

BEE JOURNAL

Vol. XXIII.

Chicago, Ill., January 5, 1887.

No. 1.

BEE JOURNAL
 Issued every Wednesday at
 923 & 925 WEST MADISON-ST, CHICAGO, ILL.
 At One Dollar a Year.

THOMAS G. NEWMAN AND SON,
 PUBLISHERS.

George Neighbour & Sons, London, England,
 are our authorized agents for Europe.

Entered at the P.O. as Second-Class matter.

TO CORRESPONDENTS.

The subscription price of the AMERICAN BEE JOURNAL is One Dollar a year.—New Subscriptions can begin at any time. Single Copies, five cents each.

Our Club Rates are as follows: \$1.90 for two copies (to the same or different post-offices); \$2.75 for three copies; \$3.50 for four copies; and for five or more copies, 80 cents each.

Foreign Postage.—To all countries in the Universal Postal Union: 50 cents extra. To all countries NOT in the Universal Postal Union, \$1.00 more than the price of subscription.

Sending Money.—Remit by Express, Post Office Order, Postal Note, or Bank Draft on New York or Chicago. If neither of these can be obtained, Register your Letter, affixing stamps both for postage and registry, and take a receipt for it; Money, sent thus, is AT OUR RISK, otherwise, it is not. Do not send checks on local banks, which cost us 25 cents each, at the banks here, to get them cashed.

Postage Stamps of any denomination may be sent for fractions of a dollar; or where Money Orders cannot be obtained, stamps for any amount may be sent.

Subscription Credits.—The receipt for money sent us will be given on the address-label of every paper. If not given in two weeks after sending the money, write to us, for something must be wrong. Do not wait for months or years, and then claim a mistake. The subscription is paid to the END OF THE MONTH indicated on the wrapper-label. This is a continual statement of account.

Advertisements for the next Weekly BEE JOURNAL must reach this office by the Saturday of the previous week.

ADVERTISING RATES,

20 cents per line of space, each insertion.
A line of this type will admit about 7 words.
 ONE INCH will contain TWELVE lines.
Transient Advertisements must be paid for in advance.
Discounts are as follows: on 10 lines and upward, 3 insertions, 5 ¢ cent.; 6 insertions, 10 ¢ cent.; 9 insertions, 15 ¢ cent.; 12 insertions, 20 ¢ cent.; 26 insertions, 30 ¢ cent.; 52 insertions, 40 ¢ cent.
 On 20 lines and upward, 3 times, 10 ¢ cent.; 6 insertions, 15 ¢ cent.; 9 insertions, 20 ¢ cent.; 12 insertions, 25 ¢ cent.; 26 times, 40 ¢ cent.; 52 insertions, 50 per cent.
 On 30 lines and upward, 3 times, 15 ¢ cent.; 6 insertions, 20 ¢ cent.; 9 insertions, 25 ¢ cent.; 12 insertions, 30 ¢ cent.; 26 times, 50 ¢ cent.; 52 insertions, 60 per cent.
 On larger Advertisements discounts will be stated, upon application.
Editorial Notices, 50 cents per line.
Special Notices, 30 cents per line.

TO CORRESPONDENTS.

The Bee Journal is sent to subscribers until an explicit order is received by the publishers for its discontinuance, and the payment of all arrearages is made.

To Canadians.—We take Canadian money for subscription or books; and Canadian postage stamps may be sent for fractions of a dollar.

When writing to this office on Business, correspondents must not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either part of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They both may be sent in one envelope, but on separate pieces of paper.

Never send Silver in Letters. It will wear holes in the envelope, or may be stolen.

Emerson Binders, made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 60 cents each. They cannot be sent by mail to Canada.

Make all Money Orders and Postal Notes payable at Chicago, Ills.—Some postmasters in the country insist on making such payable at some substitution of Chicago, but we want them drawn on the main office.

Lost Numbers.—We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails, we will cheerfully replace them if notified before all the edition is exhausted.

Always give the name of the Post-Office to which your paper is addressed. Your name cannot be found on our List, unless this is done.

BOOKS!

Sent by mail, on receipt of price, by

THOS. G. NEWMAN & SON,

923 & 925 WEST MADISON STREET,
CHICAGO, ILLINOIS.

Rates to Supply Dealers.—On ten or more copies of one kind, we allow 25 per cent. discount, and pay postage, or when the dealer pays expressage, 40 per cent discount.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the time," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quietling and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, bound in cloth, \$1.00; 2 copies for \$1.80; 3 copies for \$2.55; 5 for \$4.00; 10 for \$7.50.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the **English or German** edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. Leather, 60 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we print on them the honey-producer's name and address FREE.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. A chapter from "Bees and Honey."—10 cts.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by T. G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

"Success in Bee-Culture," as practiced and advised by James Heddon." This book consists of 128 pages; is well-printed on good paper and illustrated. It covers the whole field of practical apiculture, and is intended for specialists and those who keep bees for the money to be obtained from the business. In his preface the author says: "In the delineation of methods of management, and of implements and devices, appertaining thereto, it has been my constant aim to present such only as will approximate uniform and unvarying success, as nearly as possible, when the requisite conditions have been complied with, and thereby obviate the disappointments and vexatious losses, resulting from the complicated and impracticable in both management and utensils. Price 50 cents.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—The work of a master, and will always remain a standard.—Price \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Bee-Keepers' Handy-Book, by HENRY ALLEY.—This book contains 270 pages, and is a complete Manual of Bee-Keeping. Price, \$1.10.

Bee-Keepers' Text Book, by A. J. KING.—Revised and enlarged. Price, \$1.00.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees.—Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Details his management of bees. Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. Price, 60 cents each. They cannot be sent by mail to Canada.

"A Year among the Bees," being a Talk about some of the Implements, Plans and Practices of a Bee-keeper of 25 years' experience, who has for 8 years made the production of honey his exclusive business.—By Dr. C. C. Miller—Price 75 cents.

Poulterer's Guide, for treating diseases of Poultry, etc., by C. J. WARD. Price 25c.

Food Adulteration.—What we eat and what we should not eat. Price, 50c.

Phenol for the Cure of Foul Brood.—By Prof. Frank R. Cheshire, of London, England. Price 10 cents; 32 pages.

Moore's Universal Assistant, and Complets Mechanic.

Enlarged Edition—contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. The work contains 1,016 pages—is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man or Farmer. By mail, in fine cloth, \$2.50.

How to Propagate and Grow Fruit, by Charles A. Green, contains over 50 illustrations and two large colored fruit plates. This book tells how to PROPAGATE Strawberries, black raspberries, red raspberries, blackberries, currants, gooseberries, grapes, quince, peach, apricot, plum, cherry, pear and apple; also GENERAL RULES for propagation, with illustrations showing how to bud, how to graft, how to propagate from layers, stools, inarching, with full instructions for grafting the grape. It tells how to lay out a garden or fruit farm—how to plant, cultivate trim, etc. Price, 25 cents.

"How to Raise Comb Honey" is the title of a new illustrated pamphlet of 16 pages, by Oliver Foster, of Mount Vernon, Iowa. He says that it describes his "improvements in methods resulting from ten years' practical work and extensive experiments," and includes his "adjustable honey-case and clamp." Price 5 cents.

"Farmer's Account Book," contains 166 pages, printed on writing paper, ruled and bound, and the price is \$3.00. We will club it and the Weekly BEE JOURNAL for a year for \$3.00. If you want it sent by mail, add 20 cents for postage.

The A B C of Carp Culture, is a neat pamphlet of about 100 pages. It explains the simplest, cheapest and most effective system of carp culture, and being written by Mr. Milton P. Pierce, of Philadelphia, Pa., Secretary of the American Carp Culture Association, it cannot fail to be of inestimable value to all interested in the "finny tribes." Price, 40 cents.

The A B C of Potato Culture; "how to grow them in the largest quantity, and of the finest quality, with the least expenditure of time and labor." The book is not only a valuable one to potato-growers, but a great part of it applies to the management of almost any crop on the farm, especially to the preparation of the soil, manures, etc. Price, 40 cents.

A Brief History of the North American Bee-Keepers' Society, with a digest of its 15 Annual Conventions, and a full Report of the Proceedings of the 16th Annual Convention held at Detroit, Mich., on Dec. 8 to 10, 1885. It contains 64 pages. Price, 25c.

Photographs of Rev. L. L. Langstroth, Baron of Berlepsch, or Dzierzon, 25 c. each.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100. Large and elegant ones, with rosette, 50 cents, post-paid.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Constitution and By-Laws, for local Associations, with the name of the Society printed in.—Price \$2 per 100.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 25c., in either English or German.

Blenen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Send, postpaid, on receipt of price by

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

ESTABLISHED IN 1861

AMERICAN

OLDEST BEE PAPER IN AMERICA

BEE JOURNAL

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Jan. 5, 1887. No. 1.

Ring out, O Bells! ring silver sweet,
O'er hill and moor and dell;
In mellow echoes, let your chimes,
Their hopeful story tell!

Ring out! ring out! all-jubilant,
This joyous, glad refrain;
"A bright New Year, a glad New Year!
Hath come to us again!"

The First Monthly for January, 1887, which came to our desk was the *Apiculturist*. It is vastly improved under its present management. We congratulate Mr. Alley upon his punctuality in publishing it.

The best thing we can do to extend the circulation of the paper is to ask our subscribers to consider themselves on especially friendly and cooperative relations with our aims and purposes, and send us the names of the right kind of people, to whom we will send sample copies. When they read the paper even once, a great many of them become regular subscribers.

A Visit from Frank Cheshire may be expected next summer. Mr. Arthur Todd writes us as follows:

I received a note from Frank Cheshire, of London, England, last week, in which he tells me that he is thinking of visiting the United States the coming summer. If he does, I hope the bee-brethren will extend to him a hearty welcome.

The British Bee Journal and the AMERICAN BEE JOURNAL will hereafter be clubbed at \$3 for the two, postpaid, for a year. This change in the clubbing price is necessary on account of an advance in the club rate of the former.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

The Year 1886 has waxed old and passed away! The new year has come, has taken possession of the destinies of mankind, and changed the dial of time one figure ahead. A philosopher has well said that change, incessant change, is the constant law of nature! The flower changes into the fruit, the seed into the stalk, the boy into the man, life into death, the old year into the new year! The seasons change, the skies change, the oceans change, the whole face of nature changes! Filled with the mighty thoughts that these unvarying facts produce, we enter to-day upon the duties and responsibilities which the new year presents, remembering that the old year, with all its joys and sorrows, pains and pleasures, toils and troubles, is no more!

How rapidly the days, months and years pass on, in the sweeping tide of time! The 13 years of toil which we have spent in guiding the destiny of this JOURNAL, seem but a few months, now that they are past! But it is very pleasing to realize that it now enjoys a reputation and influence second to none in the world of apiculture! Its weekly visits to thousands of homes all over the world is welcomed with enthusiasm!

The "fleeting shadows" warn us of our approaching end, and bid us to be ready for it. Meanwhile to us is appointed the strife and peril of warfare—battling for the right, waging war on the errors of the past, and doing our share in erecting the temple to be dedicated to truth, honesty, justice and progress. If we shall do our work faithfully and well, we may expect the welcome words, "Well done!" Our co-workers in "the ages to come," will sit in judgment over our labors, and their verdict, shorn of all the prejudices of the present; time, will be based upon the just merits of the case. Let our work, then, be done faithfully and well, and with reference to the ever-advancing principles of progressive thought and action.

THE AMERICAN BEE JOURNAL is published in the interest of honey-producers, and its chief work and aim is to present the best thoughts and methods of the ever-advancing apiarist of to-day. It aims to record what is being done by practical and experienced men in every department of our pursuit, and to take every advantage of the aid offered by scientific discoveries. To show that it has done this in the past, it is only necessary to point to the copious index at the end of each volume.

It is quite unnecessary to state that we shall in the future, as in the past, endeavor to "keep abreast of the times," and place before our readers all the new things in our ever-advancing pursuit, as soon as they come to light. The record, character, power and usefulness of the AMERICAN BEE JOURNAL in the past is its guarantee for the future. It will further the interests of honey-producers by losing no opportunity to create a demand for this product, both at home and abroad—thus aiming to benefit the pursuit at large.

Our friends are invited to sustain and extend the influence of a journal devoted to their interests and pursuit; one which has demonstrated through a career of nearly a quarter of a century, its ability to sustain and promote their cause! It is, in fact, a common cause, one which all should feel proud to join in advancing.

Driven from Pillar to Post.—The believers in the "Wiley lie," about the manufacture of comb from paraffine, filling it with glucose and sealing it over with a "hot iron," are industriously engaged in finding the place where it is said to be manufactured—but each time are foiled in the attempt! A correspondent lately wrote us the following:

An acquaintance of mine says that they manufacture comb honey in Chicago, at the northeast corner of Adams and Halstead streets. He told me that he saw them capping the cells with a "hot iron," but that he did not see them making the comb. Suppose you do a little detective work and try to find out what is going on at that corner.

Upon investigating that locality the "detective" could find nothing of the so-called "manufactory;" a drug-store, two saloons, and a shoe-store were all that could be discovered! There were no basements under these stores.

One block from that corner there is a laundry with a Chinese near the window ironing collars, cuffs, etc., with a cake of beeswax by his side; and it is quite possible that this innocent laundry-man has been accused of "making comb" and "capping the cells with a hot iron!"

It is positively disgusting to notice the persistency with which it is reported that persons have seen "comb" manufactured and sealed with machinery." Yet; whenever "cornered" for the proof, they are never able to say more than somebody saw it done somewhere, by somebody.

The Standard-Bearer of the apiculture of to-day, says an exchange, is the sound, intelligent man who believes that progress is the law of our race; who holds that no man of enterprise can afford to stand still while the world goes forward—that inactivity means simply stagnation and decay, and that, the surest proof of vitality and vigor, both of muscle and brain, is the steady, forward movement of wise and practical men, who are always intent on working out better methods, and always ready and willing to enrich the general fund of knowledge with the fruits of their experience. Whenever such, in the course of their investigations, succeed in bringing to light new facts or new processes, they give a fresh impulse to industry, and make their countrymen their debtors.

Every Day the business letters that come to this office are fully attended to and finally disposed of—none are left until the next day, except those in which the writer has omitted either name or Postoffice address. We endeavor to be prompt and accurate, and if our subscribers will practice the same virtues, more than half of the little annoyances that happen will be done away with.

Clubs should be forwarded to this office as soon as two or three subscribers have been obtained. Any one having sent three subscriptions with \$2.75, may send two more with \$1.25, making 80 cents each for the five, and at the same rate for all above that number.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Bees Dying in Winter Years Ago.

Query, No. 356.—I have heard that bees did not die in winter 40 or 50 years ago, as they do now if they had plenty of honey. Is this true? If so, what has made the change?—H. W.

There were no bee-papers 40 or 50 years ago to give reports of deaths. Don't you believe a bit of it. They did die.—J. P. H. BROWN.

I am inclined to believe there is a difference, but I will not attempt fully to account for it.—C. C. MILLER.

That is not true. Bees, when insufficiently protected, have always suffered from bee-diarrhea and died in severely cold and protracted winters.—G. L. TINKER.

Do not believe all that folks say about the "good old times," for their remembrance is often incorrect. The winter of 1855-56 was the hardest winter known by Father Langstroth.—DADANT & SON.

It is true to a certain extent. The cutting off of our forests has much to do with it; this making most localities much colder than formerly.—G. M. DOOLITTLE.

I do not know that this is true. The climatic changes are greater than they were 50 years ago, and it is claimed that the foreign races are not as hardy as our native bees.—H. D. CUTTING.

I think it is true. I presume the reason is that the winters were then much milder. Clearing off the forests has changed our climate. We used to raise peaches plentifully in central Michigan; now we cannot except on very elevated areas.—A. J. COOK.

If we give the bees equal protection, and report no more than we did 40 years ago, the difference will not seem so great. Forty or 50 years ago our prairies were mostly unsettled, and the timber had not been cleared from the hills of the East. Replace the forests and the increased rainfall they are supposed to bring, and the success will return. I do not know whether the theory is true or not.—C. W. DAYTON.

I do not know that it is true. If it is true it may be attributable to the clearing up of the country, allowing the winds to sweep over the country with greater force; or it may be caused by movable combs, which allow us to take away the best honey; or it may be that chaff packing and cellars have not allowed the culling

out by nature of the weakest or poorest, on the line of the "survival of the fittest," or it may be—I do not know.—W. Z. HUTCHINSON.

As I did not keep bees 40 or 50 years ago, I cannot answer. Is it a fact though? and who can give us the proofs? It is my impression from my studies, that bees have always died to a greater or less extent in winter, and I know that the winter problem has been a matter of discussion for centuries.—J. E. POND, JR.

I helped my father work with his bees 40 years ago, and bees winter now as well as they did then, *the conditions being the same*. Bees have always been wintered in Kentucky on the summer stands, without protection. Our fathers, 40 years ago, wintered their bees in large brood-chambers, full of honey, and the bees clustered in the centre of the combs, the best material possible for bees to be surrounded with. Now-a-days bees are robbed of their nest (combs), and forced to roost on the sides of the frosty wooden walls, and these walls are packed on the outside with just enough chaff or sawdust to keep out the influence of the sun, and preserve the frost on the inside for an unlimited time.—G. W. DEMAREE.

This is partly true and partly false, at least in this locality. Forty or 50 years ago bees were put into winter quarters with much less bee-bread in the combs; as the country was cleared up pollen-producing fall weeds took the place of spring-pollen producing trees. This truth has given rise to an idea that old, tall box-hives are safer for wintering bees than flat frame hives. About 14 years ago, two farmers living a few miles away had, in autumn, 65 and 85 colonies respectively, in all depths, sizes and shapes of box-hives. In the following spring they had one live colony each.—JAMES HEDDON.

Even the meager record we have of the losses of bees in winter half-a-century ago, shows that there is but little difference between then and now. The climatic changes, produced by the destruction of our native forests in the East, will easily account for all the difference which exists.—THE EDITOR.

Moisture in Hives.

Query, No. 357.—On examining my bees on the summer stands, I frequently find the combs covered with ice and frost. Does the breath of the bees produce all this moisture? Please say "yes" or "no," as your experience may have proven.—W. T., Ills.

No.—JAMES HEDDON.

No.—H. D. CUTTING.

No.—C. W. DAYTON.

Yes.—DADANT & SON.

Perhaps not all, but I should say the most of it.—W. Z. HUTCHINSON.

If the moisture arising from the body of the bees is what you mean by "breath," yes.—G. M. DOOLITTLE.

The breath of the bees does not produce all the moisture—some of it

comes from the evaporation of the honey.—J. P. H. BROWN.

In part. The moisture may condense from the air, and freeze away from the cluster.—A. J. COOK.

Yes, but when I see ice and frost at the hive-entrance of a colony, or upon the combs, I know that the bees are suffering from the cold, and will not come out in good condition in the spring.—G. L. TINKER.

The question cannot be answered fairly by yes or no. The moisture is caused in all probability, partially by breath, and more so, by emanations or perspiration, as we might call it. The whole matter is more or less conjectural. We know that where there is no ventilation, moisture forms and freezes. We know, also, that heat and cold will produce moisture.—J. E. POND, JR.

A current of warm air coming in contact with a cold surface will part with its moisture, and if the surface is cold enough frost or ice will be formed, as we see illustrated in the stair-way that leads into a warm cellar. The heated air thrown off from a warm cluster of bees comes in contact with the cold walls of the hive, where it parts with its moisture, which adheres to the wall, and is formed into frost or ice as to the degree of cold and dampness present. Of course "breath" is warm air, but any warm air will produce the effects.—G. W. DEMAREE.

I can hardly see cause for much frost and ice aside from the vapor exhaled by the bees. Possibly a small amount of moisture might be evaporated from the honey in the cluster under some circumstances, and there might even be condensation of a small amount from the outside air if it should find the combs colder than the outside air.—C. C. MILLER.

The moisture in the hive, whether from the cluster of bees or from the honey evaporation, will condense and form frost or ice on the wood in very cold weather.—THE EDITOR.

Laying in Queen-Cells—Drone Eggs.

Query, No. 358.—Do queens ever lay eggs in queen-cells, after the cells are started? If so, did any one ever see them? Do queens lay the eggs that produce drones?—T. F. P., Ills.

I answer "yes" to all of this query.—A. J. COOK.

I never have seen them do so.—J. E. POND, JR.

They have been seen laying in queen-cells. Queens lay the eggs that produce drones.—W. Z. HUTCHINSON.

I never saw the queens do so. Not in all cases do queens lay the eggs that produce drones.—H. D. CUTTING.

I have seen queens depositing eggs in queen-cells in two instances. To the second part, yes.—C. W. DAYTON.

Yes, to both questions. My assistant once saw a queen lay in a queen-cell, and I have seen drone-eggs, by the score, laid by queens.—G. M. DOOLITTLE.

I think that queens lay eggs in queen-cells after the cells are started, but I do not know that any one ever saw them in the act. To the last part of the query I would say, yes, generally.—C. C. MILLER.

My opinion is that the queens lay the eggs often found in queen-cells about swarming time; but I never saw one laying in them. The queens also lay the eggs that produce drones. I have seen them in the act of laying drone eggs.—G. L. TINKER.

I never saw a queen laying in a queen-cell. Honest men who have produced far less honey than I have, and claim to know, say that the queen sometimes lays in the queen-cells, and sometimes the workers transfers eggs to them. Yes, queens lay eggs that produce drones. The best of fertile queens do that. I know this by personal observation.—JAMES HEDDON.

I do not believe that they do, but I do not positively know that they do not. Certainly I never saw the like. Queens lay eggs that do produce drones, and so do laying workers. But I have failed to see any evidence that laying workers ever ply their occupation of egg-laying in a hive occupied by a colony in normal conditions. I have noticed that sometimes, when a queen is introduced to a colony that has laying workers, the latter will go on laying for a short time after the queen is received, but it is not long till either the queen or the laying workers disappear. Perhaps there may be exceptions to this, as well as to other rules.—G. W. DEMAREE.

Yes, to all three questions. It is true that laying workers lay eggs which produce drones, but it is more than probable that the drones are worthless.—THE EDITOR.

Convention Notices.

The Annual Convention of the Vermont Bee-Keepers' Association will be held at the Van Ness House, Burlington, Vt., on January 13 and 14, 1887. R. H. HOLMES, Sec., Shoreham, Vt.

The next annual convention of the Cortland Union Bee-Keepers' Association will be held in Union Hall, at Cortland, N. Y., on Jan. 12, 1887. D. F. SHATTUCK, Sec.

The eleventh annual meeting of the N. W. Ills. & S. W. Wis. Bee-Keepers' Association will be held in the Grand Army Hall in Rockford, Ills., on the third Tuesday in January, 1887. There will be a two days' session. J. STEWART, Sec.

The Northeastern Ohio, Northern Pa. and Western New York Bee-Keepers' Association will hold its 8th annual convention in Chapman's Opera House, at Andover, O., on Wednesday and Thursday, Jan. 19 and 20, 1887. First-class hotel accommodations are offered at \$1 per day to those attending the convention. A generous invitation is extended to all. M. E. MASON, Sec.

The next annual meeting of the Nebraska State Bee-Keepers' Association will be held in Lincoln, Nebraska, on Wednesday, Jan. 12, 1887, at Red Ribbon Hall, commencing at 1:30 p.m. and continuing for 3 days. E. Kretzger, of Coburg, Iowa, will deliver an address on Modern Apiculture. E. M. Hayhurst, of Kansas City, and many others from abroad are expected. Members can return on one-third fare over the B. & M., U. P. and M. P. lines, by securing a certificate of payment of fare to Lincoln, from the agent of their station. In order to secure the reduced rates on return trip, members holding such certificates must present them to the Secretary of the Bee-Keepers' Association for endorsement. H. N. PATTERSON, Sec.

CORRESPONDENCE

Explanatory.—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark \odot indicates that the apiarist is located near the center of the State named; δ north of the center; ρ south; \ominus east; $\omin�$ west; and this δ northeast; $\omin�$ northwest; $\omin�$ southeast; and ρ southwest of the center of the State mentioned.

For the American Bee Journal.

Big Crops of Honey—How to Secure.

M. M. BALDRIDGE.

There are two topics, just now, of immense importance to bee-keepers who make the production of honey their main support. One is how to secure big crops of honey; and the other, how to sell them for the most money. Being deeply interested in both topics, I have given them much thought and attention during the past twenty years. In this article I will try to show the reader how to secure big crops of honey, and of the very best quality. To do this we must have bee-pasturage in abundance, and of the very best kind, and a pasturage that we can rely upon every year.

Desiring to be brief, I will at once direct special attention to Alsike clover as the honey plant for the Northern States and Canada. At the last meeting of the North American Bee-Keepers' Society, Mr. A. I. Root is reported as having said as follows: "If possible those plants should be raised for honey that have value aside from honey-production." And again, that "Alsike clover stands at the head of the list." It does not appear from the report of that meeting that these statements were disputed. At the Detroit meeting of the society, W. Z. Hutchinson reports the summing up of what was said there about Alsike clover, as follows: "Alsike can be grown with profit, as a honey plant, on land worth \$50 per acre. It has yielded more than \$25 worth of seed per acre."

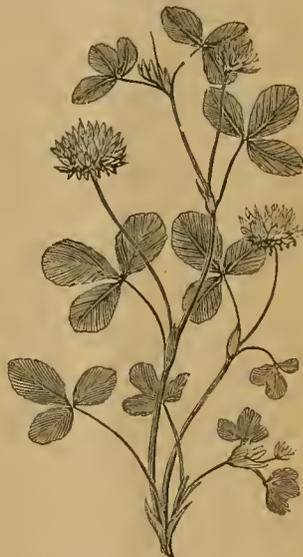

Hon. Matt. Anderson, of Dane county, Wis., has 80 acres of Alsike at this writing. He has 20 acres that he harvested for seed and hay, the past season, and from which he got "110 bushels" of seed, and "at least 25 tons of good hay, after hulling, worth enough to pay all expenses of cutting and hulling." Some years ago he sold his "whole crop on the Board of Trade in Chicago for \$11 per bushel."

I might go on and fill column after column of the BEE JOURNAL with similar quotations, but I forbear. After a careful survey of the whole question, I think I cannot do better, at this time, than to quote the following, prepared by myself, which ap-

peared in the first issue of the BEE JOURNAL for 1881, and to direct special attention to the plan of having Alsike grown extensively by farmers within range of one's apiary; also to the comparative value of Alsike and the common red, as a fertilizer, as indicated by the roots, so accurately shown in the two engravings presented:

ALSIKE CLOVER FOR BEE-PASTURAGE.

Alsike or Swedish clover (*Trifolium hybridum*), as its name indicates, is a native of Sweden, where it grows wild—being both hardy and productive. It is commonly known by the name of Alsike, that being a parish in Sweden where this clover originated. It was brought into cultivation in Sweden about the beginning of the present century, was introduced into England in 1831, and soon thereafter found its way into the German States and other parts of Europe, and was finally brought into the United States, through the Patent Office, about the year 1853.

Alsike Clover Plant in bloom.

Alsike clover is regarded by botanists as a hybrid between our common red and white clovers. The stem and branches are finer and less woody than the common red, and when cut and cured for hay, it is perfectly free from fuzz or dust. It does not turn black, but remains the color of well-cured timothy. It has, as the following cut shows, numerous branches and a multitude of blossoms which are rich in honey. The bees have no trouble in finding the honey, as the blossoms are short and the heads no larger than white clover. The blossoms at first are white, but soon change to a beautiful pink, and emit considerable fragrance. The leaves are oval, of a pale green color, and may readily be distinguished at any stage of their growth from the white or red clover by the total absence of a pale white blossom on the upper surface of each leaf, a peculiarity unnoticed by previous writers.

It ripens, in the latitude of Chicago, in the latter part of July, but needs not to be cut until August, if the weather should be unfavorable. The crop of seed is always obtained from this cutting, in which respect it is unlike the common red. It is not advisable to cut this clover more than once each season, but it may be pastured moderately during the fall. When cut for seed, it may be threshed from the field with a common clover machine; but, if more convenient, it may be stacked and threshed during the fall or winter.

Care should be taken in handling this clover, as the seed shells very easily; but this is looked upon as a point in its favor, as the land thus becomes re-seeded every year, and so early, that if the autumn proves to be a wet one, nearly every grain will germinate, and a fine growth of new plants will be secured for the following year. The seed is very fine—being about the size and shape of white clover—a pound containing, it is said, about 600,000 grains, or three times as many as the common red. The seed-pods contain 1, 2, 3, and sometimes 4 grains, which explains why it is so prolific—a moderate yield being from 150 to 200 pounds of seed to the acre.

When sowed by itself, 4 pounds of seed is a great plenty for an acre; but this is not the best plan to pursue, especially with our dry western prairies. It is much the better way to mix Alsike with timothy or the common red, or with both. When thus mixed, they are a help to each other. The Alsike, being a native of a cold climate, does not winter-kill, and besides, it acts as a mulch in winter and spring to the common red, and keeps the latter from being destroyed by the heaving-out process. As the red clover shades the roots of the Alsike, which grows close to the surface, it protects the latter from the effects of drouth. The timothy and red clover being both upright growers, lift and keep up the Alsike from the ground, which is very desirable. The stem of the Alsike is too fine to support its many branches in an upright position, and hence is more inclined to lodge than the common red. For the reasons given, the combination of the three named plants is very important, and will prove successful wherever tried.

When mixed, sow the usual quantity of timothy and red clover, and not more than 2 pounds of Alsike seed to the acre—in fact, 1 pound will be ample. If wanted for seed, it might then be best to use 2 pounds of Alsike to the acre. Timothy and red clover do no harm, as the crop may be cut so early that the Alsike will be the only plant ripe enough to furnish seed. Timothy seed being about the same size as the Alsike, cannot very well be separated from it; but such is not the case with red clover, as a fine sieve will quickly do the work.

Alsike clover, as a fertilizer, must be as good a plant as red clover, if not better, as an examination of figures 2 and 3 will show. Having often dug up specimen roots of both Alsike and the common red clovers for compari-

son and exhibition, fully as much difference in the size of the crowns and the quantity of roots and rootlets have been found as the cuts indicate. The representations are very accurate, and the reader will do well to examine them closely and note the difference, which seems to be decidedly in favor of the Alsike. Having now grown Alsike on a variety of soils for the past 17 years with good success, I know that what I have set forth in this article are facts and not theories.

Alsike Clover Root and Crown, average size, a year old. Red Clover Root and Crown, average size, a year old.

But my main object in this article is to call special attention of bee-keepers to Alsike as a honey-plant. It is well known to the fraternity that my favorite honey-plant is melilot clover, than which none better has yet been found in the United States. But melilot will never be cultivated to any extent except by bee-keepers, as no farmer would think of such a thing as growing it for hay and pasture. But Alsike clover is a plant that every farmer can and should cultivate, whether he keeps bees or not, as it is superior to the common red, for hay or pasture, for all kinds of stock.

Now, let me indicate to bee-keepers what should be done, and that right speedily. Suppose you have 50 or 100 colonies of bees, more or less, then visit the farmers in close range and ascertain how many acres they intend to seed down to grass the following spring, and induce enough of them to sow at least as many acres to Alsike, timothy and red clover, as you have colonies. The more land you can thus get seeded down the better. Induce them, if possible, to buy the seed at the cost price, but if you cannot do this, let them have it at half the cost price, but if this fails, then make them a present of as many pounds as they will sow acres. They certainly

could not and would not object to this last proposition, as it would be no more work to sow the grass seed mixed with Alsike than if it were left out. As the Alsike seed can now be purchased for about \$15 to \$18 per 100 pounds, instead of \$75 to \$100, the price when first brought here, a bee-range can now be supplied with one of the very best honey plants at a trifling expense. One hundred acres of Alsike, mixed with other grasses, in full bloom during June and July, in the neighborhood of 100 colonies of bees, would insure a large crop of the choicest honey every year, and cause the bee-keeper to swing his hat with joy. Now, if every reader of the BEE JOURNAL will act upon this advice the present winter, hundreds of tons of the finest honey will be added to the crop of 1887, and I am quite sure you will thank me for calling your attention to the project; if so, I shall feel amply repaid.

St. Charles, 6 Ills.

For the American Bee Journal

The Honey Markets, etc.

DR. C. C. MILLER.

On page 772 of the BEE JOURNAL for 1886, the editor says: "Will Dr. C. C. Miller, who has had a theory about publishing honey markets for years, tell us what he thinks about the matter proposed by Mr. Baldrige?"

I am very glad indeed to talk about a matter of such vital importance to bee-keepers. First, as to my "theory" of which friend Newman speaks: It was a very simple one, namely, that the bee-papers should give us as full information as possible about the different honey markets, especially the large cities, with the prices at which commission men were selling, etc.; in short, my theory was that the papers should do just what they have since more or less perfectly carried out.

