition entered into by the bees. This is a separate condition, and should not be loaded upon its neighbors. I believe that the quietude of the eattle was as far from the quietude of the bees us was the quietude of the bees from torpor.

ought not to eall it what it eannot be proven to be. I would be satisfied to eall it simply hibernation—not so profound as to embrace

to be. I would be satisfied to each realized hibernation-not so profound as to embrace torpor. Mr. Heddon, then, may say-Use my semi-hibernation; but we cannot do this very well as there are so many varying degrees between the conditions of the frozen ant and of the raceoon (or perhaps the bees) that a correct classification might need to be carried out to sixteenths or thirty-seconds, instead of halves and quarters; there would need to be a fixed zoro point, and undoubt-edly the condition of bees would best represent it. On the whole, the hibernation theory, though it be ever so true, is too new, too shocking; it may work better when a little older; ordinaries could not swallow it at this time if it were ever so palatable. "Its agin natur." "It takes years to accomplish a great object." So much of truth as your theory contains must come uppermost.-C. W. DAYTON, Bradford, Iowa.

Many thanks, Mr. Dayton, for the foregoing communication. The hiber-nation theory has made wonderful progress considering the shortness of the time it has been in existence, the bungling manner in which it was broached, and the opposition it has met in certain influential quarters. I calmly leave it to the test of time :-

" Time, that doth all things else impair, But makes truth flourish, fresh and fair."

Guelph, Ont.

## For the American Bee Journal. An Early Swarm, Wintering, etc.

#### C. W. DAYTON.

In consequence of a powerful col-ony of bees in the fall, and sur-rounded by 18 inches of forest leaves on the summer stand, I am enabled to report the first natural swarm as issuing on May 8-one month and 8 days earlier than in any other year. I think it must be the earliest swarm north of the 43rd parallel. I did not examine my bees this spring as often as usual, and I was not aware that there was such a colony in the yard. Its hive contained 6 combs of brood, and as that was all there was room for in the hive, they had found it too small, and artificial feeding in the open air, followed by a day or two of gathering from fruit-blossoms, led them to seek a new home.

It is usually the case that a colony must fill 10 or 12 combs with brood, or spare brood to help other colonies along, before their hive becomes too small to contain them. This colony wintered on a westerly slope in the most exposed part of the bee-yard, which is in no way protected from the cold winds of winter. I have wintered several colonies in the same position, and with the same prepara-tion for several winters; in fact there has not been a colony lost in wintering on the summer stands, and that method of wintering I have practiced method of wintering I have practiced to a considerable extent. It may have been because they were prepared for safety, instead of experiment. Here I might say to those who favor large hives: *Provided* (that word needs emphasis as it is likely to be left sight of the hence, heavest

of the bees from torpor. It would be better to eoin a new word than spoil a good, useful, and respectable word in making a "eateb-all." We have the condition; we are sure of that; but we

in the honey gathered, to have spread the brood and inserted empty combs to be filled with brood? On page 60 Mr. Dadant says that I seem to be of Mr. Dadaht says that I seem to be of the opinion that breeding should be decreased 37 days before the end of the honey harvest. This cannot be exactly my opinion, as I would not destroy brood or practice hive con-traction; but that the brood-rearing space should not be increased later than 37 days before the end of the harvest, in my opinion, provided the harvest lasted not more than that length of time.

In the article to which Mr. Dadant In the article to which Ar. Database referred, I did not occupy space to say that honey harvests may vary from 15 to 42 days, and that I work on the outside of the average of 37 days. In a former article it was stated that it sometimes takes until the honey harvest is half over to get the activity of the their greatest. the colonies built up to their greatest capacity; this would be 18 days added to 37, equaling 55 days, the length of honey harvest required that the last laid eggs might produce useful bees.

Again, on page 105, Mr. Green has it as discouraging brood-rearing 15 or 20 days before the harvest. It seems that the word "provided" was insuffi-cient to show that the time was given as an illustration; and to the ordinary reader who has not made the contents of the BEE JOURNAL a study, it would be made to appear that I had given candid advice to the effect. To help me out of the dilemma, Mr. Dadant and Mr. Green warn the readers against accepting my illustrations as actual facts applicable to uncertain-ties. While their warnings may have been given in good faith, I hardly believe that it was much the best for the reader after all. There are amongst the readers of the BEE JOURNAL two kinds of readers—the experienced and the inexperienced; and it is the beginners who follow the teachings of the others. Now it has always been my belief that any reader who would accept an illustration for a fact, ought not to be corrected, but be allowed to follow it that he may stumble and get the right kind of experience while he is yet young in the business; for being guided and prompted along without overtion of his error he is get exertion of his own, he is sure to meet obstacles, and great failures when he is older and has more to lose. Bee-keeping cannot be learned without self-experience, and if it were not for the failures, our knowledge of it would be vastly more limited.

My favorite plan for wintering bees on the summer stands, is to fill a hive on the summer stands, is to fin a live holding 5 or 6 combs solidly with capped honey, and then raise it 6 inches from the bottom-board to afford a clustering space, and sur-round the whole outfit with a foot or more of tightly-packed forest leaves. Thus arranged the bees of the colony on the courseage of winter herin a on the approach of winter begin a march for the top of the hive, taking

the honey as they go. Another excellent plan is to con-

same as potatoes are buried. There should be a passage from the entrance to the outside air, and what is the most important of all, is to leave a small space directly on the top of the mound uncovered with earth, so that the circulation may pass upward through the leaves and escape. A hive-cover will protect it from the rain. These methods of preparation if well done, I deem almost infallible, and another fall is destined to find me preparing 50 colonies for winter in that way.

Bradford, & Iowa.

#### Local Convention Directory.

1886. Time and place of Meeting. May 20.-Wis. Lake Shore Center, at Kiel, Wis. Ferd Zastrow, Sec., Millhome, Wis. May 25.—N.W.Illa, & S.W.Wis., at Pecatonica, Ill. J. Stewart, Sec., Rock City, Illa. Aug. 31.—Stark County, at Canton, O. Mark Thomson, Sec., Canton, O. Oct. 12-14.-North American, at Indianapolis, Ind. F. L. Dougherty, Sec., Indianapolia, Ind. Oct. 19, 20.-Illinoia Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills. Dec. 1, 2.-Michigan State, at Ypsilanti, Mich. H. D. Cutting, Sec., Clinton, Mich.

177 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.-ED.

Large, Early Honey-Crop.-S. F. Newman, Norwalk, 5 O., on May 12, 1886, says:

This season has been the most favorable for bees in this section that I have ever known. We have had a constant flow of honey for about five weeks from maples and fruit trees, and the weather has been very pleas-ant. We already have about 1,000 pounds of honey, and our bees are in fine condition to take advantage of the white clover when it blossoms— the lower stories of the hives being packed full of bees and honey. We expect a very prosperous season.

Success in Cellar Wintering.-G. C. Lowry, Casey,+o Iowa, on May 9, 1886, says :

Bees are in prime condition in this part of the State. I wintered mine in a good, dry cellar, and I was successful in so doing.

Reversible Frames, etc.-N. L. Minor, Bowling Green, & Mo., says:

I will never use the reversible frames, as their use disturbs the bees too much. I prefer the old Lang-stroth frames. I favor Mr. Doolittle's idea of studying how to produce the most comb honey in a poor season. I shall try to investigate this subject.

Annoyed by the Bees.-Geo. M. Deer, Riga, Mich., on May 10, 1886, writes :

My bees are doing well, and nearly all are in good condition in chaff hives. I would like to know whether there is a book that contains the law protecting bee-keepers from being compelled to move their bees to the woods or back fields to satisfy some nervous or jealous people. I have 5 acres in the village and 86 colonies of bees; the talk is that I will have to move my bees away so that people will be safe in their own houses, and along the street; and so that they can cook sweet victuals. The cidercan cook sweet victuals. The cider-mill man is growling abont getting stung sometimes. My bees are about 150 feet back from the road, and some people make an awful fuss when they go by. Can they make me move my bees? This is not an incorporated village, and my bees have done no mischief to amount to anything. They worked on meal that one man fed his horses, and they then were taken out of the shed. The owner said that if I did not move my bees he would; that is the way some talk.

11f the bees are troublesome to your neighbors, you should move them away without waiting to be compelled to do so by law. The bees in our apiary, here at the BEE JOURNAL office, so troubled our neighbors some three years ago, that we promptly moved them away. We think it a duty to society not to annoy our neighbors by needlessly keeping anything on our premises to their detriment.-ED.]

Too Cold for Honey.-Henry Alley, Wenham, & Mass., on May 11, 1886, writes:

The weather is unfavorable for bees. There is plenty of fruit blos-soms, but it is too cold for honey.

Preparing to Swarm.-Mrs. J. N. Heater, Columbus, Neb., on May 10, 1886, says :

My 69 colonies and 7 nuclei came through the winter in splendid condition, with no loss excepting one very weak nucleus which starved with plenty of stores out of their reach. They are all booming on fruit-bloom now, and some are preparing to swarm.

Bees Breeding Rapidly. - Abe Hoke, Union City, >> Ind., on May 10, 1886, writes:

I put 32 colonies into winter quarters last fall, and 31 of them came through the winter. I lost one the latter part of April by robbing, and I sold 4. I now have 26, three of which are rather light in bees, but have plenty of stores, and all are breeding very rapidly, except one. On page 762 of the BEE JOURNAL for 1885, I ject. I mark every day the degrees

stated how my bees were prepared for winter, and how I had seen bees prepared for winter when I was a boy. I said that I would prepare one in like manner, and see what the re-sult would be. The result was that all the bees are dead, but abont one quart and the queen. It is one of my light colonies. Last summer I made an observatory hive of 3 frames 12x20 inches, so constructed that it can be made into a single-comb hive. It has a glass on each side, and a wooden door over the glass. I packed this hive with the rest in dry sawdust, and the bees in it are in first-rate condition. The two outsides of the outside comb are full of brood, one-half of one outside is hatched, and the queen fills the cells as fast as young bees leave them. I saw the queen deposit 5 eggs in one minute yesterday. I have never lost a colony of hees in a straw-hive; the 2 I lost last winter were in wooden-wall hives.

Ants and Roaches.-John L. Isley, Vibbard, ~ Mo., inquires on May 8, 1886:

Please tell me through the BEE JOURNAL how to keep ants and roaches away from the hives ?

[Tansy strewn around the hives is recommended by some bee-keepers to keep them away. A sponge wet with sweetened water might be put in a wire cage to destroy them. Borax, salt or gum camphor, or powdered cloves scattered where they congregate would get rid of them.-ED.]

Storing in the Sections. - Alex. Rose, Sullivan, O Ills., on May 6, 1886, says:

My bees are storing honey in the sections now. White clover is beginis fine for an early honey harvest. Plenty of drones were sealed up some days ago.

Bees Breeding Very Fast.-Wm. Ford, Marshalltown, Olowa, on May 8, 1886, writes:

My bees wintered well in the cellar. They came out in good condition, strong in numbers, healthy and dry. My loss is 2 colonies out of 13, fall count. They are breeding very fast. They carried the first pollen on April 14. They are now working on apple and cherry bloom. We have every prospect now for a good honey season.

Solving the Wintering Problem.-Wm. F. Kanzler, Fulda, 9 Ind., writes:

It is no wonder that our valuable AMERICAN BEE JOURNAL increases in favor with the most apiculturists of this country, for the Editor does not attach to each communication his criticism (as some editors do), and he

on my elbow-shaped thermometer on the inside of the same bee-hive, and I shall do the same the year around; and if we know the exact temperature and the behavior of the bees in winter, we may solve the "wintering question."

Bees in Good Condition.-W. A. Shafnit, Brighton, Iowa, on May 10, 1886, says :

My first swarm issued on May 6. had only 3 colonies to winter, and they came through in good condition, with the aid of the BEE JOURNAL. Bees in this part of the county do not produce much honey, as they all are in box-hives. I use the new Heddon or Langstroth improved. I would like to know which queen comes out with the first swarm, the old or the young one.

[The old one, of course.-ED.]

The Season in Cuba. - A. W. Osburn, Cuba, W. I., on April 30, 1886, writes :

The winter just passed was a very poor one for honey—too much cold weather; and the spring, so far, has been the poorest of the three since I came here. All new colonies made by division have to be fed, as it is very rare that sufficient honey can be found in the parent hive, that they can spare.

Bee-Keeping in Mississippi, etc.-Lorenzo J. de Sobotker, of Riverton, 9 Miss., on May 3, 1886, writes :

I came here on Feb. 23 to take charge of an apiary of 132 colonies of brown bees; of these 83 were in onestory 15-frame hives, 10 of which were in very good condition, but 73 were very poor, and 8 of them queenless; in fact many of them went into winter quarters last year upon 5 and 6 frames, and no division-boards. From what I found, there were 100 colonies prepared for winter on the summer stands, but, according to my idea, in very poor condition; and as the winter has been very severe, and the spring very late in coming, I reached here just in time to save a good many bees, which I did by feeding with the surplus combs of honey from the 10 good colonies. The weather has been so changeable from frost to sunshine, and showery weather, since my arrival here, that I could not venture to do anything with the bees until the midall of March, when the red maple and dandelions began to bloom; followed at the end of March by an abundance of willows, and which lasted from 4 to 5 weeks; this has assisted brood-rearing very much—so much that I was obliged to extract on April 22, 23 and 26 from the brood nexts of the and 26, from the brood-nests of the strongest colories, from 84 combs, yielding 15 gallons of splendid willow honey, weighing about 11½ pounds to the gallon. I have been using the combs taken from the hives of the honey, weighing about 11½ pounds to the gallon. I have been using the with the worker brood. The hatched combs taken from the hives of the drones are but little, if any, larger colonies that died last winter, putting them between the brood-frames; in few drone-cells in the hive, and, of this I have had to be very cautions, course, these produced fully-developed

as the weather and season has been very backward for honey-production; however we now have the honey-locust, hawthorne, white clover, asters, and the dandelions yet in bloom. The willows are about out; but the bees are increasing spendidly in brood, and I am in hopes of get-ting them all right for the crop, which I think will be a poor one this year. I am told that this apiary be-gan the winter with 100 colonies in movable frame hives, and 40 in box-hives. I have been transferring 17 colonies in box-hives to movableframe hives, and have still 32 box-hives with strong colonies in them, which I intend to allow to swarm naturally. So I now have 100 colo-nies, all with queens, and 32 colonies in box-hives, on some of which I have put one-pound sections. I would call it spring count 100 colonies in movable-frame hives, and 32 box-hives. This apiary was started only last season from 40 colonies in box-hives, and they produced 7 barrels of honey of 45 gallons each, weighing about 12 pounds to the gallon; and these 40 colonies in box-hives were originally gotten from one swarm of bees that came to this place from the woods in the season of 1882.