Right here I want to thank Bro. Newman for his last improvement in adding dates to the market reports, which, in my estimation, add fully 100 per cent. to their value. What is now wanted is to have these reports correct—a difficult thing to achieve. I think an organization such as Bro. Newman speaks of on page 723, might be a good thing. But I am not very sanguine about its consummation. Bro. Newman says: "As this matter is one that interests every bee-keeper in America, we may reasonably expect that they will take hold of the matter in such a way as to bring it to a successful issue." Bro. Newman, I'm afraid they just won't. I was somewhat sanguine over this matter of being informed as to the supply, and thus properly controlling prices, and a few years ago I was appointed one of a committee to obtain for the North American Bee-Keepers' Society statistics from the bee-keepers of North America. We thought "as this matter is one that interests every bee-keeper in America, we may reasonably expect that they will take

hold of the matter in such a way as to bring it to a successful issue." But they didn't; and that, too, when all that was required of them was an expense of one cent each for a postal card. Besides, look at the apathy with regard to the Bee-Keepers' Union. Mind you, I am not saying anything against the project, but only of the apathy that prevails, and if there is a meeting in Chicago to talk it over I expect to be there.

Mr. Newman says: "To make the North American Bee-Keepers' Society such a central body would be very easy." True, "the united wisdom of apiarists ought to be able to devise the ways and means and make a success of such an institution." Very true; and perhaps they will, in spite of all my croaking.

Perhaps it is premature to discuss what they should or would do, in case such an organization were completed, but as suggestions are already made in that direction, at least by implication, it may be well enough to give a slight glance at them. Mr. Baldrige says: "Every important trade or business, almost, has an organization to control, to limit production, or to fix prices, but the honey-producers have none!" Limiting production and fixing prices might be all right, and it might be all wrong. Indeed, I am not sure that limiting production could in any case be right. I am not very familiar with the matter, but I have very serious doubts whether the action of the coal monopolists is a righteous proceeding.

Mr. Baldrige is a man of bright thoughts, and one who was an apicultural writer more than 25 years ago, when I was going to my neighbor to find out what disaster was threatened to my bees when I found the gnawings of cappings on the bottom-board. But he is not looking altogether on one side of the commission business. If I understand him rightly he thinks "the wholesale commission dealers are a curse to honey-producers," and that we should sell "on commission only" to the consumers. The objection seems to be to the commission men in the large cities. Well, commission men have enough sins to answer for, and some of them may be a bad lot, but really I would not like to see them all wiped out. There are good men among them, and I hardly feel like laying our sins at their door. I had once a conversation with one of them, who, in one sense, was "a curse to honey-producers," and yet I do not believe he was to blame for it. I knew him well from a boy, and I believe him to be an honest man, and he told me that people shipped him honey when he did not want it, and he just had to sell it for anything he could get for it, to get the dauby, sticky stuff out of the way. He did not want to handle it. Now you see this helped to demoralize the markets, just in the same way as the man bringing in his painful of broken honey into the home market and selling it for almost nothing; and yet the commission man was not to blame.

In many cases, perhaps in all, Mr. Baldrige's plan of selling on commis-

sion in the home markets is good, especially extracted honey—I am not so sure about comb honey. But it will not do in that case, as he says, to let the commission man fix the price. Neither are you any more obliged to let the commission man in the city fix the price. You can, and some producers do, fix the price below which he dare not sell, and I have never yet found any difficulty in getting him to obey instructions. So the difference between the commission man that Mr. Baldrige wants us to establish, and the one he wants us to abolish, is simply a difference in our own way of dealing. Of this and published reports I may have more to say again.

QUEEN-TRAPS AND SWARMING.

I can hardly tell what I was thinking about when I answered Query, Number 347. Very likely I had in mind using the traps to prevent swarms going off the first time issuing, thus saving the expense of a watcher, as I had been studying and corresponding about this. But to prevent swarms altogether the trap would be much worse than useless. I have tried something like it a number of times by caging the queen in the hive, and it was a dead failure every time. Indeed, with a queen free in the hive, but with its wing clipped, they will kill the old queen and swarm with a young one. I should much like to be considered a veteran, but I do not quite want to be considered in my dotage yet, and I am afraid I shall if I answer many queries as carelessly as the one referred to.

Mr. Hutchinson thinks "it is better to control or prevent the desire" for swarming. Mr. H., you cannot do it. There is the "chip" on my shoulder; knock it off, if you dare.

Marengo, 3 Ills.

For the American Bee Journal.

The Illinois State Fair.

J. V. CALDWELL, (125-203).

If any bee-keeper of the State has attended our State Fair, as I have done the past four seasons, he could not fail to notice the meager display in the bee and honey department. The writer sent a few nice crates of honey last season, which with one or two other small displays constituted the entire show from the great State of Illinois, which annually produces tons upon tons of the finest honey in the world. Of course the premiums offered by the State Board have been too small to offer us much inducement, but on the other hand the beekeepers of the State have given the Board but little encouragement to get out a more liberal premium list for bees, honey, etc. Now, fellow apiarists, let us bestir ourselves at once and see if we cannot show our brethren in Iowa and Michigan that we have the interests of our calling at heart.

The Board will soon meet to revise the premium list for 1887, and if we

do anything it must be done soon. I would suggest this plan: Let any bee-keeper who can make an exhibit next fall, or who may be acquainted with the member of the Board in his own district, write them at once, calling their attention to the matter, and urge them to favor a larger and more liberal list for bees, honey, etc. I have already written to Hon. Samuel Dysart, President of the Board, and with whom I am acquainted, calling his attention to the business, and also sent him a sample premium-list something like the Michigan State Fair list; the Board will, therefore, have an idea of what we want them to do. I think the State Board meets early in the year, so we must attend to the matter at once, and if they meet at any point where the Editor of the BEE JOURNAL can conveniently reach them, I suggest that he attend the meeting and urge the society to help us.

Cambridge, ~ Ills.

[If the Board meets in Chicago, and we are informed of the time and place, we will attend the meeting.—Ed.]

For the American Bee Journal.

Honey for all—No Monopolies.

JULIUS TOMLINSON.

On page 723 of the BEE JOURNAL for 1886, is an editorial deprecating the sale of honey by country people, at what is called ruinous prices, thus breaking down the local honey market, and compelling the "apiarist" to send his crop away for sale.

Let us see. "The bee-keeper from a distance" has, say from 50 to 200 pounds of honey. Of course he wants to sell it. He needs the proceeds to help out his scanty income. So he brings it to town. He finds the market supplied by the "apiarist." No dealer wants it. What shall he do? He cannot go to town every day—he does not want to take his honey home. He had calculated on the proceeds, and he feels that he must realize something. So he does the next best thing—"retails" it all over town. Now I fail to see anything wrong or dishonorable in this. This is a free country, and we must all of us take the chances of competition. The "apiarist" in this place has the same thing to contend with, only this difference, that the "apiarists" near by, men who have honey by the ton, break down our market. But we have this compensation, that the consumer gets cheaper honey, and people, who seldom taste of honey, are induced to buy, and finding it good, will buy again and again.

But to remedy this state of things, a closer bond of union is advised, to protect each other's interests, and to "organize for protection." It is thought that "the united wisdom of apiarists ought to be able to make a success of such an institution," and the recent Michigan State convention was called upon to "discuss" the scheme and "take the matter in hand." Now I have no objection to

discussion, but as to taking the "matter in hand," I am glad the Michigan convention did no such thing. For such a scheme, if undertaken, would surely fail. The "bee-keepers from a distance," and there are multitudes of them, could never be reached by such an organization, and if they could, no persuasion would induce them to join it. All such combinations are, in their nature, monopolies, and opposed to public policy; and no monopolies are so odious as those which seek to make scarce and dear the food products of the world. We have too much of this monopoly business in this country now, and this, with the most bare-faced class-legislation has brought many an honest toiler to penury and want.

Three-fourths of the food products of the world are consumed by the toiling poor, and if the products of our apiaries ever attain to the dignity of a prime necessity, it must be within the reach of the humblest toiler. And whether we like it or not, this is the tendency, of the honey markets to-day.

With prime extracted honey, in Chicago, at 5 to 7 cents per pound, and in other cities from 3 to 4 cents; and prime sugar from 5 to 6 cents per pound, and with the increased production of sorghum, how is it possible to advance prices by a combination? The tendency certainly is to still lower prices. Shall our honey be a necessity on the table of the poor, or only a luxury for the rich? This is the conundrum which the "combined wisdom of apiarists" is called upon to solve.

God, in his good providence, has filled His flowers with the precious nectar, with a lavish hand. He intended that honey should be plenty, and cheap. With our improved processes and fixtures, and increasing knowledge of the nature of the honey-bee, there is practically no limit to the production of honey. There is now an hundred-fold more honey produced than 25 years ago, and it is safe to assume that this increased production will go on in an accelerated ratio. And you, Mr. Editor, are doing your utmost through your most excellent paper, to help on this increasing production, and thus aiding a kind Providence in supplying His poor with this precious food. It is surprising, therefore, to find you in opposition to your life work, by advocating a scheme to make scarce and dear that which God intended should be plentiful and cheap.

Alleghan, 9 Mich.

[We desired to have this matter fully "discussed." Bro. Tomlinson has presented his view of the question very clearly. Some are presenting "the other side" quite forcibly; while others express their "doubts." We simply outlined a plan for such organization, if it was decided to have it formed—but strenuously advocated a thorough discussion of the merits of the subject before any move was made. We are always on the side of

the honey-producer, in any measure which is proposed in the interest of the pursuit; and it would, indeed, be "surprising" not only to our Bro. Tomlinson, but to myself, to find us in "opposition" to our "life work." *But such is not the case by any means, except as vainly imagined by Bro. Tomlinson.*—ED.]

For the American Bee Journal.

Flavor of Honey, its Recommendation.

W. E. BOGARDUS.

On page 760 of the BEE JOURNAL for 1886, is an article entitled, "Adulterating Comb and Liquid Honey." It was written for the *American Grocer*, to inform the subscribers of that paper about the honey they buy and sell. The writer assumes that extracted honey is no longer adulterated with glucose; that glucose is more likely to be adulterated with honey.

A traveling grocer sells a good deal of honey for me. Last year, he sold both comb and liquid; this year I have limited him to comb honey, having, comparatively, but little liquid honey, only that which I extracted from imperfect sections. Sometime ago I told him that he would find a case of honey ready for him at my house. "By the way," said he, "can't you let me have some extracted honey? I bought some in New York the last time I was there. They may talk to me about their cheap honey!" Then, with a change of countenance and a shrug of the shoulders, and a tone of voice expressive of deep disgust, he added: "But, my gracious! it hasn't any taste at all. There's a bottle of it! It looks beautiful, as nice as yours, but I want no more of it. I shall get rid of this as soon as possible."

Its appearance was certainly inviting. I glanced at the name of the firm, and wondered what it was? It reminded me of some corn-syrup which I saw a few years ago at a certain dealer's in New York, in which there floated a comb of white clover honey. I was told it was on exhibition because it promoted the sale of genuine honey. A novice without the guidance of an expert, would have preferred it. It was not necessary for me to say anything to the grocer, except that I would try to supply him.

A druggist in Paterson said that he once manufactured some liquid honey, in which there was not a drop of the real article, and sent it to New York to be tested. It was pronounced *genuine*. Naturally, and justly, that verdict destroyed his confidence in their extracted honey.

Now as to comb honey: Of course that cannot be changed after it leaves the apiarist, and, therefore, must be pure, unless the bees were fed sugar or glucose. But there is a great difference in the taste of the varieties of so-called white clover honey. Beautiful white honey, in profuse abundance,

is retailed here at 18 cents per pound, and yet there are grocers who pay me for prime sections, 20 cents per pound at wholesale, because, as they say, they have customers who will buy no other.

A gentleman from New York called this fall to purchase honey. He was a last winter's customer. Said he: "Recently I bought some very nice looking honey in New York as a present for some friends in the country, whom I was visiting. I was disappointed, for it was so far inferior to your honey in flavor. I have a nephew in Paterson who purchased a ton of nice looking comb honey in Western New York, at 12 cents per pound, which he retails at 18 cents, but it does not suit me." He paid me 25 cents per pound, and was perfectly satisfied.

I do not, of course, question the honesty of apiarists, knowing that no sweets enter *my* hives but those which the bees gather from natural sources. The yield of honey in this section is not so large as in some other sections, but I doubt whether the quality can be excelled; and certainly that should count for something. The price of honey, evidently, should be graded as far as possible, not simply according to appearance, but far more according to flavor.

Oakland, 6 N. J.

For the American Bee Journal.

Disturbing Bees in Winter, etc.

DR. A. B. MASON.

Having been so universally successful in wintering my bees for so many winters, it may not be uninteresting to some to learn of some of my bad "luck." I have thought of it whenever I have read or heard it said that disturbing bees in winter was a benefit to them. Such has not been my experience.

In November, 1883, my bees were placed in the cellar, which was under the kitchen. The hives were piled in tiers, five high, one end of the pile being under a door that we came in at from out-doors, and of course more or less stamping of the feet to remove snow was done here. The top of the upper tier of hives was not more than a foot from the floor, and were only covered with a honey-quilt. I noticed, sometime after the snow came to stay, that there was a large number of dead bees on the cellar-bottom, and I began to look for the cause. One evening, while removing dead bees from the entrances of the hives, some one entered the kitchen door above, stamping on the floor, and the bees under the door gave a very thorough buzz at every stamp, and the buzzing was less and less intense as the colonies were further from the door; the bottom tiers under the door not being disturbed at all. If the stamping was continued for a little while some of the bees would put in an appearance at the entrance. A few of the hives were entirely emptied of bees, and many more colonies were very materially weakened.

Perhaps it is unnecessary to mention that the combs in all these colonies, except some experimental ones, were left in good condition, with plenty of honey, and with no signs of diarrhea. Some may wonder why the combs were not fouled with diarrhea, but to those who know that for the last seven winters I have wintered my bees without bee-bread, the reason may be plain. But as we have been told that "the pollen theory has gone," I suppose this method had nothing to do with that theory, nor the theory anything to do with the lack of diarrhea.

Although I am taking five bee-papers, and like them all, still I find that I am more anxious about the arrival of the "old reliable" AMERICAN BEE JOURNAL than any of them. I have taken it so long that it seems like an old friend; and it seems to me to get better with age.

Auburndale, Ohio.

For the American Bee Journal.

Legislation for Bee-Keepers.

25—J. R. ROEBUCK, (35-84).

While a number have written upon this subject, there is, however, a certain feature of it that has not yet been mentioned. We need a stringent law protecting the bee-keepers against open cider-mills and the pomace therefrom. I know that thousands upon thousands of bees are needlessly killed; sometimes so many are killed as to deplete colonies, so that it is very uncertain of successful wintering; but even if wintered, a colony will be so weak in the following spring that it will take until after the honey season is over to become populous enough to gather surplus, or to commence again at the cider-mills, and go through another siege, until finally it becomes exhausted, and a loss of the colony is the result. Again, should the bees be confined for a long winter season, diarrhea from the use of cider as food will kill them before spring.

Now what shall be the remedy? While I am opposed to special or class legislation, I cannot see any wrong in asking protection against an evil that needlessly exists; and when two or more industries conflict, it becomes the duty of our law-makers to harmonize the surroundings of each so as to give them equal rights and protection. Bees will go to open cider-mills and we cannot possibly prevent them (at least I cannot). Cider-mills can and ought to be protected against the bees by tight buildings and screens, and the pomace from the apples can be disposed of so as to not injure the bees.

While I ask for a remedy I will also propose one. Let all bee-keepers circulate petitions for signatures, and present them to our legislatures, asking for a law that will compel cider-mill men to screen their mills and dispose of the pomace so as not to be exposed to the injury of bees. To effect a thorough canvass, it would be

a great help to have all of the bee-papers print petitions and enclose one in each paper, with the request that subscribers procure signatures and return the petitions to the editor of such papers, who in turn ought to arrange with a member of the legislature to have the same enacted into a law. I should like to hear from others. This, to me, seems a legitimate undertaking, and should be pressed immediately, as the State legislatures will soon be in session.

Burton City, Ohio.

[Such blank petitions cannot be enclosed in the bee-papers. It is positively prohibited by the Postal Regulations. It will take but a few minutes to write the heading on the sheet of paper, to be used for signatures, and each person circulating the petition should send it direct to the member of the legislature for that district, requesting his influence to have such a law enacted.—ED.]

For the American Bee Journal.

Are Bees Trespassers?

J. E. POND.

This question is one of some little importance at the present time, as upon the answer thereto depends the future of the industry of bee-keeping. In answering, the only practical view that can be taken, in the legal aspect of the case; as upon the law depends the whole matter.

It is a great fundamental principle both of law and of equity, that a man has a right to do what he chooses; to enter into and engage in any business he pleases, provided, however, that in so doing he does not injure or trespass upon any other man. So we may assume that any man has the natural right to keep bees; but not the legal right, if it can be shown that any other person is injured by his so doing. It is not to be assumed, however, that any fancied complaint will be considered as constituting a nuisance; the complaint must be general. The law realizes that men are human, subject to the sway of passion, and liable to complain through spite, or to satisfy a revengeful spirit; and for that reason a cause will not be adjudicated a nuisance unless it is general in its effects, and is an injury to the many instead of one.

A trespass to an individual may be a nuisance to him, but would hardly be considered a common nuisance. The form of the statute in this State, follows the common law form, and is as follows: "To the great damage and common nuisance of all persons there passing, inhabiting or being." Apply this to our bees, and it will be seen that each case must be individual; that the law of trespass may apply in many cases, but the law of nuisance seldom if ever; and that to show a nuisance will require evidence of the strongest nature and character. Some things are made nuisances by

statute; unless so defined, it must be fully and affirmatively shown, and of more than ordinary nature to convict.

I can conceive that bees may be so kept in thickly settled towns as to constitute a nuisance, but the cases will be rare, and will not happen with bee-keepers of intelligence. Each one of us must take the matter home, and see to it that the general good of bee-keepers is not injured by individual action.

Foxboro, Mass.

Convention Notice.

The New York State, the Eastern New York and the New Jersey & Eastern Bee-Keepers' Associations will hold their great united convention at Albany, N. Y., on Jan. 11, 12 and 13, 1887. This convention will be one of the largest, if not THE largest, ever held anywhere in this country, and it behooves every bee-keeper to attend. A grand exhibit of apianian fixtures is promised. Among the subjects to be brought before the convention are the following: Alsike Clover as a Honey-Plant, by C. M. Goodspeed; The Chapman Honey-Plant, H. Chapman; Rendering Old Comb into Wax, Ira Barber; Extracted Honey, Dadañt & Son; The Middle-man in the Wholesale Market, C. F. Muth; Cause of late Depression of the Honey Market, L. C. Root; Bee-Keeping by Woman, as an Occupation, Mrs. L. M. Thomas; Bee-Papers and the Supply Trade, John Aspinwall; Scientific Ventilation of Bees in Winter Repositories, P. H. Elwood; Overstocking the Honey Market, Capt. J. E. Hetherington; Outlook of Bee-Keeping in the Future, A. E. Manum; Conventions as a Means of Promoting the Financial Welfare of Bee-Keepers, James Heddon; Separators, N. N. Betsinger; Bee-Keeping as a Science, Arthur Todd; Advantages and Disadvantages of Patent Rights to Bee-Keepers, G. M. Doolittle; The Bee-Hive of the Future, R. F. Holtermann; and Foreign Honey Market for North America, S. T. Pettit. The head-quarters of the Convention will be at the Globe Hotel, State St. cor. of Pearl; Board \$2 per day. Board at the Kimball House, 89 Washington Ave., \$1 per day. All who desire to secure board at either of these hotels, will please inform Mr. Jno. Aspinwall, Barrytown, N. Y., at once.

GEO. H. KNICKERBOCKER, Sec. N. Y. State.
JOHN ASPINWALL, Sec. Eastern N. Y.
F. E. JOHNSON, Sec. N. J. & Eastern.

We Ask every subscriber to promptly renew his subscription and at the same time induce a neighbor to take it, by convincing him that it is for his interest to do so. By inducing your bee-keeping neighbor to take the BEE JOURNAL for 1887, you will be doing yourself a duty, because he may thus be educated so as not to ruin your market for honey by selling his at a ruinous price, for lack of knowing its real worth. This matter of marketing honey will be fully discussed in these columns during the next two or three months, and no one interested in honey-production can afford to do without its weekly visits.

Can you Use a Few Samples to advantage in getting up clubs—just send a postal card to this office for them, saying how many you desire, and we will cheerfully send them. A favorable word from our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter correct apicultural knowledge and promote the welfare of our pursuit.

Local Convention Directory.

1887. *Time and place of Meeting.*

**SELECTIONS FROM
OUR LETTER BOX**

Bees Wintering Well.—J. W. Bitensbender, Knoxville, ♀ Iowa, on Dec. 20, 1886, says:

Bees are wintering well so far. The coldest was 14° below zero. We have 3 inches of snow now, and fair weather.

Bees did Well.—J. A. Rickenbacher, Gahanna, ♂ O., writes:

Bees did well in this locality last summer. I commenced with 8 colonies in the spring, and I now have 22 good ones; 2 swarms absconded. Excepting three, all the increase was secured by natural swarming. The three were made by the nucleus plan. I have taken over 400 pounds of honey, about 170 pounds of which was comb honey, and the rest extracted. I sold my comb honey at 20 cents a pound, and the extracted at 15 cents a pound, in 3-pound cans. I could have taken more honey if I could have given my bees the proper attention. They have plenty to winter on. The past summer was a very dry one, but it did not appear to affect the honey-flow any. On the last of September we had a heavy frost which killed all the fall flowers.

Over-Doing the Bee-Business.—D. R. Rosebrough, Casey, ♂ Ills., writes:

I believe that bee-keeping will never be overdone in this country. It requires men of pluck to make it a success; it will never be overdone by lazy men, or by women entering the ranks of bee-keepers, for their is too much hard work connected with it. Mixed farming will not interfere, for in such cases the bees are nearly always the most neglected. Farmers engaging in the business will not influence it any; they are my best honey-customers, and the only ones that want bees; but they do not take care of them, so there are no more

bees in this county now than there were 16 years ago. Four years ago in this little village there was not 1,000 pounds of honey produced annually; this year there was 5 tons. Selling honey in one's home market is a slow way of disposing of it, but it is a sure way. It will not be overdone by specialists, for there are too many who think there is a fortune in the business, till they have tried it and found that it did not pay them. It is true that honey is cheap, but so are beef cattle, pork and wages. I am not discouraged, for if no calamity overtakes me, I will have 5 tons of comb honey next year, as I usually double my crop every year.

Slats in Honey-Board, etc.—F. M. Johnson, Augusta, ♂ Iowa, on Dec. 13, 1886, asks:

Will Mr. Heddon explain why slats in a honey-board cannot go crosswise of the frames as well as lengthwise? Using lath, and having no joints to break, there will be so much chance for brace-combs between the frames and slatted board, etc.

[Mr. Heddon replies thus: "In the first place laths are unfit to work into any part of a bee-hive. The slats of a honey-board should be smoothly sawed, and be far more uniform than laths. The objection to having the slats run crosswise of the frames is that the openings or joints are not completely broken, and after you have used this principle, you will never try to do without it."]

An Average Season.—B. Z. Smith, Tuscola, ♂ Ills., on Dec. 28, 1886, says:

The honey crop the past season was an average one for this locality. I secured 5,000 pounds of comb honey which averaged 11 3-5 cents per pound here. I put 150 colonies in a brick cellar made especially for bees. It has an 8-inch sub-earth ventilator 120 feet long, and an escape pipe 4x6 inches inside, running up through a honey-house. Give us the commission-men's reports for awhile yet, any way.

Selling the Honey Crop, etc.—Geo. Spittler, Mosiertown, ♂ Pa., writes:

The general complaint of bee-keepers is that the season just past has been a poor one for honey as well as increase, though a few apiaries have had a large increase in colonies, and some individual colonies did well in gathering honey. I notice that some correspondents complain of not being able to sell honey. I have no such complaint to make, but of course I have to sell my product at 12 and 12½ cents, both wholesale and retail, at the door; while what is sold at the stores at wholesale brings the same. Owing to the sale of honey by those who produce but little, at a low price, all have to sell at the same price, or else be called—mean. Some of us are

expecting to meet with losses on account of bees having stored honey-dew.

The Market Reports.—F. A. Snell, Milledgeville, ♂ Ills., says:

In regard to market reports, I am in favor of continuing them until we get something better. Other papers quote prices of honey, and why should we not be posted as bee-keepers through our own papers? The AMERICAN BEE JOURNAL quotations have been a help to me in selling in our towns here at home. Grocers aim to be posted.

Bees in Fine Condition, etc.—Alfonso B. Bray, Bois D'Arc, ♀ Mo., on Dec. 24, 1886, writes:

I am a small boy beginning to keep bees. I now have 12 colonies, and had only 6 last spring to start with. I have taken off 700 pounds of surplus honey from the 6 old colonies. My bees are in fine condition, their stores being sufficient to take them through the winter. I very much agree with Henry W. Haag, page 810 of the BEE JOURNAL for 1886, that something must be done to protect bee-men. The case is the same in this locality. There are so many that sell their honey for a trifle that there can be but little profit in the business. Let us unite and stick together for the next year; the result will be in our favor.

Fixing the Price of Honey.—E. Rood, of Fargo, ♂ Dak., says:

There is something wrong in allowing middle or commission men to fix and advertise the price of honey for the producer.

Outlook Good for Wintering.—S. M. Cox, Alvarado, ♂ Ind., on Dec. 21, 1886, writes:

I started with 23 colonies last spring, increased them to 64, and took 1,300 pounds of comb honey and extracted 100 pounds. I disposed of 11 colonies, and now have 40 packed in clover chaff on the summer stands. I expect to pack the rest as soon as the weather is favorable. I think the outlook for wintering is good, and I hope to be able to make a better report next year.

Chaff Hives for Wintering.—John Davis, (29), Allison, ♂ Ills., on Dec. 21, 1886, says:

I commenced last spring with 16 colonies, increased them to 29, and got 600 pounds of comb honey, for which I received 15 cents per pound; and 300 pounds of extracted honey, for which I received 8 cents per pound. I have kept bees for 4 years, and never lost any in wintering. I keep them in chaff hives on the summer stands. I would like to see reports from bee-keepers who use chaff hives.

Starters in Section and Brood-Frames.—Samuel Cushman, Pawtucket, ♂ R. I., writes :

Dr. Tinker, in his reply to Query, No. 345, says that he gives swarms brood-frames with starters only, and also sections with starters. Will he tell us why he does not use full sheets or full combs in the sections, instead of starters?

[Because it does not pay me to do so. I sell all of my honey here at home, and must produce a fancy article or lose prestige and custom. I have had many sections filled on full sheets of the best thin foundation obtainable, and I have not been able in a single instance to produce an article that would not excite suspicion that it was partly an artificial product. The presence of the foundation would be detected by the yellow cast in the centre of the comb, and often by the foundation sticking to the teeth in eating. The wax of natural comb never sticks to the teeth in eating. I use and recommend full sheets of brood-foundation in building up colonies in the spring, and at other times, but I use only starters 2 inches wide for swarms. I prefer starters 1 inch wide for sections.—G. L. TINKER.]

Season Shortened by Drouth.—Wm. Gemmill, Shannon, ♂ Ills., on Dec. 23, 1886, says :

I commenced the season of 1886 with 45 colonies of bees, increased them to 76 by natural swarming, and had about 2,500 pounds of comb honey in two-pound sections, and 500 pounds of extracted honey. I have 74 colonies now in the cellar in good condition. The past was a fair season, but cut short by drouth.

Large Surplus Crop.—Frank McNay, Mauston, ♂ Wis., on Dec. 25, 1886, says :

My four apiaries are in excellent condition for winter, after storing a surplus of 25,000 pounds of honey.

Cellar-Ventilation, etc.—Wm. Hill, Prophetstown, ♂ Ills., on Dec. 21, 1886, writes :

I had 25 colonies in the spring which I increased to 45, by natural swarming. I put my bees in the cellar on Dec. 3. We had one cold night before I put them in, and they became somewhat frosty, but they have dried out nicely, and are now very quiet. I keep the temperature as near 45° as I can. They seem to be the quietest at that degree of temperature. I had 3,900 pounds of honey the past season, 1,200 of which was extracted, and the balance comb honey; and average of 156 pounds per colony, spring count. I ventilate my cellar with a 3-inch pipe that connects

the cellar with a chimney. When it gets very cold I intend to shut off a part of the draft, or all of it, so as to keep the temperature as near 45° as possible.

Favorable Winter so Far.—W. Mason, Fillmore, ♂ Ind., on Dec. 27, 1886, writes :

So far we are having a very mild winter. Several times snow has fallen, but not deep. Bees on the summer stands are doing well this winter, and as a rule they have plenty of stores. I look for good reports in the spring, if the winter continues favorable. I weighed a part of my colonies on Nov. 12, and the rest on Nov. 25, and stored them in a beehouse. To all appearances they are now in fine condition. My colonies run a little below the average last fall. My bees reared a large crop of brood in August and September, there being a few swarms cast as late as Aug. 27. The fall crop of surplus honey was lost by the over crop of fall brood, and no doubt it will require more winter stores on this account.

The Honey Crop of 1886.—E. F. Meeker, Duncan, ♂ Ills., on Dec. 23, 1886, writes :

I started last May with 80 colonies of bees, and I have increased them to 131. I took off 11,000 pounds of honey, 7,000 pounds of which was in one-pound sections. My crop is nearly all sold. I have all races of bees, and have been cross-breeding for the past three years.

The Season of 1886.—R. Bacon, Verona, ♂ N. Y., on Dec. 22, 1886, reports as follows :

Failures attended the most of our bee-work through the past season in this locality. Spring opened quite well for bees, but later everything in their line changed. White clover, which looked very promising in the start, failed to yield much honey; basswood was almost a total failure, and we got but few swarms. Very many colonies had to be fed for winter, and the small crop of honey secured had to be sold very cheap. Taking it all in all, it was a hard year for bee-keepers, and makes them feel a little discouraged.

Raising the Price of Honey.—Mrs. L. Harrison, Peoria, ♂ Ills., says :

I have a favor to ask of the "Honey Producers' Association," when it meets at Chicago, and it is this: Will they please raise the price of corn? Dry corn, raised last year, only brought 25 cents per bushel in central Illinois, at the nearest railroad station: the corn was raised on land worth \$65 per acre. Honey is low, but no lower than other produce, and the business was never on a better basis than at present. Little more than ten years ago, honey was seldom seen, and only inquired after at drug-

stores. But now it is handled by all first-class dealers in groceries. The business is not overdone; there are thousands of men, women and children in the United States who never tasted honey. People do not buy molasses, as they did a score of years ago; they are afraid of everything in the form of syrups, and honey is silently taking their place. I would like to see the price of honey higher, but all the "resolves" of producers will not affect it more than the Pope's bull against the comet.

Winter Stores.—John Baldwin, Steamburgh, ♂ Pa., asks :

Some of my bees in the cellar are short of stores, and I feed them once a week, by turning half-a-tumbler of syrup on the bees and combs. Is that right?

[While the plan you have adopted has been successful in many instances, enough good honey for winter stores should have been "laid by" in the combs, early in the season.—ED.]

Prices of Honey—Double-Walled Hives.—A. W. Fisk, Bushnell, ♂ Ills., on Dec. 27, 1886, writes :

I read with interest Mr. Baldrige's article suggesting the idea of organizing a union convention for the purpose of taking measures for protection against the ruinous low prices for honey. It is my impression that a convention of this kind, properly organized and managed, would benefit us more than any other organization, and I hope this subject will be freely discussed, and some wise measure devised to put up, and keep up, the price of honey. We are experimenting here with double-walled chaff hives, and I think if they are properly constructed they cannot be excelled for summer and winter protection and management. I am wintering a colony of bees in a double-walled hive. I have 6 colonies in double-walled plastered hives, and some in double-walled chaff hives, all on the summer stands. I also have a few bees in single-walled hives in the cellar, and all are doing well so far, although we have had no very severe weather.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices :

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Issued every Wednesday by

THOMAS G. NEWMAN & SON,
PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL.
At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

The Report of the Indianapolis Convention is now published in pamphlet form, uniform with that of last year. It will be sent postpaid for 25 cents to any address.

We have also bound it up with last year's, together with the History of the Society; this we will mail for 40 cents. Or if you send us one new subscriber (with one dollar) besides your own renewal, we will present you with a copy by mail.

Money Orders can now be obtained at the Post Office at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Reader, do you not just now think of one bee-keeper who does not take the Weekly BEE JOURNAL, and who should do so? Perhaps a word or two from you will induce him to do so. Will you not kindly oblige us by getting his subscription to send on with your own renewal for next year? When you do so, please select any 25 cent book in our list, and we will send it to you post-paid, to pay for your trouble. We are aiming to get 5,000 new subscribers for 1887, —will you not assist us to obtain them?

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

As a premium to the second largest club we will send my mail, postpaid, a copy of the "Farm Account Book," worth \$3. The postage is 20 cents.

As there is another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal," on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

We anticipate a largely increased list of subscribers for 1887, as \$1.00 cannot be invested by any bee-keeper that will bring him better returns.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

Frank Cheshire's new book on Bees and Bee-Keeping, can be had at this office.—Vol. I, bound in cloth, \$2.50, postpaid.

Premium Worth Having.—The New York World and the AMERICAN BEE JOURNAL (both weekly) will be sent for one year to any address in North America for \$1.90. And in addition PRESENT to every such CLUB SUBSCRIBER a "History of the United States," containing 320 pages and 22 fine engravings, bound in leather and gilt.

This "History" will be sent FREE by express at the subscriber's expense; or will be mailed for 10 cents extra to any place in the United States or Canada.

It is arranged chronologically by years, from 1492 to 1885. Every event is narrated in the order of its date. These are not confined, as in other works, to political matters, but embrace every branch of human action.

This premium is worth the whole of the money sent for both periodicals, and should induce thousands to subscribe, and thus get two unrivalled weeklies for nothing.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principle, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

Preserve your Papers for reference. If you have no BINDER we will mail you one for 60 cents, or you can have one FREE if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Fifty-Two Dividends from the investment of one dollar is just what every subscriber of the AMERICAN BEE JOURNAL receives. Can any better interest be found for the investment of one hundred cents? If so, where?

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Our Book Premiums.—To encourage all our present readers to get one or more additional subscribers we will present 25 cents' worth of books for every new subscriber (accompanied with \$1 for one year's subscription), sent direct to this office. Thus for five new subscribers with \$5, the getter up of a club gets \$1.25 in valuable reading matter, to be selected by himself from our list on the second page of this paper. It will pay you to devote a few hours to the interests of the BEE JOURNAL. Every one who keeps bees ought to take it. We will furnish sample copies free in any quantity to those who intend to get up clubs. We expect to get 5,000 new subscribers for 7.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

As Bread is the Staff of Life, so is judicious advertising the staff of business! You may as reasonably expect one "good square meal" to suffice for three months, as to expect one advertisement to bring in business for that length of time! Many persons cannot remember anything longer than about seven days. To stop advertising in a dull season, is like tearing out a dam because the water is low—either plan can but result in disaster.

Enterprising queen-breeders and supply-dealers know the value of advertising "all the year round." Persistently keeping their name and business continuously before buyers, will eventually place them on the successful side, if they have a valuable article to sell.

A "sign" is a mute invitation to those who may pass a man's place of business; a "circular" will only reach the one to whom it is personally addressed; but an "advertisement" in a well-conducted and widely-circulated paper (like the **AMERICAN BEE JOURNAL**) has an influence "far and wide;" it finds customers and almost compels them to consider the claims of the wide-awake advertiser. To yearly advertisers the **AMERICAN BEE JOURNAL** offers special inducements. This is just the time to make a contract for the year 1887.

We Keep this Notice standing all the year round: "Always give the name of the Postoffice to which your paper is addressed. Your name cannot be found on our list unless this is done," and yet many ask us to change their address without even mentioning to what Postoffice it has heretofore been sent. It often costs us more to find their old address than they pay for the **BEE JOURNAL** for a year; as we may have to examine our subscription lists in every State, Province and Territory in North America. Please be more careful in the future, and never omit your name, Postoffice, county and State.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for 1887, will richly repay every apiarist in America.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Market is well supplied with all the grades, and the demand is light. Prices are nominal at 11@12c. for white in 1-lb. sections. Fancy white in scant pound sections, 13c. Very little extracted is being sold, and prices range from 4@7c. **BEEWAX.**—22c. R. A. BURNETT, 161 South Water St. Dec. 8.

NEW YORK.

HONEY.—In consequence of a large stock of comb honey on this market, fancy prices cannot be maintained. Fancy white honey in paper boxes, or glassed, are in better favor here than the unclassified honey, hence the difference in the price. We quote present prices as follows: Fancy white in 1-lb. paper boxes, or glassed, 13c.; same unclassified, 12c., and in 2-lb. glassed sections, 10@11c.; of grades 1 to 2 cts. per lb. less. Calif. comb, 8@10c.; fancy buckwheat 1-lbs., 8 1/2@9c., and 2-lbs. 7 1/2@8c. Extracted white clover, none in the market. Calif. ext'd, 6+10-lb. cans, 5@6c.; buckwheat, in kegs and barrels, 4@5c. **BEEWAX.**—21@23c. **McCAUL & HILDRETH BROS.,** 34 Hudson St. Dec. 7.

BOSTON.

HONEY.—The demand has improved. We are selling one-pound packages of white clover honey at 13@14c.; 2-pounds at 11@12c. Extracted, 5@7c. **BEEWAX.**—24 cts. per lb. Jan. 1. **BLAKE & RIPLEY,** 57 Chatham Street.

DETROIT.

HONEY.—The market is a trifle more active. Best white comb honey in 1-lb. sections, 11@12 1/2c. Buckwheat, 10c. Extracted, 7@9c. **BEEWAX.**—23c. Dec. 13. **M. H. HUNT,** Bell Branch, Mich.

CINCINNATI.

HONEY.—There is a quiet tone prevailing, but the demand is fair for choice comb and extracted honey, in small packages. Manufacturers buy very sparingly. The supply is large and prices are downward. We quote prices for extracted honey, 3@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way. **BEEWAX.**—Good demand, —20@22c. per lb. for choice yellow. Dec. 21. **C. F. MUTH & SON,** Freeman & Central Aves.

CLEVELAND.

HONEY.—The market is not very active and prices a little lower. Choice 1-lb. sections of best white sell at 13@14c.; second grade 1-lbs., 10@12c.; choice white 2-lbs., 11@12c. Extracted, slow at 6c. **BEEWAX.**—Scarce at 25c. Nov. 17. **A. C. KENDEL,** 115 Ontario Street.

MILWAUKEE.

HONEY.—The demand for honey is only moderate and the supply ample, of very fine quality and in extra good order. We quote choice 1-lb. sections of white at 12@13c.; 2-lbs., 11@12c.; dark waxed. Extracted white, in barrels, half-barrels and in kegs, 8@9c.; in tin packages, 5 1/2@7c.; dark, in barrels and 1/2-barrels, 5@6c. **BEEWAX.**—Nominal at 25c. Dec. 13. **A. V. BISHOP,** 142 W. Water St.

SAN FRANCISCO.

HONEY.—The market has been rather duller the last week, but prices are well maintained, particularly for choice white extracted and choice white comb honey, as both kinds are not freely offered. We quote: 3 1/2@4 1/4c. for extracted, and 9@12c. for comb; with easier sales for the best grades, than for the darker honey, as none seem to be able to use the dark just now. **BEEWAX.**—Dull at 19@22c. Dec. 11. **SCHACHT & LEMCKE,** 123-124 Davis St.

HONEY.—Trade is quiet. Extra white comb 11c; amber, 7 1/2@10c. Extracted, white, 4@4 1/4c.; amber, 3 1/2@3 3/4c. **BEEWAX.**—20@23c. Oct. 18. **O. B. SMITH & Co.,** 423 Front Street.

KANSAS CITY.

HONEY.—Demand is good for all grades, and receipts have been very large. Comb and extracted. Home bee-men have kept out of the market until this month; having glassed every lb. section on both sides they are reducing prices, selling 60 lbs. of glass with 160 lbs. of honey, making our market lower. There crop is about 70,000 pounds. We quote: White clover 1-lbs., 12@13c.; 2-lbs., 11c.; 1/2-lbs., 13@14c.; dark 1-lbs., 10c.; 2-lbs., 8@9c.; California 2-lbs., 9@10c. Extracted white clover, 6c.; dark, 4@5c.; white sage Calif., 5 1/2c.; amber, 5c. **BEEWAX.**—22c. Nov. 20. **CLEMENS, CLOON & Co.,** cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 3 1/2@4c. Extra fancy of bright color and in No. 1 packages, 1/4 advance on above prices. Extracted in barrels, 4 1/2@5c.; in cans 5@6c. Market dull. **BEEWAX.**—Firm at 20 1/2c. for prime. Dec. 20. **D. G. TUTT & Co.,** Commercial St.

THE CHAPMAN HONEY PLANT.

Having expended thousands of dollars in bringing before the people one of the most wonderful honey-producing plants known in the United States, or even in the world, and testing it honestly and fairly, wish to say through your valuable **JOURNAL** that the seed contains so much oil that nothing but fresh seed will grow, or by thrashing, if the seed is bruised or broken, it will not grow for this reason. And by the advice of many prominent bee-keepers, I have decided to sell the limited amount of seed I have raised this season at the following prices, and will send to those who have already ordered the amount of seed due them at this low price: One-half ounce 50 cents; 1 ounce, \$1; 2 ounces, \$1.50; 4 ounces, \$2; 1/2 pound, \$3; 1 pound, \$5. One pound of seed is sufficient for half an acre, if properly thinned out and re-set. Write all orders plainly, and give your post-office in full. **H. CHAPMAN,**
52A2t Versailles, Cattaraugus Co., N. Y.

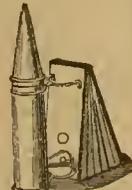

P. S.—See official report of the Committee in next issue of **AMERICAN BEE JOURNAL.**

Wooden Pails for Honey!

We can furnish regular **Wooden Water-Pails**—well painted on the outside, and with 3 iron hoops and a tight-fitting wood cover, at \$2.25 per dozen. They will hold 25 lbs. of honey, and when empty, can be utilized for use as an ordinary household pail.

THOS. G. NEWMAN & SON,

Vandervort Foundation Mill.

6 Inch, Price, \$20.00. It makes the finest extra thin Foundation for comb honey. For Sale by **THOS. G. NEWMAN & SON,** 923 & 925 West Madison Street, **CHICAGO, ILL.**

What Mr. Beyer says: "Please accept my beat thanks for the splendid seeds received from your firm. It would be a rather lengthy list if I should name all, but will say that amongst 35 first, and 3 second premiums awarded me at our fairs in Northern Indiana and Southern Michigan, 25 first premiums were for vegetables raised from your seeds. What firm can beat this?"
 AUGUST BEYER, So. Bend, Ind.
 Seed of this quality I am now ready to sell to every one who tills a farm or plants a garden, sending them FREE my Vegetable and Flower Seed Catalogue, for 1887. Old customers need not write for it. I catalogue this season the native wild potato. JAS. J. H. GREGORY, Seed Grower, Marblehead, Mass.

HEDDON'S CATALOGUE

For 1887, (40 pages,) NOW READY.

The New Hive.

I have many more testimonials like the following, from Leading Bee-keepers of this country. See 1887 Catalogue, to know what Prof. Cook, W. Z. Hutchinson, F. P. Stiles, T. L. VonDorn, F. Boomer, and Doctors Tinker, Mason, Miller and others think, after many of them have thoroughly tested the New Hive:

Your hive is novel, and I propose to try it. E. J. COOK, (Bro. to Prof. Cook.) Owosso, Mich., Feb. 11, 1886.

Please send me descriptive circular of your new hive; the thing seems a novelty to me, and I am anxious to understand it. W. S. CASSON, Cyothiana, Ky., Jan. 22, 1886.

I have been reading your book and I regard it as a most valuable acquisition to our bee-literature. Your new hive is a wide departure from the old order of things, and I can see much to commend it, in the hands of a master. J. W. PORTER, Charlottesville, Va., July 2, 1886.

I note with pleasure your improved reversible and interchangeable hive. I consider it THE hive, though my experience in the bee-business has been limited, yet I see in this hive a great revolution in handling bees, making it a pleasure to handle them. S. J. JACKSON, Southern Agt. of the Southern Despatch fast ft. line, Atlanta, Ga., Aug. 9, 1886.

I have in use 20 hives embracing your late inventions, and to say that I like them would be stating it mildly. Your principles, I think, have come to stay. I find there exists considerable prejudice against your new hive, it being so much different from the hives in general use here, and I predict that because it is so different, requiring a system of management peculiar to itself, it will not meet with such general approbation as it deserves. D. S. HALL, South Cabot, Vt., Oct. 4, 1886.

When I first saw your new hive, in your home apiary, a year and a half ago, its construction and system of management being so different from any other hive, I was not favorably impressed with it, but in canvassing the subject in my own mind afterward, I thought of the excellent results that had attended the use of your other inventions, and it occurred to me that possibly this might afford me equal satisfaction. The more I studied the hive, the plainer its advantages appeared to me, and I determined to give it a comprehensive trial. After the past season's use of nearly 100 of them, I am prepared to endorse more than you claim for it. In my judgment, it will revolutionize our business, and be who would produce honey at a profit, will not be slow to adopt this live as soon as he realizes how much it lessens the cost of production. While my own financial interests would be enhanced, were its sale restricted, I am not selfish enough to desire to keep my brother bee-keepers from enjoying so good a thing. Wishing you the ample success that your labors in the cause of bee-culture justly merit, I am cordially and fraternally yours, DWIGHT FURNESS, Furnessville, Ind., Oct. 10, 1886.

No Circulars sent out, unless asked for. Send address (plainly written) to

AMERICAN
ESTABLISHED
1861
BEE JOURNAL
OLDEST
BEE PAPER
IN
AMERICA

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Jan. 12, 1887. No. 2.

All New Subscriptions will begin with the year, and until further notice we will send the back numbers from January 1, unless otherwise ordered.

A meeting of the Maine Bee Keepers' Association will be held at Mechanics Falls, Maine, on Jan. 25-27, 1887, and it promises to be one of exceptional interest and importance, on account of the recent movement for a consolidation of the different bee-associations of the State, in one society, which is to be incorporated by the Legislature.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

How to Secure a Copy Right on a Book is a query from a correspondent. He says he is writing one, and wants to publish it on his "own hook." We are free to say that publishing on one's own hook is quite risky business; but that is none of our business, and we will answer the question. Get the title page printed, and send two copies of it with one dollar to the Librarian of Congress, Hon. A. R. Spofford, Washington, D. C., asking him to send you a copy right. The dollar is to pay for registration and clerical fees.

As War in Europe may be announced any day by cable, most people are interested to know something about the great states which will first be involved. "Francis Joseph I., and the Austria-Hungary Empire" by Geo. M. Towle, gives, in *Frank Leslie's Popular Monthly* for January, a clear and well-written picture of one Power. "When Greece Meets Turk," by Oscanynn, tells the story of another. The whole January number of this periodical, with its attractive reading and charming pictures, is a prize for young and old.

The California Bee-Suit.—We have received a letter from Mr. Bohn, who was defendant in a suit for trespass said to be committed by his bees on a neighbor's vineyard, stating that the trouble was all over now. Mr. Bohn, assisted by the National Bee-Keepers Union, made a very vigorous fight, and the united resistance was too much for the fruit-growers. They now admit, says Mr. Bohn, that the bees have not been troublesome during the past year. This shows the value of united action, and the moral weight of the "backing" Mr. B. had in the National Bee-Keepers' Union! Of course all are well aware that the Union should have thirty thousand members instead of three hundred! On this point we commend to every bee-keeper the following from one of our correspondents:

The moral effect of numerical strength is great, and many battles have been won by sheer force of numbers, and without striking a blow. So with us; if we can show an unbroken front, composed of a majority of the bee-keepers of the country, and cause it to be understood that each and every one of us are pledged to pull together in unison and harmony for defense of our rights, we shall bear down all opposition by this moral weight alone.

The very fact that so few are enrolled as members is a disgrace to those who are engaged in the pursuit of bee-keeping. Let all arouse from sleep, join the Union, and thus make it a "sure defense."

The Uses of Honey are many and ever-increasing; and as people become more and more acquainted with the various purposes to which the product of the labors of the honey-bees can be put, the greater will be the demand for it. But perhaps one of the newest ways in which honey is employed, is recorded in an account given in a scientific periodical in Italy, wherein is described an Italian method of preserving bodies in a soft and flexible condition for several months, and by that means enabling them to be dissected without the least danger to the preparator or the anatomist. To this end, the bodies are placed in some sort of receptacle, and then covered with a layer of the thickest and purest honey that can be obtained. The using of honey for this purpose may not be the means of increasing its demand, but it serves to illustrate the preserving power which pure honey possesses, and also may be a new idea to many.

Catalogues for 1887.—Those on our desk are from

James Heddon, Dowagiac, Mich.—36 pages.
E. T. Flanagan, Belleville, Ills.—8 pages.
G. W. Stanley, Wyoming, N. Y.—12 pages.
Victor W. Clough, Geneseo, Ills.—8 pages.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for reference and examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1887, will richly repay every apiarist in America.

One of the Many Topics to be discussed at the convention at Andover, Ohio, on Jan. 19, is the following which we notice as quite a lengthy programme: "Can the bee-keepers of the United States form a combination and control the price of honey?" This is one of the *living issues* of to-day, and is receiving a very thorough and exhaustive examination.

A correspondent suggests that a rousing convention be held in Chicago early in May, "especially devoted to matters *outside* of honey-production," taking up the vital subjects heretofore much neglected, such as "cost of production, and the proper selling price for honey, and how to maintain it," etc., etc.

If it is thought best to call such a convention, it ought to represent every portion of the United States, either by the personal attendance of representative bee-keepers, or their written views on the subjects to come before the meeting. It should also be stenographically reported and published, and made an "authority" for American apiarists. The object of the present preliminary discussion, is to ascertain the views of apiarists all over the continent of North America, and decide whether it is desired to hold such a convention.

The AMERICAN BEE JOURNAL will not yet take any side in the controversy, but will await the decision of the mature judgment of the solons of apiculture AFTER a thorough discussion of the question of desirability and practicability.

Alabama now has an organization of apiarists, known as the "The Alabama Bee-Keepers' Association. It was organized last November, and S. G. Wood, of Birmingham, was elected President; Geo. H. Hoyle, of Mobile, Vice-President; and J. M. Jenkins, of Wetumpka, Secretary and Treasurer. The object of the association was declared to be the advancement of the bee-keeping interests of Alabama.

The Secretary desires to have the following notice made public, and we therefore give it a prominent place in this paper:

The association will meet annually, and its next meeting will be at the time and place at which the Alabama State Fair is held, or the call of the President. Any bee-keeper living in Alabama may become a member of the association by forwarding his or her address and 25 cents to the Secretary and Treasurer. The fellowship and co-operation of Alabama bee-keepers is earnestly desired. The Secretary will cheerfully correspond with bee-keepers desiring further information concerning the association, and will mail a copy of the constitution and by-laws to all applicants as soon as printed.

We Keep this Notice standing all the year round: "Always give the name of the Postoffice to which your paper is addressed. Your name cannot be found on our list unless this is done," and yet many ask us to change their address without even mentioning to what Postoffice it has heretofore been sent. It often costs us more to find their old address than they pay for the BEE JOURNAL for a year; as we may have to examine our subscription lists in every State, Province and Territory in North America. Please be more careful in the future, and never omit your name, Postoffice, county and State.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Double Hives for Wintering.

Query, No. 359.—Is it an advantage to winter two or more colonies in one hive? Why are not double hives more generally used? What is their worst disadvantage?—Glenville, Ky.

I can see no practical advantage in this system.—H. D. CUTTING.

I have never practiced such wintering. Some like it; others do not.—G. M. DOOLITTLE.

I do not think it is. The worst disadvantage is that it is often desirable to move one of the colonies to a new location.—G. L. TINKER.

Yes, there is an advantage, as it economizes the packing material, also the labor of packing, when bees are protected upon the summer stands. Their worst disadvantage—and it is a big one—is that the hives hinder in the manipulation of the bees in the working season.—W. Z. HUTCHINSON.

In the case of small colonies it is. Double hives are too inconvenient to manipulate. One colony might require the hive to be manipulated that would very seriously interfere with the other colony.—J. P. H. BROWN.

Double or triple hives have no advantage that we can see. We tried them. Their worst feature is that you cannot disturb one colony without disturbing all that are under the same roof.—DADANT & SON.

I do not think there is any advantage. The disadvantages are in the bother and trouble of changing back and forth, which are enough to keep me from that method.—J. E. POND.

It is an advantage to winter 2 colonies in one hive, but it is more convenient to move two single hives close together than it is to manage so cumbersome a hive as a double hive would be. I have had as many as 6 colonies in a hive. The worst disadvantage was the loss of queens.—C. W. DAYTON.

Yes. Double hives are heavy to handle, and I would not want any thing but a single hive at the time of putting on supers. The use of double hives, however, as laid down in "A Year Among the Bees," I consider of very great advantage.—C. C. MILLER.

They have been used over and over, and discarded. They are not convenient for summer. It is better to put several hives together in the winter. Many do this, and winter their bees very successfully.—A. J. COOK.

In theory it looks as though two or more colonies divided off in the same hive would be to the mutual advantage of the several colonies lodging so closely together; but in practice the plan has not been worth the extra trouble to me. I suppose that the chief objection to a "double hive" is that they are inferior to the single hive for honey producing. I am more and more convinced that the less complication there is about a hive the better it will work. The hive does not gather honey; it is the bees that do the work. Hence the hive that is the most simple and handy to work with, is the best. I am sure that time will prove this to be true.—G. W. DEMAREE.

If one can think of no better way to conserve the heat of a cluster of bees, than to place another cluster by its side, he might do so with some little advantage in that direction. About all the disadvantage there is in double hives, is that they will make the cost of honey production enough more than what it will be by the use of readily movable hives, that their user will be left far behind in the race. It may take time, but I trust all will see it by and by.—JAMES HEDDON.

While "double hives" may be of some advantage in wintering weak colonies, they are too costly and inconvenient for general use.—THE EDITOR.

Removing Propolis Stains.

Query, No. 360.—What is the best way to remove from the fingers propolis and the stain it leaves?—Prof., N. J.

The cheapest and readiest material is kerosene oil.—J. P. H. BROWN.

Good soap and soft water has always answered my purpose.—G. L. TINKER.

I should like an answer to that question myself. I generally let it wear off.—G. M. DOOLITTLE.

Use a little alcohol; it will remove all propolis instantly.—H. D. CUTTING.

Use home-made soap and wash thoroughly in very warm water.—C. W. DAYTON.

I have used naphtha and alcohol, and have also found that rubbing with a piece of pumice-stone would remove the stains.—J. E. POND.

Use a soap that contains some "gritty" material that will scratch it off. I am not certain, but I think alcohol will dissolve the propolis.—W. Z. HUTCHINSON.

Alcohol, linseed oil, turpentine, or ammonia. Alcohol or ammonia are preferred, because they leave no unpleasant smell behind.—DADANT & SON.

The best thing I have tried is soap and warm water, and the friction of a soft corn-cob. The fumes of sulphur will remove vegetable stains. But the stain left by propolis soon disappears without any remedy, if you will not worry about it.—G. W. DEMAREE.

Alcohol takes off propolis very readily; so will spirits of turpentine. It is wonderful to see how a little alcohol will remove the propolis.—A. J. COOK.

Pour a little ammonia on your fingers. You can also take it off by rubbing grease on your fingers and washing in very hot water.—C. C. MILLER.

We have used alcohol for removing the propolis from the fingers, and have always found it very effective.—THE EDITOR.

Rearing Queens on their Heads.

Query, No. 361.—Lately I saw this sentence in the BEE JOURNAL: "Queens cannot be reared standing on their heads." I want to know if this is so, and, if it is, how often should a hive be inverted to accomplish this object during the swarming season?—C. E. B., Ohio.

It is generally believed that queens cannot be reared on their heads. How often to reverse will depend upon circumstances.—H. D. CUTTING.

Queens are "reared" with their heads toward the apex of the cell, which usually points "downward." While thus seemingly "standing on their heads," the latter is protected and supported by a soft, delicate, and most elaborately woven cushion of the finest silk.—J. P. H. BROWN.

"Standing on their heads" is the natural position for queens to be reared. The brood-combs should be inverted every 5 or 7 days. Though I have successfully run an apiary through one season on that plan, I could not determine the exact time.—C. W. DAYTON.

All my experience goes to prove that 999 out of every 1,000 queens are reared "standing on their heads." The other one is in a horizontal position. If stood the other way, heads up, perhaps they might not hatch, but I have little or no experience along that line.—G. M. DOOLITTLE.

I am not so anxious to prevent natural swarming as to practice inversion for the purpose, even if it is effectual. I believe it to be an unreliable preventive, although the bees complete no cells. Swarms often issue without having started queen-cells.—G. L. TINKER.

I think I have seen one whom I consider good authority state that inverting once a week will prevent swarming, but if it be true that bees will sometimes swarm without starting queen-cells at all, how can inverting prevent such bees from swarming? I have, however, had no experience in the matter.—C. C. MILLER.

We find that turning causes the cells to be destroyed, and seems to cause bees to give up swarming. The frequency would depend upon circumstances. I should have little fear of swarming if hives were inverted every week, though we found one inversion enough in every case. The bees gave it up, and went pell-mell into the sections.—A. J. COOK.

In opening queen-cells I have never found the queens standing in any other position than "on their heads." If queen-cells were always built in such a position that inversion would destroy the inmates, no queens could be reared if the combs were inverted about once a week. If inversion prevents swarming, I think it is rather by awaking new determinations among the bees, than by killing embryo queens.—W. Z. HUTCHINSON.

Inverting is impracticable, in my opinion, and the trouble stated in the query is the least connected with the method. If an intimation was given as to whether it is desired to rear queens or not, the question might be answered by some one who had made a test in that particular direction. I should say, do not invert at all.—J. E. POND.

I suppose the person who wrote that "queens cannot be reared standing on their heads," was aiming to be witty, but he spoke the truth notwithstanding. A majority of queens are reared with their heads down, but not "standing on their heads." Reversing the hive will not destroy young queens unless they are handled so roughly that the young queens are dislodged from their natural position in the cells while in the larval or chrysalis state. Reversing cannot be depended upon to prevent swarming. I mean that the plan is not practicable, and perhaps no other plan is. We must prevent *increase*, not swarming.—G. W. DEMAREE.

While I do not claim to have made special and thorough tests of inverting, as applied to the destruction of queen pupa or nymph, from what I have observed while largely experimenting with inverting for other purposes, I have concluded that it will not result in a practical method of controlling swarming.—JAMES HEDDON.

Queens are *not* reared "standing on their heads." Though the head points downwards, their bodies are *upheld* by fine silken cords, and protected by elaborately-constructed net-work.—THE EDITOR.

Premium Worth Having.—The New York World and the AMERICAN BEE JOURNAL (both weekly) will be sent for one year to any address in North America for \$2.00. And in addition PRESENT to every such CLUB SUBSCRIBER a "History of the United States," containing 320 pages and 22 fine engravings, bound in leather and gilt.

This "History" will be sent FREE by express at the subscriber's expense; or will be mailed for 10 cents extra to any place in the United States or Canada.

It is arranged chronologically by years, from 1492 to 1885. Every event is narrated in the order of its date. These are not confined, as in other works, to political matters, but embrace every branch of human action.

This premium is worth the whole of the money sent for both periodicals, and should induce thousands to subscribe, and thus get two unrivalled weeklies for nothing.

Correspondence.

Explanatory.—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark ⊙ indicates that the apiarist is located near the center of the State named; ♂ north of the center; ♀ south; ♂ east; ♀ west; and this ♂ northeast; ♀ northwest; ♂ southeast; and ♀ southwest of the center of the State mentioned.

Apicultural Legislation.

J. F. LATHAM.

When viewed from a strictly practical stand-point, it seems that the pursuit of bee-keeping, as an industrial vocation, presents but very limited requirements that demand special legislation; surely not to the extent called for by other agrarian pursuits. While foraging, the bee is beyond the control of its master—a free rover, free in its flight, from artificially prescribed limits. The food of the bee, when derived from the floral adornments of Nature, is but a spontaneous effusion, the bounty of the One Cause, a wonder-working demonstration of occult power, over which the "lords of creation" can exercise no control, and who ought to exercise sufficient rationality to deter a desire to control.

Within the bounds of the apiary the bee is a possession of the proprietor, and directly or indirectly under his control. When needed, the bee-keeper should possess sufficient endowments to constitute "legislative" function commensurate to the surroundings—the direct exigencies of the bee-yard. If an apiary be located sufficiently near the property or place of legitimate employment of another as to actually endanger the lives or well-being of the occupants, it seems that a remedy exists in the application of "common law," by which such irregularities may be adjusted, as often called for in other pursuits. Mr. A possesses no legal or moral right to keep bees on his own land in the shadow of the fence separating them from Mr. B's barn-yard, which is in constant use for yarding his domestic animals; or sufficiently near his dwelling-house and its surroundings to be a constant annoyance to the occupants, even if he (A) is entitled to the nominal credit of "priority of location," as referring to homestead rights. Neither has B the right to establish a stock-yard by the side of A's apiary. The conveniences of public travel are entitled to a like consideration. No one is obliged to turn from the highway, while pursuing a legitimate calling, to avoid a nuisance existing on private property, whether such a nuisance be constituted in a colony of bees, a mad bull, or any other endangering obstacle.

As to the feasibility of legislation, granting and securing to a single apiarist exclusive territorial rights beyond his private possessions, but little need be said or written. Special law-making is at best but too often the result of preconceived aggressions; an attempt to reduce to servility the surplus energy of vigorous industry, for the maintenance of indolence, imbecility, and the gratification of a depraved thirst for notoriety. "The earth, and the fullness thereof" are not, and can never be made the specific possessions of any single individual, class or association of individuals. The laborer is worthy of the meat which the Eternal edict imperatively demands that he shall eat by the sweat of his brow, minus restrictions by Divine legislation. Feudal attributes have not as yet become requisites of modern bee-keeping. Every yeoman has a right to keep bees on his possessions, if he chooses so to do; certainly not beyond.

In a radical aspect, it seems that if an apiarist possessing but an acre of land could be legislated into the control of all the bee-pasturage within the circumscribed limits of the flight of his bees, the tenor of the same legislation would give him control of all the vegetation that might produce nectar within the same limits; even depriving a neighbor, a mile distant, the right to cut basswood lumber, or destroy the nectar-producing shrubs and weeds that were overgrowing his grazing land. A person not characteristically qualified to make a success of bee-keeping, as a matter of course must succumb to the "inevitable," leaving the blank of his departure to be filled by the fittest survival. From the above fact it is quite certain that the genuine apiarist will never lack room in which to exercise his talents; and that, too, without the need of a "special legislation."

For the American Bee Journal.

The Honey-Producers' Association.

EUGENE SECOR.

On page 774 of the AMERICAN BEE JOURNAL for 1886, Mr. M. M. Baldridge discusses the above subject in connection with several others along the same line. While an association of that character might do some good, it would not, in my judgment, be a panacea for all our ills. It seems to me that the commission men come in for more than their share of criticism. I do not believe them all to be angels, by any means, but perhaps on a closer acquaintance we might be able to discover where wings ought to be. They do not fix the price of honey—or if they do, it is the producer's fault in not confining them to a selling price. If I send a consignment of honey to a commission house, and write them to hold it for a certain price, or await further orders, I think they would follow instructions if they were a reputable firm—and none others should be trusted. If they did

not, I should probably not send them any more.

The trouble is, one of my neighbors, who is not a millionaire, and who might want to use the money for his crop, sends the same house his honey also, and writes them that he wants it worked off as soon as possible, even if they have to shade the price a little, as he has a note at the bank which must be met at a certain date. The commission men will probably sell this man's honey first. The grocer who bought it can undersell the one who would buy mine. Not to be outdone by his neighbor grocer he bears the market in order to get his as cheaply as the other man did. And so it goes. The trouble is in the producers who do not fix their own prices. Mr. Baldrige says the same thing. Now what are we going to do about it? It seems just as impossible to fix the price of honey in the world's markets as it is to fix the price of wheat.

I live in the "wheat belt." I know there have been more bushels of wheat sold during the past year at less than the cost of production than above it. The farmers know it too, but what folly it is to talk of getting these farmers to combine and hold their wheat for paying prices! They must either sell it or the sheriff will. Even if they *could* hold it, they lack organization and unity of purpose. And you might preach the benefits of a producers' association to them as long as Noah preached to the antediluvians, and few would be saved but the preacher. They would not come to his meeting. They would not read his tracts. So with honey-producers. One out of a hundred might identify himself with the organization, but where are the ninety and nine? Slumbering in the security of blissful ignorance. Seventy-five of the number will never hear of it, because they do not read the bee-papers. They will go on dicking their honey off to Tom, Dick and Harry, for what they can get, until it becomes so cheap that they will take no interest whatever in the business, and let their bees die. The law of the survival of the fittest will in time fix things.

Butter is a staple article. It has a market value governed by supply and demand, the same as wheat; yet thousands of pounds of what is called butter are annually sold at less than 10 cents per pound—below the cost of production. Butter is also a luxury. Wealthy people are willing to pay a fancy price for a really fine article. Some dairymen know how to "get there," and supply this demand. They make money while the other fellows eke out an existence competing with "oleo." Honey is *not* a staple. The only way to sell it is to reach the palate. We have very little trouble selling our best grades of honey at a price above cost of production.

I do not see any other way out of these low prices than to produce the best at the lowest possible cost, and await the result. If honey is cheaper than it used to be, we produce it more cheaply. The best appliances and the best methods will win. Let us "grin

and bear it." They who *stick* are the one's to succeed. Remember Lot's wife.

Now as to the reports of honey in the bee-papers, I do not see what harm that does. Almost every other thing is quoted in the produce papers. Are hogs any cheaper because the daily papers quote them?

Forest City, § Iowa.