Early Swarms and Drones,-Dr. H. R. Dorr, Worden, 9 Ills., on May 11, 1886, writes :

I had a fine swarm of Italian bees yesterday, the first this season. Bees in this neighborhood have come In this heighborhood have come through the winter in finer condition than ever before. I began the winter with 14 colonies on the summer stands, with a new kind of packing, and to my astonishment (but great pleasure) I saw them all safely through, and almost as strong as in the auturn I had drones flying from the autumn. I had drones flying from several colonies on Sunday, April 18. Who can do better for this latitude?

Promising Season, Small Drones, etc.-W. C. R. Kemp, Orleans, 9 Ind., on May 13, 1886, writes thus:

The honey season is now upon us in Southern Indiana, and promises to be one of the best we have had for several years. Bees came out of win-ter quarters in splendid condition—no losses of any consequence. The ab-sence of the product of plant-lice, sometimes called "bug-juice," con-tributed largely to this condition, but bees gathered considerable honey-dew, and with other kinds of wholesome honey, came through all right; not-withstanding the usual quantity of pollen held its place in the hive. I have a colony now that is a problem that I cannot solve. The queen is an ordinary-looking Italian, apparently young; fully one-half of the brood is drone, and the other half worker. The drone brood are all in workerdrones. I should say one-half of the entire colony are of these diminutive drones. I opened the hive to-day and found two queen-cells scaled up. I began capturing and pinching the heads of drones, and served her majesty's head the same way. I then proceeded to decapitate all the un-hatched drones, and the Plymouth Rocks had a square meal for once. I would be pleased if some of the savants would give a satisfactory explanation of this condition of the colony described above. The prospect for a bountiful honey crop all over the country I think is better than the average season.

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., May 17, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

<sup>77</sup> HONEY.—Comb is coming forward more freely and prices now are 15\[2010] how for 1-h, sections. Ex-tracted is in light demand at 5207c. California comb boney, in 2\[50], sections, 9202c. BEESWAX.-23224c, per 1b, Not much offered. R. A. BURNETT, 161 South Water st.

At One Bollar a Year.

#### ALFRED H. NEWMAN. BUSINESS MANAGER.

To Correspondence. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a Binder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few hours, to get subscribers.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent nd the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

Our New Catalogue of Bee-Keepers' Supplies for the spring of 1886, is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it.

" Don't Stop "-tbat is what many write to us about their papers, when their time is nearly out. One subscriber says : "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It runs out with this month ; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

The Convention History of America and the AMERICAN BEE JOURNAL for one year, will be elubbed for \$1.15.

#### OUR CLUBBING LIST.

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

The American Bee Journal ...... 100.. 

#### Honey as Food and Medicine.

23" To create Honey Markets in every village, town and eity, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine." and seatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine " are sold at the following prices :

Single copy, 5 ets.; per doz., 40 ets.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15,00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Kendall's Horse Book .- No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 25e., in either English or German.

To any One sending us one new subseriber with their own renewal (with \$2.00), we will present a copy of the new "Convention History of America."

Advertisements. E HORSE. By B. J. KENDALL, M. D.

A TREATISE giving an index of diseases. and the symptoms : cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison ; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse ; a valuable collection of recipes, and much valuable information,

Price 25 cents-in English or German.

#### THE BRITISH BEE JOURNAL

#### AND BEE-KEEPER'S ADVISER.

The BAITISH REE JOURNAL is published every Week, at Ten Sbillings and 10d. per abbum, and contains the best practical information for the time being, showing what to do, and when and how to dn it. It is edited by T. W. Cowan, Esq.

The British Bee Journal and the AMERICAN BEE JOURNAL, one year, for \$3.50.

You will be interested in perusing a beantiful catalogue which explains fully about the best hives, and gives almost as much information about the best methods of getting honey, as the regular works on that subject. This is no catch-penny scheme, but every statement made may be verified, because the implements used are of the simplest kind, and at the same time the most predical. Send your name plainly written with your post-office also plainly written upon a postal card, and the names and addresses of any bee-keepers you may know and get this pamphlet free. Address, J. M. SHUCK, DES MOINES, IOWA.

# COMB FOUNDATION !

## Reduced 5 Cents per pound.

UNTIL Further Notice, we will sell brood foundation at 40 cents per lb., and thin, for surplus honey, at 50 cents per pound. This reduction from the prices quoted in our Price Lists for 1886, is made on account of the decline in the price of

CHAS. DADANT & SON, Hamilton, Ill. THOS. G. NEWMAN & SON, Chicago, Ill.

Thirty-First of May.-A. L. T., in Vick's Magazine for May, gives these inspiring lines:

To-day sweet Spring has kissed her buds, And said good-bye to all her flowers, And whispered to them of June's birth, Of warmer airs and shining hours. And, thus, the faint regret we feel, The fleeting tonch of sorrow, Is banished with this sweetest thought,— The Summer comes to-morrow.

Mr. A. J. King has returned from Chba. His address is 336 Webster Avenue, Jersey City, N. J.

S. P. Roddy, of Mechanicstown, Md., has sent us his circular and price-list of bees.

A Canadian prophet predicts that the month of May will terminate in furiously hot weather. It seems to have come already -for at this writing (on Friday) it is "redhot."

Mr. O. O. Poppleton has returned from Florida to his home at Williamstown, Iowa. He expects to return to Florida next fall. His health is much improved, and so is his wife's.

The Indiana State Fair is to be held at Indianapolis, Ind., from Sept. 27 to Oct. 2, 1886. The premiums on Bees, Honey, and Aplarian Supplies amount to \$93.

Mr. C. F. Muth, of Cincinnati, has sustained considerable loss at his farm in Indiana, by the late storm. Many trees were blown down, bee-hives over-turned, etc.

From Bodd, Mead, & Co., 755 Broadway, N. Y., we have received the excellent story entitled, "From Jest to Earnest," by E. P. Roc. It is gotten up in cheap form, and is sold for 25 cents. It is the complete book which usually sells for \$1.50.

Rees Annoying Our Neighbors.-On page 314 of last week's issue, we answered Mr. Deer's question relative to the above subject, in a few lines, advising the removal of the bees. In this week's issue, on page 330, Mr. Heddon gives his views of the matter. He is quite correct in saying that "our relations with our neighbors are more or less a continual compromise "-and that compromise can usually be effected by some little kindness or courtesy—or an occasional present of honey. If such a compromise caunot be effected, and if the bees are a real annoyance, surely they should be moved without waiting for the process of law.

Mr. C. H. Dibbern, of Milan, Ill., criticises our advice as follows :

our advice as follows: Your comments in reply to Geo. M. Deer, on page 314, in regard to complaints of neighbors being annoyed by bees, reminds me of the recipe to keep hens from scratching, viz: "Cut their heads off." Now most of us are not so situated that we can at any trivial complaint of a neighbor, 'fold np our tents like the Arabs, and as silently steal away." I have neighbors living on three sides of my apiary, within 300 feet, and I have no serious complaints. The only fault-finding I have had to contend with, was by bees specking clothes on wash days, early in the spring. This can be gnarded against to some extent by not putting out any colonies from the cellar for a day or two before each wash-day, which usually occurs on Monday.

I have noticed that the most complaints about bees heing an annoyance, rest on very slight foundations; usually there is some other motive behind these complaints, such as spite, jealousy, etc. It is notorious that some people cannot see others prosper, especially if aided by the hees, which they imagine " work for nothing and board themselves." The best way to allay all such complaints, is to treat all our neighbors in the spirit of the Golden Rnle. A section or two of nice honey presented to a faultfinding neighbor occasionally, has a wonderful influence on them. Then, too, should their chickens happen to stray linto our yards, we must not shoot them, or raise a great fuss about it; but go to work and fix our fences so that they cannot readily get over, or through them. Also, much depends upon the kind of bees one keeps. I have feared that should the vicions Cyprians be generally iotroduced, they might make us a "world of trouble." I would advise all beekeepers so situated that there might be troubled by their bees annoying others, to cultivate such strains of bees as have a gentle disposition – such as the Italians, Albinos, etc. There are some persons probably who would not be satisfied, for reasons already stated, short of compelling one to "move on," and it seems to me that there ought to be some law to proteet ns against such unreasonable people.

If the complaints of neighbors are inspired by jealousy or ill-will, then the case is quite different. Mr. Deer admits that his neighbors claim that he must move his "bees away so that people will be safe in their own houses, and along the street, and so that they can cook victuals." He also admits that the bees "worked on meal that one man fed his horses," and the result was that they "were then taken out of the shed." "The owner" of the horses, continues Mr. Deer, "said that if I did not move my bees, he would."

If Mr. Heddon and Mr. Dibbern will read the letter on page 314 again critically, we imagine they will agree with ns. If they do not, however, it will simply be a case of agreeing to disagree. They do not look through our spectacles. We prefer to agree with our correspondents, but unfortnately we cannot always do so—though we respect their opinions just the same.

"How to Raise Comb Honey" is the title of a new illustrated pamphlet of 16 pages, by Oliver Foster, of Mount Vernon, lowa. He says that it describes his "improvements in methods resulting from ten years' practical work and extensive experiments," and includes his " adjustable honeyease and clamp." It can be obtained for 5 cents, either of Mr. Foster, or at this office.

We have Received a copy of the "Proceedings of the Davenport Academy of Natural Sciences." This is a book of 350 pages, and covers a period of over three years. It is very interesting and instructive, giving some valuable bistory of the discoveries in connection with the "mound builders" of the great West-particularly in lowa. It is beautifully printed and profusely illustrated.

Crossed the River.—Two more heekeepers have crossed the river of death. Mr. J. M. Clark, of Hillsdale, Mich., on May 21, 1886, writes of them as follows :

We have this month lost by death two of our llillsdule bee-keepers. They are W. B. Dresser, who has often been beard from through the columus of the AMERICAN BEZ JOURNAL, and Wm. Moshier, who has been quite a successful bee-keeper for an invalid, which he has been all his life. Both of these were very estimable young men, and we shall miss them sadly.

Putting on Sections for Surplus Honey.-Mr. F. L. Dougherty, in the Indiana Farmer, gives his method thus:

It is hard to define just the exact time when the surplus boxes should go on, as much depends on the general condition of things. The experienced eye can easily tell the proper time, in fact the very humming in the air will tell him what the bees are doing. At the proper time the cells unoccupied with brood will be filled with honey, the combs at or near the top will be built ont, and the bees will be adding little patches of white comb here and there, showing that they are gathering more than what is required to supply their immediate wants, and they are needing more room.

An Advertiser in lowa, writes as follows: "I advertised considerable by circulars, near home, but as most of my orders came from New York, Vermont and Ohio, where I sent no circulars, the AMERICAN BEE JOURNAL obtained the orders for me."

As this was only a 5-line notice, and inserted only twice, does it not demonstrate the wisdom of employing our columns when it is desired to reach bee-keepers with any announcement?

The Journal of Progress remarks that " an advertisement in a good trade paper, representing your line of business, is the best kind of a traveling salesman. It has most of the merits and none of the vices of the "traveling man," besides many advantages that are entirely its own. It travels in all directions at once. It visits your customers continually. It talks with thousands of tongues, and has the confidence of its hearers.

The Catalogue of the D. A. Jones Co., (Limited) is received. It contains 16 pages of prices and descriptions of Bee-Keepers' Supplies.

A Circular is on our desk descriptive of a Drone and Queen Trap, gotten up by J. A. Batchelder, Keene, N. H.

Replies by Prominent Apiarists.

## Introducing Queens.

Query, No. 254 .- I will get a pound of bees about June 1, and will previously have reared a queen for them. I will put them on comb foundation. What is the best and safest way to introduce the queen to them ? -Canton.

You had better buy them with the gueen. Otherwise introduce her by caging her 48 hours. - DADANT & SON.

I should put the queen with one frame of her brood and bees into the hive that I intended to put the pound of bees in, and then let the bees from abroad run in at the entrance .-- G. M. DOOLITTLE.

I think I would risk putting her with the bees\_without any introduc-tion; but I would rather have the bees on a frame of brood.—C. C. MILLER.

I would introduce her in the same way as I would introduce a queen to an ordinary colony. As the bees will be queenless, and will have no brood, they will be almost certain to accept a queen offered in any manner.-W. Z. HUTCHINSON.

I should cage her for 24 hours, then if the bees seemed in a friendly mien, I should let her out. If the bees did not seem well disposed, I should leave her caged 48 hours. I can always tell when liberating a queen whether I must re-cage her for a longer time.— A. J. COOK.

I would cage her on top of the frames, and as soon as the bees quit "balling" the cage—if they "ball" it at all—f would turn her loose. I would not meet with one loss in a thousand when proceeding in this way. My cages are so arranged that the bees release the queens by eating out the soft candy with which the cage is provisioned. This feature of an introducing-cage is indispensable, in my estimation.-G. W. DEMAREE.