For the American Bee Journal.

Apicultural Progress.

JAMES HEDDON.

Whoever looks back over the great progress of apiculture during the last two decades, will not fail to discover that inseparably connected with this progress is the one of mechanical invention. Perhaps I might well have said that this invention constitutes the major portion of that progress. Yes, surely, a look backward verifies the statement. Where would we be to-day had the Langstroth hive, honey-extractor, comb foundation machine, bellows smoker, under beveled honey-knife, and scores of lesser manufactures never been devised?

When looking outside of our art, how readily we discover that inventions have enabled us to live better and have more comforts of life than the kings and queens of a century ago. It is no wonder that civilized nations have devised ways and means to stimulate these inventions by way of patent offices. There are, however, serious objections to these offices, and the laws and rulings connected with them. They are expensive (sometimes vastly so), and they beget falsehood and perjury.

Two or three years ago I wrote an article in *Gleanings* discussing the feasibility of establishing among beekeepers an honorary patent system. Some one smiled and said: "Oh! pshaw, no apicultural inventor could realize protection through any such arrangement. We have too many dishonest men in our ranks." I am aware that there are dishonest beekeepers, but they are not in the majority by any means, and among the more intelligent who lead the van, I am glad to say they are largely in the minority. Before I wrote that article for *Gleanings*, I looked the ground over carefully—I have been looking it over ever since, and to day I feel positive that if the honorable men of our class—men who readily see or can be shown the right, will (and I believe they will) use their influence for right and justice, we can inaugurate a protective system not only cheaper, but much better, and freer from fraud than the patent system which is now trying to protect the world's inventors in their right to the results of their own labor. The patent office now stands in the way of moral protection. While we all know that laws governing conduct are absolutely necessary, the student of human nature does not fail to discover that these necessary laws have a tendency to remove from the human heart a

part of the deep convictions of conscience.

Apropos to the above I have had to smile at the ignorance or frown on the thievishness of a few who have sent letters asking a question that cannot be answered this side of an expensive suit in the United States courts: "What will your patent-claims hold?" The best answer to such a question—the most appropriate answer—may be found in the following illustration:

When this country was new, and nearly all the land belonged to the government, the settlers very few, and the timber free to any taker, a resident named Joseph Industry conceived the idea of chopping a large quantity of wood, which he thought would be needed by a railroad, which he felt sure must come that way in a few years. He began the work of cording up the wood as fast as spare time from the farm would admit, and after a few years had a pile 4 feet high and 200 rods long. By and by he noticed parties taking wood from different places in the pile. Several times he asked those who had taken wood if they did not know that this wood was the result of his labor, and rightfully belonged to him; and they said "y-e-s," but it was "awful good" wood, much better than their own, and they did not think he would care if they took a *little*; that they could have chopped down the same trees had they chosen to do so.

Finally he shouldered his rifle, making up his mind to protect his wood at all hazards. One day while sitting on the pile, he saw a neighbor, Dave Indolence, carrying wood away, and called to him to stop. Dave answered by asking him how far his rifle would carry up. Joseph replied that its range was about 80 rods; when Dave said, "If that is your claims' I'll take the wood and you can fire away, for its a hundred rods down here; you see you didn't fix up the results of your labor in the right shape."

I find that it is a too common opinion that it is only by virtue of law that property in invention, exists. Certainly we know that *legal* property—property which the law will protect—exists in invention only by virtue of that law; but morally, property in invention is a law in nature, and the *right* of property in invention will be recognized by every honest man the moment he realizes that fact.

Property never was nor never will be produced by law; it must be the product of labor. It must be earned. There are many men who legally own a large amount of wealth who never earned it, but surely some one did. If property could be created by law, our government might support all its people in that way; aye, legislate them all rich.

If property in invention did not exist in the nature of things, a statute to protect such property by law would amount to legal robbery.

In the article for *Gleanings*, which I have referred to, I proposed for consideration something like this: In the main we would follow the rulings of the patent office. Regarding the question of prior invention, we would

not spend a minute nor a cent discussing it. We would give the right to the prior publisher for reasons of justice, practicability and morality. 1. An inventor does nothing for the public until he publishes his invention; consequently they owe him nothing before that time. 2. It would do away with all falsehood and perjury, claiming the invention to be old. If it could not be shown in publications, and that it had not been abandoned, the claim would hold good; and if it could, it would not cost a dollar to show it, and invalidate that claim.

There are other equally superior rulings that we might have, and as our class is so small, and our publications (which form the popular sentiment) so few in number, I believe such an honorary inventor's-rights-system, and also wholesome regulations regarding the marketing of our honey, and receiving what it is worth, "priority of location," etc., can all be fixed successfully and greatly to our advantage. I am in favor of responding to Mr. Baldrige's call, and desire to hear the honest expressions of those who are more interested in justice and the welfare of our class, than in simple controversy.

Dowagiac, 9 Mich.

For the American Bee Journal.

The Marketing of Honey.

N. J. SHEPHERD.

In selling almost any kind of farm products there is considerable difference in the price received, and in a great majority of cases a considerable proportion of this is due to the way or condition in which products are sent to market. Honey is no exception, and in many cases the cause of the low prices received is largely due to the condition in which it is sent to market.

Like all other products, it must be made neat and attractive in order to sell to the best advantage. Boxes or frames made so that the comb will present a clean, neat appearance, aids materially in securing a good price. To send honey to market, as is often done, taken out of the frames or boxes and dumped into a jar or bucket, cut or broken into convenient pieces, and allowing a goodly portion of the best to run out and settle at the bottom; then to sell the comb to one purchaser and the liquid honey to another, and that not clear of small bits of comb, is certain to give dissatisfaction to the purchasers, and a less quantity will supply the demand. Taken generally, if properly managed, the home market is the best. Of course this may be easily overstocked where there are quite a number engaged in the business in the same neighborhood, and of course another market must be found.

Many new purchasers are either made permanent or lost entirely by the first purchase, and if we expect to build up a paying business every reasonable effort must be made to please

our customers, so that they may be made good consumers. The more consumers we can make the larger the demand, and the readier the sale the better prices we can secure. When it can be avoided, the comb should not be broken, unless it is cut up and put into glasses so that an equal amount of liquid will be sold with the comb; or the comb sold entire. If boxes are used, have them neatly made of planed lumber. Shingles are often rough, and if covered in some places with old comb, it hardly presents an attractive appearance sufficient to induce rapid sales. We are all interested in this, as it aids in making sales.

Disturbing Bees in the Brood-Chamber.

VICTOR W. CLOUGH.

The criticism on page 810 of the BEE JOURNAL for 1886, concerning the "non-swarming system," forcibly reminds me of my neighbor who says: "Bees! Well, I should say so; I have known all about them all my life. I want no bee-literature, or care to investigate any improved hives; the old kind are good enough for me." This old veteran has about 20 colonies, and for his whole apiary I would not give him one non-swarming hive. It seems needless to explain why. He is continually mourning over the poor season, no profit in bees, etc. Is there not a reason for all things? His bees have the same latitude, same fields, and exactly the same chance as mine, excepting in the house, which divides the difference. There is no season that my bees fail to procure a good yield of honey, and they are one of the most profitable investments I have. I never have any loss in winter. But one of my neighbors, who persists in overhauling the brood-chamber, in one winter lost 40 colonies.

I have a few colonies in common hives that I manipulate for surplus honey, their productions being from 50 to 100 pounds, and cast one and two swarms each. In the last three years those in the non-swarming hives have never swarmed, and produced 250 pounds of honey. All these are arranged in the same orchard, the bees visit the same fields, and why the difference in the yields, if not in the construction of the hives?

The critic recommends a "frequent disturbing of the brood-chamber" for a large surplus of honey. I wonder if he advocates punching a hen's nest in order to secure a greater hatch! One is as reasonable as the other. What a desirable job it would be, if the apiary contained a hundred or more colonies. This "frequent disturbing" is work which I do away with, and those who have faith in its usefulness are the ones I wish to compare notes with.

With my system I never move a brood-frame or disturb my bees in any way, only to remove the full sections and replace with empty ones. Here is what makes bee-keeping so easy

and simple. All the difficulties and inconveniences of swarming are laid aside, and this is all left to the hive to perform, which it faithfully accomplishes.

Geneseo, N. Y.

For the American Bee Journal.

Basswood vs. Linden.

S. T. PETTIT.

On page 805 of the AMERICAN BEE JOURNAL for 1886, appears a short report on the above heading, in which Dr. A. B. Mason complains that I take the ground in the *Canadian Bee Journal* that Canadian basswood honey is superior to the United States basswood honey. The report reads as follows:

"The Doctor thought it perfectly right to make Canadian articles distinctively Canadian, but it should not be done by casting unwarranted stigmas upon our productions. We should not try to elevate ourselves by pulling down others." Most certainly, I fully agree with the Doctor, that we should not cast "unwarranted stigmas" upon the productions of others; "nor try to elevate ourselves by pulling down others."

I confess that I am not a little surprised that any one, especially Dr. Mason, should disagree with me in this matter. I am fully persuaded that if the Doctor will take the trouble to get average samples of basswood honey from the different points of the United States, especially from near the southern limit at which this tree produces honey, and compare them with Canadian linden honey, that he will be the first to acknowledge the superiority of Canadian linden honey.

Mr. Muth, than whom perhaps no other man in the world handles more honey, classes United States basswood honey with late dark honey, and prices it accordingly. Before taking this ground, I took a great deal of pains to understand the matter, and consequently I feel quite solid in the position that I have taken. Without a question, basswood honey taken in the United States in our latitude, when the bees gather it under favorable circumstances, that is, not gathering at the same time inferior honey from other sources, the article is of the very best quality, and quite equal to Canadian honey. But it should be kept in mind that this strip or belt bears but a small proportion to that of the whole of the United States. In writing the article complained of I referred to the United States as a whole.

There was honey at the Industrial and Colonial Exhibition at London, England, from nearly all the British Colonies, and I am proud to say that samples of Canadian linden honey were the clearest and brightest on exhibition. Canadians would be very sorry indeed to have their fine, bright, sparkling linden honey classed with late, dark honey, and the price ruled down to the price of that article. Mr.

Macpherson did right in saying that there was no intention to cast a slur upon American honey. Not at all; I simply stated what I still believe to be a fact, and so, of course, I have no apology to offer.

Belmont, Ont.

[United States basswood honey is by no means *dark*, and is not so classed in this city. That it varies in different localities is true, but it is never dark.—ED.]

For the American Bee Journal.

Developing the Honey Market.

R. F. HOLTERMANN.

The remark in Mr. Baldrige's article on page 774 of the BEE JOURNAL for 1886, which, it appears to me, requires consideration, is that in regard to commission men. He states that they are responsible, to a great extent, for the present low prices of honey. Look, for a moment, at the great fall in the price of honey in Canada, as in the United States, for the last ten years. I do not believe that one per cent. of the Canadian honey has been handled and sold on commission; in fact, I am safe in saying that it is a practice which we have not resorted to, and in spite of that, surely no one will deny that our prices are low, and have dropped as low, proportionately, for about ten years, as in the United States.

In regard to allowing retailers to sell only at a certain figure, as do flour producers on Fox river, I need only to say honey has not yet become flour; it may be on the road to it—let us hope so at least; but families cannot do without flour. Our home market for honey has, as yet, to be developed, and I know it is quite difficult enough to do this, and if we offer such obstructions as indicated, we must suffer by hindering the development of our market. It is right enough to endeavor to secure a uniform retail price for a uniform article, but compulsion is not the method to be adopted.

As to what our aim should be, it is to sell as low as we are compelled to do, and have a fair remuneration for our product. This question will right itself; honey will find that level, and if it is below it now, the cheapness will develop the market, and eventually those not able (through locality, ability, or other circumstances) to sell as cheaply as others, will drop out; the remainder, or more properly, those under favorable circumstances, will remain and secure remunerative prices. But this is aside from the question at issue. We can never by any organization regulate the price of honey. Those likely to become members of such an organization are the same who do not demoralize the market; the others you cannot reach.

In Canada, whatever your movements are for the advancement of apiculture, they are outside of it, and they do just as they see fit, and you find you are behind, for you have only

tried to do as you saw fit. On the other hand, I would not say beneficial results may not be obtained by an organization, which would have for its aim the union of bee-keepers in marketing their honey.

In every large city let a wholesale and retail (or retail only) honey-store be started by the honey producers' company, and competent persons put in charge to supply the existing demand for honey, and make every effort to create a further demand. Then let the organization have an early report of the honey secured for the season, etc. What we will secure by this method is this: The bee-keepers themselves will become the retailers in our cities, and they can put a stop to any practice injurious to their interests, and the middle-men will be greatly done away with; and without loss to the bee-keepers they can cheapen honey for the consumer. These two points alone are of immense value.

Brantford, Ont.

For the American Bee Journal.

Controlling the Honey Market, etc.

L. N. TONGUE.

I am glad to see bee-men coming forward on this important subject. The question to decide is, how can the object be accomplished so as to effectually take the honey out of the hands of those who ruin the price of honey? My plan is this: Let the Bee-Keepers Union have control of the matter. From statistics they can ascertain the honey crop next season, so as to fix a price that will pay the producer a reasonable compensation for his labor and capital, having in view the interest of the consumer as well. There is reason in all things, and I believe the Manager and Advisory Board of the Bee-Keepers' Union are as well qualified to judge correctly in the matter as any. (I would not wish to be understood to say that others are not as well qualified.) Some may ask, how can the market be controlled in this way? Why, just have leaflets distributed to each member of the Union, giving prices fixed upon by the managers.

The next thing to be done is this: Let each member canvass his locality, and buy up all the surplus from small producers, putting the same into the hands of middle-men to sell at a price fixed by the managers, thereby controlling the market most effectually. How about the funds to purchase this honey? As for my part, I would rather pay two dollars for this purpose than to pay one dollar to fight lawsuits. How about the men that are compelled to sell? Why, advance a reasonable sum, holding their crop as collateral security.

How is it, bee-men? Is this plan feasible? If not, give a better one. It seems to me something might be done to secure a reasonable price for our honey, and stop flooding the market by small producers.

Bee-men are asked their opinions as to publishing quotations on the honey

market. My answer is this: If the plan proposed above, or some better one, is established, how is the wholesale man going to get honey to sell? This plan is going to bring the wholesale buyer *at your door*.

LEGISLATION — PRIORITY QUESTION.

In regard to the priority question, I for one am utterly opposed to any such legislation. I have no patience to write upon the question. I say down with it. In my opinion such a law would be unconstitutional.

Wonewoc, Wis.

For the American Bee Journal.

Successful Bee-Keeping, etc.

L. J. KEYES.

I have been interested in reading the reports of bee-keepers from different parts of the country, as to the amount of honey produced by given colonies of bees, and must say that I am somewhat surprised that none exceed my own efforts, taking into consideration the fact that three years is the extent of my experience in manipulating bees for honey. In this section of country the past season has fallen short of the average for honey, yet from 18 colonies put out in the spring, I harvested a few pounds over 1,400 pounds of comb honey in one-pound sections, and increased the number of colonies to 35, which I have put into the cellar in the finest condition possible.

I have come to this conclusion, by observation, that one hour's neglect in the beighth of the honey harvest is a loss to the bee-keeper. As soon as sections are filled they should be raised, giving room for work below while the capping is going on above. The hive I use contains eight frames, and is somewhat smaller than the Langstroth. Ah, some of the older members of the fraternity say, too small, too small; but remember this country is not California, nor Florida, but away up north; and, again, where are your 10-frame hives that go very far in advance of my small hives?

My section-cases are to exactly fit each other, and each section is provided with a full-sized tin-divider which makes them queen-excluding, hence there is no brood in the sections. I allow natural swarming, removing the old hive at the proper time to secure all returning bees in the new one. The section-cases are removed from the old hive and placed on others where the work will be continued, and thus work once begun in the sections it never ceases until completed, the capping being done 2 or 3 stories higher than where the honey was put in.

For wintering I use a rim the size of the top of the hive, 2 inches high (or wide), covered with burlap on both sides, and filled with dry forest leaves. The hives are tiered up, and the entrance left wide open. This plan of wintering suits me because it proves safe, which is all any one could wish.

In regard to the market I would say, if the National Bee-Keepers' Society would place a man in every large market to sell the members' produce, thus controlling the price, and take it out of the hands of commission men, I would join it and help support it, for it is so very unsatisfactory to deal with those who care nothing for your goods, so long as they get ahead of their competitors, and get their commission.

Nora Springs, 3 Iowa.

For the American Bee Journal.

U. S. Honey-Producers' Association.

SAMUEL RAU.

The idea of a United States Honey-Producers' Association, as advanced by M. M. Baldrige, meets, in the main, my hearty approval, and if not too late, I second the motion for immediate action. Something of this kind is certainly the "one thing needful" for our pursuit just now. We need more thorough organization for our own protection. With very few exceptions, all the other pursuits are organized, from the doctors who stand by the cradle of our infancy, to the funeral directors who make the last grab at us as we go down to that bourne from whence no traveler e'er returns. This organization could gather statistics of the honey-yields in the different sections of our country, and fix prices accordingly. There would be, as a matter of course, some obstacles to overcome, but "where there is a will there is a way," and they can be surmounted.

The nail manufacturers, makers of stove castings, the tile men, manufacturers of stamped tin-ware, and many others that I could mention, regulate the prices of their productions quite successfully in this way, and why cannot we do the same? Then this organization would be the proper authority to give market quotations and reports. Leaving honey on commission is practiced some in this locality, and I gave it a trial last fall, but it was not successful with me. I went to a reliable party in a neighboring town, who was engaged in the drug and grocery business, and proposed to furnish him good honey in neat cases; he was to sell it at not exceeding 20 cents a pound, and pay me 15 cents per pound for what he sold. He accepted my proposition, and I furnished him the honey. But a fence-corner bee-keeper, who had a few colonies of bees, and kept a jewelry store, placed a few pounds of honey in his show-window and labeled it "16 cents per pound." His honey was inferior to mine, but resulted in the demoralization of the honey-trade in that town; and after leaving my honey on sale three months, only one pound of it was sold. So I departed for more inviting fields.

It seems to be the little birds that spoil the grapes. Those who have a few colonies of bees in a fence-corner behind the pig-pen, bring their honey to market in a slovenly condition, sell

at other people's prices, and thus ruin the market. I refer to the home trade. We should be able to produce finer honey, and sooner or later, teach every one to distinguish between superior and inferior grades. I see no good reason why I should sell my fine-bred and well-developed horse for the same price that McCracken sold his ring-boned and spavined nag up at Cobtown; neither will I sell first-class honey for what some one sold third-class.

I hope to see immediate action taken in this matter. In a multitude of counsel there is wisdom.

Columbiana, 6 Ohio.

For the American Bee Journal.

Uniform Price for Honey.

B. H. STANDISH.

I have been so busy producing honey and trying to make a living out of it, that I never have taken time to write an article for publication, and I only do so now because a subject of vital importance to me has been broached. In looking about, it is not difficult to find other occupations in which men, with no more capital or tact, are more sure of fair pay for services, than bee-keepers; but I cannot enter any of those occupations. I have spent a long and expensive apprenticeship in this. I find my capital invested in a business for which there is seldom a buyer. If such should come to me, I would have to study up some other business before it would be justice to my family to embark in it. I am in it, and like many others, I am forced to stay in it, as a doctor is forced to stay in his profession. Therefore I wish to help to correct its evils.

A man in Iowa says that he is glad that honey is being sold at 10 cents per pound. Perhaps the bee-keepers of that State can sell their honey without loss at that price this year. But how will it be next year? Unless producers do something about it, prices will be about the same then—at least not much higher—though the crop be one-fourth of the present crop. It has been my experience that every other year, on an average, brings either a light crop or a failure. Now if we sell the full crops at the cost of production, how are we to pay for the family crust out of the average?

I intend to have the commission merchants with whom I deal, sign an express contract, or I will not send them honey next year. This contract must have the following three points in it: 1. I am to fix the price at which the honey may be sold. 2. They must accept my weights. 3. If the honey is not sold I am at the expiration of 60 or 90 days, I am to have the privilege of transferring it, by paying freight and cartage.

Now, what I want is an Estimating Committee for the Mississippi valley; one for the Atlantic coast; and one for the Pacific coast, composed of prominent and active bee-keepers who are to estimate the size of the

crop before shipping-time next year, and to fix a proper price for the same; issuing printed circulars to me, and to every other honey-producer in the land, with the above contract, or its equivalent, to be sent by producers to all commission men for signature, before shipments are made to them. This established price should be printed in all bee-papers instead of the present tricky system. Bee-keepers can be reached through the bee-papers, for probably nine-tenths of all prominent producers take them. These producers in nearly all cases would adopt the common price of the Estimating Committee.

Commission men then would be restrained from underbidding one another. Also those who are dishonest would be prevented, by the terms of the written contract, from making false returns. Prices in the large centres of trade would be fixed—by producers, not by sellers. Prices in small towns are largely influenced by prices in commercial centres. We could then have something to say about the prices in our home market.

Let me illustrate the influence of the present commission system on our home markets by the following:

I produce honey enough to supply our little village, and I usually have done so, after a few smaller producers have sold out. This year I placed some honey in a grocery on sale. A traveling commission man saw it, and the following conversation between him and the groceryman followed: "What do you pay for that honey?" "I pay 14 cents per pound." "Well, I will sell you honey and warrant it just as good in every particular at 10 cents per pound. You see it is put into our hands on commission, and it does not make any difference to us at what price we sell it. We get our commission just the same." The grocer ordered a year's supply, and when it came it was as nice as was ever sold; but how much will my brother bee-keepers down near Rockford get for it? It needs no argument, but experience, to convince bee-keepers that not only their efforts to bolster up the market, but also the efforts of honorable commission men are paralyzed by the unscrupulous, who receive honey without firm instructions as to its sale.

Now is the time to appoint an Estimating Committee for next year. The working expenses of this committee need not exceed 10 cents per each producer. What do others think about it?

SELECTIONS FROM OUR LETTER BOX

Organization for Honey-Producers.

—S. H. Mallory, Decatur, 9 Mich., on Dec. 31, 1886, writes :

I am heartily in favor of a honey producers' association, but I am doubtful about ever controlling the honey market. There are too many of the slipshod class of bee-keepers to think of buying them out, as Mr. Baldrige suggests. But there are various ways in which such a society might do good. But I think that bee-keepers should be thoroughly organized; and the sooner the better.

The Market Reports.—John Conser, Glenn, 6 Kaus., says :

In regard to excluding the market reports of honey, given by the commission men in bee-papers, I say yes, so far as commission men are concerned. We have been damaged by their reports, as I think they make the prices to suit their business. I think that a good way to get correct reports, would be to let the secretaries of the bee-associations give the monthly reports in the leading bee-papers.

A Little Bee-Man's Report.—Vincent Quinn, Penn Yan, 10 N. Y., writes :

I thought I would send in my report. Pa gave me one Italian colony in May. I beat pa, for I picked out his best colony in the yard. I got 60 pounds of honey, and it cast one swarm. Pa helped me to rear three queens to form nuclei, and I built them up to strong colonies. I now have 5 colonies in the cellar, and they are doing well.

Bees in a Green-House Cellar.—Joseph Heacock, Jenkintown, 6 Pa., on Jan. 1, 1887, writes :

I have my bees in one end of a green-house cellar. In the other end is a 10-horse-power steam boiler. A fire is kept up day and night from fall to spring for heating the green-house. A partition made of boards extends across the cellar between the bees and the boiler, and this is covered on one

side with black, tarred roofing-paper. Where the bees are, it is as dark as in any dungeon—no ray of light can penetrate it. It is entirely below ground, but very dry, and the temperature remains at about 60° all the time. The bees are quiet at all times. I have just been in to see them. They came out on the alighting-board to see what I wanted, the same as they do when approached on a summer evening with a light. I have had bees for about 10 years, but I never gave them any attention until the past summer. In December, 1885, I found that some of my colonies were almost without food. I put up the partition in the cellar, took in the light colonies and fed them. The result was that they came out very strong last spring, while those that were left on the summer stands were very weak until almost midsummer.

Bees in Good Condition.—John D. Abel, Forest City, 10 Mo., on Dec. 30, 1886, writes :

I have 21 colonies on the summer stands, not packed, but with plenty of food for winter. I got scarcely any honey last summer. I intend to place one and two pound sections on all the hives in the spring. I place a thick paper on the hive, then the top-board upon the paper. My bees seem to be in good condition now.

Bees in a Clamp.—A. McInnes, London, Ont., on Jan. 3, 1887, says :

I have 13 colonies in a clamp. The clamp never needs to be disturbed in winter or summer. It always has the same appearance. I keep the temperature from 40° to 50°, Fahr. My clamp is more for spring, as I can keep the temperature at 60° or 70°, or any degree desired. I have 4 colonies that are very weak; there was only about one-half of a pound of bees in some of them. I am too near the city, and the bees get into the candy shops in the fall of the year and get lost. We are having very cold weather and lots of snow. My clamp is covered completely with snow. I can see the temperature every morning. The cold weather does not seem to lower it more than 1 or 2 degrees a day.

Excellent Results, etc.—Elias Fox, Hillsborough, 10 Wis., on Dec. 28, 1886, writes :

I send you a photograph of my Italian apiary, consisting of 60 colonies; also of my mother, myself and family, and my dwelling, work-shop and ice-house. On April 15, 1886, I took from my cellar 40 very weak colonies. On April 25 I was called away for ten days, and during the time it turned cold, and my bees dwindled so that on May 13 my 40 hives contained probably enough bees to make 5 good colonies. I then bought 2 more, increased the whole to 60, and took 3,400 pounds of honey, and my bees have more honey than they will consume. One colony gave me 130 pounds of fine honey in sections, and a fine

swarm, which gave me 50 pounds of extracted honey. Two other colonies gave me over 200 pounds each, and a fine swarm on July 4. From these 2 colonies I took 75 pounds of comb honey, and each had at least 40 pounds when put into the cellar on Nov. 15. I had some colonies that gave me no surplus at all, and some but little, but on the whole I think they did well, considering the condition they were in last spring.

[The "photo" is a nice one, and is placed in the Bee-Keepers' Album on our desk. With your bright-looking wife and three children, matronly mother, nice home and bees, you ought to be extremely happy.—ED.]

Fixed Price for Honey.—Joel Helsler, Huntington, 6 Ind., writes :

In regard to a fixed price for honey in the United States, I would say, 16 cents per pound for choice comb honey, and 12 cents per pound for extracted.

Farmer Bee-Keepers, etc.—Wm. Robson, Rolla, 10 Mo., on Jan. 1, 1887, writes :

For 20 years I have not known honey so low in price as during the past season. For the past 14 years I have been handling bees here, and I must say that I have never known white clover to yield so much honey as it did through June, and up to July 15. The farmers who happened to have a colony or two were very much elated over their surplus honey; some brought it to the stores in wash-boilers, some in wash-tubs and pails, utensils that looked as though they were for other purposes than being besmeared and daubed with such an unsightly mass of comb and honey; for which they received in store pay from 10 to 12½ cents per pound. Consequently the market was not as good as in former years, for those who have been trying to tempt the taste with their one and two pound sections of honey. This question is often asked of me: "Why do you ask such a large price for your honey? Three pounds for half a dollar is too much. I can get it at the stores for a bit." (meaning 12½ cents). Some people would try to make a person believe that if it was honey that was enough; but for my part, give me something else besides wash-tub honey. My bees have been put into winter quarters with ample stores, but not as strong in bees as I would like.

Splendid Season and Crop.—S. J. Church & Son, Cedar Rapids, 6 Iowa, on Dec. 30, 1886, write :

From 93 colonies, spring count, we obtained 11,000 pounds of honey, and 50 pounds of beeswax, and increased them to 130 colonies. All are wintering nicely in a cellar 12x12x7 feet, with the temperature varying from 40° to 50° above zero, but the most of

the time at 45° above, which we think is about right. Our honey was all extracted but 2,000 pounds, and nearly all was sold in our home market; one bakery took the bulk of it at \$6 per 100 pounds in barrels. Our comb honey sold for 10 cents per pound to grocers. We saved for spring feeding in the frames 600 pounds. The average per colony, spring count, is about 120 pounds. It was the best season and best crop we ever had. We worked on the tiering-up plan.

Poor Season for Honey.—S. H. Moss, Colchester, Ills., on Dec. 29, 1886, says:

I began in the spring of 1886 with 70 colonies. I have 120 packed for winter in good condition. My honey crop was 2,800 pounds of comb honey in sections, and 1,200 pounds of extracted. The season for honey was very poor. White clover was cut short with the dry weather, and the fall crop amounted to nothing.

The Season of 1886.—J. F. McMillan, Healey, Ills., on Dec. 25, 1886, writes:

In December, 1885, I put 35 colonies in the cellar; some of them were very weak, as the fall flow of honey was very poor. I lost some, and after spring dwindling was over I had 22, some of which were weak. As soon as they commenced breeding nicely I equalized them as nearly as I could. I prevented swarming, so I had only 4 swarms, and one absconded. I made 3 nuclei, as I had procured an Italian queen. The flow of honey from fruit bloom and white clover was good, but basswood was nearly a failure. The fall flow was better than last year. I secured 920 pounds of comb honey, and 80 pounds of extracted. Some of my neighbors got but little. My bees are in the cellar now.

Good Report.—7—P. J. England, (23-35), Fancy Prairie, Ills., on Dec. 28, 1886, writes:

I have secured 4,635 pounds of extracted honey, and 15 pounds of comb honey from 23 colonies, spring count. I have also increased my apiary to 35 colonies.

Severely Cold Weather.—M. A. Gill, Viola, Wis., on Dec. 31, 1886, writes:

One morning this week the temperature was 36° below zero. But the outlook is better, for it was up to 25° below zero yesterday. I have one cellar with 107 colonies in, that ranges from 47° to 51°, but another one with only 25 colonies has been down to 34°; but I think I have arranged it to-day so I can keep it above 40°. I would rather, if possible, that the temperature would never touch below 50° after Jan. 1. This may not be orthodox, but I think the facts are pointing that way for this climate. My yield the past season was small, on account of drouth and hail storms

which killed the timber. I had 6,000 pounds of extracted honey, and 600 pounds in one-pound sections. I still intend holding on to the bees, and hoping for that "good time coming."

Use of Separators.—H. M. Moyer, Hill Church, Pa., says:

If one will produce comb honey in the best and most marketable shape each and every year, he must use separators; at least in this locality. I wish that I had never tried to produce honey without separators. In entrance sections it is a little better, but also not satisfactory.

Poor Season.—C. P. Hewett, Kingston, Wis., on Dec. 18, 1886, wrote thus:

The past season was a very poor one. I have Italian, Syrian, and native bees, but have built up a strain of hybrids that are one-third larger than the other bees, and appear to be an established strain. They are the first out in the morning, and the latest out at night.

Governing the Price of Honey.—L. Eastwood, Waterville, O., says:

The first thing I read when I get the BEE JOURNAL is the market reports. Do not throw them out. I do not think the price of honey can be governed by laws or rules, any more than that of any other produce. The small bee-keeper usually "knows it all," and will sell his little mess of poor honey when he thinks best, which really affects the market much the same as "cow-grease" might affect the butter market. This must regulate itself, on the principle of supply and demand, and quality. In regard to "priority of location," I would say that at present I have the field here; but others were here before me, and should new bee-keepers come in, the question would simply be "the survival of the fittest."

The Way to Winter Bees.—F. A. Gibson, Racine, Wis., on Jan. 4, 1887, writes:

All of my colonies wintered last year except three, which were queenless. I doubled up some, sold some, and commenced the spring with 75. They did splendidly the past season. I took 2,000 pounds of comb honey, 6,000 pounds of extracted, and each colony has from 40 to 50 pounds to winter on. I allowed no increase. I have sold all my comb honey at 12 and 15 cents per pound; most of the extracted is sold at from 9 to 12 cents per pound. The bees are doing nicely in the cellar, which is at a temperature of 42° to 45°. I visited them when it was 42°, and found several large clusters hanging below the hive 6 inches. I do not put on bottom-boards in winter. In my estimation this is the way to winter bees. I keep the hives about a foot apart each way, with cushions of sawdust over the bees.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Market is well supplied with all the grades, and the demand is light. Prices are nominal at 11@12c. for white in 1-lb. sections. Fancy white in scant pound sections, 13c. Very little extracted is being sold, and prices range from 4@7c. **BEEWAX.**,—22c. R. A. BURNETT, Dec. 8. 161 South Water St.

NEW YORK.

HONEY.—In consequence of a large stock of comb honey on this market, fancy prices cannot be maintained. Fancy white honey in paper boxes, or glassed, are in better favor here than the unglazed honey, hence the difference in the price. We quote present prices as follows: Fancy white in 1-lb. paper boxes, or glassed, 13c.; same unglazed, 12c., and in 2-lb. glassed sections, 10@11c.; off grades 1 to 2 cts. per lb. less. Calif. comb, 8@10c.; fancy buckwheat 1-lb., 8½@9c., and 2-lb., 7½@8c. Extracted white clover, none in the market. Calif. ext'd., 40-lb. cans, 56@6c.; buckwheat, in kegs and barrels, 46@5c. **BEEWAX.**,—21@23c.

MCCAUL & HILDRETH BROS., 34 Hudson St. Dec. 7.

BOSTON.

HONEY.—The demand has improved. We are selling one-pound packages of white clover honey at 13@14c.; 2-pounds at 11@12c. Extracted, 5@7c. **BEEWAX.**,—24 cts. per lb. Jan. 1. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—The market is a trifle more active. Best white comb honey in 1-lb. sections, 11@12½c. Buckwheat, 10c. Extracted, 7@9c. **BEEWAX.**,—23c. Dec. 13. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—There is a quiet tone prevailing, but the demand is fair for choice comb and extracted honey, in small packages. Manufacturers buy very sparingly. The supply is large and prices are downward. We quote prices for extracted honey, 3@7c. per lb. Nice comb brings 12@15c. per lb. to a jobbing way.

BEEWAX.—Good demand, 20@22c. per lb. for choice yellow. Dec. 21. C. F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—The market is not very active and prices a little lower. Choice 1-lb. sections of best white sell at 13@14c.; second grade 1-lb., 10@12c.; choice white 2-lb., 11@12c. Extracted, slow at 6c. **BEEWAX.**,—Scarce at 25c. Nov. 17. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—The demand for honey is only moderate and the supply ample, of very fine quality and in extra good order. We quote choice 1-lb. sections of white at 13@13½c.; 2-lb., 11@12c.; dark not wanted. Extracted, white, in barrels, half-barrels and in kegs, 6@6½c.; in tin packages, 6½@7c.; dark, in barrels and ¼-barrels, 5@6c. **BEEWAX.**,—Nominal at 25c. Dec. 13. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—The market has been rather duller the last week, but prices are well maintained, particularly for choice white extracted and choice white comb honey, as both kinds are not freely offered. We quote: 3½@4¼c. for extracted, and 9@12c. for comb; with easier sales for the best grades, than for the darker honey, as none seem to be able to use the dark just now. **BEEWAX.**,—Dull at 19@22c. Dec. 11. SCHACHT & LEMCKE, 122-124 Davis St.

HONEY.—Trade is quiet. Extra white comb 11c.; amber, 7½@10c. Extracted, white, 4@4¼c.; amber, 3½@3¾c. **BEEWAX.**,—20@23c.

Oct. 18. O. B. SMITH & Co., 423 Front Street.

KANSAS CITY.

HONEY.—Demand is good for all grades, and receipts have been very large of comb and extracted. Home bee-men have kept out of the market until this month; having glassed every lb. section on both sides they are reducing prices, selling 60 lbs. of glass with 160 lbs. of honey, making our market lower. There crop is about 70,000 pounds. We quote: White clover 1-lb., 12@13c.; 2-lb., 11@12c.; California 2-lb., 9@11c. Extracted white clover, 6c.; dark, 4@5c.; white sage Calif., 5½c.; amber, 5c. **BEEWAX.**,—22c. Nov. 20. CLEMONS, CLOON & Co., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained in barrels, 3½@4c. Extra fancy of bright color and in No. 1 packages, 4 advance on above prices. Extracted in barrels, 4½@5c.; in cans 5@6c. Market dull. **BEEWAX.**—Firm at 20½c. for prime.

Dec. 20. D. G. TUTT & CO., Commercial St.

The Report of the Committee on the Chapman Honey-Plant.

The Committee appointed by the North American Bee-Keepers' Society at the annual meeting held in Detroit, Mich., in December, 1885, to investigate the merits of the honey-bearing plant now being cultivated by Mr. Hiram Chapman, of Versailles, N. Y., met at that place on July 28; one member of the committee, Mr. Manum, of Bristol, Vt., was not able to be present, but as each member of the Committee was furnished with a sufficient number of plants to afford opportunity for observing their growth and habits, and also to gain some information concerning the value of the plant as a honey-producer, a letter from Mr. Manum, in which he gives the result of his experience and observation, is herewith appended.

This plant, which Mr. Beal, of the Michigan Agricultural College, and Mr. Scribner, Assistant Botanist of the United States Department of Agriculture, tells us is *Echinops Spheerocephalus*, is an imported perennial, native in Central France, and like all of the family to which it belongs, very rich in honey. This plant will probably be popularly known in this country as the "Chapman Honey-Plant," so named on account of Mr. Chapman being first to cultivate it, and being first to bring it to the notice of those engaged in bee-keeping.

We found three acres of the plant in bloom, the height of the mature plant being from 3 to 4½ feet, and each root bears from 5 to 15 round balls or heads from 1 inch to 1½ inches in diameter. These heads stand upright, and the entire surface is covered with small, white flowers bearing bluish stamens. The stalks and leaves nearly resemble those of the common thistle that, were it not for the head, the difference would not be easily noticed. There is, however, in this particular, a very marked difference, the appearance of the head being aptly described by its botanical name, which signifies round-headed and in appearance like a hedge-hog.

The flowerets on the top of the head open first, then they open later along the sides of the ball, continuing in the order of nature around the entire surface of the sphere. Near the stem the last flowerets open, after the blossoms on the top of the heads have disappeared and the seed capsules of the first blossoms have hardened.

Unlike the thistle, the seeds are provided with no balloon by which they may be borne by the wind. The seed is in weight and appearance very like a small grain of rye, is enclosed in a capsule, and falls directly to the ground if not seasonably gathered, not spreading more than oats if left to fall without harvesting.

From the time of the appearance of the bloom upon the tops of individual heads, until the fading of the last blossoms upon the lower part of the head near to the stalk, is about 8 days, the continuance of the blooming depending upon the nature of the soil and the season; but the heads or buds sent out from each individual shoot and forming each individual cluster, vary in degree and size, so that the natural term of blooming and honey-bearing may be safely reckoned at from 20 to 30 days. The term of blooming may also be prolonged to a considerable extent by cutting back a portion of the plants, and the facility with which the honey harvest may be thus prolonged constitutes an important feature when estimating the value of this plant. The plant is hardy, easily propagated, perennial, and appears to flourish in all kinds of soil, and there is no danger of its becoming a pest or noxious weed. It does not bloom until the second season, and as it does not spread in seeding, its extirpation would be easily accomplished.

Its seed may be scattered in waste places, or it may be sown in drills or hills like onion seed. It seems to be characteristic of the plant to root out all other vegetation, and take possession of the soil. No weeds, and but very little grass was seen growing in the three-acre plot observed. (A ten-acre field sown broad-cast, and harrowed in like rye, has also made a vigorous growth, and seems to be taking possession of the soil in opposition to

quack-grass and weeds.) As to the value of the plant to the honey-producer, there appears to be no room for doubt, whether quantity or quality, or both, be considered. Within reach of Mr. Chapman's apiary no other resources were accessible for honey-gathering, the severe and prolonged drouth having destroyed all other honey-yielding blossoms, and yet in some instances the bees were making an excellent showing in the hives. No definite conclusion could be reached as to the probable returns in pounds of honey from a given area. That the returns would be satisfactory was evidenced by the fact that the entire area was "alive with bees," and they visited the flowers from daylight until dark, and sometimes 8 or 10 bees were upon a single head at one time. Mr. Hubbard, who cultivated some of these plants, obtained from Mr. Chapman, reported that he had counted the number of visits made by bees to a single head from 5 a.m. to 7 p.m. He reported the number as being 2,135, actual count.

In order that the Committee might have some idea of the quantity of nectar secreted in the flowers of a single head, the day before our arrival, Mr. Chapman had wrapped a thin paper about a head, the half of which was in full-bloom, and tied the paper around the stem with tape, thus preventing the bees from appropriating the nectar for 24 hours. Upon removing the paper on the forenoon of the day of our visit, the flowerets were found to be dripping with nectar, and the drops sparkled in the morning sun. Each of us have made similar tests with like results since that time. We cheerfully and confidently recommend this plant to the bee-keepers of North America, as a most valuable acquisition to the list of bee-ferage plants.

We believe that a trial of the plant will, better than any other words of approval from us, publish its own commendation.

Respectfully submitted,

L. C. ROOT, A. I. ROOT, N. W. McCLAIN.

Mr. Manum, another member of the Committee, reports as follows:

BRISTOL, Vt., Oct. 7, 1886.

MR. L. C. ROOT, Chairman of the Committee on the Chapman Honey-Plant—DEAR SIR: As I failed to put in an appearance when the Committee met at Mr. Hiram Chapman's, in July last, it is not only due to you, but to Mr. Chapman and the Convention as well, that I make a short report of my experience with the Chapman Honey-Plant. 50 roots of which Mr. C. so kindly sent me last spring. The plants thrived well through the summer under moderate cultivation, and planted on light, sandy soil. I did not take extra pains with them as I wished to test their hardiness. The plants commenced to bloom on July 14, and continued to bloom until Aug. 21, making 39 days that they continued in bloom, and from the first day of their blooming until the last the little flower-balls were covered with bees every day, from early morning until dark, rain or shine. (We had no very heavy rains during this period,) the bees constantly going and coming. I have counted 16 bees on one ball at one time, all sucking the sweet nectar from the richly-laden flowers of the Chapman Honey-Plant.

At Mr. C.'s request I covered three of the balls with tissue paper and two with muslin. On the following day there were several bee-keepers here. I removed the paper from the balls, lo and behold, the flowers were filled, yes, covered, as it were, with honey. We found by holding the hand under one of the balls, and jarring it, the honey dropped in the hand enough to make several drops. In a moment a bee lit on one of the uncovered balls and never moved until its sac was filled, and it flew away. On timing them, I found that five bees filled themselves and flew away in 2 minutes and 20 seconds from the time the first bee lit on the plant. The two balls that were covered with muslin were now uncovered, but the honey seemed to have evaporated, as there was but little visible, although I had noticed bees alight on the muslin and try to suck the honey through the cloth. This fact was conclusive to me that the bees could smell the honey through the cloth.

I find that by cutting back the plants in June, they will bloom later in the season. This would be of advantage, perhaps, to those who are favored with an abundance of buckwheat for their bees to work on during August, as by cutting it back it would then commence to bloom the last of August, thereby affording good pasturage for bees in September.

In conclusion I must say that I am very well pleased with the plant, judging from this first year's trial, and I venture to say that the time is not far distant when it will be extensively cultivated for its honey-producing qualities. I expect to plant an acre next spring. Were it possible for me to meet with you at the Convention, I would move a vote of thanks to Mr. C. for having introduced this valuable plant. It is valuable not only to bee-keepers, but to the florist as well, because it is a very beautiful plant, and so very rare withal. I remain yours truly,

A. E. MANUM.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal1 00..	
and Gleanings in Bee-Culture2 00..	1 75
Bee-Keepers' Magazine1 25..	1 25

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

Convention Notices.

☞ The Northeastern Ohio, Northern Pa. and Western New York Bee-Keepers' Association will hold its 8th annual convention in Chapman's Opera House, at Andover, O., on Wednesday and Thursday, Jan. 19 and 20, 1887. First-class hotel accommodations are offered at \$1 per day to those attending the convention. A general invitation is extended to all. M. E. MASON, Sec.

☞ The Wisconsin State Bee-Keepers' Association meets at the Capitol in Madison, Wis., on Thursday, Feb. 3, 1887, at 9 a.m. All progressive bee-keepers are earnestly invited to attend, and supply-dealers are requested to exhibit their best implements and inventions. The State Agricultural convention will be in session at the same time, commencing on Feb. 1 and closing on Feb. 4, which will be an additional inducement for many to attend. Hotel rates are from \$1 to \$3 per day. Return tickets will very probably be given over the principal railroads at reduced rates.

F. WILCOX, Sec.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

As a premium to the second largest club we will send my mail, postpaid, a copy of the "Farm Account Book," worth \$3. The postage is 20 cents.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

Simulus' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Our Book Premiums.—To encourage all our present readers to get one or more additional subscribers we will present 25 cents' worth of books for every new subscriber (accompanied with \$1 for one year's subscription), sent direct to this office. Thus for five new subscribers with \$5, the getter up of a club gets \$1.25 in valuable reading matter, to be selected by himself from our list on the second page of this paper. It will pay you to devote a few hours to the interests of the BEE JOURNAL. Every one who keeps bees ought to take it. We will furnish sample copies free in any quantity to those who intend to get up clubs. We expect to get 5,000 new subscribers for 1887.

The Report of the Indianapolis Convention is now published in pamphlet form, uniform with that of last year. It will be sent postpaid for 25 cents to any address.

We have also bound it up with last year's, together with the History of the Society; this we will mail for 40 cents. Or if you send us one new subscriber (with one dollar) besides your own renewal, we will present you with a copy by mail.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

A New Crate to hold one dozen one-pound sections of honey.—It has a strip of glass on each side, to allow the honey to be seen. It is a light and attractive package. As it holds but one tier of sections, no damage from the drippings from an upper tier can occur. We can furnish the material, ready to nail, for 9 cts. per crate. Glass 1½c. per light, extra.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have just gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

If you want a good printing office and newspaper, just write to James B. Gray, of Waverly, N. Y., who has a prosperous business to sell, on account of failing health.

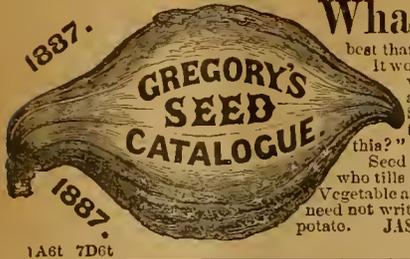

Advertisements.

What Mr. Beyer says: "Please bear thanks for the splendid seeds received from your firm. It would be a rather lengthy list if I should name all, but will say that amongst 33 first, and 3 second premiums awarded me at our fairs in Northern Indiana and Southern Michigan, 25 first premiums were for vegetables raised from your seeds. What firm can beat this?"

— AUGUST BEYER, So. Bend, Ind.

Seed of this quality I am now ready to sell to every one who tills a farm or plants a garden, sending them FREE my Vegetable and Flower Seed Catalogue, for 1887. Old customers need not write for it. I catalogue this season the native wild potato.

— JAS. J. H. GREGORY, Seed Grower, Marblehead, Mass.

A Year among the Bees,

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x13 "	8 00
For 3 " " 10x13 "	10 00
For 4 " " 10x13 "	14 00
For 2 frames of any size, 13x20 "	12 00
For 3 " " 13x20 "	12 00
For 4 " " 13x20 "	16 00

DAVIS' PATENT HONEY CARRIAGE, REVOLVING COMB-HANGER.

Tool Box and Recording Desk Combined.

Price, complete, only..... \$18.00

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

READY TO SHIP. — Langstroth Brood-Box Frames, prepared to nail, at 50 cents per 100; 50c for \$4.00. I have several thousand of those Nice Brood-Frames in the lot, which if ordered before Apr. 1, may be had for \$3 per 1,000, freight prepaid by C. W. DAYTON, Bradford, Iowa. 2D1f

SEEDS Large Garden Guide Free to all. You should have it. Best varieties, all tested, at low prices. COLE & BRO., Seedsmen, Pella, Ia.

AMERICAN
ESTABLISHED IN 1861
THE OLDEST BEE PAPER IN AMERICA
BEE JOURNAL

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Jan. 19, 1887. No. 3.

I Love to see the setting sun,
Sunk splendidly from sight;
I love to watch, while one by one
The stars peep out at night,
All Nature's charms, in short, I love,
Her forests, fields and bowers;
But, O, all other things above,
I love her many flowers.

He Who is Afraid of stings and thorns will never obtain the famous honey of Mount Hybla, for there the roses are guarded by the thorns, and the honey is defended by the bees.

There will be a **Rush** for supplies needed in the apiary after awhile, and we cannot do better than to urge all to look over their stock, ascertain what will be needed, and get it on hand before it is necessary for use—thus avoiding the perplexity consequent upon its possible delay in reaching them in time.

It is **No Longer an Open Question** whether newspaper advertising pays. What a business man now considers in this connection is how, when and where it can be done to insure the best returns on the investment. Have something of value to sell; then select the paper which sends the greatest number of copies to those who should use the article. Use as few words as possible, and let them be printed in large type, so as to catch the eye. These are some of the secrets of successful advertising.

Mr. E. C. Jordan, proprietor of the White Sulphur Springs in Fred Co., Va., and one of the foremost apiarists of that State, sent a useful Christmas present to the AMERICAN BEE JOURNAL. (It was delayed in transit, and was not received until Jan. 14.) It consisted of a heavy iron inkstand, with bottles for three colors of ink, and its name is "The Virginia." It is so heavy that it would be very difficult to upset it. Mr. Jordan has our thanks for his thoughtfulness, as well as for the nice present.

Many Encouraging and enthusiastic letters have been received, during the past month, showing the hearty welcome which the AMERICAN BEE JOURNAL receives at the homes of its many subscribers. We cannot spare the space in the JOURNAL necessary to print them, but our appreciation is none the less, for that. The following, from two of the most prominent bee-keepers in America, may be taken as samples of them all. We hereby tender our thanks to all for their "kind words," whether they have expressed their appreciation or not. One prominent bee-keeper remarks as follows:

"I have often wondered how you can give us so good a paper at a dollar a year! It has been with much pride that I have seen the AMERICAN BEE JOURNAL rise from where it was when it came into its present editor's hands up to the great excellence of today. It has especially seemed to excel all past records during the year 1886, and I am proud to say that no bee-paper in existence (and I subscribe, for them all) can begin to compare with it!"

Another correspondent and prominent apiarist writes:

"I deem the AMERICAN BEE JOURNAL the best and most valuable of any I receive (and that comprises all that are published in the United States, Canada, and England). Its editor seems to be actuated by a desire not only to instruct and benefit, but also to make the AMERICAN BEE JOURNAL a distinctly high-toned periodical."

In order to keep up to the present "standard of excellence," the AMERICAN BEE JOURNAL needs five thousand new subscribers, and we hope to get them during the present year. Many are working with a will for its prosperity, and if a few more would do likewise, we should soon have the desired number of subscribers to make it pay at the reduced rate of a dollar. We would ask all to kindly do what they can to send us new subscribers for 1887.

The **Union Convention** at Albany, N. Y., was held last week. It was attended by those who usually go to such meetings in that State. The following were the officers elected for the ensuing year: President, W. E. Clark, Oriskany; Vice-President, Ira Barber, De Kalb Junction; Secretary, G. H. Knickerbocker, Pine Plains; Treasurer, J. L. Scofield, Chenango Bridge.

President Clark was re-elected, a fact which speaks well for his management during the past year. In his annual address he recommended delegate conventions instead of mass meetings, as heretofore held, and a corresponding better service to our pursuit. He said:

One of the most important topics we are to consider is, how can we cheapen the cost of producing honey, a subject of more import to bee-keepers than any other. The subject of the middle man is also worthy of consideration. I do not think we can dispense with the middle man; but it is not right that he should make more money on one crate of honey than he does on two barrels of sugar. Comb honey is as much a luxury as butter, and ought to command fair prices to the producer. In conclusion, President Clark thought the best interests of the industry would be served by having a delegated convention, instead of assembling in a general way, as now.

Any One who cannot debate a point or theory without attacking the motives of his opponent, does not understand the first principle of friendly discussion.

The **Canadian Bee-Lawsuit** was brought before the Convention of the Ontario Bee-Keepers' Association, at Toronto, and "it was decided to take no action—the defendant not being a member of the association, and it being manifest that the lawsuit had grown out of a dispute between neighbors." The action in this case, McIntosh vs. Harrison, was taken by the plaintiff "to compel the defendant to abate a nuisance in the shape of bees kept on his premises." As we understand that the apiary has been destroyed by fire, there will be nothing to complain of—the nuisance (if there was any) having been abated long ago.

As Mr. Harrison was not a member of the Ontario Bee-Keepers' Association, or any other society of bee-keepers, including the National Bee-Keepers' Union, it seems that he had no claim to the assistance of any one—especially in a neighborhood quarrel. Everything indicates that a bad state of feeling and much vituperation pervaded both litigants, and but for this, in all probability no lawsuit would have occurred.

At the Toronto convention Mr. J. B. Hall, of Woodstock, who had been cited as a witness in the case, expressed the firm belief that the judges would give a fair decision, when the matter came before a full court. We hope that such will be the case, and await the verdict of the court.

We have Received a copy of "The Book of Plant Descriptions, or Record of Plant Analyses," by Prof. Geo. G. Groff, a learned apiarist of Lewisburg, Pa. This valuable acquisition to botanical literature contains a synopsis of the terms most frequently used in plant descriptions, a schedule of botanical laboratory work, and a list of suitable subjects fortheses.

The book is prepared for the use of both teachers and students, and is a very nice assistant to those interested in plants and flowers. It could also be used to an excellent advantage by bee-keepers, as by its use they would be enabled to analyze, and keep a record of the many honey-plants which beautify their surrounding country. The price is 45 cents per copy.

Mrs. McKechnie, of Angus, Ont., who personally manages about 100 colonies of bees, occupied the chair during part of the recent sessions of the Ontario Bee-Keepers' Association, and did so very gracefully. The Rev. W. F. Clarke asks:

"Is not this the first recorded instance of a lady bee-keeper filling such a position?" and then he adds, "Score one for Canada!"

No; 'Tis well! but it is NOT the first! We have been present at conventions where Mrs. L. Harrison has filled the chair very gracefully. One of which was at a session of the Northwestern Society, held in Chicago!

The **South Platt, Nebr., Bee-Keepers' Association**, lately organized with nine members, and representing 186 colonies of bees, elected as officers the following: President, Geo. W. Warren, Harvard; Vice-President, J. R. Kidd, Clay Centre; Treasurer, A. B. Reed, Glenville; Secretary, C. K. Morrill, Harvard. The meeting adjourned to March 7, 1887, at the Court House in Clay Centre.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Feeding Bees in Winter.

Query, No. 362.—What is the best way to feed bees to the winter, that are short of honey? I have 2 colonies that have been robbed of their winter stores, and I wish to save them if possible.—H. W., Mass.

See my article on feeding bees, on page 741 of the BEE JOURNAL for 1886.—G. M. DOOLITTLE.

Put candy over the frames, and cover it with a woolen quilt or blanket. The bees should be in a cellar.—W. Z. HUTCHINSON.

Give them frames of sealed comb honey.—J. E. POND.

Put in full frames of honey, if you can get them; if not, use a soft candy made from coffee A sugar and water. Place it on top of the frames in cakes or bars.—H. D. CUTTING.

Put them into the cellar and lay some sugar candy over the frames as near as possible to the bees. The candy is quickly made, by mixing honey and powdered sugar.—DADANT & SON.

Make a candy of granulated sugar and lay it over the frames; or, what is better, use the "Good" candy, made of powdered sugar and extracted honey. Comb honey can be fed in the same way.—G. L. TINKER.

Pile combs of honey one upon the other, with the sides flatwise over the cluster, until there is enough to last until spring, after which adjust the packing.—C. W. DAYTON.

Feed "Good" candy, or else fill the combs *à la* Dr. Miller. I prefer candy laid over the combs, if one must feed. I should never permit bees to go into winter with so little food.—A. J. COOK.

I will let others answer that have had more experience. It is a blunder to have bees in such condition. The time to feed is when they can fly freely.—JAMES HEDDON.

I think the very best way is to give combs of honey, either laying them on top of the cluster or hanging right in or beside the cluster. At any rate, see that the bees get to the honey.—C. C. MILLER.

I am now wintering some of my colonies on a mixture of standard A sugar and extracted honey. The sugar was mixed into a stiff mass by adding extracted honey and kneading the mass until it was stiff enough to pack into shallow frames, and these were placed right over the cluster on

the tops of the frames, and covered up warmly. These colonies had a fight on Dec. 18, and were in splendid condition. Granulated sugar will not answer for this purpose. A few colonies fed on the best unrefined New Orleans sugar, mixed as described above, are also doing well.—G. W. DEMARE.

Lay a frame of sealed honey on 1/2-inch sticks on top of the frames, immediately over the cluster, and cover with the quilt. Bee-candy placed in the same position will answer, but not as well as the honey. When you put the colonies out in the spring, the same robbers will "clean" them again, unless you are very careful.—J. P. H. BROWN.

Place frames of honey flatwise over the frames, being careful not to chill the bees, by letting the warm air escape.—THE EDITOR.

Steam in a Bee-Cave.

Query, No. 363.—I have 15 colonies of bees in a small, dry, warm cave; but since I put them in, there is steam in the cave. Is this steam injurious to bees? If so, what shall I do about it?—G. W., Mo.

Give a little ventilation.—DADANT & SON.

The steam results from evaporation, the bees causing it in throwing off the water part of their food, and, with me, it does no harm.—G. M. DOOLITTLE.

I would make some small ventilation at the top and bottom, care being taken not to reduce the temperature too much.—J. P. H. BROWN.

The steam will do no harm if the cave is warm enough, and there is ventilation for the steam to get out.—G. L. TINKER.

If the temperature is high enough, I do not think the dampness injurious. There is probably no better method of removing the dampness than by ventilation.—W. Z. HUTCHINSON.

Probably not if bees remain quiet. Ventilation would remove the steam. The steam indicates saturated atmosphere, which I should feel afraid of.—A. J. COOK.

I infer that the cold air rushing in when the cave is entered, caused the steam, in which case it would not be injurious. The disturbance produced by visiting the cave often may be detrimental.—C. W. DAYTON.

Ordinarily, no. A ventilator pipe reaching to within 3 or 4 inches of the floor would help you. If you had given the degree of temperature, it would be a help in answering such questions.—H. D. CUTTING.

Dampness will do no harm, if the temperature is not too low. To get rid of the "steam," open ventilation, and raise the temperature.—JAMES HEDDON.

It may, and it may not be. If the cause is lack of ventilation (and I should judge it was), ventilate; but be careful and not reduce the temperature too low, or render it unequal.—J. E. POND.

I do not know whether there is any harm in the steam. It may be that upon opening the cave, the air therein being cooled shows steam, whereas any one in the cave before you opened it would say there was no steam in the cave. At any rate I think I should want some provision for ventilation, for if the air is sufficiently pure otherwise, I should not be much afraid of the steam. Still, you can tell better about it by seeing whether the bees appear quiet.—C. C. MILLER.

If there is "steam" in your cellar, I think you will find everything dripping wet after awhile. The reason that bees will not winter in a cellar in this climate, is on account of dampness. In my fruit and vegetable cellar, which is frost-proof, there is a curtain of burlap hanging at an inner door, to keep the cold air from entering when the outer door is opened, and this cloth shutter is sometimes as wet as water can make it.—G. W. DEMAREE.

Though the steam is quite harmless, it can easily be removed by giving very slight ventilation.—THE EDITOR.

Dampness in a Bee-Cellar.

Query, No. 364.—I built an addition to my house, 16x20 feet, and it is only single boarded, and a rough floor laid over the cellar. I put 36 colonies in on Nov. 9, all in good condition, and the cellar is wet and cold, so the water stands in drops on the under side of the cover, and the bees are very uneasy. My bees are in one-story Simplicity hives, just as they were on the summer stands. What would be best to prevent such dampness?—New York.

Not knowing the temperature, I should say it was too cold.—H. D. CUTTING.

See my answer to Query, No. 363.—JAMES HEDDON.

If you can keep the temperature of your cellar between 45° and 48°, the drops of water will do no harm. I should judge that the cellar was too cold.—G. M. DOOLITTLE.

Keep the cellar warmer. If the temperature were up to 45° Fahr., and well ventilated, it would be different. The main thing, I think, is to keep the cellar between 38° and 45°, Fahr.—A. J. COOK.

You made a mistake in putting your bees into the cellar. I should use a small stove to temper the atmosphere, and to keep it as near 45° or 50° as I could.—J. P. H. BROWN.

In my opinion, such a repository as you describe, is a perfect "bee-killer." I should put a coal-stove in that cellar and keep the temperature at the point where the bees are most quiet.—W. Z. HUTCHINSON.

If the moisture is on the under side of the hive-covers, they need more upward hive-ventilation. If it is on the cover of the cellar, it will do no harm. The driest of atmospheres contain some moisture which may condense and adhere to cold surfaces. To prevent the dampness on the cover of the cellar, keep a fire in the room above, or cover the floor of the room with sawdust.—C. W. DAYTON.

The best would be to make some fire in that cellar, and with a little ventilation it would soon be dry. We would put some straw or fodder over that floor.—DADANT & SON.

The dampness of itself will do no harm. Keep the temperature equable at about 45°, Fahr. If you cannot do that, your bees would be better off on the summer stands.—J. E. POND.

I should put a stove in the cellar and dry it out by a slow process—give ventilation at the tops of the hives until the bees are dry and quiet. Want of proper exhalation from the bodies of the bees is the cause of all uneasiness and disease in bees during the winter months, and cold is at the bottom of all this. Such is my experience in my apiary.—G. W. DEMAREE.

Perhaps plaster of Paris, or lime, put in occasionally might help matters. Let in what air you can without cooling the cellar too much. You might try a hive or two with a little more upward ventilation, or perhaps better still, give very abundant air at the entrance.—C. C. MILLER.

Dampness does no harm of itself. It is cold and dampness that does the mischief. A damp cellar should be kept warmer than a dry one, because at the same degree cold is more severely felt in the former, owing to the more rapid conduction of heat. We feel the cold on a damp day much more keenly than on a dry day. If the cellar is wet and cold, warm it up, by all means. It is entirely practicable to use a stove in a cellar where there are bees, to warm it up and drive out the dampness, the wet and the cold, and thereby save the bees. The light may be closed in by any safe and suitable means. A faint light, especially in the evening, does little injury.—G. L. TINKER.

Put a fire into the bee-cellar at once, and keep the temperature at that degree which insures quietude to the bees.—THE EDITOR.

Convention Notices.

☞ The Northeastern Michigan Bee-Keepers' Association will hold its fifth annual meeting on Wednesday, Feb. 2, 1887, in the Common Council Rooms, at Bay City, Mich.
W. Z. HUTCHINSON, Sec.

☞ The next meeting of the Hardin County Bee-Keepers' Association will be held in Eldora, Iowa, on Feb. 12, 1887, at G. W. Ward's office, at 10 a. m. Our monthly meetings are very interesting, and we hope for a large attendance.
J. W. BUCHANAN, Sec.

☞ The Northeastern Ohio, Northern Pa. and Western New York Bee-Keepers' Association will hold its 8th annual convention in Chapman's Opera House, at Andover, O., on Wednesday and Thursday, Jan. 19 and 20, 1887. First-class hotel accommodations are offered at \$1 per day to those attending the convention. A general invitation is extended to all.
M. E. MASON, Sec.

☞ The Wisconsin State Bee-Keepers' Association meets at the Capitol in Madison, Wis., on Thursday, Feb. 3, 1887, at 9 a. m. All progressive bee-keepers are earnestly invited to attend, and supply-dealers are requested to exhibit their best implements and inventions. The State Agricultural convention will be in session at the same time, commencing on Feb. 1 and closing on Feb. 4, which will be an additional inducement for many to attend. Hotel rates are from \$1 to \$3 per day. Return tickets will very probably be given over the principal railroads at reduced rates.
F. WILCOX, Sec.

Correspondence.

Explanatory.—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark ⊙ indicates that the apiarist is located near the center of the State named; ♂ north of the center; ♀ south; ♂ east; ♀ west; and this ♂ northeast; ♀ northwest; ♂ southeast; and ♀ southwest of the center of the State mentioned.

Sections Filled with Comb.

G. M. DOOLITTLE.

When I first began bee-keeping I found that one of the greatest hindrances to my being a successful comb honey producer, was that of getting the bees to work early in the season in the boxes or surplus arrangement. Often the best part of the season would pass away before a bit of work would be done, save in the brood-chamber, the result of which was little surplus honey in marketable shape, with the body of the hive overloaded with honey, and but weak colonies of bees (owing to the honey crowding out the queen) for winter. This state of affairs worried me, and I began experimenting earnestly to see what could be done to overcome the difficulty. I soon found that wherever a frame of brood was placed, if within a reasonable distance of the main cluster, then the bees would commence work on either side of it, especially on the side between this brood and the main cluster.

Taking advantage of this fact which I had learned, about ten days before the main honey harvest commenced, I would place an empty frame in the centre of many of the colonies of bees, leaving them there for 8 or 9 days, when they were generally found full of nice white drone-comb which contained brood in the egg and larval form. I now cut these combs in pieces about 3 inches square, and fitted a piece into as many boxes as I had colonies which refused to work in the surplus apartment. As soon as such boxes were placed on the hives, the bees would take possession of them, at once going to work, and in a day or two work would be commenced in the rest of the boxes also. As this was in the days of 6-pound boxes, this piece of comb was all out of sight so that the darker color of this central comb did not show to injure the sale of the honey. However, I did not like the practicing of anything that looked like putting the best side out, so I kept on experimenting, when I soon found that a few partly-filled boxes left over from the previous season answered the same purpose, only I had to use about three times as many as I did of the brood. As this took many more such boxes

than I would have on hand as a rule, I still used the brood to some extent.