I should either put the bees on two frames of comb, and one of brood too old to rear a gueen from, and run the queen into the entrance at dusk; or put the bees on two frames of comb, and put the queen between them on a and put the queen between them of a frame of her own brood. In either case I should not open the hive for 3 or 4 days. A novice perhaps had better put the bees on the comb and brood, cage the queen and keep her among the bees for 2 or 3 days, and then let her out if the bees were quiet, but not so long as they seemed angry and clung to the cage in bunches. There is no absolutely safe method of introduction. so far as I can learn .---J. E. POND, JR.

Sprinkle the bees in the shippingcage with sweetened water, to which add 15 drops of the essence of peppermint to one pint of water. Treat the queen in the same way. Start the queen in the same way. Start the bees into the hive and let the queen run in with them, is one of the many ways you can do.-H. D. CUTTING.

## Transferring and Italianizing Bees.

Query, No. 255 .- 1 have 50 colonies of pure Italians on Langstroth frames, and I am buying and moving 40 eolonies of blacks in box-bives to within a mile of my home apiary. How can I best transfer and Italianize them to secure the most surplus honey ?-Texas.

Rear Italian queens, and at the time of transferring give an Italian queen after removing the black one. Any of the bee-books will tell how to transfer.-G. M. DOOLITTLE.

Transfer all the best worker combs with the worker brood, and fill out with frames filled with foundation. Rear Italian queens in the home apiary, and at the close of the early honey season, supersede all the black queens, introducing Italian queens in their places.—G. W. DEMAREE.

According to the old or Heddon method, as described in my Manual. This should be done at the swarming season, or a little earlier.-A. J. COOK.

Practice "modern transferring ' <sup>2</sup>as advised and practiced by Mr. Hed-don. Rear queens during the honey harvest, keep them in nuclei until the honey harvest is over then in-troduce them to the full colonies of blacks.—W. Z. HUTCHINSON.

Any of the standard directions for transferring and Italianizing are good, but to tell you how to do so to obtain the most surplus honey, is a difficult matter, as location makes such a great difference.—H. D. CUT-TING.

Unless the combs are very nice and straight, you will do as well to use foundation. Mr. Heddon's plan of transferring, as given in the BEE JOURNAL, is good. Rear Italian queens in nuclei of full-sized frames, and add the nuclei, queen and all, to the black colony during the honeyflow, having killed the black queen.— C. C. MILLER.

Transfer them by my plan called "modern transferring," which has been detailed in the BEE JOURNAL and Prof. Cook's book, and also in mine. For the sake of more honey mine. For the sake of more honey and Italianizing, move those black bees out of your home field, and rear queens for them in your home apiary. Move them six miles away.-JAMES HEDDON.

the above work. Some advise wait-ing till a swarm issues from the boxhive before transferring. I do not myself believe transferring as ordinarily advised pays. I much prefer the method described some 2 or 3 years ago by Mr. Heddon.-J. E. POND. JR.

## Using Empty Combs.

Query, No. 256.-Having lost all of my bees (19 colonies) during the winter and spring, I have ordered two 3-frame nuclei with Italian queens. I propose to send for bees by the pound ; how shall I proceed in order to utilize my empty combs to the hest advantage ?-J. C.

Put the combs in close boxes so that they will be safe from moths, and use them as rapidly as needed by the bees.—A. J. COOK.

Give the bees as many combs as they can cover; also furnish them with queens, and as fast as the bees increase in numbers, add more combs. Produce extracted honey. - W. Z. HUTCHINSON.

Watch so that mice and worms do not infest the combs ; keep them well spread apart in a cool, airy place; and give them to the bees just as fast as they can use them.—C. C. MILLER.

I would buy bees in box-hives "cheap," and "drum" out two or three swarms from each box-hive. using the empty combs to hive them on, and rear queens from the nuclei for each swarm. My next choice would be to buy bees by the pound, and fight the the moth-worms with the fumes of brimstone.-G. W. DEM-AREE.

can rear queens from one You nucleus, and if you get enough bees by the pound, you can soon have the most of your combs in nse. Keep your queens hard at work, and add an empty comb as often as practicable.— H. D. CUTTING.

I should get an untested queen with each pound of bees, and upon arrival I should take a frame of brood from the nuclei and put with a bive of combs, hiving the bees and queen upon them. Later on, these colonies can furnish brood in place of the reaching the bird of the nuclei to hive other pounds of bees on.-G. M. DOOLITTLE.

Put one queen with 2 pounds of bees in a hiveful of comb during the white clover bloom. This will make a good colony promptly.—DADANT & SON.

Hive the bees on the empty combs and give queens to them. Fill up by adding more combs as fast as the queen can occupy them. Work care-fully and intelligently in this way, and if the season is fair, each pound of bees Transfer the bees from the box-hives at once, and Italianize them as instructed in the text-books, of which "Bees and Honey" is of the best. It would require a page or more to an-swer this question, and as good an answer as I can give will be tound in the text-books of which swer this question, and as good an answer as I can give will be tound in the text-books of which the book "Bees and Honey" carefully, also the AMERICAN BEE JOURNAL, for valuable information and instruc-tion.—J. E. POND, JR.

## Shinning Bees by the Pound.

Query, No. 257.-1. How do you proceed to pnt up bees by the pound in a wire cloth, section-box cage? 2. What prevents the bees from running up from the cage and out of the funnel, while you are getting more to shake in ? 3. How do you manage to get the weight? or do you estimate the weight by the bulk ?-C. W. C.

have had no experience with sending bees by the pound, except in the shape of a nucleus, which I consider the best plan of sending bees.-G. M. DOOLITTLE.

1. I would not use the section-box device to ship bees in. For a pound of bees I use a plain, cheap box 6 inches wide, 414 inches deep, and 14 inches long. The bottom is nailed to the side-pieces, and a board 5 inches wide and as long as the bottom is wide, is nailed across the top of the On the under side of this cenbox. ter board is a pocket made of thin cotton-cloth which is filled with wet sawdust. The ends and the openings at the top on each side of the padded center-board, are covered with wireeloth. The soft candy-1/2 pound to each box-is secured in a little box made of "section stuff," which is slatted at its top, and is nailed to the bottom of the shipping box. 2. The wire-cloth at one end is left unnailed until the bees are all in the box. The funnel is smooth and nearly perpendicular, and the bees slide down and cluster in the box. 3. The box is set on scales, the funnel placed in posi-tion, the weight taken, and the "pea" set forward 1 pound. The bees are brushed into the funnel till the beam tills. I use a turkey quill to brush down the bees that stick to the inside of the funnel. The wire-cloth is then nailed down, and the package is ready to be directed and shipped. When I send a queen with the bees, she is caged with her suite, and the cage is rastened to the side of the inside of the shipping box. With my sawdust pad and the queen caged with the bees, I am sure that I can ship a pound of good, healthy, young bees to nearly any place on the globe. The pad of wet sawdust keeps the bees 'quiet when nothing else will. Shipping bees by the pound is any thing but pleasant—try it.—G. W. DEMAREE.

#### Convention Notices.

The 5th regular meeting of the Hill County Bee-Keepers' Association will be held on the drst Tuesday in July, 18-6, at the apiary of Hon. J. M. McDaniel, of Peoria, Tex, At the same time and place will be held a bee-keepers' honey picnic. I. A. GOONITCH, Sec.

The Northwestern Illinois and Southwes-tern Wisconsin Bee Keepers' Association will bold their next meeting at Mr. Ed Whitlesey's. 2% miles south of Pecstonica, Ills. on May 25, 1896. J. STEWART, Sec.

The Illinois Central Bec-Keepers' Association will hold its next meeting at Mt. Sterling, Ills. on Tnesday and Wednes-day, Oct. 19 and 20, 1886. J. M. HAMDAUOH, Sec.

The next annual meeting of the Michigan State Bee-Keepers' Association will be held in Ypsilanti, Mich., op Dec 1 and 2, 1886. H. D. CUTTING, Sec.

Explanatory .- The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark () indicates that the apiarist is located near the center of the State named; δ north of the center; ♀ south; ↔ east; +O west; and this of northeast; ~ northwest: & southeast; and ? southwest of the center of the State mentioned.

#### For the American Bee Journal.

The Western Bee-Keepers' Convention.

The semi-annual convention of the Western Bee-Keepers' Association was held in Kansas City, Mo., on April 29 and 30, 1886. President Hayhurst called the meeting to order at 10 a.m., and the reports of the Secretary and Treasurer were read and adopted. A communication was read from the Corresponding Secretary of the North American Bee-Keepers' Society, requesting that a committee be appointed to make a display of the be appointed to make a display of the honey-producing plants at its meeting in October next. This was deferred until the next day. While the com-mittee on questions for discussion were preparing them, the President asked, "How did you winter your asked, bees?

L. W. Baldwin-My bees are wintered mostly in the cellar. I left 25 colonies out-of-doors. I weighed 17 colonies placed in the cellar, and found they had consumed 4 pounds of honey in 100 days. I also weighed those out-of-doors. I had 15 colonies packed with 21/2 inches of leaves all around and on top. Those consumed. on an average, 6 pounds, and 10 colo-nies packed on two sides and on top, averaged 8 pounds per colony. This averaged 8 pounds per colony. shows that shutting colonies only on as many combs as they will occupy,

as many comos as they will occupy, and well packed, saves stores. I gave upward ventilation to those in the cellar. My apiary wintered well. R. F. Muir—I cannot winter my bees in the cellar on less than 5 pounds of stores. I have never weighed any of those out-of-doors.

Jas. II. Jones-I wintered 95 colonies out-of-doors, packed, and 50 in the cellar. Those on the summer stands wintered the best. My cellar was not right; it did not have suffi-cient ventilation, and the combs molded.

A. A. Baldwin-1 think that the best point in packing bees out-ofdoors is to keep them from being caught from the cluster. I have lost three times as many bees, on an average, in colonies not packed than those packed on all sides and on top.

R. B. Leahy-I have had some ex-I did not double up my nuclei last fail, and lost one-third. I have used

no packing in wintering bees out-of-doors, and 1 have lost only those spoken of.

The Constitution was amended by adding Art. 10, viz: "The annual dues for each male member shall be 50 cents."

The committee to prepare ques-tions reported, and the convention adjourned till 1:30 p.m.

The opening session was well represented by bee-keepers from Missouri, Kansas, Nebraska and Iowa, and the attendance was larger than at any previous meeting. Several ladies were present.

#### AFTERNOON SESSION.

The President called the meeting to order at the appointed time, and Mr. A. A. Baldwin was called on for his essay on "The best method of hand-ling bees for comb honey." Several points in the essay were discussed.

Jas. II. Jones-There would be more money made to take out a part of the bees from the swarm and return the remainder to the parent colony, and would in that way get the swarming fever out of them. I have practiced returning the entire swarm, and I find a great deal of trouble in my bees sulking.

" Is it best to unite weak colonies in the spring ?"

A. A. Baldwin—I think that the best way is to unite them at the com-mencement of the swarming season. Up to this time we have two queens

for breeding. Jas A. Nelson-I would unite queenless colonies with those having a queen.

Jas. H. Jones-If we do not want increase we can take the smallest and unite them with the next strongest, and continue until the colonies are strong. I think that the plan of nursing weak colonies up to the honey season and then uniting them is a good one.

An able article was read from Clemons, Cloon & Co., on "The honey market," which contained among other interesting statements, "that comb honey should be placed on the market in packages of from 24 to 40 pounds each, and that the sections should be unglassed and weigh one pound each." They would not advise the use of ½-pound sections.

The usual subject on the best race of bees was thoroughly discussed.

J. D. Ghering-My bees are mostly blacks, and I produce as pretty honey as the market affords. I do not find the Italians disposed to finish up their honey as perfectly as the blacks. I have tried placing the honey from the Italians on the hive of the blacks to finish up, with a good deal of satisfaction.

"Is it necessary to have a honeyboard with open-top frames in getting comb honey?"

R. B. Leahy-I have never used a dozen honey-boards in working for comb honey, and I do not have any trouble with the queen getting into the sections.

John Conser-I have not had any trouble with queens in the sections. I have a space of 14-inch above the frames.

A. A. Baldwin-Most of the beekeepers using the open-top frame have now gone back to the honey-board. Honey in sections is colored more with open top-bars, especially on old colonies. I think that we must have a honey-board if we want to get honey for the market.

"Can more honey be produced from a non-swarming colony than a colony and its increase ?"

Jas. II. Jones-I had a colony that did not swarm for two years, and it is my opinion that if I can have my bees non-swarming, I can get more honey. It is the swarming fever that injures our honey crop. I think it destroys at least one-third of the product.

John Conser-1 do not see any very material difference in colonies on either side.

A. A. Baldwin-I think we cannot decide without several years' experience, and it is the safest way to get a light increase.

J. S. Atkins-One-third of my bees do not swarm, and I always get the heaviest amount of surplus from those that do not swarm.

"Which is the best way to get increase, by natural swarming, or by dividing colonies ?"

John Conser—If you want bees, divide colonies; if honey, let nature have its course.

A. A. Baldwin-We must feed liberally with honey or sugar in order to be safe in making colonies by division. Adjourned to 9:30 a.m.

#### SECOND DAY.

The meeting was called to order by Vice-President R. B. Leahy. The Association invited members of sister organizations and representatives of the press to take part with it as honorary members.

An essay from Mr. Jos. Nysewan-der, was read by the Secretary, and the convention unanimously adopted it as its sentiments. It is as follows, on

#### DOES BEE-KEEPING PAY?

It behooves every one who contemplates engaging in a pursuit, or who is following a certain line of business, to consider well its possibilities both as to failure and success. If we can determine upon a reliable basis that the possibilities are plausible, and that success depends upon our own energies, tact and experience, we have at least solved one phase of the business that will be an incentive in prompting us to continue persistently in it until we have mastered it and success has been attained.