The next season I began getting combs built during fruit-bloom, going to each hive every five days and cutting out the comb before any of the larvae in the cells were large enough to soil the comb. These combs thus obtained were fitted into the boxes, which, in addition to those left over from the previous year, gave me all I needed, so that the using of brood was entirely dispensed with, except occasionally on a very obstinate colony which would scorn all my persuasion except brood. I have never known brood placed in boxes to fail in making the most obstinate colony work in them, and I sometimes resort to it now in these days of sections and comb foundation, putting the sections, when finished, in the third grade of honey.

Upon the advent of comb foundation, to supply my lack of poorly-filled sections, I would place frames filled with foundation in the centre of strong colonies of bees prior to the honey harvest, so as to get the foundation drawn, feeding, if necessary, to accomplish this object, so that I might have all the sections filled with comb which I needed. This latter plan I have seen recommended by many others since I adopted it, scores having secured by its use crops of nice white honey exceeding by far any hitherto produced.

After passing through all of this experience, and becoming so thoroughly convinced that I was right, as to write several times for the AMERICAN BEE JOURNAL and other newspapers, that I considered "sections filled with comb left over from the previous season better than money in a bank," imagine my surprise on reading the advice given by Mr. Dibbern, on page 774 or the BEE JOURNAL for 1886, where he says that to bring Mr. Thielmann's ideas up to modern times, he should "after extracting cut out the combs, melt them up, and burn the old sections." After all these years of labor and experiment to accomplish a thing which to me and others seems the very height of perfection, why are we now called upon to "cut out the combs" and "melt them up?" I have carefully re-read Mr. Dibbern's article, and I fail to find any reason given for such a procedure; neither do I find any reason given for the burning of the old sections.

With me, sections five years old are as clear and bright as any. To be sure, he says that sections "must be scraped of every particle of propolis," but there is no reason given for preferring new sections, after being so scraped, to old ones. Many of us cannot afford to purchase sections for the fun of burning them up, even if Mr. D. can. As I said of "modern transferring," so I say of this "modern comb honey production," if any man has plenty of money to "throw at birds," I do not object to his doing so, providing he does not cause his family to suffer; but I do object to having it made to appear that if we would keep abreast of the times, we, who cannot

afford it, must go to such a needless waste of time, labor and money, as Mr. D's modern honey-producing calls for. If Mr. D's surplus arrangement is so faulty that his sections are soiled the first year so as to be unfit for use the second, I would advise him to look about and get something better.

I perfectly agree with all that Mr. D. says about getting "honey in the best possible shape," and putting it upon the market in "faultless packages," having all graded and in workmanlike shape, as it should be, but I do not see why all this cannot be done without all the labor, expense and waste he advises in his last paragraph.

Borodino, © N. Y.

The Honey Market Reports.

DR. C. C. MILLER.

In continuation of what I formerly said on page 6, there is this objection to the wholesale commission man: He stands as an additional middle-man, and must have his pay for his labor in the form of the commission, and from this results the fact that the producer gets just so much less, or the consumer pays just so much more than he otherwise would. But this same objection holds equally against wholesale dry-goods merchants, or, indeed, wholesale merchants of any kind, and we could hardly dispense with all wholesale merchandising. It is all right to cultivate the home markets, and probably none too much has been said urging this, but certainly we must not go to the opposite direction so far as to say that no honey whatever must be sent to the city markets. Much can, no doubt, be done to increase the consumption in the home market, but there are cases in which the home market is in such condition that it is but right that the denizens of the city should have a taste of our delicious sweets.

Whatever may be in the future, in the past the only thing to be done was to sell to the city wholesale buyer or send to the wholesale commission man. I have done both ways, and where I could sell outright for cash I liked that plan much the best, but if, by shipping to a commission man, my honey would net me 10 to 20 per cent. more than outright sale would bring me (as has been the case), then the commission man was a blessing to me.

As to publishing the reports of commission men, there is some weight in the objection that Mr. Baldrige makes, that they get a good deal of free advertising; but I am not sure that they are to blame for it. If we cannot get the information any other way, we must be glad to get it through them, even at the expense of giving them a free advertisement. The thing we want is, to have all the light and knowledge we can get, and what objection is there to getting it from the commission men?

If honey is sold in a certain city at a certain price, is it not right that this fact should be published? Mr. Baldrige says: "They are to a great extent responsible for the present low prices that prevail everywhere for honey." There is, I believe, much truth in this. It results from the fact that some of them report the price of honey at a figure lower than that for which they are actually selling.

A producer, Smith, sends some honey to a commission man, Jones, and Jones sells it at 13 cents per pound when his market report reads 11 cents. Thirteen cents is really the market price, and there is no difficulty in selling at that price, and Jones is selling all honey of like quality at that price, but by quoting it in the papers at 11 cents, he makes Smith believe he is getting an extra price. So far, no great harm is done, for Smith gets just the same for his honey as if the market quotation had been correct. But here is where the trouble comes. A producer in the country taking the report as literal truth, and basing his price upon the printed report, sells his honey for 2 cents less than he ought, thus demoralizing the market. What is the remedy? Exclude the commission men's reports? Before their reports were given, we had quotations of wholesale buyers, and their prices were still lower, and the producer in basing his price upon the printed quotation, did not always discriminate between the two, but if 11 cents was quoted it meant all the same to him whether it was buyers' or commission men's quotations. What shall we do then? It will hardly do to omit reports altogether.

Friend Newman, on page 771 of the BEE JOURNAL for 1886, says: "Of course market quotations on honey must be published," (and he is surely right) "and if not supplied by the commission men, they must be made by the producers, or a selected committee by the producers' association." As yet the producers' association cannot make them, and I can hardly see how producers can make them, so at present it seems to be left to the editors and wholesale buyers and commission men.

But the difficulty comes back, can we get reliable reports? As already intimated, there have been cases where it looked to me as if the quotations were too high. At any rate, after shipping to a point where a high figure was quoted, I have received much less than the quotations. In this case did the dealer quote a higher figure than he had any idea of obtaining for the sake of custom, or did he quote what he really could sell for and was selling for; and did this attract such large shipments as to suddenly depress the market?

The whole matter of obtaining reliable quotations is in some places beset with difficulties, but at present I see no better way than to continue the present plan, and if there are any who make dishonest reports, let such reporters be reported. It is not a very difficult thing to find out by

making inquiries something about prices in the large cities, and if there are those who give wrong quotations, if they know the matter is being looked after they may be induced to be more careful. I see no reason why we may not have as reliable quotation for honey as for other products.

Marengo, 3 Ills.

For the American Bee Journal.

Marketing an Over-Production.

C. W. DAYTON.

Many are wedded to the idea that because honey is a glut on the market in Chicago, it ought to bring a corresponding price away out here in the country. This is turning relations bottom upwards, and for the sake of apiculture it should be deserted.

In a recent issue of *Gleanings*, three causes for the low price of honey are given as over-production, general depression of trade, and adulteration. Of the first we have lack of consumption; the second has no effect, except in paying debts already contracted; and as to adulteration affecting the price of pure honey, it is hardly admissible. It is certain that the more glucose there is in the honey the lower will be the price of the mixture be, but when we come back to a pure article we will find the old and corresponding price that is regulated entirely by consumption at present, and has fair prospects of being so regulated for years. Adulteration does not affect standard gold.

When we have produced more than will be consumed as a luxury, then it must supersede other sweets. I find white clover at 7 to 8 cents per pound with the corresponding lower grades to be an able competitor. It is reported that the price of cane-sugar is now at or below the cost of production. The general consumer has not yet learned to supersede sugar with honey; they cannot at present, because there is not enough honey produced for the purpose. There are some "weak hearted" bee-keepers who have not the push and vim to place their product before the consumer, who are trying to sell their product at home, and are thereby advancing the making of honey a cheap article of food, even while it might remain a high-priced luxury. I know of grocerymen who buy nice comb honey at 10 to 11 cents per pound in trade, and sell it at 15 to 20 cents per pound for cash. I know of others who buy comb honey built crosswise of the rows of sections, for 10 cents per pound, and will not pay any more for my choicest one-pound sections that can be removed from the crates like so many bricks.

I have become so disgusted with grocerymen that I often forget them when selling honey. There are bee-keepers in my neighborhood who advertised honey at about 6½ cents per pound, while 9,000 pounds was easily sold at 8 to 10 cents per pound, and there was hundreds of calls for more.

I have driven to the most business corner in a city and retailed 500 pounds in pails, pitchers and jars, in 4 or 5 hours, and in this I have not mentioned an exceptional instance. But the greatest excellence usually comes with the greatest labor, and this saying is as true with selling honey as it is with anything under the sun. A good salesman, in my opinion, exercises more home-made science than a dozen who handle bees; and the fact that a grocer makes as much in a few hours by handling honey over the counter, as the bee-keeper does in bending his back over the hives all summer, attests the truth of this statement.

It requires ingenuity, skill, and no small amount of energy to go into a dull town and collect a crowd to sell them honey. The production of honey is a very pleasant business—it is the down-hill side of bee-keeping. To sell the honey is beginning to appear like up-hill business, and we should not be slow in learning to share the good with the bad, if as such we are disposed to view it. When one finds a soft retreat, and makes it known, he may soon enjoy much company. A perfect honey-producer should be an expert at handling bees and selling honey as well.

When we have become so numerous that it will pay regular honey buyers in our towns, then it is probable that the usual bee-keeper will take his honey to town and accept the price offered by the buyer, who sells it again, as do the above-mentioned grocermen. I like to pass by the grocermen when out selling honey, as then I may reach home without being duped.

In other years I shipped honey to the large markets. The highest price obtained for extracted honey was 6 cents per pound, and the lowest was nothing per 300 pounds. This year, being somewhat at leisure, I experimented a little in the honey market, and purchased of a producer near by, the finest comb honey, at a price that netted him less money per pound than was realized for my extracted.

One apiarist shipped his extracted honey to St. Louis and realized 2½ cents per pound.

Yes; the greatest bar to the consumption of honey is adulteration, but the adulteration comes about in this wise: Years ago when Mr. Doolittle and others obtained 25 to 30 cents per pound for honey, the merchants and others found it profitable business mixing honey with sugar, as that was cheap. The improved methods of handling bees rendered honey more plentiful, and consequently the price began to fall. This necessitated the use of a cheaper and poorer basis for its manufacture, and as a matter of course it ended with glucose.

On this the lovers of honey innocently feasted until they were sick and disgusted. Upon looking around themselves, they discovered that there was the real "bee-honey" and the adulterated, so they inquired for "bee-honey," and had confidence in bee-keepers. Then was extracted

honey of good sale. Presently the apiarist, to obtain a larger yield, perceived the idea of taking the honey from the combs as soon as it was gathered, and before the water had evaporated from it.

From some of these reasons there are many who can say that extracted honey ferments, or that there has been too much of the stuff sold. Take a fine article that has remained in the combs until it is thoroughly ripened, and we will find those who will not even look at it, much less taste of it. Others will taste, and buy a trial pound; the next time it will be 10 pounds, and end with a 100-pound keg for winter, the last time around.

It is not the over-production or present adulteration of honey that is the greatest obstruction to the use of extracted honey. People have been duped and be-fooled so much that they think there cannot be any good honey outside of the combs, and many have not the faith to experiment. It may be seen that the apiarist of today must tear down and remove much that has been done heretofore, and begin to build from near the foundation.

Excluding Market Reports.

M. M. BALDRIDGE.

On page 771 of the BEE JOURNAL for 1886, the Editor requests his readers to express themselves upon the matters set forth on page 774, in my article on the "Honey Producers' Association," but cautions them "to take time to think before writing."

On page 810 of the same volume, an Iowa reader hastens to tell what he thinks about my "proposition to exclude the market reports from the bee-papers." He says: "If two editions were published to accommodate both factions," that he would "rather have the one containing the market reports." It is evident to me that this Iowa correspondent is not a very critical reader, and that he did not "take time to think before writing." Why? Because there is nothing in my article about excluding "the market reports from the bee-papers!" What I had to say was simply in regard to excluding, from the bee-papers, the market reports on honey as fixed and manipulated by the *wholesale commission men*. This being the case, will this Iowa reader please "take time to think" over and answer the following question? Suppose the honey-producers of the United States would form an association, and from its members select a committee competent to fix a fair, living price for honey, based on supply and demand, for both producer and consumer, which market report would you then rather see in the bee-papers—the one thus prepared and agreed upon by the association, or those fixed and manipulated as now by the wholesale commission men? Come, now, get right down to busi-

ness and give us your best thoughts upon the subject.

On page 811 of the same volume, a Michigan reader tells what he thinks about "excluding the market reports of commission men." He says these reports "are generally the first thing" that he reads; that he would rather dispense with "any other part of the paper," and that they "benefit" the bee-papers "as much as they do the commission men."

I regret to see that this Michigan correspondent did not "take time to think before writing." But, if he did "take time to think," he forgot to send us the thoughts we so much desire. He says the market reports of commission men are "generally the first thing" he reads, but neglects to tell *why*. Will he please tell us why he reads them, and of what value they are to him, or to honey-producers? Does he read them for the express purpose of being governed by them in the sale or the purchase of honey at home or abroad? If so, then that is one of the reasons we want them to keep out of the bee-papers. If honey-producers wish to *donate* their honey to retailers or consumers, they can do this without any further aid from the wholesale commission men.

But, says the Michigan reader, these market reports are of as much "benefit" to the bee-papers as to the "commission men." Now, is this true? Pray tell us of what benefit it is to a bee-paper to have the price of honey fixed and manipulated by commission men instead of by honey-producers? Does any one suppose that it does a bee-paper any good to have its readers disgusted and disheartened by such low prices as the commission men have fixed and manipulated for them in the past to be governed by? Do you think a bee-paper is benefited when the low prices of commission men cause its readers to quit the business in disgust, and become non-subscribers? Again, do you think it benefits a bee-paper to publish market reports on honey that no honey-producer would be willing to show to his honey customers? Nor in fact to a honey-producer whom he thinks might be governed by them? Perhaps it has never occurred to you, nor in fact to the proprietors of the bee-papers themselves, that there are many subscribers who refuse to increase their circulation simply because of the market reports of wholesale commission men. In fact I know of many subscribers who keep the bee-papers out of sight of their friends and neighbors, simply for the same reason that many grocers do their trade periodicals. Now this practice would be changed in case the bee-papers contained simply the market reports of honey producers. Then there would be nothing in the bee-papers which the honey-producers would be unwilling to have others see and read.

Now let me call the attention of the readers to some of the benefits the commission men secure by their free advertising in our bee-papers. These standing free advertisements

secure them other farm products to sell on commission besides honey. They do not in fact need to expend a dollar in legitimate advertising to get all the farm produce to sell on commission they desire to handle. So, you see, what a nice thing it is for the commission men to get control of a whole column of our bee-papers, free gratis, for nothing!

In view of the foregoing, who now thinks that the bee-papers are really benefited as much as the commission men?

St. Charles, 3 Ills.

Ontario Bee-Keepers' Association.

REV. W. F. CLARKE.

The adjourned annual meeting of the above-named body was held in the City Hall, Toronto, Jan. 5 and 6, 1887. The meeting had been adjourned from September last, to give time for the return of the commissioners who had been to England in charge of the display of Canadian honey at the Colonial and Indian Exhibition. The expectation that these gentlemen would be present, and give a report of their doings, was a special attraction of the occasion. Three out of four were on hand, but to the regret of all, Mr. D. A. Jones had been detained in England too long to admit of his arriving in time for the meeting. The others, Messrs. S. T. Pettit, president of the association, S. Cornell, and R. McKnight received the hearty congratulations of their fellow bee-keepers on their safe return.

President Pettit, in the course of his annual address, said: The events of the year 1886 truly mark an epoch in the progress of our association. It has emerged from its chrysalis state to enjoy its higher and better, its fully-fledged legal existence. Through the generous assistance given by the members of this association, your commissioners succeeded in putting on exhibition at the Colonial Exhibition the largest, and perhaps the finest display of honey ever made in the world. The English people of all classes received your commissioners with marked attention, and treated us with the greatest kindness and courtesy. Our brother bee-keepers over in the Mother Country gave us a royal reception, and vied with each other in making us feel happy and at home during our stay with them.

The President introduced Mr. J. A. Abbott, of Southall, England, son of a noted English bee-keeper. Mr. Abbott, who was warmly greeted, briefly expressed his appreciation of the hearty reception tendered him. Mr. Abbott was elected an honorary member of the association.

A resolution was introduced looking to legislation with a view of exterminating foul brood. Mr. F. Malcolm, Mr. J. B. Hall and others testified to the prevalence of the disease in various quarters, and urged the necessity of vigorous measures being adopted in order to stamp it out.

A memorial from the Oxford Bee-Keepers' Association was presented, asking for action in regard to the matter. There was considerable discussion as to the possibility of enforcing legislation, if it were obtained.

Mr. Abbott, in reply to a question, said there was no law in England in regard to this disease; in fact, there was no legislation on bee-keeping at all.

The resolution was laid on the table, but at a subsequent session was taken up again, and a committee appointed to confer with the government and endeavor to secure a stringent law to suppress foul brood.

Mr. Cornell introduced a resolution asking aid from the public funds to enable the association to invite Mr. Cheshire to pay a visit to this country and deliver lectures on bee-keeping. He said that he had sounded Mr. Cheshire on the subject, and believed he would come if his expenses were guaranteed. He spoke of Mr. Cheshire's eminent ability, and scientific researches, expressing the opinion that no other living man equaled him as an authority on apiculture.

Rev. W. F. Clarke concurred with Mr. Cornell as to Mr. Cheshire's great acquirements, and spoke in the highest terms of his book on bee-keeping. Still he thought there were serious objections to the proposal made. It would be impolitic to ask the government to make a special grant of money for this purpose. They had shown great liberality in connection with the exhibit of Canadian honey in England, which they had aided to the extent of \$1,000, and they had promised an annual grant of \$500 in aid of this association. We must not keep crying "give, give," or we should be looked upon as greedy and hard to satisfy. We might by asking too much, jeopardize what we had already obtained. By and by, when the fruits of the liberal expenditure made began to be manifest, we might, perhaps, ask for more. With all respect to Mr. Cheshire, he doubted if his lectures would be of much practical value to Canadian bee-keepers. His scientific researches taxed the intellectual capacity of our most advanced bee-keepers, but in the practical work of the apiary, he could teach us very little, from the difference of climate and circumstances between this country and Britain. We would not think of getting English agriculturists or horticulturists to come here and instruct our farmers and gardeners. When any of them settled here, they had to become learners to a large extent. It would be the same with English bee-keepers. It would be wiser to invite some leading United States bee-keepers to come over to our associations, and he believed they would cheerfully do so, if their expenses were paid, and the cost would be much less while the gain would be far greater, than to bring a lecturer all the way from England.

Mr. Abbott conferred in the opinion that British bee-keepers could not instruct their Canadian brethren, owing to the difference between the two countries. After some discus-

sion strongly setting against the project, the resolution was put and negatived by a large majority.

THE ENGLISH EXHIBIT.

The evening session having been devoted to a reception of the commissioners to the Colonial and Indian Exhibition, and the hearing of their reports, Mrs. McKechnie, of Angus, the second vice-president, was, in the absence of first Vice-President Pringle, called to the chair, which she filled with much grace and ability.

Rev. W. F. Clarke, chairman of the reception committee, expressed the sense of obligation which all felt in view of the task these gentlemen had undertaken and fulfilled on behalf of the honey interests of Canada. When their reports were heard he believed all would feel that they had acquitted themselves nobly, and earned the lasting gratitude of all the bee-keepers of this country. This feeling had become so general in advance of their formal report being submitted, that it had been proposed that something should be done in the way of a presentation, or a reception banquet, but difficulties had interposed, rendering anything of this kind impracticable, still he felt sure the commissioners would not consider that their welcome lacked cordiality, or their gratitude sincerity on this account. He understood that no written report had been prepared, but that each gentleman was to give his own individual account of things, and he had no doubt that what they had to say would be heard with the deepest interest. After their addresses, he had a motion to propose on behalf of the reception committee.

President Pettit gave an interesting account of his impressions of the exhibition, particularly in regard to the honey exhibit. He quoted the following notes in regard to honey exhibits from the other Colonies of the Empire:

CAPE COLONY—Two Samples. One good one, and one dark and poor.

GHANA, West Africa—One sample. This was granulated at top and bottom, liquid in the centre, and quite dark. It had the flavor of brown sugar, and I think it can never become popular.

VICTORIA, Australia, had some broken sections. Honey dark, thin, and the flavor resembling the juice of baked sweet apples. The sections were well finished, and separators were used.

QUEENSLAND—Honey very thick. About as dark as buckwheat, with one-third clover mixed with it, but more transparent. The flavor was very good, and agreeably pleasant; unlike anything on exhibition, and might possibly become a dangerous rival to the Ontario product.

QUEBEC had 3 pounds of clover and one of buckwheat.

BRITISH GUIANA—Honey dark and thin, of peculiar but somewhat pleasant flavor. Liquid on top, settled granules to the bottom. Does not set solid. Color, from light to dark, bottom to top. Resembling raw sugar, the lightest colored of which is placed in the bottom, and then a semi-transparent thin honey poured upon it.

The President said there was some fair honey from New Zealand, while that from the West Indies was fair in flavor, but dark. Not one of the honeys he had noted, with the exception, perhaps, of that of Queensland, need be feared as a rival to Canadian honey in the British markets, or the markets of Europe. As people there became educated to light honey, it would take the preference over any other quality. He made no comparison with British honey; it was good, and some people said it was superior

to Canadian. If the bee-keepers of Ontario worked together harmoniously and took the greatest pains to send the best honey to the British markets, by degrees Ontario honey would find its way in that country and in Germany, and the bee-keepers of Ontario would have a ready market for all the honey they could produce.

Mr. Cornsil said: The experience of the commissioners was that the honey would have been disposed of far more readily if it had been done up in small packages, the large packages being very unsuitable for making an exhibit. When the small packages had been sold, the delegates hunted around London for some small receptacle into which the large tins could be subdivided, and at last they found a small can holding about two ounces. It took five persons some weeks to fill thousands of these cans, which sold like hot cakes to visitors to the exhibition at twopence each.

The Ontario exhibit had been well advertised. The *Pall Mall Gazette* interviewed the delegates, and in this way thousands were led to inquire for the Ontario honey exhibit. As a result of this exhibit, about £930 clear of all the expenses had been handed to Mr. Couse, secretary of the association, for distribution among the Ontario exhibitors, which was a fair Canadian price.

A trip to London quickly took the conceit out of a man, even out of a bee-keeper. The bee-keepers of England knew as much of their business as any other body of men; and they treated the Ontario delegates in a most hospitable manner.

Mr. McKnight said great credit was due to the one lady and the 26 Ontario men who had sent over their honey to England, not knowing what its fate might be; and the thanks of the association were due to the Ontario legislature for the generous grant it had been given. To the Dominion representatives at the Exhibition, Sir Charles Tupper, Mr. Chipman, and the others, the thanks of the association were also due, those gentlemen having rendered the delegates every possible assistance. He ventured to say that no exhibit from Canada had done more to advertise the country than the Ontario exhibit, and he had been told by a prominent English government official that nothing had done more to remove the erroneous impression which prevailed in Great Britain respecting the climate of Canada than this same exhibit. He said that Mr. Cowan, the president of the British association, would visit the Dominion next year, and he hoped every bee-keeper in Canada would show him every courtesy. The greatest care had been exercised to get the honey over in good condition. There were 700 cases altogether, and of these only 12 sections, next to nothing at all, were broken. In the event of any Canadian bee-keeper shipping honey over there in the future, he would advise that comb honey should be exposed as much as possible. The results to Canada from the Colonial Exhibition generally would undoubtedly be great.

Ontario, it was acknowledged, had made the best and most sensible exhibit of all. Her apples, cheese and honey had created a tremendous sensation. The two former ranked high in the English market, and before long, he believed the honey would attain just as high a position. It was not an over-estimate to say that 100,000 people must have tasted Ontario honey at the Colonial.

Rev. W. F. Clarke said he regretted that Mr. D. A. Jones, of Beeton, had not yet arrived from England to complete the quartette of encouraging reports. He moved "That the members of the association hail with pleasure the return of their commissioners after the fulfilment of the task which they undertook, and that the thanks of the association were due them for the eminent services they had rendered; that the association expressed its deep sense of obligation to the bee-keeping brethren and sisters of the Old Land for the great courtesy and kindness extended to the Ontario commissioners, and that the association rejoice in the presence among them of Mr. Abbott, a member of the British Bee-Keepers' Association." Adopted.

Mr. Abbott said he would have pleasure in conveying to the British Bee-Keepers' Association the sense of the resolution just passed. He spoke very highly of the Ontario honey exhibit, and said the only honey he had ever seen to compare with it was some sent over from Italy and Switzerland a few years ago. He reminded the association that every year the production of honey was on the increase in Great Britain, and prices were coming down. Ten years ago he could get what was equivalent to 50 cents a pound, now he could only get 14 cents. In order that Canadian honey might compete successfully with English, it would have to be put on the market at a cheaper price than the English, and he believed the Canadian bee-keeper could not fairly expect to get more than 8 cents a pound for extracted.

SECOND DAY.

After some discussion on hives, and queen-excluding honey boards, the report of the Secretary-Treasurer was read and adopted.

Under the Act of Incorporation, which now rules the association, it is ordered that the officers shall be a President, Vice-President, and a Director from each of the thirteen agricultural districts into which the Province of Ontario is divided. Previous to the election it was resolved, that the old constitution be rescinded, and that the association accept and act under the new order of things established by statute. It was found that all the districts were not represented, and a resolution was passed that directors be appointed by so many of the districts as could be filled, and instructions obtained from the government, as to filling the two vacancies that were left.

The following gentlemen were elected officers of the association for the ensuing year: President, S. T. Pettit,

Belmont; Vice-President, J. B. Hall, Woodstock; Directors, 3rd District, M. B. Holmes, Delta; 4th, W. C. Wells, Phillipston; 5th, S. Corneil, Lindsay; 6th, Jacob Spence, Toronto; 7th, W. F. Clarke, Guelph; 8th, J. F. Dunn, Ridgeway; 9th, Martin Emigh, Holbrook; 10th, R. McKnight, Owen Sound; 11th, A. G. Willows, Carlingford; 12th, Lewis Travis, Alvinston; 13th, F. H. Macpherson, Beeton; Auditors, G. B. Jones, Toronto, and F. Malcolm, Innerkip.

The meeting decided to make Hon. A. M. Ross commissioner of agriculture of Ontario, and Sir Charles Tupper honorary members of the association, in recognition of their valuable assistance.

It was agreed to ask the directors of the Industrial Exhibition Association to increase and improve the accommodation in the apiary department at the Fair Grounds.

Mr. Malcolm presented an invitation from the Oxford Bee-Keepers' Association to hold the next annual meeting of the association at Woodstock. The invitation was accepted.

The following resolution, moved by Mr. Malcolm at the Wednesday's meeting, was adopted: That a committee be appointed to take steps to secure legislation to stamp out the disease known as foul brood by quarantine or other measures.

The question of taking action in the case of McIntosh vs. Harrison was brought up. The action in this case was taken by the plaintiff to compel the defendant to abate a nuisance in the shape of bees kept on his premises. It was decided to take no action, the defendant not being a member of the association, and it being manifest that the lawsuit had grown out of a dispute between neighbors. Mr. J. B. Hall, of Woodstock, who had been cited as a witness in the case, expressed the firm belief that the judges would give a fair decision, when the matter came up for final hearing before a full court.

Mr. David Chalmers read a brief paper on the presence of bee-bread in honey exhibited at the Toronto Industrial. As one of the judges on that occasion, he deemed it his duty to call attention to this matter.

Mr. Hall stated that bee-bread would be found in sections where swarms were hived on "starters" instead of full combs, and the surplus chamber from each colony was transferred to the new swarm. On motion, Mr. Chalmers received thanks for his remarks.

The association then adjourned.

At a meeting of directors held immediately after adjournment, Mr. W. Couse was re-appointed Secretary-Treasurer, in accordance with the statute.

Guelph, Ont.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for reference and examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

1887. *Time and place of Meeting.*
 Jan. 19, 20.—N. E. Ohio, N. Pa., &c., at Andover, O.
 M. E. Mason, Sec., Andover, O.
 Feb. 2.—N. E. Michigan, at Bay City, Mich.
 W. Z. Hutchinson, Sec., Rogersville, Mich.
 Feb. 3.—Wisconsin State, at Madison, Wis.
 F. Wilcox, Sec., Mauston, Wis.
 Feb. 4.—Fremont Progressive, at Fremont, Mich.
 Geo. E. Hilton, Sec., Fremont, Mich.
 Feb. 12.—Hardin County, at Eldora, Iowa.
 J. W. Buchanan, Sec., Eldora, Iowa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

Severe Winter, etc.—E. E. Ewing, Rising Sun, ♂ Md., on Jan. 8, 1887, says:

We have had a severe winter here thus far. The cold weather set in a month earlier than usual, and has been pretty steady and severely cold about all the time. Last season was a poor one for honey in all the Middle Atlantic country. There are not many bees kept here except in box-hives. Half of the farmers, perhaps, own from 1 to 5 colonies, which are likely to suffer before spring opens.

Swarming—That "Chip."—W. Z. Hutchinson, of Rogersville, ♂ Mich., writes:

There is no man from whose shoulder I should be more delighted to knock a chip than from that of Dr. Miller. In regard to this question of controlling or preventing the desire to swarm, mentioned by the Doctor on page 7, let me ask if the Doctor has read Mr. Simmins' little book on the prevention of swarming. If he has, and knows that Mr. S. is incorrect, why has he not told us long ago?

Regulating Prices of Honey.—J. A. Bayard, Athens, ♂ Ohio, writes as follows:

The proposition for a combination of honey-producers, to fix the price of honey in the markets of this country, looks like a big contract, when we take into consideration that the business embraces almost an entire continent, with all its varied climate and conflicting interests. An umpire, chosen to take the matter in hand, would find it very difficult to draw the line, so as not to interfere with the export trade, and thereby throw the vast surplus on the home market. If California should rebel by refusing to enter the combination, we should find her low-priced honey competing successfully in all the markets of the country, enjoying a monopoly of the business; while the rest of us would be hanging on to the ragged edge, "waiting for something to turn up." As a merchant in times past, I know

what combinations mean, as most manufacturers in certain lines of goods are compelled to combine in order to keep each other restrained within certain limits, under heavy penalties. This plan always worked well in staple goods, and is recognized by business men everywhere. How far the principle would work in the case under advisement, I trust ere long will come to the surface in a movement in the right direction.

Cider-Mills and Bees.—J. Lee Anderson, Lawrence, ♂ Ills., writes:

On page 9, Mr. Roebuck says: "Let all bee-keepers circulate petitions for signature, and present them to our legislatures, asking for a law that will compel cider-mill men to screen their mills and dispose of the pomace, so as not to be exposed to the injury of bees," etc. It seems to me that if Smith owns a cider-mill, and the land upon which it stands, that there can be no law made that can compel him to "screen" his mill against Jones' bees that are kept from one to three miles away. But if a law of any kind can be made, it would be one to compel Jones to keep his bees on his own premises. I am not interested in any cider-mill, but I am interested in bees, having nearly 100 colonies, but that does not prevent my using "reason and common-sense," which, on the whole, is about as good law as can be made. Is not that so?

[Class legislation, except in rare cases, is undesirable to the general public, and should be discouraged. We gave no endorsement to the plan proposed by Mr. Roebuck; and only stated that blank petitions were, by law, prohibited from being enclosed in the bee-papers.—Ed.]

My Experience with Bees.—Wm. H. Davis, Cherry Valley, ♂ Ills., on Jan. 5, 1887, says:

I knew nothing about bees a year ago. But I obtained 13 colonies in the fall of 1885, and since then I have read "Bees and Honey," and the BEE JOURNAL. I put the bees into the cellar, and in the spring they all came out in good condition. I have increased them to 35 good colonies, and took off 1,600 pounds of comb honey. I received about 200 pounds of black honey, which I sold for 8 cents per pound; the other I graded and sold for 10 and 12½ cents per pound at home.

Good Results.—G. Crouse, Ithaca, ♂ Mich., on Dec., 29, 1886, writes:

We had our first colony in July, 1884, my wife living them in a common hive with movable frames. They built 8 frames of comb and stored some honey, and we fed them 5 pounds of granulated sugar. In the fall I put some corn-stalks around the hive, leaving the entrance open so the bees could fly in fair weather. They wintered all right. During the summer

of 1885 we increased them to 5 colonies, by dividing them, and got 75 pounds of comb honey. These bees were hybrids. In the fall of 1885 my wife's father gave her a colony of Italians, making in all 6 colonies, which we packed in chaff hives, and left on the summer stands. They all came out in good condition last spring. We now have 13 strong colonies in chaff hives on the summer stands. I have sold 2 colonies at \$5 each, and have had 1,190 pounds of surplus comb honey in 1½-pound sections. We have sold nearly all of it in our home market at 12½ cents per pound for light, and 10 cents for dark. My wife worked in her father's apiary two seasons, so we were somewhat acquainted with the habits of the little workers when we commenced. Basswood was nearly a total failure in this locality.

Controlling Swarming, etc.—David Rawhouser, Columbus City, ♂ Iowa, on Jan. 6, 1887, says:

My bees did well last summer. I commenced the honey season with 100 colonies; I now have 160 in my cellar, and they are doing well. I took 8,000 pounds of comb honey last season. I have been looking for the man for years that could step up boldly to knock off such a "chip" as the one now on Dr. Miller's shoulder; but the man always fails to control or prevent the desire for swarming. Mr. Quinby offered \$100 for a non-swarming hive. But it has not been forthcoming. It seems that Victor Clough dare not strike at the "chip" now up, either.

Wintering Bees in a Bee-Cellar.—Otto Bussanmas, Bevington, ♂ Iowa, on Jan. 3, 1887, writes:

Last November I built a bee house and cellar purposely for my bees. It is 14x24 feet; a brick floor is in it, and 5-inch tiling lengthwise, entering the floor 4 inches underneath; also a furnace in one end, to heat it if necessary. The cost of the cellar was \$250. On Nov. 15 I put 89 colonies into it. I can keep the temperature at 35° without using the furnace. Is it advisable to raise it to 45°? I use cloth and burlap for covers, 3 or 4 thick, and some excelsior in the caps. I use Langstroth hives, leaving the entrances open, and no top-ventilation. So far I have had the temperature in the cellar at 35° to 45°, by using the furnace. Four or 5 colonies were restless, and their hives contained many dead bees on the bottom-boards.

[Yes; use the furnace, and keep the temperature at 45°, Fahr.—Ed.]

The Season of 1886.—Abe Hoke, Union City, ♂ Ind., on Jan. 7, 1887, writes:

I began last spring with 26 colonies. One proved to be queenless, and I gave them brood and they reared a queen and gathered enough honey for winter. I increased my apiary to 37 colonies, by natural swarming. I sold

3 colonies, doubled back one, and put 33 into winter quarters, 15 in straw hives placed in brick cases 4 inches thick, with 15 inches of hay over the top; and 17 colonies in straw hives cased on the outside with $\frac{3}{8}$ -inch lumber, well painted, and $\frac{1}{4}$ of an inch space between the straw and the casing. I got about 800 pounds of comb honey, and about 100 pounds of extracted. I have one colony in a 3-comb observatory hive packed in dry sawdust. My bees are all on the summer stands, and I think they have plenty of honey to last until the latter part of March. Good comb honey sells, at wholesale, for 15 cents per pound. The price of honey is too low, and we ought to combine to raise the price. I sold honey 20 years ago at 40 cents per pound, wholesale, and I can now buy as much with 10 cents as I could then with 40 cents. Then I would have had, altogether, 100; now I have 800 pounds as the result of the season's work.

Milk-White Honey.—M. G. Maddock, Marion, Ia., asks the following:

Is unadulterated candied honey ever of a milk-white color?

[Yes; we have had pure, linden honey, which, when granulated, appeared very much like lard. Its quality was excellent.—ED.]

Contemptible Conduct.—J. M. A. Miller, Galva, Ills., writes:

My 50 colonies of bees are all in the cellar, and seem as quiet as on a summer day. I notice that the winter problem has finally largely settled down to cellar wintering, and in my opinion it will so remain. Our honey market was nearly ruined last fall, by men that happened to produce some honey, and then coming to town and selling at the groceries all they could at a nominal figure, and then peddling it all over town; thus not only injuring the market, but destroying the grocery trade that they first sold to. Is not such conduct contemptible?

Wintering Drones—Selling Honey. Allen Latham, Lancaster, Mass., on Jan. 8, 1887, writes:

Bees seem to be in good condition so far, and bid fair to winter without loss. They have had one flight since the advent of winter (the middle of November, here). That flight was a little before Christmas. We are now having a cold spell, it being 18° to 20° below zero some mornings. When they had their flight I saw drones fly from one hive, thus showing that drones can be wintered. In this hive was a late swarm that became queenless, and reared a queen late in the fall, and, it seems, having kept the drones so long, it concluded to keep them forever. Though as to that, I saw one of the drones giving a free, but not willing, ride to one of the workers. I started the season with 5

colonies, had one given to me, and bought a pound of bees, and with this help I increased my apiary to 16 colonies, besides a small log hive and a glass one for curiosities. I took the glass hive and some honey to the town "cattle show." It attracted much attention, and has helped me to dispose of my honey. I sell my honey at 25 cents per pound for clover, apple, goldenrod and aster honey, and 20 cents per pound for buckwheat honey. I am building up a home trade, and the trade as yet keeps up with my supply. The BEE JOURNAL comes regularly, and I could not well get along without it. Its regularity bears a great contrast to certain other bee-papers.

Bee-Keeping in Arizona.—J. H. Brown, Prescott, Arizona, on Jan. 7, 1887, says:

I obtained 50 pounds of honey per colony, fall count, and one-half swarm per hive. Our honey is dark, and some of it is strong, but improves with age. Our mixed bees are a terror, and if the Holy Land is like the bees, I do not want to go there. But bees with less energy might not pay at all. I think they go 8 or 10 miles at times for honey.

Results of the Season.—W. F. Roe, Candor, N. Y., on Jan. 7, 1887, writes:

I commenced the season with 60 colonies in 10-frame Langstroth hives, in fair condition. I increased them to 100 colonies, and took 2,000 pounds of comb honey in 1-pound sections, about one-half white and one-half dark, and 500 pounds of extracted honey. I worked some of my neighbor's bees on shares, and got 15 swarms for my share, making me 115 colonies. They are all heavy with natural stores; 65 colonies are in the cellar, and 50 are packed in sawdust on the summer stands. I am selling my honey at 7 cents per pound for extracted, and 8 to 10 cents for comb honey.

Home Market for Honey, etc.—D. Y. Kennady, Batavia, Iowa, on Jan. 6, 1887, writes:

In the fall of 1885, I had 28 colonies, 18 in chaff hives with tops packed with straw, and 10 in Langstroth hives well packed in straw. On Feb. 16, 1886, I moved them 25 miles on the cars. They all wintered nicely except one late swarm that starved, and I lost 2 in April. I do not know the cause. They left plenty of honey in the hives. That left me 25 colonies in good condition, but, owing to the drouth, one-third of them did not swarm. I increased them to 48, and secured 1,500 pounds of honey in one-pound sections, which I sold for 12½ and 15 cents per section in my home market. It was all sold by Nov. 15, and I could have sold three times that amount at the same price. I hope that I will be able to supply the demand next year. I now have 28 colonies on the summer stands in

chaff hives, packed the same as last year; and 20 colonies in the cellar in the Langstroth hive, with two-ply of carpet over them. The cellar ranges in temperature from 36° to 42°. They all seem to be in good condition at this time, and each has from 30 to 50 pounds of natural stores for winter. All that I know about the business I have learned in the AMERICAN BEE JOURNAL in the last two years.

Drones Flying on Christmas.—Col. R. Walton, Industry, Pa., on Jan. 10, 1887, says:

My bees did very well the past season. I sold all but 15 colonies, and they increased to about 40. I obtained a splendid yield of comb honey, and sold the most of it at home for 20 and 25 cents per pound. It was a remarkable season for nectar. The bees that I had out on shares did better than they have for 6 or 7 years. One or two colonies are carrying their drones through the winter. This is something new to me. They had a flight on Christmas, the drones and young bees flying and roaring as if it were in June. I should like to know if others have ever had such to happen. My bees are in prime condition. Well, Mr. Editor, I would like to enter my protest against taxing bees, and also against bee-legislation.

Selling Honey at Home.—Uriah Stephenson, Gladstone, Ills., on Dec. 12, 1886, writes:

Eighty colonies, spring count, have produced 7,100 pounds of honey, mostly extracted, and I increased them to 107 colonies. By properly grading it, putting it up in suitable packages, and taking it around, it recommended itself, and I am satisfied that I could sell three times as much if I had it, and at much better prices than commission men can. Talk about there being an over-production of honey—surely there is not as much produced as would be consumed in the country around our apiaries, if we would only go around and present it in proper condition, and not wait for them to come to us. As for those inexperienced bee-keepers, I made my best sales all around them, to their nearest neighbors. I have no fault to find with commission men. Bee-keepers are to blame. If we would go around the country, I affirm that we can sell all our honey, and every year the trade will be better, instead of throwing it all on the commission men's hands, and making it a drug. I have 115 colonies in a good, dry cave, 40x8 feet, and 10 feet high in the centre, with all apertures closed as tightly as I could make them; and while the mercury is far below zero outside, it is at 47° in the cave. I put the bees away in the latter part of November, and I expect to be able to make a good report next spring.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1887, will richly repay every apiarist in America.

At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

Stimulus' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Market is well supplied with all the grades, and the demand is light. Prices are nominal at 11@12c. for white in 1-lb. sections. Fancy white in scant pound sections, 13c. Very little extracted is being sold, and prices range from 4@7c.
BEE SWAX.—22c. R. A. BURNETT,
Dec. 8. 161 South Water St.

NEW YORK.

HONEY.—In consequence of a large stock of comb honey on this market, fancy prices cannot be maintained. Fancy white honey in paper boxes, unglazed, are in better favor here than the price. We quote present prices as follows: Fancy white in 1-lb. paper boxes, or glassed, 13c.; same unglazed, 12c., and in 2-lb. glassed sections, 10@11c.; off grades 1 to 2 cts. per lb less. Calif. comb, 8@10c.; fancy buckwheat 1-lbs., 8½@9c., and 2-lbs., 7½@8c. Extracted white clover, none in the market. Calif. ext'd, 10-lb. cans, 5@6c.; buckwheat, in cans and barrels, 4@5c.
BEE SWAX.—21@23c.
MCCAUL & HILDRETH BROS.,
Dec. 7. 34 Hudson St.

BOSTON.

HONEY.—The demand has improved. We are selling one-pound packages of white clover honey at 13@14c.; 2-pounds at 11@12c. Extracted, 5@7c.
BEE SWAX.—24 cts. per lb.
Jan. 1. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Few sales are reported. Best white comb, 12½c.; Fall comb honey, 10@11c. Extracted is offered for 6@8c.
BEE SWAX.—Firm at 23c.
Jan. 10. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—Demand for all kinds has been very slow since Christmas, and occasional concessions have to be made to effect a sale of comb honey. We quote prices for extracted honey, 8@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way.
BEE SWAX.—Good demand, 20@22c. per lb. for good to choice yellow.
Jan. 11. C. F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—The market is not very active and prices a little lower. Choice 1-lb. sections of best white sell at 13@14c.; second grade 1-lbs., 10@12c.; choice white 2-lbs., 11@12c. Extracted, slow at 6c.
BEE SWAX.—Scarce at 25c.
Nov. 17. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—The demand for honey is only moderate and the supply ample, of very fine quality and in extra good order. We quote choice 1-lb. sections of white at 12@13c.; 2-lbs., 11@12c.; dark not wanted. Extracted, white, in barrels, half-barrels and in kegs, 6@8½c.; in tin packages, 6½@7c.; dark, in barrels and ½-barrels, 5@6c.
BEE SWAX.—Nominal at 25c.
Dec. 18. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8½@11. Extracted, white, 4½@4¾c.; amber and candied, 3¾@4c. Trade is quiet.
Jan. 10. O. B. SMITH & CO., 453 Front St.

HONEY.—As generally at the beginning of the year, honey is very quiet, but prices are well maintained, in consequence of the continued absence of the needed rains; and although it is too early to say anything regarding the next crop, prospects are not so good as they were last year at this time. Large orders from Europe remain unexecuted, prices being under 4c. here and owners refusing to sell for less than 4½c. at which price we quote good to choice honey. Comb honey firm at 8@12c.
BEE SWAX.—Active at 19@21c.
Jan. 10. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—The demand is light, and stocks of all grades are large. We quote: White clover 1-lbs., 12c.; dark 1-lbs., 8@10c.; white clover 2-lbs., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 6c.; dark, 4½@5c.; white sage, 5@5½c.; amber, 4½@5c.
BEE SWAX.—20@23c.
Jan. 13. CLEMONS, CLOON & Co., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 3¾@4c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4½@5.; in cans 5@6c. Market dull.
BEE SWAX.—Firm at 20½c. for pressed.
Dec. 20. D. G. TUTT & CO., Commercial St.

The Fremont Progressive Bee-Keepers' Association will hold its semi-annual meeting in conjunction with the Farmers' Institute, at Fremont, Mich., on Feb. 4, 1887. GEO. E. HILTON, Sec.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1 00..	1 00..
and Gleanings in Bee-Culture	2 00..	1 75
Bee-Keepers' Magazine	1 25..	1 25
Bee-Keepers' Guide	1 50..	1 40
The Apiculturist	2 00..	1 70
Canadian Bee Journal	2 00..	1 75
Rays of Light	1 50..	1 35
The 7 above-named papers	5 25..	4 50
and Cook's Manual	2 25..	2 00
Bees and Honey (Newman)	2 00..	1 75
Binder for Am. Bee Journal	1 60..	1 50
Dzierzon's Bee-Book (cloth)	3 00..	2 00
Root's A B C of Bee-Culture	2 25..	2 10
Farmer's Account Book	4 00..	2 00
Guide and Hand-Book	1 50..	1 30
Heddon's book, "Success"	1 50..	1 40
A Year Among the Bees	1 75..	1 50

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

Premium Worth Having.—The New York *World* and the **AMERICAN BEE JOURNAL** (both weekly) will be sent for one year to any address in North America for \$2.00. And in addition present to every such **CLUB SUBSCRIBER** a "History of the United States," containing 320 pages and 22 fine engravings, bound in leather and gilt.

This "History" will be sent **FREE** by express at the subscriber's expense; or will be mailed for 10 cents extra to any place in the United States or Canada.

It is arranged chronologically by years, from 1492 to 1885. Every event is narrated in the order of its date. These are not confined, as in other works, to political matters, but embrace every branch of human action.

This premium is worth the whole of the money sent for both periodicals, and should induce thousands to subscribe, and thus get two unrivalled weeklies for nothing.

As there is another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

All New Subscriptions will begin with the year, and until further notice we will send the back numbers from January 1, unless otherwise ordered.

We will Present Webster's Dictionary (pocket edition), and send it by mail, post-paid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the beekeeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Our Book Premiums.—To encourage all our present readers to get one or more additional subscribers we will present 25 cents' worth of books for every new subscriber (accompanied with \$1 for one year's subscription), sent direct to this office. Thus for five new subscribers with \$5, the getter up of a club gets \$1.25 in valuable reading matter, to be selected by himself from our list on the second page of this paper. It will pay you to devote a few hours to the interests of the BEE JOURNAL. Every one who keeps bees ought to take it. We will furnish sample copies free in any quantity to those who intend to get up clubs. We expect to get 5,000 new subscribers for 1887.

The Report of the Indianapolis Convention is now published in pamphlet form, uniform with that of last year. It will be sent postpaid for 25 cents to any address.

We have also bound it up with last year's, together with the History of the Society; this we will mail for 40 cents. Or if you send us one new subscriber (with one dollar) besides your own renewal, we will present you with a copy by mail.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

As a premium to the second largest club we will send my mail, postpaid, a copy of the "Farm Account Book," worth \$3. The postage is 20 cents.

We Keep this Notice standing all the year round: "Always give the name of the Postoffice to which your paper is addressed. Your name cannot be found on our list unless this is done," and yet many ask us to change their address without even mentioning to what Postoffice it has heretofore been sent. It often costs us more to find their old address than they pay for the BEE JOURNAL for a year; as we may have to examine our subscription lists in every State, Province and Territory to North America. Please be more careful in the future, and never omit your name, Postoffice, county and State.

A New Crate to hold one dozen one-pound sections of honey.—It has a strip of glass on each side, to allow the honey to be seen. It is a light and attractive package. As it holds but one tier of sections, no damage from the drippings from an upper tier can occur. We can furnish the material, ready to nail, for 9 cts. per crate. Glass 1½c. per light, extra.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have just gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

Advertisements.

YOUTH'S COMPANION (new subscriber) and this paper (old or new subscriber), both 1 year for \$2.05. Choice Italian Queen (to new customers, to advertise my stock), 50 cts.—Regular price 65 cts. Two sittings of **Brown Leghorn Eggs** for \$1, and warranted to reach you in good condition, and produce birds that will score from 80 to 95 points. Clean **Alyake Clover Seed** at \$7.50 per bushel. **Small Fruit-Plants** at one-half the usual price.

I can and will furnish any paper to the U. S., at prices that will astonish you. Write for large 20-page Catalogue and Club-List for 1887. Reference given in your own county or town. Orders booked now. **ADDRESS, BOX 36, Thornhill, Onondaga Co., N. Y.**—Stiply this, and nothing more." 3A1t C. M. GODDSPEED, Thorn Hill, N. Y.

What Mr. Beyer says: "Please accept my best thanks for the splendid seeds received from your firm. It would be a rather lengthy list if I should name all, but will say that amongst 33 first, and 3 second premiums awarded me at our fairs in Northern Indiana and Southern Michigan, 23 first premiums were for vegetables raised from your seeds. What firm can beat this?"

Seed of this quality I am now ready to sell to every one who tills a farm or plants a garden, sending them FREE my Vegetable and Flower Seed Catalogue, for 1887. Old customers need not write for it. I catalogue this season the native wild potato. JAS. J. H. GREGORY, Seed Grower, Marblehead, Mass.

A Year among the Bees,

BEING

A Talk about some of the Implements, Plans and Practices of a Bee-keeper of 25 years' Experience, who has for 8 years made the Production of Honey his Exclusive Business.

BY DR. C. C. MILLER.

Price, 75 cents, by mail. This is a new work of about 114 pages, well-printed and nicely bound in cloth. Address,

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

THE BRITISH BEE JOURNAL is published every Week at Ten Shillings and 10d. per annum, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited by T. W. Cowan, Esq.

The British Bee Journal and the AMERICAN BEE JOURNAL, one year, for \$3.00.

HUMPHREYS' HOMEOPATHIC SPECIFIC No. 28

In use 30 years. The only successful remedy for Nervous Debility, Vital Weakness, and Prostration, from over-work or other causes. \$1 per vial, or 5 vials and large vial powder, for \$5. SOLD BY DRUGGERS, or sent postpaid on receipt of price.—Humphreys' Medicine Co., 109 Fulton St., N. Y. 45A12t

THE HORSE,

By B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents—in English or German.

Muth's Honey Extractor,

Perfection Cold-Blast Smokers, SQUARE GLASS HONEY-JARS, etc.

For Circulars, apply to CHAS. F. MUTH & SON, Freeman & Central Ave., - CINCINNATI, O. P.S.—Send 10c. for Practical Hints to Bee-Keepers

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x18 "	8 00
For 3 " " 10x18 "	10 00
For 4 " " 10x18 "	14 00
For 2 frames of any size, 13x20 "	12 00
For 3 " " 13x20 "	12 00
For 4 " " 13x20 "	15 00

The NEW Heddon Hive.

We have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

The engraving gives a good idea of the hive. The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cover, bottom-board, and top and bottom of each sectional case has one-half of a regular bee-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

A SAMPLE HIVE includes the bottom-board and stand; a slatted honey-board, and cover; two 8-inch brood-chambers, each containing 8 frames; two surplus arrangements, each containing 24 one-pound sections, one with wide frames and separators, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

It is absolutely essential to order one nailed hive as a pattern for putting those in the flat together correctly.

HIVES READY TO NAIL.—In filling orders for these hives, in the flat, we make 6 different combinations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers:

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 frames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—interchangeable, but not reversible.—Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus stories as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-chambers. Price, \$2.50 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nailed hive. Price, \$3.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deductions from the above prices: Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at 1/2 cent each, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives, 5 per cent. discount; for 25 or more hives 7 1/2 per cent.; for 50 or more, 10 per cent.

THOMAS G. NEWMAN & SON,
923 & 925 West Madison-St., CHICAGO, ILL.

Large Garden Guide Free to all. You should have it. Best varieties, all tested, at low prices. COLE & BRO., Seedsmen, Pella, Ia.

WANTED.—Some one with or without experience, but with some ready cash, to join me in rearing Bees and producing Honey, and to take a half interest in 100, 150, 200, or 250 colonies of bees. My honey crop the past season was 19,000 pounds. Correspondence desired.

M. M. BALDRIDGE,
50C2t ST. CHARLES, ILLS.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Jan. 26, 1887. No. 4.

Mr. Schroder, in Southern Austria, writes us as follows concerning the weather and bees there :

We had a very fine November, but it was quite rainy during December, though there were some fine, warm days when my bees were on the wing. They flew on Dec. 20, and worked on the *Nespolia Japonica*.

Prof. Foster, who predicted last summer that this would be a cold winter, with great fluctuations of temperature, now advises ice men to put up large quantities of ice, as there will be a large demand for it next summer, and the opportunities of gathering ice will not be so favorable the following winter.

That means that a hot summer followed by a mild winter is predicted.

Many of our readers have sent us the names and addresses of their bee-keeping neighbors, to whom we have sent a sample copy of the BEE JOURNAL, so that they may see just what it is doing for them and the apicultural pursuit generally, and give them an opportunity to become regular subscribers. We hope others will feel free to do the same.

Take Time to Think.—This is the best advice we can offer to our readers. Now, while the bees are in their winter repose, plan for the future. It will be money in your pockets to do this. In the morning, when the mind is the clearest, think and decide what you intend to do, and then devise the best method of doing it. Think of what improvements you should make in your apiary, in your bees, and in your bee-pasturage, in your surroundings generally, and then make your plans for accomplishing these improvements. Think of the hives, sections, cases and crates you will need, and then procure them, so that they will be on hand just when needed. This advice would save thousands of dollars every year to bee-keepers, if they would but heed it! Read, study, and "post up" on the pursuit, and you will never regret it. If you do this, you will be wiser, happier and richer!

Ruining the Home Market.—L. W. Itzenhouser, of Lakeview, Mich., has no doubt thoughtlessly ruined his home market for honey, by selling fall honey in the comb, after having sold all of his clover and linden crop of honey in that town. It was a very unwise transaction, and we mention it just to warn others from a like fate. Have nothing but the best honey put into the sections, extracting the dark, and sell it for manufacturing purposes, or keep it for feeding to the bees in the spring.

Indignation ran high in that town, and the honey was denounced as an adulteration; it was stated by some that he fed his bees with "black-strap molasses," and had the bees store it in the sections. The buyers were indignant, and said anything that came to their minds, without waiting to know whether it is true or not.

A neighbor, Mr. J. Essinger, came out with an explanatory card, in the *Lakeview Enterprise*, on Dec. 24, in which he stated the following :

I had a field of red Lancaster wheat that was sown on low ground, and just when the wheat was nicely headed out, we had a frost that injured the heads so that there was but very little wheat in them, and the juice that should have filled out the kernels remained in the stalks; therefore, the stalks remained green, and after the wheat was cut the juice began to ooze out of the stubble, and in a couple of days it turned dark, just about the color of molasses, and it was sweet and sticky, and so abundant that in gathering up the sheaves of wheat, our boots and clothes became perfectly wet and drenched with it. And here comes the secret of the dark, strong honey. There were thousands of Mr. Itzenhouser's bees gathering the juice from the stubble and carrying it home. This I can prove by Mr. Biddle, Mr. White and Mr. Bassett, who are my neighbors and helped me harvest my wheat. I have eaten some of the dark honey, and think it is the same that was gathered from my wheat field.

Mr. S. J. Youngman, of Cato, Mich., wrote us as follows about this affair on Dec. 27, 1886 :

Mr. L. Itzenhouser, being a large producer of honey, has taken great pains to control the home market at Lakeview, having made nice show-cases to hold his comb honey, while the extracted is offered in cans and other vessels with neat labels. Mr. Itzenhouser put the honey on the market and disposed of it as fast as the busy bees could gather it; first the white clover, then the linden were disposed of, and the customers were thus unsuspectingly led on to tackle the dark honey gathered from the buckwheat and other fall bloom, and perhaps some of the "vile stuff" gathered from the stubble is no better than the honey-dew which troubled us some time ago. The only remedy is to either keep the stuff off the market, or sell it cheaply for just what it is, and thus try and not to be unjustly charged by those not well informed in the mysteries of bee-keeping, of adulteration.

This should be a warning to all—never to allow any fall honey to be put into the sections, or offered for sale after being extracted without fully explaining what it is. We cannot be too careful to maintain a home market after having once created it. Let us hang this red signal out as a warning to all!

"**The Outlook of Bee-Keeping in the Future,**" was the subject of an essay by Mr. A. E. Manum, of Bristol, Vt., at the late convention at Albany. As Mr. Manum is an experienced apiarist, the subject was placed in good hands. From 715 colonies of bees he obtained 30,000 pounds of comb honey, besides 6,000 pounds of extracted honey.

The Good Old Times.—On page 4 will be found a query, why more bees die in winter now than they did 50 years ago. Of course they do not; it is only one of the fallacies of the times; as the replies to the query show most conclusively. The same discount with the present, and admiration for the past has been exhibited in every generation. The "good times" have always been in the past; and the present have always been the "evil days." An exchange remarks as follows on this subject :

We are told that more children die now, and that life is shorter. All this is untrue; there has never been, in the history of the world, any time as good as to-day, and life is growing longer. In Geneva, Switzerland, they first kept an account of longevity. In the 16th century the average life was 21 years; in the 17th century, 25 years; in the 18th century, 33 years; from 1801 to 1833, 39 years; from 1814 to 1833, 40 years.

We see that in Geneva in the 16th century, the average age was 21 years, and in the 19th century, 40 years. Fifty years ago, the Life Insurance Company in Philadelphia, used a table in which the expectation was 28 years. The life-table of the United States, calculated in 1860, made it 41 years. At no previous period in the history of the race has sanitary progress approached that of the 19th century.

The Bee-Keepers of Cedar Valley, Iowa, have organized a society, which they have named a "Produce and Supply Union." Its constitution says :

The objects of the Union are: 1. To provide effective means for the even distribution of honey. 2. To prevent, as far as possible, reckless sales. 3. To find a wider market. 4. To secure higher and more even grades of honey, uniform packages and prices. 5. To purchase supplies (as nearly as practicable) of one house or firm, and thereby obtain lower prices and a uniform grade. 6. This Union is a compact between its members to secure a more ready sale for honey, even, uniform package and wider market, but not a monopoly.

The Secretary is H. E. Hubbard, of La Porte City, Iowa, who will send copies of the constitution and by-laws to all applicants.

Mr. E. C. Jordan, the apiarist of White Sulphur Springs, Va., sent a Christmas present to the Rev. T. DeWitt Talmage, consisting of a Virginia ink-stand and some of the excellent honey of "old Virginia." The Winchester, Va., *Times* says his reply was as follows :

I received your valued Christmas present, the ink-stand, made out of a cannon of the late war. Many thanks! Surely we must be near the time when the sword shall be turned into a ploughshare, for here we have a gun changed into an ink-stand. I thank you also for the honey that tastes of your bright Virginia fields.

Catalogues for 1887.—These on our desk are from

G. B. Lewis & Co., Watertown, Wis.—32 pages—Bee-Hives and Sections.

E. Kretschmer, Coburg, Iowa,—32 pages—Bee-Keepers' Supplies.

J. H. Martin, Hartford, N. Y.,—4 pages—Chromo Cards, etc.

A. F. Stauffer & Co., Sterling, Ills.,—12 pages—Hives and Apiarian Supplies.

Cole & Brothers, Peila, Iowa,—40 pages—Flower and Vegetable Seeds.

Plant Seed Co., St. Louis, Mo.,—64 pages—Vegetable and Flower Seeds.

James J. H. Gregory, Marblehead, Mass.,—56 pages—Vegetable, Flower and Grain Seeds.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Wintering Bees Under a Kitchen.

Query, No. 365.—Where the cellar under the dwelling house is partitioned off in rooms to match the ones above, which room would be the best to winter bees in, the one under the kitchen where a fire is kept all day, and being occupied with the inmates of the house during the day, or the one under the parlor where there is no regular fire kept, only on extra occasions, probably not to exceed a dozen times during the winter? Will the noise in the kitchen, resulting from the daily exercise of the family, be injurious to the bees under such room? If so, would the lining of the cellar-room overhead, with thin lining boards, flooring boards, or plastering, deaden the sound from above so as not to be injurious to the bees below? If it would be, which of the three would be the best? If not, is there any material that could be filled between the two floors that would answer the purpose? If so, what?—A. J., Ohio.

Put them in that part which has the most even temperature. Noise will not injure if there is no jar.—DADANT & SON.

Put the bees under the kitchen. I have no fear from the noise. I have wintered bees perfectly under exactly such conditions.—W. Z. HUTCHINSON.

The room that is freest from dampness and preserves the most even temperature, say from 40° to 50°. Noise will not hurt the bees, but jars and vibrating motions will.—J. P. H. BROWN.

After several such trials I never could ascertain that kitchen noise made any difference with the bees. I would prefer to place the bees in the warmest apartment.—C. W. DAYTON.

Put the bees under the kitchen. Noise without a jar does not injure bees; if they are so arranged that they stand on the ground without touching any part of the wood-work to the house, they will be all right.—G. M. DOOLITTLE.

It will depend upon which will give the nearest to an equable temperature. The noise will probably not affect them unfavorably.—J. E. POND.

I would prefer the room under the parlor in preference to the one under the kitchen. If you use a non-conductor of noise, it will be of heat also. I have several times seen that the noise and jar from rooms above is detrimental to bees.—H. D. CUTTING.

I would put them under where the fire is kept above all the time. I have no fear of noise. A simple floor above is enough. The fire above tends to keep the room below from getting too cold, and can be made to aid ventilation.—A. J. COOK.

It is very hard to be sure about such things, and you will find out better by trying some in each place. Even then, you may not decide correctly, for if one room is full and the other contains only a few, these latter will probably have the advantage. I think that under the kitchen would be the better place, and although the noise may do no harm (I hardly think it will), I should rather have the cellar plastered overhead.—C. C. MILLER.

I know little practically of wintering bees in the cellar, but I am aware that noise does not interrupt bees, and they are not interrupted by slight concussion when closely clustered, if it is not too continuous. Laying a double floor and filling the space between with lime mortar, will deaden the sound and remove all apprehensions on this account. So far as I have seen, this plan practiced in erecting warm buildings the workmen use "poor mortar," that is, add only enough lime to make the mortar sufficiently compact not to crumble.—G. W. DEMAREE.

I should put the bees in that part of the cellar in which the temperature was the most suitable, without regard to the noise made above. As the cold of a room in which no fire is kept affects the temperature of a cellar beneath several degrees, I should line that cellar room overhead in preference to the other. For the space of 3 feet I lined my cellar overhead on the north side, and filled in with the fine shavings made in sawing white poplar. The temperature now varies but little from 41° without a fire, and no moisture can be seen about the hive or cellar. Moisture appears and water will run out of the entrances of the hives at about 36° and below. This was last January. A fire in the cellar made the air sweet and pure, and dried up the moisture.—G. L. TINKER.

If the temperature is always high enough there, I would put the bees under the parlor. If not, I would put them under the kitchen. Disturbance sometimes seems to aggravate the causes of bee-diarrhea, but when the primary cause is not present it does no harm. I have proven this to be true.—JAMES HEDDON.

Put the bees under the kitchen. Bees cannot hear—therefore noise will not disturb them, if there be no jarring. Lining is unnecessary.—THE EDITOR.

Bee-Spaces Between Cases.

Query, No. 366.—In tiering up sections, should a bee-space be left between the cases rather than to have the sections rest on each other?—Catskill.

Most certainly, every time.—A. J. COOK.

A bee-space is left between mine.—C. C. MILLER.

In my practice I want the sections to come together, or as nearly so as practicable. The first and second bee-space is all right.—H. D. CUTTING.

Let the sections rest on each other.—C. W. DAYTON.

There ought to be a bee-space between the tiers of sections.—W. Z. HUTCHINSON.

Not necessarily. A bee-space facilitates rapid handling.—G. L. TINKER.

To my mind such space is unnecessary; but some prefer it.—G. M. DOOLITTLE.

We should prefer to have them rest on each other, if practicable.—DADANT & SON.

The sections are kept cleaner from propolis by allowing them to rest immediately on each other; though I would allow $\frac{1}{4}$ inch bee-space, and it works well.—J. P. H. BROWN.

This question is a mooted one. As for myself I prefer continuous passage-ways, and the sections come out cleaner and nicer than where a bee-space is allowed.—J. E. POND.

According to my practice, yes. I have tried both ways on a large scale, and I could never "tier up" cases crowded with bees without smashing bees, if there was no bee-space intervening between the cases. My bees enter the cases through the bee-spaces as readily as when no bee-spaces intervene.—G. W. DEMAREE.

Every time, and with the dawn of a little more light, no one will ever think of such a thing as allowing the sections to come nearer together than will allow a bee-space between—JAMES HEDDON.

In tiering up, each method (with and without a bee-space intervening) has its advantages and disadvantages. Where no bee-space is given, the sections are kept cleaner than they are where it is provided. Either plan will be successful.—THE EDITOR.

Raising the Hives in the Cellar.