At this time, when very few things really do pay a profit, the agricultur-ist and others have made tests of various kinds of adjunct pursuits, as well as vocations by which a liveli-hood may be honestly earned, and yet independently. I believe where there is the faintest hope for remuneration nothing has been exempted from these tests. The agriculturist feels the necessity of diversified farming, and to make all the additions to his chosen pursuit that will contribute to his have been cared for so long and so resin. I use foundation in the sec-jucome; for, since the production of diligently will more than repay all tions in pieces 2x3 inches. I do not

the leading crops do not at present pay largely and are necessarily mark-eted at minimum figures, everything within the scope of his control is brought into requisition for Lis financial enhancement. Remumeration is the all-absorbing topic of the day. It is in such times that a business that is new in its nature will receive the most thorough and practical tests, and will grow in favor or be promptly discarded in proportion to its real and deserving claims.

As to the profits of apiculture: It is a significant proof in its favor that the interest taken in the business is largely increasing and spreading year by year. As an indication of this increased interest the number of beepapers that have lately been presented to the public, and that are being sustained, as well as the department in agricultural papers devoted to the subject goes to prove; for they have not so much created a demand, as to meet one.

As to remuneration : We too often overlook the fact that we must learn a business before it will yield us a profit. If we expect to go into any kind of business and reap a profit at once without first thoroughly master-ing the details of it, we will more than likely fail; and too frequently we attribute the failure to the business instead of ourselves, where the fault rightly belongs. In the minds of those who have skillfully followed the business, I believe there is no question as to the profits of aplculture, and that as a pursuit, although irregularities and a lack of proper management may have created gross misapprehensions by some as to it as a business. As a cause of the former the bee only improves "each shining bour," and sometimes it is the case that when it could work most effectually—that is, when the hive is full of bees and the flowers are laden with excluding the light of the sun for a protracted period will as certainly exclude the rays of hope as to a profitable season; and then, the flowers do not secrete nectar equally abundant every year. But the specialist calculates on irregularities, and is content to average the poor seasons with the abundant yields, and so far the average has proven itself such as to make the business altogether a success.

Even if rightly managed we should not decide bee-keeping a success or failure by a single year's trial; for what is the crop that can be produced with absolute certainty? <sup>-</sup>Failures will come. They will come to the farmer, and they will come to the bee-keeper, but it would be utter foolishness to discontinue a business because of an occasional failure. There is one characteristic that a beekeeper must have, and that is diligence, and that through failure as well as success; to feed when the bees ought to be storing away honey, and to spend when he ought to be receiving, for in due time in the "golden future" the "shining hour" will come, when these little creatures that

efforts thus bestowed upon them, and an over abundant season will fully make up the loss of a poor yield.

While it is conceded that nature and the bees do their part, the question arises, is there not danger that the honey market will be overstocked so as to make the business unprofitable? Let us not be selfish enough to anticipate such a condition of things. Shall we let the tons of nectar "waste its sweetness on the desert air" because of the plea that there is no one who wants it? I believe that the list of 300,000 persons who now keep bees could be more than doubled, and there would still be a demand for the product; for instead of its being looked upon as a rarity and a luxury, it would be considered a staple article.

Nature is rich in her treasures, and the earth yields profusely her fruits for the benefit of mankind, and if by skillful means we are enabled to utilize her wealth and gather in her treasures to add to the common wealth, we not only do that which redounds to our greatest profit, but it is more honorable than to contend over that which is already produced. Let us be assured that there is yet a com-petency for faithful efforts in apiculture as in other rural pursuits, and that Nature will yield from her bountiful storehouse in proportion to our skill and diligence,

## R. F. Muir-I think that putting the best side of the pursuit out induces many to go into the business, and creates thereby many failures. do not believe that there is more than 1 per cent. that succeed in the busi-

it pay are the supply dealers. R. B. Leahy—Every pursuit that is honest should be upheld, and so long as it is conducted properly it should not be put down.

C. M. Crandall-I do not think that it is good policy to flatter others in regard to the profits of the business, but I am heart and soul with Mr.

Nysewander's essay. P. Baldwin—I believe that 98 per cent. of the scientific bee-keepers succeed in the business. I do not think that the pursuit can be justly estimated from the whole number of bee-keepers.

" The use of foundation, its benefits, " were discussed as follows: etc.

John Conser-1 think that the nearer we can get to natural comb the better. I use thin foundation with high side-walls in sections; in brood-frames as heavy side-walls with thin base as possible. I use wax put on with a pencil-brush in fastening foundation, and I use wired brood-frames enough to keep the top-bar

from sagging. L. W. Baldwin—In using founda-tion I have had some losses from its sagging. This year I am going to use strips of foundation 4 or 5 inches wide, made from refined wax. I want it made about 5 square feet to the pound. I fasten it in the brood-frames with a composition of  $\frac{1}{3}$  wax and  $\frac{1}{3}$  resin. I use foundation in the secthink that anything is saved by using full sheets either in sections or broodframes.

Pres. Havhurst-I have used 400 or 500 pounds of foundation. I have never used it in sections, as I do not produce honey in sections. The prin-cipal use I make of it is in brood-frames, I have never made any very extensive experiments in getting natural combs built. I shall continue to use it fastened with wire.

"Will the bees gnaw away the foundation about the wire ?"

Pres. Hayhurst-I think they will sometimes. I get my foundation drawn out in upper stories.

A. A. Baldwin-I think the time to use foundation in brood-frames is during fruit-bloom, and I lately examined some colonies and found that in two days they had drawn out the foundation and were putting in brood. I do not think that it sags at this time with 5 square feet to the pound. In sections I would use a very thin base and not too heavy side-walls, because the bees in drawing it out leave too much yellow comb.

"Do the bees cut away the foundation at the bottom of the brood-frames?"

A. A. Baldwin—In some instances. R. B. Leahy—I use six cross wires to the frame, and two diagonal wires. I never have any trouble with sag-ging. I make it by putting a thin sheet on each side of the wire, and pressing them together. I have the tops of my sections grooved and run a little wax along the edge of the foundation.

Jas. II. Jones-I put foundation in sections by using beeswax and resin.

P. B. Thaxton—I use wide frames, six sections to the frame, and put in each section a block about half the depth and thickness of the section, beveled on two edges, and lay the along the edge. I then give the frame a light shake downward to remove the blocks.

C. M. Crandall-f do not think that it is necessary for the average bee-keeper to use wired frames. In using foundation in sections I have tried in a small way for three years to use it without separators, and I have had no sections perfect. I cannot place them in the crate.

Pres. Hayhurst-I think that the wires are absolutely necessary, and I shall stick to them.

"Is there any gain in using full sheets of foundation ?" Some of the members thought not.

J. D. Gehring-White clover yields slowly in my section of the country, and that is the reason I use full sheets in sections.

"How do you prevent after-swarms?"

A. A. Baldwin—Cut out the queencells on the seventh day, and after one or two days introduce a virgin queen or a queen-cell.

" Is it advisable to clip the queen's wing?"

L. W. Baldwin-I think that it is one of the grandest things connected

the queens and hived them on the old stand.

John Conser-As a general thing swarms settle with a queen; I then hive them in a hiving-box and put them into the hive. If it is necessary to repeat the operation, I do it, and have had no trouble.

P. B. Thaxton-1 think that clipping the queen's wing is one of the grandest things in handling bees. I hive the swarms on the old stand.

The Secretary was instructed to correspond with the Secretary of the North American Bee-Keepers' Society, requesting them to appoint the meeting for 1887 at St. Louis, or some other city in the West. The closing hour of the convention

was spent in a general experience meeting in which all took part, and was enthusiastic and profitable. The was enthusiastic and profitable. display of apiarian fixtures was not as those exhibited were: J. M. Shuck's reversible hive; L. W. Baldwin's sidestoring and chaff-packing hive: smokers, queen-cages, feeders, etc., from R. B. Leahy; and a fine display of extracted honey by John Conser.

The convention adjourned to meet in Kansas City, at the call of the executive committee.

P. BALDWIN, Sec.

For the American Bee Journal.

#### Dr. Miller's New Bee-Book.

#### WM. F. CLARKE.

One of our great poets (I forget which) says, "In every work, regard the author's end." He sets out to do Judge him by the a certain thing. Judge him by the performance of that, and not of something else which he did not undertake to do. Dr. Miller does not propose, in his little book, to lay down a methodical system of bee-keeping, or to produce a complete treatise on the subject, but to write about some of the things that interest bee keepers in the style of "a familiar chat." He promises to describe his own methods. not assuming that they are the best, or making invidious comparisons with the methods of others, but giving full permission to his readers as they

and permission to instructed as they glance from page to page, to exclaim, "Ob, how foolish! I know of a good deal better way than that!" But he modestly hopes that "some may find a hint here and there that may prove useful"—he might have safely said all.

This book is in reality a substitute for a visit to the Doctor's apiary. There are thousands of bee-keepers in the United States and Canada who, if they could pay such a visit at a cost of only 75 cents, would pack their satchels for a start in double-quick time. Well, the next best thing is to buy and read "A Year Among the Bees." By so doing you will see where and how the Doctor lives, what his apiary looks like, and be introduced to the whole family, including the father and mother-in-law, three miles off. You will get a glimpse of one of the grandest things connected Mrs. M. chasing her husband with a that his experience and observation bee-smoker and a switch of golden-have brought him to the point as 15 swarms at one time, and secured rod, Charlie taking out full sections reached at the Detroit Convention in

at the rate of nearly 1,000 an hour, and Aunt Emma who, though some-times "decidedly 'stuck-up," is literally " as sweet as sugar."

The Doctor does not meddle with any of the vexed questions that agi-tate the equinimity of bee-keepers. The pollen theory, reversing hives, hibernation, the Heddon patent, etc., he relegates to a temporary oblivion, and the entire army of belligerent hee-keepers find "Othello's occupa-tion gone," as they linger amid these peaceful pages. One is reminded of the old hymn :--

"There shall I bathe my weary soul, In seas of heavenly rest, And not a wave of trouble roll Across my peaceful breast !"

Well, it is pleasant after the din and smoke of battle, or the wrack and fury of the storm, to get into a quiet nook where sunbeams linger, and soft zephyrs whisper the sweet music of peace !

A large number of practical subjects are discussed, such as :-- taking bees out of the cellar; hauling and overhauling bees; hives, covers, and stands; feeding meal and symp; the honey harvest; frames and supers; sections; shop for bee-work; management of sections and starters ; separators; getting bees to work in sections; precautions against robbers; fumigating honey; protection from stings; swarming and its prevention; queenrearing; fall feeding; marketing honey; putting bees into the cellar; cellar ventilation ; hee-pasturage, etc. The views of a bee-keeper of such long experience on these and other topics cannot but be suggestive and provocative of thought. He must be indeed a stolid bee-keeper who is not interested and profiled by "familiar chat" on such themes.

The Doctor is not one of those who pool-pool a bee-sting, or have at-tained the state of indifference to its infliction, and is evidently of the opinion that there is a little of the spirit of bravado in certain quarters regarding this matter. A great many iron-clad bee-men will be disposed to make fun of his confession. " A bee inside my clothing makes me very etc., but I know of one nervous,' whom nature has not endowed with a pachydermaton's hide, who read that chapter with the truest sympathy and instead of exclaiming, "Oh how fool-ish!" involuntarily said, "That's ish !" involuntarily said, "That's so !" at the close of every sentence ! Various methods and devices are

given in detail with measurements and particulars enabling those at all mechanical to avail themselves of the wisdom that has come from a quarte. of a century's familiarity with bees and this fact should commend the book to beginners, and those who have not been long conversant with bee fore. Such cannot but find it very useful, while it will be read with bee lore. interest by the oldest veterans in the business, whether in Europe, Asia, Africa or America.

The most interesting passage in the book, to my mind, is found on pages 27 and 28, where Dr. Miller shows December last. Let a colony come out of winter quarters strong and with combs fullof stores, and it wants no tinkering. Like a darkey said, its "boun' for de kingdom," and nothing short of some dire catastrophe, such as the loss of its queen, can stop it. Colonies cannot become strong and populous too early in the season, and they will build up more quickly by having plenty of stores in the live, than they will by having food doled out to them day by day. Bees have more sense than some human beings. They will not increase and multiply unless they see a rational prospect of their children having bread to eat. While they have more wisdom than the improvident and reckless poor, the improvident and reckless poor, they are more true to nature than the self-pleasing rich, who do not want to be bothered with children. Give bees plenty with which to support a numerous progeny, and they like nothing better than to have a house full to overflowing with children; and this condition of an apiary in early spring is far more important to its prosperity and profitableness than any particular set or kind of "fixins."

The Doctor sets an example which it would be well for bee-keepers generally to follow when they write for the papers. He refuses to say "we" when he means "I," and if the printer runs out of big "I's" toward the close of the book, tells him to use little ones. That's good.

" Pigmies are pigmies still though perched on Alps, And pyramids are pyramids in vales."

Guelph, Ont.

For the American Bee Journal.

#### Marketing Honey.

#### W. MASON.

On account of some observations taken of honey in the markets last fall, and the honey season being near at hand, I desire to make a few suggestions in regard to the unmarketable condition of honey placed on the markets—both of comb and extracted honey—by some of our honey-pro-ducers. I do not wonder at our honey consumers manifesting some disgust and prejudice toward our honey, as to purity and quality, from the un merchantable condition in which it is

placed on the market. I hold that every honey-producer makes his own market for his honey trade. Every honey-producer should be careful to always put his honey in the best possible shape to attract the attention of the consumers, and its appearance should bespeak the quality it represents. If it is honey in sec-tions, the sections should be bright and clean, and never used the second time, as they become stained and besmeared with propolis, and broken or split, as I have seen on the markets. This manner of marketing honey will ruin any producer's trade, and I was

cleaned off. This gives honey a good appearance, and inquiry is soon made, if not labeled, as to who the producer is. We cannot be too careful in preis, we cannot be too careful in pre-paring our honey, either for home trade or for shipping, and we should never suffer rough, unsightly honey to leave our premises; even at a re-duced price. Some of it we can use in our families, and the balance feed head to the back back to the bees.

We must make our honey do its own advertising both in purity and appearance, and put such guaranty appearance, and put such guaranty on it that when our consumers try it they will buy again; thus enabling us to obtain a fair price for our honey, The only trouble I have in this line is in not being able to supply my customers, as I am always short of honey at, the end of the season. While I am not a large producer, my effort this season will be to accom-modate my trade. I have orders now waiting for at least 500 pounds as soon as it is produced; and I hope to get a good supply, as I have 30 colo-nies in good condition for honeygathering.

## Prevention of Swarming.

#### ERWIN STANHOPE.

My plan to keep bees from increasing, and to turn their swarming habits to honey-producing, is as follows: I use the S-frame Langstroth lows: I use the s-traine Langstroth hive, and a box on top just 20 inches long in the clear. The box holds 13 frames just 5x10 inches in the clear, which hang crosswise in the box. The frames are made of heavy  $\frac{1}{4}x1\frac{1}{2}$  inch stuff, and each frame holds 2 sections 5 inches outside by  $\frac{1}{4}$  inches wide. Each box has an entrance at the bot Each box has an entrance at the bot-tom of one end. Now suppose we are looking for swarms, the queens being clipped. We have some boxes ready, sections with starters all in if a large sections with starters all in it a large swarm, and two boxes, one on top, with 52 sections. When the swarm comes out cage the queen and hang her in among the sections. Move the old hive away and cover it with a sheet. Put the sections, queen and all on the old stand. The bees will go into the boxes. (Sometimes a swarm will fly out once or twice, but held the queen and they will soon hold the queen and they will soon quiet down.) The next day toward night, move the old hive back near the boxes. The bees will work hard the boxes. The bees will work hard in the sections, and they will put in lots of bee-bread. But do not be afraid, for it will be all right in the fall. After 7 or 8 days cut out all the queen cells but one; or, what is better, let a young queen out on the comb. Put the sections, old queen and all on top of the old hive; put the old hive on the old stand, and you will see big work. In 15 to 18 days let out the old queen, and the young queen about to say that it ought to. Extracted honey should be well rip-ned, with no pieces of comb in it; then put up into clean jars with the honey on the outside of jars well 26 sections. Do not cage an unfertile Mr. Barber's immediate neighborwill make way with her; or if any-thing has happened to the young

queen. It is quite necessary to use sections 1½ inches wide, for if they are more than that they will try to make two combs in one section, as they want to make brood-comb after swarming. I have been running my bees on this plan for a number of years, and it is very satisfactory. Mears,+o Mich.

#### For the American Bee Journal.

## High Temperature in Bee-Cellars.

#### W. H. STEWART.

In Mr. Barber's essay on "Wintering Bees in Cellars," on page 809 of the BEE JOURNAL for 1885, he says: the BEE JOURNAL for 1855, he says: "It is quite often said that no one has learned the secret of wintering bees, so that they can be wintered safely every time, but I deny the asser-tion." (Italics are mine.) Mr. B. bases his denial on the fact that he has wintered bundreds of aclouing for bases his denial on the fact that he has wintered hundreds of colonies for the last 25 years, and bringing "S0 per cent. out as good as when they were placed in winter quarters, and losing none." He tells us that he winters his bees in a "warm, damp celler," and if we do not misurder.

winters has bees in a "warm, damp cellar," and if we do not misunder-stand him, he keeps the temperature in his cellar up to from "60° to 90°." He also says that "the cellar must be closed, with no currents of air, either hot or cold, passing through it." Will Mr. B. please tell us how he keeps his cellar thus warm m his it." Will Mr. B. please tell us how he keeps his cellar thus warm in his cold climate, and at the same time "damp" without injecting a current of hot, or warm, damp air? Again, will he please tell us how he can keep a "constant draft" through his "ven-tilator from the top of the room" without a volume of either warm or cold air equal to that which passes up through the ventilator passing up through the ventilator, passing into the cellar, and thus keeping up a constant current through it?

constant current through it? Ite says that his "plan of wintering bees is no theory, but is one that is practiced by scores of bee-keepers in Northern New York, and invariably without loss in winter." How can it be possible that in the same State, and only a few miles distant from Mr. and only a few miles distant from Mr. Doolittle's locality, "scores of bee-keepers" should be wintering hun-dreds of colonies without loss, and the wide awake Mr. Doolittle never become acquainted with the fact? Why should Mr. D. have such winter troubles, and suffer such losses? There seems to be a mystery con-pacted with this matter. nected with this matter.

Further, Mr. B. tells us that what he claims for his plan of wintering is, that it is the safest plan; and in the next to the last paragraph he tells us that" where but few bees are kept where he lives, they have no trouble in wintering them in any cellar where vegetables will keep without freez-ing." How can Mr. Barber's 60<sup>°</sup> to 90<sup>°</sup> cellar be safest, as he claims, when his neighbors winter bees without loss, in cellars of any kind where the temperature stands as low as 33°

hood does this area of country extend, where bees can be wintered in small quantities without loss "in any cellar where vegetables will keep without freezing?" Why does it not extend as far as Central New York where Mr. Doolittle lives?

Did Mr. Barber live where he now does during his "early experience," when he "had all the trouble in wintering that many are experiencing now?" and when he "tried every place and manner of wintering" at that time that looked reasonable ? Did he try them in small quantities in "any cellar where vegetables will keep without freezing?" If so, why all the troubles in wintering; then and none now, in the same kind of a cellar?

Mr. B. claims, secondly, that wintering in cellars where the tempera-ture is  $60^{\circ}$  to  $90^{\circ}$ —" is cheapest;" and yet he tells us that "they will use more feed in a warm than in a cool one." Is more feed cheaper than less? I believe that a warm cellar is better than a cold one for wintering bees; but Mr. B. states as much in favor of cold ones as warm ones.

I am not doubting in the least that Mr. B. is of late successful in wintering bees in his warm room, and his neighbors at the same time as successful in using all sorts of cellars that do not freeze; but I do question whether it is all in the temperature warm for the many, and cold or warm for the few colonies. My opinion is that at the present time there is growing in Mr. Barber's vicinity some plant or plants that were not there 25 years ago, and that from such source, his bees now get sufficient fall honey to keep up breeding until winter sets in; and thus both he and his neighbors have plenty of young bees for winter and spring.

I wish to thank Mr. B. for the plan that he gives us for laying a floor on which to stand the hives; and also for the idea of placing them in a com-pact form, so that if a live bee leaves one hive it has not far to go to find and enter another. But how to invariably winter bees in a cold climate without loss, is still an open question. Orion, 9 Wis.

Sheboygan County, Wis., Convention.

At an adjourned meeting held on May S. 1886, at Sheboygan Falls, Wis., an organization was effected, and the an organization was enected, and the name of the old society, the "Sheboy-gan County Bee-Keepers' Associa-tion," which has been inactive for several years past, was adopted, also the constitution and by-laws with slight amondments. The officers slight amendments. The officers elected are as follows : President, II. The officers elected are as follows: President, H. F. Shadboldt, Winooski; Vice-Presi-dent, W. H. Hawkins, Sheboygan Falls; Secretary, Miss Mattie B. Thomas, Sheboygan Falls; Treasurer, Mrs. H. Hills, Sheboygan Falls.

Matters of interest to bee-culturists were discussed, and the meeting ad-

For the American Bee Journal. Feeding Sugar to Bees.

#### W. Z. HUTCHINSON,

I wish to thank Mr. H. E. Hill for his kind words and the kindly manner in which he criticises on page 281. It is pleasant to know that 1 belong to that class of contributors whose writings "are eagerly sought after," but I hope no one blindly follows where I lead. All are expected to use their own reason.

I should consider it the height of folly for Mr. J. B. Hall, or any one else who successfully winters his bees else who successfully winters his bees upon natural stores, year after year, to feed his bees sugar for fear that they *might* not winter well if he did not; but if he wintered them on sugar because honey was dear and sugar cheap, I should consider it wisdom. The advice to feed sugar for winter stores is not intended for those who are uniformly successful with natural stores; but if those who do lose their bees quite frequently from diarrhea, learn that they can prevent such losses by feeding sugar for winter stores, will they be expected to desist simply because those who are successful without sugar fear that the practice may assist in giving color to the unjust accusation that some bee-keepers secure their honey by feeding the bees sugar? Do those, who are opposed to the practice really expect such a sacrifice on the part of their less fortunate brothers? If they do, it shows most conclusively that while they may understand bee-culture, they are lacking in their knowledge of human nature.

Perhaps the majority of successful bee-keepers-those who succeed in wintering their bees and in selling their honey (of which J. B. Hall is a shining example)—do not use sugar, and probably never will; but is it to this that their success is attributable? The use of comb foundation has helped to give standing to the Wiley, sensational, artificial-comb-honey story. Shall we stop using foundation? Rogersville, & Mich.

For the American Bee Journal.

## Honey-Interests, etc., of Florida.

#### JOHN Y. DETWILER.

Subsequent to the late cold wave I was in receipt of numerous letters from apiarists inquiring as to the prospects of securing bees, and other prospects of securing bees, and other information relating to the apicul-tural resources of this locality—the east coast of Volusia County, Florida. Believing that what would in all probability interest those inquiring, probability interest those inquiring, would also be appreciated by the majority, I submitted my report of the damage as nearly as then could be determined, for which I am taken to task by a correspondent on page 217. My object was to dissuade any construct from heating in this south apiarist from locating in this section

making a personal visit to see the extent of the damage for himself.

I will not enter into any discussion I will not enter into any discussion as to the extent of the damage done to the mangrove. Dr. B. F. Fox. county superintendent of public schools for Volusia county, who has been in Florida since the war, ex-presses his opinion that 99 per cent. has been destroyed. I should judge that 95 per cent., which I think will be admitted, is sufficient to warrant a personal visit before establishing an union with the Source of Eldow a personal visit before escatorshing an apiary. Mr. R. S. Nelson, of Eldora, 12 miles down the river, estimates 75 per cent. killed in his locality. Allow me to furnish an extract from a private letter from Mr. II. W. Funk, of Bloomington, Ills., who was re-cently in Florida looking up a loca-tion for an apiary. He says: "I was at Tampa during the cold snap; the mercury was down to 18° above zero. I did not think that they (the mangrove) were hurt much, although they looked black on the top. I hear from a boat captain who stopped at Cape Sable, that they were frozen down Cape Sable, that they were frozen down there. The orange trees were not hurt much. A few days after, the leaves dropped off fast. All pine-apples, bananas and cocoanuts were killed. Up along the St. Johns river, from Ocala to Palatka, the orange trees were frozen black, and most of the leaves stuck to them. I think that those trees were damaged or killed;" and in conclusion he remarks that the outlook does not warrant him in establishing an apiary in Florida.

A letter to the Troy Kansas Chief, from a former neighbor from Doni-Marion Co., Fla., says: "Of my orange trees the large ones were more or less injured, and the small ones killed to the ground. Lemons, grapefruit, fig and Japan plums were killed to the ground; these are all put back two years in growth," etc. So much in reply to paragraph three of the

In reply to paragraph three of the article on page 217. In reply to paragraph four, I will simply say that the article in ques-tion related to the east coast of Florida. exclusively, with the exception of the reference to the groves in the interior, which, from authority above quoted, will sustain my position. A vast dif-ference exists between the east coast of Florida (the subject of the article on page 102) and the State at large. In proof, let the Hawk's Park correspondent, who so ably compiled the statistics of Florida's vegetable and animal production, furnish the parties he so anxiously wishes to locate here, through the AMERICAN BEE JOUR-through the AMERICAN BEE JOUR-NAL, with the exports from New Smyrna for the past few years out-side of oranges, honey, and turtle, or other productions of salt water; then the readers will know just what they can expect to raise and export in order to keep up an existence; then the full import of his fourth paragraph will be made manifest.

As an inducement to show np the exports of New Smyrna, Daytona, or any or all other places on the Halifax, Hillsborough or Indian rivers, outside journed to Saturday, Sept. 4. at 10 a.m. I to engage in bee-keeping without first of oranges, honey, and the food pro-

ducts of salt water, I enclose the fol-lowing clipped from the Halifax Journal of April 15, 1886 : "Any one in the vicinity of Day-tona 'showing up' a fifty, sixty, or a hundred acre orange grove, a ten acre corn, rice, sugar-cane, tobacco or cotton field, will secure the Halifax Journal for fifty years as a premium." While we earnestly desire to secure good neighbors, and render every available means in our power to in-form them of what they must expect should they locate among us, we do not forget that it is due to them that they should be truthfully informed on they should be truthfully informed on such subjects as are necessary for their comfort and welfare, should they locate among us. When neces-sary I propose to state facts when they are called for, so far as they have come under my observation. Instead of looking upon the dark side of the matter, I have unbounded hope for the future of the East Coast of Florida, and I would say that I know of no time better than the present to serure a home in this locality.

New Smyrna. O Fla.

For the American Bee Journal.

Fall Feeding vs. Spring Feeding, etc.

#### J. C. RAWLINS.

In the article on "Iloney for Bees in Winter." on page 247, by J. E. Pond, Jr., I think he bit the nail on the head about the consumer's idea when sugar is fed to bees. Why I think so, is that last year, in Feb-rnary and March, we fed 35 pounds of molasses sugar to 85 colonies, and some people think (or say they do) that is why our honey granulates. They say that much honey will not They say that pure honey will not granulate for 2 or 3 years after it is taken. It is very hard to get them to understand how honey is gathered in such large quantities.

I have been a close observer on the I have been a close observer on the subject of feeding, and I think that bees should be fed early in the fall, and given a little more than you think they will consume by the mid-dle of the next April. Colonies that were very populous last fall, but were extracted from late, and fed only a little, and that when the weather was cold and have been fed this spring when very cold, are now weak. But those whose hives were left full of honey, and not disturbed until the past week, are very strong. We feed to stimulate brood-rearing, but if they have plenty in the hive the queen, according to nature, knows when to begin her part in the reproduction of her species.

Mr. S. J. Youngman, in his article on page 248, says: "The cells if left too long must be carefully watched, for when the first queen hatches the bes will destroy the remaining cells." But I think that the *queen* does this work. I think I have proof of this; for twice I have found the queen at work on the cell, one time I know that she was by herself. This was in

ducts of salt water, I enclose the fol- it failed to hatch, I raised the cover and placed one on the comb over the bees; in about two hours I looked in, and what a beauty I beheld ! It was

a fine yellow queen biting at the cell, and not a bee helping. Another thing he said about bees swarming: "I have also known bees to swarm and not leave anything nearer a queen than newly laid eggs. That is a new idea for me. Was it a natural swarm ? I am working in the apiary of Mr. Z.A. Clark. I am a hire-hing, but one that careth for the bees. Arkadelphia, 9 Ark.

#### For the American Bee Journal.

## An Apiary in Ontario, Canada.

#### R. F. HOLTERMANN.

As Mr. J. B. Hall, of Woodstock, Ontario, is known as one of Canada's most successful apiarists, although not owning the largest number of colonies; and as it is also well known that he never wields the pen and gives any of the numerous bee-papers a report of his doings and the result of his experience, a description of his apiary will not be amiss.

The Quinby hive is used. The top-bar is square, not as formerly **V**-shaped. The bar (an inch deep, I think), I understand, acts in a measthe queen down, and the workers are less liable to build comb joining the lower story and supers. Perforated lower story and supers. Perforated metal is used between the body of the hive and the supers or upper the hive and the supers or upper story. No drone comb is wanted for store comb, if there is no drone conb in the body of the hive, and the per-forated metal is used to keep the queen from the upper part. The bees will not appropriate the drone comb above for storing honey, but true to the instinct to desire drones, they will leave the drone-colls empty for will leave the drone-cells empty for brood-rearing.

I fortunately arrived on the evening when Mr. Hall was going to remove his bees from their winter quarters, yiz: April 19. The house and grounds viz: A pril 19. The house and grounds being new, the water had obtained access to the cellar to a depth of 8 inches, and had to be pumped out; otherwise the bees, owing to the ex-traordinary season, would have been removed earlier. The temperature of the repository was at 62°, and the bees were clustering more or less about the hive-entrances. The stands, anothing lids and half-stories were cushions, lids and half-stories were all ready outside, and a carrying-stand for 2 colonies, having four legs and a pair of handles for two men, facilitated the work very much.

The hives were piled in rows back to back, to the ceiling, or nearly so, to back, to the celling, or nearly so, and four or five abreast—over 200 in all. The men carried, Mr. Hall ex-amined, and I—observed. The ex-amination consisted of lifting the hive and tapping to discover the strength of its colony. An experi-orad backgener will understand how enced bee-keeper will understand how transferred  $a \, la$  Heddon, and a cell out to do this. Only one colony given at the time. But thinking that, showed by the entrance any signs of

diarrhea, and this had the disease since December. They appeared strong and flew well in the morning. Several others had starved, but the balance appeared to be in good con-dition, although Mr. Hall says that they were not quite as good as they were the previous spring. In their flight in the morning-which was a beautiful one-they spotted their hives but little. As nearly as one could esti-mate there were 3 bushels of dead bees in the cellar.

The brood-chamber is but little disturbed during the season, twice only, as a rule, for the purpose of examining their condition, in the spring and in the fall. Comb and extracted honey is produced, and the stock on hand consisted of no more than would be consumed in the house

before the coming honey-season. Mr. Hall breeds his bees not for color, but excellence as honey-pro-ducers, winterers, etc. They showed (with the exception of the various races he is experimenting with, for various experiments are in progress most of the time) a mixture of Ger-man and Italian blood. He keeps a record of what quantities of honey his colonies produce, and the results of his large experience convince him that he can produce 80 pounds of comb honey as readily as 100 pounds of extracted. Later I will give his interesting account of his experiment with the Caucasian bee.

Bees throughout this part of Canada have done remarkably well, storing and capping honey, and actually drawing out cells along the top-bars in full-framed colonies.

Brantford, Ont.

For the American Bee Journal.

#### Troublesome Bees.

#### JAMES HEDDON.

I have noticed Mr. Deer's ques-tions, on page 314, and I do not believe that any one should move his bees because it is claimed that they are "troublesome." They cannot be expelled until the nature and extent of the annoyance is such as to legally declare them a "nuisance."

Some neighbor may be annoyed be-cause they are handsomely paying their owner. Another, because he ignorantly thinks, or fears, that they work on the blossoms and injure fruiting. Again, others may think that because a bee sometimes gets into the rain-water barrel or pump, to their discomfiture, that all must go. It is not so at all.

Our relations with our neighbors are more or less a continual com-promise, and a nuisance is something greatly disproportionate to its use-tulness. Bees may become a nui-sance, but I do not believe that Mr. D's bees have become such.

If we do not claim and defend ALL of our rights now, we shall sorely neglect a duty that we owe to the generation of bee-keepers that will follow us.

Dowagiac, 9 Mich.

#### Local Convention Directory.

1886. Time and place of Meeting.
July 6.—IIIII County, at Peoria, Tex. II. A. Goodrich, Sec., Massey, Tex.
Aug. 31.—Stark County, at Canton, O. Mark Thomson, Sec., Canton, O.
Oct. 12—14.—North American, at Indianapolis, Ind, F. L. Dougherty, Sec., Indianapolis, Ind, Oct. 19, 20.—Illinois Central, at Mt. Sterling, Ills. J. M. Hambaugh, Sec., Spring, Ills.

Dec. 1, 2.-Michigan State, at Ypsilanti, Mich. H. D. Cutting, Sec., Clinton, Mich.

**IF** In order to have this table complete, Secretarles are requested to forward full particulars of time and place of future meetings.—ED.

**Display of Honey-Plants.**—Mrs. C. Robbins, of Indianapolis.⊙ Ind., Corresponding Secretary of the National Bee-Keepers' Society, writes :

The committee of arrangements for the National Bee-Keepers' Convention to be held at Indianapolis, Ind., on Oct. 12-14, 1886, think that a display of honey-producing plants and flowers from as many different States as possible would add considerable to the interest and educational feature of the Convention. Therefore, the committee invite such a display, and will arrange them in any a manner that is desired after reaching here.

Constructing a Honey-Room.-D. M. 1mlay, (94-81), Seward, o+ Nebr., on May 15, 1886, writes :

Bees wintered well in this locality, and have made their living since April 8. I notice a few white clover blossoms, which, by the way, is rapidly gaining a foothold on the "Great American Desert." Our honey crop is still all from heart's-ease and buckwheat. My loss, as indicated above, is mostly from robbers, and on account of weak colonies to start with. Will not some of the "doctors" in bee-culture give us some information as to the construction of a room in which to store surplus honey, so as to have it as dry as possible, and yet have it clean and free from dust?

Fremont Progressive Convention. —Samuel Odell. Secretary of this new bee-association, gives this report:

The "Fremont Progressive Bee-Keepers' Association" was organized with 12 charter members at Fremont. Mich., on May 8, 1886, and the following officers were elected for the ensuing year: President, Geo. E. Hilton; Vice-Presidents, A. E. Upton and A. M. Alton; and Secretary and Treasurer, Samuel Odell. The membership-fee was placed at 25 cents for gentlemen; ladies to be admitted gratis. Then followed discussions on various topics of importance to bee-

keepers, after which an interesting essay was read, entitled, "Does beekeeping pay?" by Geo. E. Hilton. An invitation was extended to all who may desire to become members of the association, to give their names and 25 cents to the Secretary. The convention then adjourned.

**Prevention of Increase.**—7—A. P. Cowan (73—71) Grattan,+oMich., says:

As I have not seen an answer to Query, No. 238, I will state that I have tried the plans usually recommended, and found them to fail in this locality. My plan is this: As the bees swarm, kill or make use of the old queen, and let the swarm return. After 7 days destroy all queencells except one, and it is done. At least I treated 40 colonies so last season, and not one swarmed again. I clip my queens'wings, for convenience.

Grand Season Expected. – P. P. Nelson, Manteno, 0+ 1118., on May 14, 1886, writes :

For the past two years bees in this locality have been working on the reversible order. My bees went back from 40 colonies to 12, but now I have 27 good, strong colonies. We have had the most favorable spring for bees that I have ever experienced. The honey-flow began on April 22, and in 4 days the combs were glistening with honey, and new comb was started. Everything indicates a grand season for bees and honey.

Colony Taken from a Bee-Tree.--R. M. Burwell, D. D. S., of West Winsted, ~ Conn., on May 14, writes:

Last fall 1 found a bee-tree that had been cut. The bees were clustered on a limb and were building comb there. They had dwindled to about 4 quarts. I brought them home in a tin pail and put them on full sheets of foundation; fed them granulated sugar syrup, and left them on the summer stand. (This was in September.) They wintered, and are strong, and as good as any of my colonies. I enjoy looking over my bees, the houey I get from them, and more yet, the reading of the BEE JOURNAL.

Driving Bees, etc. – Lorenzo J. de Sobotker, Riverton, Miss., on May 11, 1886, writes :

The weather here has been very propitions, pleasant and warm for bee-keepers. For the last week the bees have been doing well, increasing in brood, colonies growing into strong ones, bees working upon honey locust, hawthorne, white clover, and some minor bloom, and storing in the surplus arrangements. I have found, this season, that from the middle of April untit now, driving bees a la Heddon, from "gums" into movableframe hives, is the best plan of transferring, and keeps down swarming thereby. I accomplished the same results in the movable-frame hives by the use of the honey-extractor. Colony that Does Not Swarm,—L. R. Williams, Paris, & Texas, on May 17, 1886, says:

Bees are gathering some honey now, but are not swarming much. Colonies are strong, and they work well. I have one colony of Italian bees that are the best honey-gatherers I have. It has a fine, large three-yearold queen, and they have never swarmed. It is a strong colony, and has a great many fine drones. Doesany one know why they do not swarm? (My brood-chamber is 12½x 16½ inches, and 11½ inches deep; and the honey-chamber is 12½x16½ inches, and 5½ inches deep, each containing 11 frames.)

Holly.-A. A. Dodge, Palma Sola, 9 Fla., on May 7, 1886, writes:

I send a specimen of a honey-plant and also a piece of honey-comb made from its honey. Will you please name the plant? It is nameless in this part of the country. The bees are gathering honey from it, and also from the scrub-palmetto. Bees are 40 days behind the usual season, on account of the cold winter and spring months; but they are now prospering finely.

[The plant is *Ilex glabra*, one of the many species of "Holly."—T. J. BURRILL.]

Fine Weather for Bees.—J. H. Andre, Lockwood, Q N. Y., on May 13, 1886, says:

Bees seem to be doing just fairly well. I think that if some who are talking about their bees booming and rushing, would examine the hives well they would find nothing better than last season, that came through the winter well. We have had very tine weather, however, for about 35 days, and the bees have not been shut in a single day—only a part of a few days on account of showers. I fear a drouth now, which will be very bad at this time of the year, as the season is the earliest it has been since 1865, and clover will blossom in a week or ten days. A dry time now would shorten the crop very much, but our old stand-by, raspberry, will help us along as usual. Fruit trees have about half of a full crop of blossoms, and a week or ten days earlier than usual. We have not had enough frost to kill anything since about April 5.

Cloudy, Chilly May.—Jas. McNeill, Hudson, N. Y., on May 17, 1886, says:

I had my first swarm of bees on May 14, on which date fruit bloom closed—two weeks earlier than usual. Bees have wintered well. In my home apiary ont of 155 colonies only 2 were queenless; nearly all the rest are in fine condition. We have had a cloudy, chilly, wet May so far; so that bees did not get much more than a living out of fruit-bloom.

THOMAS G. NEWMAN & SON. PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL. At One Dollar a Year.

#### ALFRED H. NEWMAN. BUSINESS MANAGER.

Special Notices.

To Correspondence. - It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on onr list.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a Hinder for the BEE JOURNAL to any one sending us four subscriptions-with \$4.00direct to this office. It will pay any one to devote a few hours, to get subscribers.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides their own, with \$3, for one year, we will present a copy of this valuable book.

Our New Catalogue of Bee-Keepers' Supplies for the spring of 1886, is issued, and will be sent to any one desiring a copy. Send name and address, plainly written, on a Postal Card for it.

" Don't Stop "-that is what many write to us about their papers, when their time is nearly out. One subscriber says : "This has been a year of disaster, and it is not convenient for me to send you the money now to renew my subscription. It runs out with this month; but don't stop sending it. I will get the money to you within three months." Such letters are coming every day, and so for the present we have concluded not to stop any papers until requested to do so.

The Convention History of America and the AMERICAN BEE JOURNAL for one year, will be elubbed for \$1.15.

#### Honey and Beeswax Market.

Office of the AMERICAN BEE JOURNAL, Monday, 10 a. m., May 24, 1886.

The following are the latest quotations for honey and beeswax received up to this hour :

#### CHICAGO.

HONEY.—Comb is coming forward more freely and prices now are 156016c, for 1-1b. sections. Ex-tracted is in light demand at 567c. California comb honey, in 2b. sections, 9612c. BEESWAX.—23624c, per ib. Not much offered. R. A. BURNETT, 161 Sonth Water St.

#### NEW YORK.

NEW YORK. HONEY.-We now quote : Fancy white comb in i-b. sections, 1223c; in 2-b. sections, 96210c, Funcy buckwheat honey in i-b. sections, 902, in 2-b. sections, 762c. Off grades 1622c, per lb. less. Extracted, white,667c; buckwheat, 5654c. Call-fornia, 566c; Southern, as to color and flavor, per galon, 564c. EED COAR-51020c;

ESWAX.-27@28c. McCaul & Hilbretu Bros., 34 Hudson St.

#### BOSTON.

HONEY.-One-lb. sections, white clover, 13@15c; -pound sections, 11@13c. Extracted, 6@8c. BEESWAX.-25 cts, per lb. BLARE & HIPLEY, 57 Chatham Street. 2

#### SAN FRANCISCO.

HONEY.-White and ex. white comb, 114@136.; dark comb, 6140.8c. White extracted, 514@5146.; amber, 4644.c.; dark and candled, 33404c. BEESWAX.-Quotable at 20023c. wholesale. O. B. SMITH & Co., 423 Front Street.

#### DETROIT.

HONEY.-The market is almost bare of comb boney, and very little is wanted. Best white in i-b, sections 14 ets. BEESWAX.-Scarce at 25c. M. 11. HUNT., Bell Branch, Mich.

#### ST. LOUIS.

HONEY.—Choice comb, 10@12c. Strained, in barrels, 465c. Extra fancy of bright color and in No, 1 pickages, M advance on above prices. Ex-tracted in barrels, 5655. BEESWAX.—Firm at 22c for prime. D. G. TUTT & CO., Commercial St.

#### CINCINNATI.

HONEY.—Trade is perhaps duller than usual. Wcquote: Extracted baney brings 46.8c., and choice comb honey brings 126.5c. in a jobbing way. BEESWAX.—In demand at 206 25c. for yellow. C. F. MCTH & SON. Freeman & Central Are.

#### CLEVELAND.

HONEY.-There is an excellent demand for best 1-h. sections of white honey, and all arrivals sell readily at 14c.; 2-hs. and glassed sections sell slowly at 12c. Extracted, 7@×c. BEESWAX.-Scare at 25@2vc.

- Scarce at 25@28c. A. C. KENDEL, 115 Ontarlo Street.

#### RANSAS CITY.

HONEY.-Sales of comb are good, while extrac-ted is very duil and low. One-pound sections are scarce; stocks of all othergrades are well supplied. (Calif. 2-bs. bring 116/12c; Eastern 2-bs., 126/13c; 1-bs., white, 146/15c; dark, 126/13c. Extracted 56/6c; Southern, 32/64c. BEESWAX.-23c.

CLEMONS, CLOON & CO., cor. 4th & Walaut.

#### MILWAUKEE.

HONEY.—The market scenes quite dull for all qualities of comb honey, with but a moderate de-mand for extracted. We quote : Choice, white 1-lb, sections, 17 alve.; the same in 2-lbs., 16@17c.; dark 2-lbs., 15@16c. Extracted, white, in barrels or kees, 7@8c.; dark, in same packages, 5@7%c. R kegs, 7638C.; Gark, n. 5 BEESWAX.-24625c A. V. BISHOP, 142 W. Water St.

Frank Leslie's Sunday Magazine for June, 1886, is especially noticeable for its numerous full-page illustrations, some of which are exceptionally fine. The Luray Cave, in Page Co., Va., is the subject of several fine cuts. A beautiful picture is a reproduction of a painting by Augustin Lhardy, entitled "Preparations for a Day in tin Lhardy, entitled "Preparations for a Day in the Country"; and a number of contrasted scenes on the two rivers, the Ehlne and the Hudson, give some idea of the beauty of these two famons streams. An antiquarian interest attaches to the article on the first edition of the "Filgrim's Pro-gress," with reproductions of its quaint engrav-ings and a fac simile of the text. A beautiful re-production of one of Giacomelli's bird-pictures shows the belmet-crested humming-bird and its nest. Many other beautiful pictures fill the num-ber, while the literary partion is up to the high level of this favorite family magazine. Published by Mrs. Frank Leslie, 53-57 Park Place, New York.

Frank Leslie's Popular Monthly for June, 1888, opens with a very vivid sketch of the statesman who at this moment rivets public attention-Wm. E. Gladstone-grappling boldly with a problem which for a century has taxed the intellectual powers of the leading men in power in England-a government for Ireland which shall insure the well-being of the people and retain the Island as contented part of the British Empire. All the articles savor of the pleasant summer days ; and the stories-by Mrs. M. A. Dennison, Jane Fay Alston, Chas. H. Shinn, Annie J. Duffell, and others-make this number a charming one to read at home, or travelling, or stretched in hreezy shade.

200 COLONIES of Choice Italian Bees for Sale. For terms, address, W, J. DAVIS. (box 148), YOUNGSVILLE, PA. 13A9t

Mr. George Grimm, of Jefferson, Wis., was married to Miss Marletta Bullock, on May 20. They took a wedding trip to St. Panl, Minn., and will be "at home" on the 10th of June. The BEE JOURNAL extends its best compliments.

Jordan's "White Sulphur Springs," near Stephenson Depot, Fred Co., Va., opened on June I, and will continue until Oct. 1, 1886. The 20-page circular is on our desk. Mr. E. C. Jordan, one of Virginia's most prominent bee-keepers, is the proprietor. Honey is one of the delicacies provided without stint to his guests.

In England the spring is said to be fully a month later than usual ; while in the central part of the United States it is quite a month earlier than usual. A correspondent in England remarks that up to May 1, there had "not been more than six days free from frost this year, and no three days only have the bees carried natural pollen briskly." This is a strange report for that "garden spot of the earth." Usually the month of May is delightful there, and the fragrance from the universal bloom fills the air with the loveliest of perfume.

The Oleomargarine Lobby at Washington has issued a pamphlet for eirculation to Congress, entitled "Honest Words to Honest Men." The idea of the makers of that fraud-imitation butter-claiming to be honest, is too absurd for anything I Is it honest to call their product butter, sell it for butter, and get the price of butter for a fraudulent imitation? Congress has now spent a week over the consideration of a law to tax it out of existence, but so far but little has been accomplished towards that desired end. Can we ever hope for that body to pass a law against the adulteration of honey and other food products? Our faith in its accomplishment is very weakwe cannot expect it.

N. E. Cottrell, Burdick, Ind.-Circular of Bees and Queens is received.

Another Suit Against Bee-Keeping. -Mr. Marshall J. Darling, of Waterbury, Conn., has been sued by his neighbor, Geo. Stanley, in the District Court for \$500 damages. The trial comes off on June 7, 1886, and good lawyers have been engaged to try the case. Mr. Darling gives the following facts eoneerning it :

I am a mechanic, and work in the shop. have for 4 or 5 years kept a few bees both for pleasure and profit. Last year they increased from 8 to 19 colonics. The plainfor pleasure and profit. Last year they increased from S to 19 colonies. The plain-tiff, George Stanley, owns an adjoining lot; fifve families live there, in two houses. In March Mr. Stanley told me that his tenant would move if I continued to keep bees, for they came in at the windows and stung the family; and also spotted clothing around the house. I told him that if he would put screens on his windows I would pay for them, but he refused to do that. He says I must get rid of them. I told him that I never have had any trouble with my neighbors, and did not want any, and I would sell all that I could of them. I sold 8 colonles, ieaving 11. Now they have commenced to swarm, and I have had two swarms this week. A few days before Mr. Stanley brought this suit. I had arranged to move my bees into the country, where I could keep more of them, but my lawyer tells me not to move them now. not to move them now.

It seems that this is to be a test ease, to ascertain whether it is lawful to keep bees in the suburbs of a city or not, and will affect many who now are engaged in the pursnit in that State.

It appears that Judge Cole has issued an injunction, restraining Mr. Darling from keeping becs on his premises on Cossette Street.

The New Haven News of May 22 contains the following concerning the suit :

is thought that the vexed question, which has long troubled legal minds in this locality, will be settled in this case, namely, whether bees are "feræ naturæ."

whether bees are "feræ nature." This question was encountered in a pleas-ant controversy put of court some years ago between Judge John W. Webster and Farmer Plumb, of Prospeet. Judge Webster was excessively pleased at discovering bees in their wild state, an autumn pastime in which he is an acknowledged expert. The mode of spying out the home and honey of the wild bee requires unusual sagaeity and patience. A number of bees must be captured in their flowery heaving about the the wild bee requires unusual statistical statistical patience. A number of bees must be captured in their flowery haunts about the fields, confined in a small box, taken to high ground, and one by one allowed to escape from different points. They always fly in a bee line for their primitive hive, usually hid in a hollow tree. It may be a mile or more from the place where they are captured, but the point whither the different lines conin a hollow tree. It may be a mile or more from the place where they are captured, but the point whither the different lines con-verge is a sure indication of their home. On one occasion the judge had found a hive in a very large oak tree, one of the finest in a large firest owned by Farmer Plumb, of Prospeet. A neighboring ebopper was secured and set to work. While he was thus engazed, Farmer Plumb, came down to the bee-tree with an old Queen Ann musket on his aboulder, and opened conversation with the judge by exclaiming: "What are you doing here?" "Exercising the inalienable rights of an American citizen." replied the judge. "Haven't I any rights here?" asked the farmer. "I bought this wood land forty years ago, and paid bard-earned money for it. There is no mortgage on it, and I-sup-posed I had some rights in it." "True," replied the judge, "you have some few rights, but I want you to under-stand that ny rights to this particular tree are paramount to your rights. The ancient custom of acquiring possession of a bee-tree and its products ought to be well known to vou."

to you."

to vou." The question was argued at length pro and con, and during the controversy the farmer threatened and made demonstrations of violence with his musket. The judge, undannted, walked towards him and assured bim that during a long acquaintance with the law he had become familiar with its principles in regard to bees.

"Those bees," said the judge, "are 'fcræ naturæ,' and no law is better settled than that where a man finds bees 'feræ naturæ,' he is entitled to the bees and the means of securing the hongy."

he is entitled to the bees and the means of securing the honey." The judge then ordered the tree cut down. This version of "feræ naturæ" was too much for the old farmer to grasp. His musket fell from his hand, and he staggered back, bewildered, against the fence. The judge secured a large quantity of honey without further interference, and although the issue was never tried, it seems that to this day the common law of the land declares some bees to be "feræ nature."

Dividing for Increase.-A correspondent who is a beginner, desires to learn how he may with safety avoid watching for natural swarms, in order to hive them. He should either use a swarm-eatcher or divide for increase, instead of letting the bees swarm. Mr. F. L. Dougherty, in the Indiana Farmer, gives the following instructions :

The proper time to make a division is just The proper time to make a division is just about the time the bees have begun prep-arations to cast a natural swarm. This can only be determined of course by examina-tion of the frames. If, on opening the hive, you find queen-cells are being built, you know, of course, what to expect; although cells may be started and afterwards abandcells may be started and afterwards aband-oned, but if on examination you find egga or young larva in the queen-cell, it is hardly necessary to wait longer, but make the division at once. In natural swarming, the old bees, with the old queen, constitute the cluster, consequently the division should be made to follow this rule as near as practi-cable. To do this open the hive near the middle of the day, take out one frame of bees, brood, honey, and the old queen, place this in the new hive, remove the old hive to a new location, setting the new hive where the old one formerly stood. Bees know little of the hive, but are governed by the location. The bees that are in the fields and all the old bees in the hive removed, as they go out will return to the old location they goout will return to the old location and enter the new hive ; thus tbrowing the working bees into the new hive where the work is to be identical with that of natural swarming.

Rich, Biooming and Variegated as the roses of June, comes the American Agriculturist for this month, with its one hundred original illustrations and original articles, by forty-four well-known writers in various parts of the Union, from the Atlantic to the Pacific. The second paper, in the series of the Homes of our Farmer Presidents, will be written by Donald G. Mitchell (Ike Marvel); subject, George Washington. The accompanying engraving will probably be as large as that of Jefferson's Home, which was the first of the series, to-wit: 27 inches long and 17 inches wide. The engravings of Our Farmer Presidents are to be presented to all subscribers of the American Agriculturist as they appear. Price of the American Agriculturist, English or German, \$1.50 per year. We will club it with the AMERICAN BEE JOURNAL for \$2.25 a year, each subscriber to receive both papers and the special engravings and descriptions by American authors as they appear.

Honey in Coffee, says a correspondent in the Bee-Keepers' Record, is better than sugar: this is a most excellent way to use it when candied, especially by those who have a prejudice against eating it. He then adds, "Try it also in tea."

F. J. Crowley, of Batavia, N. Y., has sent us his reduced price-list for this spring.

#### AND Replies by Prominent Apiarists.

fIt is useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.-ED.]

### Taking Care of Empty Combs.

Query, No. 258 .- 1. What is the best manner of taking care of empty combs to prevent bee-moth from destroying them, until such times as they can be used? 2. Will the bee-moth molest the combs if hung in a rack 3 or 4 inches apart, in a dry and airy room ?-Subscriber.

1. I have the best success by hanging them up in a dry, light room. 2. You will have to look after such combs as contain bee-bread, no mat-ter where you put them.-G.W. DEM-AREE.

The plan suggested is good. If worms are already started, the combs must be heavily fumigated with sul-phur.—C. C. MILLER.

The plan suggested is the best I know, but the moths will trouble them some even then. If they trouble too much, fumigate them.---W. Z. HUTCHINSON.

1. Putting them where the bees can have access to them, or by burning sulphur in the room in which they are stored. 2. To a certain extent, yet it helps wonderfully.—G. M. DOOLIT-TLE.

I have but little trouble if the combs are in a dry, airy room, but they should be carefully examined from time to time, and if you find any trace of moths on the combs, fumigate them with sulphur.—H. D. CUTTING.

Combs containing pollen are unsafe hung up in a dry, airy room if moths can get at them. As suggested in this department last year, there is no better plan than to stack them up in empty hives over a strong colony of bees.—G. L. TINKER.

2. No, not if not too warm, and left there too long. Your second question gives my idea of the best solution of your first .- JAMES HEDDON.

I always keep my combs in a perfactly close box, in which they are hung. They are then never troubled with moths.—A. J. Cook.

the moth can be kept out of the honey-house all summer as well. We keep thousands of extractor combs every season, and never have any trouble.-DADANT & SON.

1. If any moth worms are seen, give the combs a vapor bath with fumes of burning sulphur. 2. The worms are not apt to be found in combs placed as mentioned; but frequent examinations should be made, and the sulphur fumes applied when worms are found. -J. E. POND, JR.

### Lubricating Foundation Dies.

Query, No. 259 .- Does the use of lye in lubricating dies of foundation presses injure the foundation or make it disagreeable to the bees? A neighboring bee-keeper claims that it makes the foundation brittle, and that he has hard work to make bees stay in the hive when it is used.-J. M.

I should say not, when some of our shrewdest and best bee-keepers have used it for years.-A. J. Cook.

I have used foundation that was made by the use of lye, and that which was made by using starch; 1 have noticed no difference in the respect mentioned.—W. Z. HUTCHIN-SON.

The honey-bees have no use for an alkali in their fabrications, and it would not be strange if it were dis-agreeable to them.—G. L. TINKER.

I have used foundation made by manufacturers who use lye as a lubricator, and I never had any trouble on that account. A great deal of foun-dation is worthless on account of its being made of wax rendered from moldy, rotten combs.—G. W. DEM-AREE.

So far as my experience has gone, I have found no trouble from it.—C. C. MILLER.

I am certain that lye injures the quality of the wax. Try a small quantity by melting it with a slight trace of lye, and then compare it with a sample of the same wax not thus treated.—H. R. BOARDMAN.

Any material which you use on a press will remain on the foundation, more or less; and will be more or less injurious; hence, the inferiority of the presses. We should certainly not use lye in any case. - DADANT & SON.

I have used foundation made with lye, starch and soap, and I could not see any difference. I have had no trouble in having the different kinds accepted by the bees.—H. D. CUT-TING.

If you will put a piece of No. foundation or wax into lye ten times Put them in a cold room carefully as strong as the die-book needs, you boxed up. If they are kept there during our cold northern winters, the moth will not hatch out of them, and by using screen doors and windows ment.—JAMES HEDDON.

### Superseding Queens.

Query, No. 260 .- 1. Would you supersede a queen on account of old age, as long as the colony is prosperous? 2. What is the best general rule in regard to superseding queens ?-H. D. S.

1. It would depend upon circumstances. 2. The third year.-H. D. CUTTING.

1. No. 2. Let the bees do the super-seding.—G. M. DOOLITTLE.

1. No. As long they do good work leave it to the bees.—A. J. COOK.

1. No. Let the bees do it.-W.Z. HUTCHINSON.

1. No. 2. Supersede queens only when they show signs of decline.—H. R. BOARDMAN.

1. Not unless I desired to change the stock. 2. A very good rule that rarely fails in getting good queens is to let the bees do their own superseding .- G. L. TINKER.

1. No. 2. Supersede them when they begin to fail, or else let the bees do it. They usually do it before you can notice that the queen is failing.— DADANT & SON.

1. I do not recommend the practice of superseding queens on account of age. The bees know better when to supersede than I do. 2. The best rule is to leave it to the bees. They may make some mistakes, but the apiarist will make more mistakes than the bees will.-G. W. DEMAREE.

So long as a colony is prosperous, I doubt if I would take great pains to supersede her, leaving that for the bees to do. But if by swarming or otherwise, a queen should come into my hands at a time when I could my hands at a time when I could easily replace her with a younger one, I would most likely replace her if she were two years old, or older.— C. C. MILLER.

1. No. 2. As soon as the queen fails of normal prolificness, put a young one in her place if the bees do not do it before you, which they usually do in my apiary.—JAMES HEDDON.

1. No sir, as I replied awhile ago, I now have a queen five years old this spring, and I shall not supersede her, if she keeps the cells filled with eggs. 2. Supersede when the queen shows failing powers, or when you desire for any reason to make an exchange.-J. E. POND, JR.

#### System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. the prices are reduced, as follows :

The larger oncs can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

**Explanatory.**—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark  $\bigcirc$  indicates that the apiarist is located near the center of the State named;  $\eth$  north of the center;  $\blacklozenge$  south;  $\circlearrowright$  east;  $\diamond$  west; and this  $\checkmark$  northeast;  $\backsim$  northwest:  $\circlearrowright$  southeast; and  $\blacklozenge$  southwest of the center of the State mentioned.

For the American Bee Journal. Robber Bees—Pollell ill Sections, G. M. DOOLITTLE.

Robbing in early spring is one of the most vexatious things that a beekeeper has to contend with. There is no other season of the year that the bees are so persistent in stealing as at this time, and for this reason the plans that work well in stopping robbing at other times, are of little value now, especially as the colonies usually attacked are those weak in bees, so that as strong resistance cannot be made as at other times. Having had quite a trial with robber bees this spring, and coming off victorious. I thought perhaps the readers of the BEE JOURNAL would like to know how I conquered.

At first, as soon as I found a colony being robbed. I used the old plan that I had always used, which was, carrying the robbed colony into the beecellar in the evening and leaving it in there for a few days until the robbers had forgotten the place of attack, when they were put out again. Of course, before putting them in I put in food for them if I had reason to believe that they were robbed short of stores.

This plan usually works well if the colony is not too weak, and I much prefer it to most of the plans given for stopping robbing. But I happened to have 2 colonies which were quite weak, and every time I put them on their old stand again, they would allow the robbers to enter their hive unchallenged. Presently a thought struck me, and near sunset I threw the entrances of these two hives wide open and watched till I found that there were only four colonies in the yard which were doing the robbing, as all the rest of the bees had stopped flying by this time, while these 4 kept busy at work carrying honey from these two hives until nearly dark. When night stopped operations I fed them to the cellar.

The next day, at about 11 a.m., I took a wire-cloth cage and a large funnel used in forming nuclei, which I have before described in the BEE JOURNAL; I then went to one of the colonies which was doing the robbing the night before, and taking out a frame well covered with bees, I lightly tapped it so as to cause the bees on it to till themselves with honey, when it was hung in a covered box. I then went to the second hive marked the night before, and took a frame of bees from that in the same way, being sure in each case that I did not get the queen. The bees on the first trame were by this time well filled with honey, and were shaken down through the funnel into the box, while those from the second hive were put in with them as soon as full of honey.

The box of bees were now put in a warm room, and an empty hive placed over them to keep all dark. Bees from the two other hives marked were put in another box and treated in the same way. In about an hour a loud roaring was heard in these two boxes, showing that the bees had by this time realized their queenless and lost condition, but they were left undisturbed for three hours more, or until 3 o'clock. At this time I went to the cellar and got the queen from each of the weak colonies, marking which came from each hive, when one was put into each box of bees. They were now left until nearly sunset, when they were found all clustered and quiet like a swarm. In less than one-half hour after the queen was given them, all was quiet, thus showing how glad they were to have the queen.

At sundown the two hives were brought from the cellar and put on their stands, when the frames were spread apart in the center of the little cluster of bees, and the bees from one of the boxes shaken down between the combs to the bottomboard of the hive. In going down they took with them most of the bees on either side of the opening between the frames, so that a general mixing was the result. The combs were now put back in their places again, and the hives closed.

In the morning I took solid comfort in seeing these bees seize their own comrades of less than 24 hours ago, when they came to the usual stealing-place for honey. These robbers would no sooner touch the alighting-board than their own sisters of yesterday would catch them and treat them as all robber bees are treated. The result proved that all robbing was at once effectually stopped; the two weak colonies are now fairly strong, while the robbing colonies were not materially injured.

#### POLLEN IN SIDE-SECTIONS.

A correspondent wishes to know how I keep the bess from storing pollen in the side sections, where I place brood behind, so as to coax the bees to work in them at once, as I have given in the BEE JOURNAL.

In reply I would say that I do not think that I have had 50 sections in all my experience with pollen in them. As I use separators, the sections coming between the separators and the thin division-boards used in my hive, has a tendency to keep the pollen out. Again, the frame of brood is only left behind the sections intil a good start is made therein, when it is taken out, the partly full sections moved back where the brood was, and a wide frame of empty sections put between it and the hive. If the trame of brood were left longer there might be pollen stored in the sections; yet I think there would not be much where both separators and divisionboards are used.

### Taxation of Colonies of Bees.

#### W. J. ROBERTS.

On page 309, Mr. T. B. Blair asks whether bees are subject to taxation. He pretends to offer no reasons why a man should not be taxed for his bees, except the one that when his tax is due he may not have (because of the rigor of winter, or some other cause), the bees which have previously been assessed. The same line of argument might, with some force, be urged against taxing a man for anything in the nature of property personal. All that lives is liable to perish, and all inanimate things are liable to be destroyed or carried away.

As to what is subject to taxation, Desty, in his work on that subject, on page 51, says: "When there has been no compact with the Federal Government, or cession of jurisdiction for purposes specified in the constitution, the right of taxation by the State reaches all the *property* and business within the State," citing among other cases the following by the Supreme Court of the United States: Nathan vs. Louisana, 8 How., S2; Prudence Bauk vs. Billings, 4 Pet., 514; McCullouch vs. Maryland, 4 Whart, 316.

If bees can be considered property, there can be no question as to their being liable to taxation. Whether or not they are property in the eyes of the law, depends upon the condition in which they may be found. Animals are divided into two principal classes, one of which is wild, and the other tame. The latter class are subjects of absolute property : the former are not, while at liberty and unreclaimed. Bees belong to the wild class. If they exist in a hollow tree on a man's land, they cannot be claimed as his property. To be sure, if a stranger should go on the land and disturb the bees, he would be guilty of a trespass ; but interference with the bees would Constitute no element of damage. But should the owner of the land take the bees from the tree and hive them, they would then become his property.—Gillet vs. Mason, 7 Johns., 16; and they would continue to be, so long as they should remain in his possession and under his control; and they are considered under his control is able to regain his possession of them.-Goff vs. Hills, 15 Weud., 550.

As there is no constitutional provision either Federal or State, prohibiting the taxation of bees, they are subjects of taxation when hived, if the legislature shall choose to exercise its power. Here in Iowa the local authorities have no right to assess a man's bees for taxation, as they are exempt from taxation by legislative enactment. The legislature has undertaken to enumerate such animals as may be assessed, and bees are not included in the list.

Keokuk, Alowa.

For the American Bee Journal. Management for the Most Honey, W. M. WOODWARD.

This is the one subject of the most practical interest at this season to every bee-keeper. How can I obtain the most honey? Limiting the subject to comb honey as the one presenting the serious difficulty, and the time to the honey harvest, I would proceed as follows:

I would use a hive adapted to tiering-up, and so arranged as to have the comb-building done in one single space. Nothing is made by dividing the work of the young bees into two, three, or more places. I have held that side-storing with top-storing must pay best; but after testing it well I find that my old colonies adapted only to top-storing bave outdistanced those—their equals—with work divided between the top and the two sides. The use of divided labor brings about substantially the same conditions as so many weak colonies, hence less work is accomplished than in a single body. My present view is that a case 12-inches wide, or 12½ inches, is wide enough, and should contain four rows of 4½x4½ inch sections. I would make the broodchamber the same size as the surplus case inside and outside, and use 9 frames.

The next point which I much desire to make, is to get as many frames *full* of brood as possible, up to the white clover harvest; and then contract to just that space and hold them there, or try hard for it, at least. I have found but little difficulty in keeping plenty of brood in the hive if I could only get the honey out of the way; and I think it is desirable to produce much more brood than some recommend during the honey season. I wish to breed only from my best bees, and to get all the good queens I can from them early, and want all the brood I can get to build them up for the late honey-flow.

My next procedure is as follows: Supposing that we have arrived at the opening, or the beginning of the bloom of the surplus crop; with hives full of bees and frames tull of brood, and that with special attention to getting it well up to the top-bars of the frames. I make it a point to have on hand sections with nice, drawn comb to fill one case all round; but if not, I put what I have on the strongest colonies, and raise them as fast as they are tilled, or have bees to use them, taking cases in which the bees are at work (if honey is coming

in fast), bees and all, and placing them upon the next best colonies until all are at work in the surplus department with a will. I then shade well and raise the cases, placing empty ones (always filled with full sheets of foundation) under them, and thus keep them on the jump until the end of the crop.

of the crop. The point of danger is this: Bees work upon only one idea, and the successful bee-keeper is the man who is able to dictate what that idea shall be, *i. e.*, whether they shall gather honey or rear queens and prepare to swarm. The "nick of time" is the opening of the first surplus-yielding flowers. The power to control lies in opening an abuudance of room ready to receive their first honey, so as to get the very first, and all, as nearly as possible, in the sections. I do not have the majority of my colonies swarm when able to carry out this plan, and yet I get my full complement of increase by moving every old colony that swarms, and dividing them up so as to save all the best queen-cells, and then build them up as described above. It is my aim to run every colony through without swarming, except those I encourage to swarm early, and sometimes remove the queen and brood and compel them to rear queens from the egg.

When swarms occur, I count it no loss, but proceed to hive them on 3 wired frames with full sheets of foundation; and I now use side-cases made to hold sections crosswise of the frames and cases, and filling the vacant space of the hive. This is the only way I have found side-storing to pay, and with swarms it does pay, and pays well; as I have no difficulty to get my honey finished off nicely at the side, even better than at the top, and that without the use of separators.