Query, No. 367.—I have excavated under the house, and put in a furnace to heat my house, and I also have dug a cyclone cellar and put my bees into it. The temperature ranges from 42° to 54°. Now, by raising the hives up nearer the rafters I can increase the temperature as high as 60° or 65°. How would it do about Feb. 1 to raise the hives up so the bees would go to breeding fast?—G. M. G., Minn.

I would not disturb them until they were ready to put out permanently.—J. P. H. BROWN.

Do not go too fast. March 1 will be soon enough in your locality. Are you sure you can raise the temperature 20° by simply raising the hives from the floor toward the ceiling?—H. D. CUTTING.

As the result of two experiments, I think this plan would be advisable. I have more to learn of that method, however. I will be better prepared to answer about next April or May.—C. W. DAYTON.

I should say do not do it. My very best colonies, the past season, were those which did not have a particle of brood, not even eggs, when removed from the cellar at the time elm and soft maple were in bloom.—G. M. DOOLITTLE.

I should not do it. If your bees are in health, just "let well enough alone" until it is time to put them out.—JAMES HEDDON.

You can try it, but I should not on very many. I believe it unwise to raise the temperature in the cellar above 50°, Fahr.—A. J. COOK.

I should prefer to leave them as they are, rather than to risk them in the higher temperature.—J. E. POND.

It cannot do much harm, but we would not do it, for you will probably lose as many bees by restlessness as you will gain by breeding.—DADANT & SON.

I think the plan a good one. Why not raise part of the bees and leave part at the bottom, and then tell us which does the better?—W. Z. HUTCHINSON.

I do not feel at all sure about it, but I should feel afraid to try very many in that way. Try a small number and see how it works, and be sure to report. For one, I should much like to know the outcome. I feel afraid that under ordinary circumstances bees would not be quiet at 60° or 65°, and I think I should rather have them quiet, whether they bred or not.—C. C. MILLER.

If it is desired to keep bees quiet and save their strength and vitality until a time when their activity will be of some account, then the temperature of the cellar should not go above 50°, for the reason that at 50° and above, the bees are always active in the hive. Again, I should not want to force them, if I could, beyond their natural disposition to rear a little brood about Feb. 1. Rearing a great amount of brood in February and March will not be profitable for many reasons. It is the bees that are reared in April and May, and up to the middle of June, that gather the most of our surplus.—G. L. TINKER.

As an experiment, there may be no harm in trying it on a part—and then comparing results. Still we fail to see a good reason for the experiment. They will breed soon enough for all practical purposes without it.—THE EDITOR.

Convention Notices.

☛ The Northeastern Michigan Bee-Keepers' Association will hold its fifth annual meeting on Wednesday, Feb. 2, 1887, in the Common Council Rooms, at Bay City, Mich.

W. Z. HUTCHINSON, Sec.

☛ The Fremont Progressive Bee-Keepers' Association will hold its semi-annual meeting in conjunction with the Farmers' Institute, at Fremont, Mich., on Feb. 4, 1887.

GEO. E. HILTON, Sec.

☛ The next meeting of the Hardin County Bee-Keepers' Association will be held in Eldora, Iowa, on Feb. 12, 1887, at G. W. Ward's office, at 10 a.m. Our monthly meetings are very interesting, and we hope for a large attendance.

J. W. BUCHANAN, Sec.

☛ The Wisconsin State Bee-Keepers' Association meets at the Capitol in Madison, Wis., on Thursday, Feb. 3, 1887, at 9 a.m. All progressive bee-keepers are earnestly invited to attend, and supply-dealers are requested to exhibit their best implements and inventions. The State Agricultural convention will be in session at the same time, commencing on Feb. 1 and closing on Feb. 4, which will be an additional inducement for many to attend. Hotel rates are from \$1 to \$3 per day. Return tickets will very probably be given over the principal railroads at reduced rates.

F. WILCOX, Sec.

Correspondence.

Explanatory.—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark ⊙ indicates that the apiarist is located near the center of the State named; ♂ north of the center; ♀ south; ♂ east; ♀ west; and this ♂ northeast; ♀ northwest; ♂ southeast; and ♀ southwest of the center of the State mentioned.

For the American Bee Journal.

The Illinois Central Convention.

The Illinois Central Bee-Keepers' Association met at the Court House in Mt. Sterling, Ills., at 10:30 a.m., on Nov. 24, 1886.

After the usual routine of opening, Mr. J. M. Hambaugh, of Spring, Ills., read the following essay, entitled,

HIVES, FRAMES, AND SECTIONS.

It has been said by a noted apiarist, that "all other things being equal, bees will gather as much honey in a nail-keg as in anything else." While we cannot exactly admit this, it is about as true to state that bees in one of the modern improved hives, with no more attention paid them than was paid to them in the primitive days of our ancestors, would probably yield no better results than the proverbial nail-keg, or ancient logs and straw-skeps. It then follows that to enhance the production of honey, we must not only be equipped with the proper means, in the way of hives and fixtures, but we should also be equipped with a knowledge of how and when to act; the latter being fully as important as the first.

Prior to the invention of the movable-frame hive, bees were a source of mystery, and comparatively little was known of the nature and habits of these wonderful little insects, aside from the "business end," with which all seemed to be familiar. The old methods by which the bees instructed the aborigines in this important branch of their physical anatomy, still remain with them to this day, terrorizing many with the thoughts of so pointed an industry.

It was the inventive genius of Father Langstroth that perfected the work begun by Huber, Munn and others, and brought forth the most progressive and useful of all other inventions in the apicultural world, namely, the first practical movable-frame hive. All honor due to Father Langstroth for this great invention, and his scientific researches as given in his invaluable work, the "Hive and Honey Bee." The invention of the movable-frame hive has been the source of all practical improvements, and has been the key whereby to unlock the mysteries connected with this most wonderful and mechanical little insect.

To thoroughly understand their wants, as regards their dwelling-house and great laboratory, we should be conversant with their nature and habits. We should first understand their wonderful power of reproduction, and their instincts of great strength numerically, during the most important period of their existence—the laboring days of summer—and as the days wane back to the season of their long nap, they again decrease in numbers back to that of probably not over one-third or one-fourth of their prime condition in summer.

To suit these requirements, our hives must be so constructed that we can adapt them to these requirements with the greatest possible ease and dispatch. They must be so arranged that we can contract or expand the brood-chamber at our wish. Our brood-frames should all be of exact dimensions, cut by machinery, and be interchangeable with all the hives throughout the entire bee-yard; likewise should all hive-bodies, supers, covers, stands, etc., be of exact dimensions, and interchangeable. In my estimation the chief and most important item for first consideration is the adopting of the brood-frame, after which all other requirements must be made to suit.

In the consideration of the brood-frame, we must cater to the natural instincts of the queen as regards her power of reproduction. We should give her every resource whereby she will be enabled to ply her vocation uninterrupted, and in accordance with laws governing her nature. We should work for the bees as the most essential requisite, for with our hives literally boiling over with bees, the season permitting we can rest assured of the harvest.

In this consideration, take a peep at the bees in their abode, when left to "their own sweet will" in the construction of their combs and brood-chamber. Having transferred many colonies from box-hives and old fashioned "bee-gums," I have taken pains to notice how the bees prepare the combs for the reception of the brood, and how the queen proceeds in her avocation of egg-laying, when left to her own will. It is evident that deep combs, with brood beneath the stores, is in accordance with their laws, and if any one will examine the brood-nest in early spring, he will find near the centre of each a small patch of sealed brood in the centre of two or three of the combs, from the size of a silver dollar to that of a hand, and immediately around this will be found larva in various stages of development, and on the outside of all, freshly laid eggs; this is conclusive evidence that the queen directs her movements in a circle, commencing in the centre of the comb, as near as the nature of circumstances will admit. This leads to the conclusion that the brood-frames should be made large and roomy, if we desire to obtain the best results numerically from the queen.

We should have the combs large and uninterrupted with horizontal bars and bee-spaces through the centre of the brood-nest. I believe them

to be a detriment to the strength of the colony, as the queen is bound to lose time in her onward march from cell to cell, when she is confronted with these bars and spaces, and thrown out of her natural path. I do not believe that a hive is perfect in its construction, that will not give the queen full power of reproduction as nature has endowed her. When this very important item has been accomplished, we must also be prepared to meet the needs of the most populous colonies, by giving plenty of room at home, and not allowing them to vacate for the want of room.

We will suppose that it is on the eve of the honey flow, with the hives boiling over with bees, and young ones hatching by the thousands daily. We must now look to the surplus department, which every wide-awake apiarist has in readiness for the harvest. We must be prepared to have it gathered in the most marketable shape in comb form. To do this, we must cater to the wants of the markets, and see how the consumers desire their honey prepared, and what style of package receives the most ready sales; by consulting the markets we see quotations are given in comb form put up in one and two pound sections, and occasionally in one-half pound sections, but it is generally conceded that the one and two pound sections are the standards, and hence the proper size for the markets; other sizes do not meet with general favor, hence the need of adopting these sizes.

As it is an essential point to have all of our comb honey put in nice, marketable shape, a word or two upon this subject will not be out of place. I would have the surplus receptacles easy of access, and so made that if the strength of the colony demands, we can use one, two, or as many tiers as we please, and as fast as the sections are completed and fully sealed, they can be easily and quickly removed, and empty ones given in their place. I would have each and every section as it is taken, built in a manner that will be marketable, and admit of crating for shipment. This important item has led to many devices, whereby we might accomplish this end, chief among which is the use of separators.

This seems to come nearer accomplishing the object than any other method, yet it has its opponents on the ground that the separator is objectionable to the bees. They are more reluctant to enter the sections, and will not gather as much honey with their use as they will without. The separator also takes up valuable room, making two bee-spaces between each row of sections, where one bee-space will accomplish the purpose without separators. To do away with them, some use full sheets of comb foundation in the sections, and claim a success; while others claim that more than starters in the sections is a detriment to the honey, causing a centre lining that destroys the finer melting properties to the taste, thereby damaging the market value.

Another method by which the sections may be nice and evenly drawn

out, without the use of separators, as advocated and practiced by some, is by giving the bees ready access to the sections from all four sides of the sections, having bee-spaces at the sides as well as the top and bottom; but, as the "proof of the pudding is in the eating thereof," we must await future developments, and should we succeed in getting our surplus honey in proper shape without their use, we shall have accomplished quite an item.

Viewing the subject from a financial stand-point, our hives should be constructed on the principle of accomplishing the greatest results with the least outlay of money and time. They should be of as few parts as possible, and so simple of construction that they can be operated by the novice. Should we adopt one-half of the devices suggested by the bee-fraternity at large, especially for the production of comb honey, we should shortly have a veritable curiosity shop; hence, to sum up, I will say that we should adopt large brood-frames to insure the very best results numerically, and a hive that will accommodate ten frames, or contracted by the use of division-boards to any number less. The surplus department must also be as easily expanded or contracted to suit the strength of the colony, and harvest the surplus in the very best shape for market in one and two pound sections.

I have found from practical experience that the wintering of bees on large combs has been much more successful than on small ones, under the same form of treatment in out-door wintering, coming through to spring stronger in numbers, building up more rapidly, and in much finer condition to meet the clover harvest.

The foregoing ideas that I have been free to express, have come through no solicitations from others, for certainly I have no "ax to grind," but are my individual ideas, gained from four years of experience in the production of honey by modern improved methods. If I am wrong in any of my ideas, I will thank any one to set me straight, and will cheerfully stand correction. We live to learn, and let us live conscious of the fact that we can never attain to so high a standard of perfection but that we can be taught something from our fellow-man.

W. T. F. Petty said it was well to disturb the queen a little to the convenience of the apiarist, even if it should prove that the colonies should not be quite as strong numerically, which he doubted.

Mr. Camm asked the dimensions of the frame that he (Mr. Petty) uses, to which Mr. P. replied, 18 1-6x4 $\frac{3}{4}$ inches, with closed ends, and frames spaced 1 $\frac{1}{2}$ inches from centre to centre. His hives are interchangeable, using one, two or three sectional brood-chambers.

To a question as to the way of removing the frames, should the bees glue them, Mr. Petty answered by asking the reason for removing them. Mr. Wallace considered it essential for removing and introducing queens,

etc. Mr. Petty claimed that he could find a queen in a sectional hive in one-fourth the time that others could in the large frame hives, by blowing a little smoke in at the entrance, when the queen would soon appear on top of the frames, where she could be easily captured. Mr. Petty uses wedges in place of set-screws; Mr. Black said that set-screws were essential to overcome swelling and shrinkage caused by variable weather. Mr. Petty said that tight, secure lids would avoid this difficulty.

Mr. Camm said that he did not disturb and handle bees as much as he used to; he had hives in which some of the combs had not been disturbed for years. He did not favor large combs as much as he used to, and he believed in interchangeable frames, thus being able to take drone comb from the brood-nest, and put above, etc. He prefers for general use a frame 12 inches long by 10 inches in depth.

Mr. Hambaugh considered it necessary to have all combs readily movable and interchangeable. It was essentially necessary in the spring in spreading brood, building up weak colonies, etc. He believed that strong colonies were the prime factor in honey production, and that we should labor to that end, and large combs were an advantage over small ones in this respect.

AFTERNOON SESSION.

President Camm, in his annual address, spoke at length of the magnitude of bee-keeping; of its growing importance as an industry; the sale of comb foundation the past season, of but one firm, aggregated 53,000 pounds, which was sufficient evidence of the magnitude of the business. He spoke of the necessity of finding a market for our product, and favored the idea of a union of bee-keepers with uniformity of prices, and placing a salesman upon the road to sell our product by sample. He said that the bee-keepers had no time from home duties to go upon the road. He spoke of the great necessity of putting our honey up in the most attractive shapes, etc.

THE USE OF SEPARATORS.

Mr. Petty said that he had used sections with full sheets of foundation, but the results were unsatisfactory. Some of the sections were bulged, while others were not fully drawn out. He had trouble with the salesmen, by their not being easily removed from the crate. Since using separators he saw no perceptible difference in production, while the honey was in far better shape for the market. He wanted, when his name was attached to a section of honey, for it to stand on its merits. He uses broad frames with wooden separators attached thereto.

Mr. Cullinan considered separators a detriment, especially tin, as heat in a cluster was necessary to the secretion of wax, and tin is a non-conductor of heat. He thought a great deal depended upon having the hives level.

Mr. Hambaugh said that anything put in the hive that would drive out

the heat was detrimental to honey production; that it was better to put up with some little inconveniences. The bulged and imperfect sections could be sold in the home market, and used upon our own daily tables, and the ones more perfect could be crated for markets at a distance. We cannot very easily afford a shortage, when the per cent. of imperfections are not too great. He believed that separators, especially tin, were a detriment to honey production.

Mr. Camm said, in looking over a large number of his sections, that it was difficult to tell which was top or bottom, and whether separators had been used or not. He considered that he got as much honey suitable for market without separators, and combs more securely fastened at the bottom. Mr. Petty said that bees did not start so many sections at once where separators were used, and left fewer incomplete ones. Mr. Hambaugh asked if bees would start as quickly with only starters in the sections, as they would where full sheets were used, and if as much honey would be obtained from the former as from the latter.

Mr. Camm said that consumers would educate themselves as to what was best in comb honey, sooner than bee-keepers would educate themselves to supply that which is best. He thought that the "fish-bone" could easily be detected, and worked against the honey-trade. He said that it was not the most honey that we were working for, but the most money.

Mr. Petty said that if the apiarist would label his honey that was drawn out on full sheets of foundation, and also that which was made from starters only, he would find that the honey built on starters would take the best.

"How can we keep the bee-yard clean of weeds?" was asked.

Mr. Cooper said he believed the lawn-mower the best. He had used sawdust, but found it blew around a great deal, making it unpleasant.

Mr. Hambaugh had found from experience that where chickens were allowed to run in the apiary they would make ugly work, especially in the morning, by scratching and throwing full the entrances to the bee-hives, making considerable work and no little annoyance. Besides, he had met with several narrow escapes from fire by sparks catching from the smoker, and concluded to do away with the sawdust under his hives. He laid his apiary off facing the southeast, and then set dwarf fruit of various kinds, 8 by 10 feet apart. He then made a small mound for each hive to rest upon, from old bleached ashes that had been used for soap-making, so that a fruit-tree would stand at the southwest corner of each hive. He had not yet used the lawn-mower, but thought that he would by another year, as he believed this about the most satisfactory plan.

"Is shade a benefit to the bees?" was then asked.

Mr. Petty said that the bees would be better off without it, and that they should be in open territory, with lots of ventilation.

Mr. Camm said that bees should have shade in the heat of the season, to prevent the combs breaking down.

"Will it do to move bees about the middle of November?" Mr. Camm replied, "Yes, provided they can have a flight right away." Mr. Petty said that there was nothing in the gorging idea, and that he would not hesitate to put them into the cellar for winter immediately on arrival.

Mr. Cooper then suggested the idea of raising wrens, as they were a benefit in eating worms, moth, etc. Mr. Camm agreed with Mr. Cooper.

"How do you sulphur honey so as to keep it free from moth?"

Mr. Petty said that he had but little trouble with moth; he crated his honey as soon as taken from the hive, and had noticed that when honey was paced in a dark room, moth would collect. He advised fumigating with sulphur, the fumigator to be at the top of the comb.

Mr. Hambaugh advised putting in a close room impervious to moth millers.

"What should be the difference of price between comb and extracted honey?"

Mr. Wallace said that 150 pounds of extracted honey could be obtained as easily as 50 pounds of comb honey.

Mr. Camm said that he considered 8 cents per pound for extracted better than 12½ cents for comb honey. He could get 150 pounds of extracted to 100 pounds of comb.

Mr. Petty said that he sold comb honey at 15 cents per pound, and extracted at 8 cents; he thought that he could make as much at one as the other.

"Will honey keep that has been extracted from well-ripened sections, and sealed in air-tight vessels?"

Mr. Hambaugh stated that he had never tried the plan. He had extracted as often as every seven days, with no bad results; his honey was put in barrels and placed in the cellar. He thought that the results would have been larger had he extracted oftener.

Mr. Camm had seen honey in the hands of dealers, that had soured. He thought it was on account of its being placed in a damp cellar. He considered a damp cellar the worst place in which honey could be placed.

Mr. Petty had noticed signs of fermentation from what he considered the best of honey when placed in air-tight glass jars.

"Is a bee-space between the tops of the brood-frames and the supers of any advantage?"

Mr. Black said that it was an advantage. He had tried putting sections directly on the frames, and did not want any more.

Mr. Cooper had tried the same, and did not like it. He left a ¼-inch bee-space between the honey-board and sections.

Mr. Petty said that the difficulty of brace-combs could be obviated by making the bee-space ¼ of an inch instead of ⅓ of an inch. Mr. Camm confirmed Mr. Petty's statement.

Mr. Petty said that he had done away with the slotted honey-board,

and that one bee-space was all-sufficient.

Mr. Hambaugh stated that bees in their natural state built their combs straight, with no obstructions, making continuous passage-ways from bottom to top, and considered it a vital point to construct hives with continuous passage-ways as near as possible.

"Are side passage-ways in sections and supers of any advantage?" Mr. Camm replied that he had tried this plan, and believed there was an advantage. Bees seemed to attach the section all around in better shape.

The convention then adjourned till 9 a.m. on the following day.

THURSDAY SESSIONS.

The convention assembled at 9:30 a.m., when President Camm read an essay on "The Different Races of Bees."

His experience had extended to Syrians and Cyprians. The Syrians he thought were inclined to breed up too late. They came through winter in fair condition, built up very fast, brought in honey like water, but the cappings seemed to lay directly on the honey, presenting a greasy appearance. They were very irritable if the combs were disturbed, but easily subdued with smoke; also very nervous and fidgety when being handled. They invariably crossed with blacks, and the crosses were no better, if as good, as the pure bloods. He would not have Cyprians. He could not subdue them with smoke. They are vicious and cross. They are good honey gatherers, and for rearing queens, as he could get one-half dozen queens from one frame. They swarmed later than any other bees, but made up for the lost time. The queens had a trait of flying when being handled.

Mr. W. J. Cullinan, of Mt. Sterling, then read the following essay on

MARKETING HONEY.

I shall not attempt a complete and exhaustive treatise upon this subject, but merely outlining its principle features, leave them to be drawn out and rounded up by those whose riper experience in the matter will give to their utterances greater weight, and make them of much more value to the listener.

It is with pleasure that we view the rapid advancement that is being made in the science of apiculture, the vast improvement in methods of manipulations of lives and frames, as well as the breeding of the bee itself; while gazing on this pleasing picture we cannot shut our eyes to the fact that honey has not as yet been given its rightful place among the commercial products of the world. And why, we ask, is this thus? It is because, in the great struggle that has been made to attain pre-eminence in the breeding of bees and the production of honey, we have, in a very marked degree, lost sight of that equally important concomitant of the business, viz: The profitable disposition of the article which we produce.

That we have learned the art of producing honey is amply attested by

the millions of pounds now annually thrown upon the markets of the world; that we have *not* learned to dispose of the same in an advantageous and profitable manner, the over-crowded and constantly glutted state of those markets proclaims in thunder tones.

Some cry over-production! To such I would say that there is no over-production, nor is there likely to be, if we but educate the people to its use as we produce it.

The practice of forcing honey in large consignments upon the commission men and dealers of the great trade-centres of the country, is doing more to break down prices and ruin the business of the apiarist than anything I know of in the category of evils to-day. And so wide-spread and general has this mania become that prominent commission merchants are advertising that they will not receive consignments of honey without previous arrangement with the owners. Prices quoted in the over-glutted markets of New York, Boston and Philadelphia become the standard for Cincinnati, Toledo and Chicago—in fact, the *whole country*—and the demand ever unequal to the supply, the tendency is always downward. And so it seems that if this state of things continues, the bee-keepers must be content to work for a very small profit in the future.

I have a remedy for this much-to-be-deplored state of affairs, and it is contained in one short sentence, viz: "Work up your home market!" These few words contain volumes; they are the key to the whole problem, and if acted upon they will work miracles toward keeping up the price of honey and creating a demand therefor. The secret lies in keeping the honey out of the hands of commission men, out of the large cities, and bringing into actual contact with the consumers in the country.

Having lost its rightful prestige through the folly and neglect of our ancestors, it remains for us by persistent endeavor in wise methods to restore it to its proper place in the commerce of to-day. Consumers having long since learned to exclude it from their every-day list of edibles, and regard it as a luxury to be indulged in only on rare occasions, no longer run after honey as they would after meat, flour and other staples, and consequently we must run after them and solicit their patronage if we would market our product.

Had I a large crop of honey to dispose of, I would start out and canvass the surrounding country, taking in as much territory as the amount of my crop would warrant. I would have my honey in attractive shape, my comb honey in one and two pound sections, extracted in one, two and three pound glass jars, ten-pound tin pails, and fifty-pound kegs. I would stop at every house, show them what I had, explain its merits, and I would *make sales*. In a month or so I would canvass the same territory again, and so continue till all was sold.

In placing honey in the hands of dealers, I should select such as under-

stood its merits best, and could best explain them to his customers, and would push its sale; those who leave it to sell itself are not the proper persons to handle honey.

Dr. J. P. H. Brown, of Augusta, Ga., in an essay read before the Texas convention in 1883, and published in the AMERICAN BEE JOURNAL for that year, truthfully said: "Not one grocery merchant in fifty knows how to handle honey. The expert salesman, like the expert producer, must have a natural fitness for the business. When a merchant is willing to undertake it, and displays the necessary tact and ability to introduce the commodity to his customers, the bee-keepers of the neighborhood should sustain him; because there would be a likelihood of his being better able to keep up the price and extend the sales, than if it was put in the hands of half-a-dozen grocerymen of the town to sell at all sorts of prices, and to be offered in all sorts of shapes." I presume all can verify the truth of these remarks, which are as applicable here as in Georgia.

Honey placed in the hands of dealers to be disposed of, should always be in the most attractive shape possible. The day is past when honey can be sent to market in uncouth shape, and command a paying price. Wherever progressive specialists have planted themselves in a community, loose comb honey defiled by bee-bread and dead bees, is no longer considered "a dish fit to set before the gods;" and must, in the near future, together with the log-gum and box-hive, join the silent army of the things that were.

I have found comb honey to sell well here in the one and two pound sections, the one-pound being preferable. I do not think a smaller section would sell to any extent in towns of this size. Extracted honey I have found to take best in pint and quart Mason jars. Larger packages do not seem to sell well in the stores, but in soliciting orders I have sold considerable in 10-pound and still larger lots.

As to the time of selling, I would advise to begin as soon as customers can be obtained, but not to *push* its sale early in the season. The demand for honey is never very great until the advent of cool weather. There is always a lull in the honey-trade at the time new sorghum comes into market, but this lasts but a few weeks, and the honey-trade goes on again.

In conclusion I would say, bide your time; be in no hurry; show no disposition to sacrifice your product, and, my word for it, you will be able to dispose of the same in due season, and at remunerative prices.

These, in brief, are my methods. If any one has other or better methods, or can improve upon those which I have given, I shall be glad to hear them.

Mr. Hambaugh had found from personal experience that the small producers were the ones that ruined the markets. Grocerymen were inclined to place their own price on the honey of unposted producers, who would

accept the price rather than return home with their honey.

Mr. Middleton said that he had no trouble in selling honey in Jacksonville markets. He had never got less than 15 cents per pound for comb honey.

The convention adjourned until 1:30 p.m., when it was again called to order.

It was decided that Mr. Middleton should mail to each member of the society, packages of white California sage seed, now in his possession, at the expense of the society.

The subject of uniting the two societies in one—the "Illinois Central" and the "Pike County Association"—was then discussed, and the idea met with favor. It was unanimously decided to retain the present officers, and meet with the Pike County Association at their next annual meeting, for the purpose of uniting with the same, the name to be changed to the "Western Illinois Bee-Keepers' Association," or some other equally appropriate name.

Mr. Petty then related his experience of the past in wintering bees, being largely in favor of cellar wintering. He stated that he had weighed his colonies when put into the cellar and when taken out, and the consumption of honey would aggregate about 6 pounds. He had not lost a colony of bees in five years, but had lost a few weak nuclei through neglect.

In regard to a question from Mr. Camm concerning Alsike clover, Mr. Cooper said that it was preferable to the red for hay; it was not so dusty, and kept much better in the mow. He would sow no more red clover when he can get Alsike. His neighbors sowed it and were well pleased with it.

Is pollen in the combs a detriment to bees in confinement? Mr. Petty said it was not of sufficient detriment to pay for removing it. Mr. Hambaugh said under certain circumstances that it was, such as during long confinement and continuous cold, with no relief by cleansing flight. Mr. Camm thought if the pollen was kept from souring, it would not injure them, and that sour honey was as conducive to disease as pollen.

"Would you extract honey from the brood-chamber during a honey flow?" Mr. Hambaugh said that he would not, unless it was necessary to give the queen laying-room.

"Will it do to feed dry sugar to bees in confinement?" Mr. Camm said, "yes," if it was Porto Rico, a soft sugar.

The convention then adjourned, to meet as stated above.

J. M. HAMBAUGH, Sec.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It **will pay** any one to devote a few hours, to get subscribers.

Glassed and Unglassed Honey Sections.

C. M. CRANDALL.

The market quotation from Kansas City, Mo., casts reflections on what the commission firm terms "home bee-keepers." I am so fortunate as to be one of the "home bee-keepers" referred to, and had a good percentage of that 70,000 pounds of honey that was said to be kept out of the Kansas City market until late. The assertion that the "home bee-keepers" held their honey till about Dec. 1, or until that report was made, was untrue. I have had honey in the Kansas City market every hour since July 1, 1886; I also had glassed and unglassed, side by side, in not less than three commission houses; and so have Messrs. L. W., A. A. and P. Baldwin, J. H. Jones, C. K. Ormsby, A. R. Matthews, John Conser, and others. More than 60 per cent. of our crop sold by Oct. 15, and fully 90 per cent. of it was glassed; but it was not as bad a case of "glassing" as the commission firm would have the vast army of intelligent readers believe.

They say that 160 pounds of honey has 60 pounds of glass on it; while the truth is that when we glass both sides there is less than 36 pounds of glass on 160 pounds of honey. While they have been selling honey consigned to them for 11 to 13 cents per pound unglassed, the "home bee-keepers" have been selling their honey (not a whit better) through other commission houses for 14 and 15 cents per pound, and both sides glassed.

While the commission firm in question has been fighting glassed honey, and denouncing it as a fraud, our customers have demanded glassed honey, and if that commission firm would read the BEE JOURNAL they would see in the New York quotations glassed honey quoted at 1 cent per pound higher than unglassed, and that, too, in a market where 70,000 pounds would cut a small figure.

I will say for the benefit of all commission firms, that as long as our customers demand honey glassed, the "home bee-keepers" will furnish it, and they will not "hold back till late," and then throw it on the market and reduce the prices, but will do as we did this year, and for the last twelve years, namely, stock the Kansas City market early in July, and try to keep the honey market up, and not try to run it down, as that commission house has tried to do for the last two years. If they had staid with the "home bee-keepers" and held the market up, we could have obtained 15 cents for our "home bee-keepers'" 70,000 pounds, as well as the hundreds of thousands of pounds shipped to Kansas City from other points.

In conclusion I wish to say this to bee-keepers who ship honey to the Kansas City market: When you send a fine article, limit the commission merchant to some price. I have seen thousands of pounds of honey in Kansas City shipped from Iowa, Wisconsin, Michigan, Illinois and other

points—as nice an article and in as fine condition as any—sent here without a price set on it, and I have seen that honey sold this year for 11 cents per pound, when, if we had all held for 14 or 15 cents, it would have brought that. The bee-keepers of western Missouri and eastern Kansas have always tried to hold the market up, and have always succeeded, until honey from other points was thrown on the market and sold at the first offer. Independence, Mo.

[This illustrates one of the evils complained of concerning the "Honey Market Reports." It is one that never should have existed—that of wedging *free advertising* into market quotations. Hereafter we shall omit all such matter, and confine the reports to the figures without remarks, except to express the state of the market—such as active, dull, lively, quiet, etc. We hope that all other bee-periodicals will do likewise; and thus do away with one abuse of the privileges heretofore granted.—ED.]

Legislation for Bee-Keepers.

J. E. POND.

The question of priority of location of an apiary is one on which my views are so well known, that I need not, neither do I care, to discuss it; but the question of legislation on that subject is one on which more light is needed, and for that reason may well have a small share of attention.

Special legislation has at all times, in civilized nations, been a matter of serious thought, and one that has been severely criticised. It is simply making laws for the protection of a certain class against all others, and as a consequence the means of creating monopolies. The importance and gravity of the question is such, that only for the strongest possible logical reasons, or perhaps (unfortunately) for the bribe of a large sum of money, has any special law affecting the relations of business ever been passed.

So far as apiculture is concerned, the Congress of the United States has no power to legislate in the matter; each and every State alone having the right under the federal compact to make laws that will govern or control. Now the question arises, can any State make any law whatever, that will give any one man more rights than another to keep bees in a certain locality, that will work fairly and impartially? If so, what? In the first place, bees are foragers, and do not confine their predatory visits to any given field; neither can they be so confined; hence the illustration of breeders on the plains has no force here.

Originally, society in a crude state had no boundaries; there was land enough for all. Soon, however, increase of population made such

boundaries necessary, and the land tenure obtained. Apply this to bees: If a certain man owns all the land for a radius of five or six miles from a given centre, and keeps his bees at that centre, he may well claim that no one else shall keep a colony on his land; but how about the case, should he place his apiary directly on the boundary between himself and his neighbor? Again, suppose the neighbor owns all the land save one-fourth of an acre; can any equitable law be framed that would say the owner of the one-fourth of an acre may keep bees, while the owner of the rest of a large township shall keep none?

In my opinion, the whole question resolves itself to this: Bee-keeping, like every other occupation, should be governed by the same general laws, competition alone being allowed to control. The man who is the best qualified by study and experience, and who by the application of his mental powers can produce honey the cheapest, will be the winner in the race. In other words, the "survival of the fittest" is the only law that can be made that will prove just and equitable.

If the state of things were such that a certain person was obliged by law to keep bees, then perhaps equitable laws could be framed to protect him; but so long as we all in common have the legal right to labor in a certain field or not, the choice being our own, it certainly is cowardly on our part to ask for any protection that is not given equally to any other branch of business. As a lawyer, I might as well ask that no bee-specialist should attempt to occupy my field, as for him to ask that I should not be allowed to keep bees, simply on the question of priority.

Foxboro, Mass.

For the American Bee Journal.

Disturbing Bees in Winter.

P. M. PUHL.

In regard to disturbing bees in winter, my experience has been the reverse of Dr. Mason's, as described on page 8. In November, 1883, I put 149 colonies into a cellar under a kitchen, the hives being placed 5 tiers high, about 3 inches from the ceiling. The kitchen was 15x23 feet, and was the children's play-room, when not in use. When they were in it, I would go into the cellar to hear what effect it would have on the bees, and it seemed like being in a boiler-shop with all hands at work. I would give the children a signal to stop playing, so I could hear if it bothered the bees. But they were as still as could be.

I swept the floor once a week, and five times during the winter I scraped the dead bees from the bottom-boards with a wire hook. I had one colony that I could get at conveniently, and I uncovered it every time that I went into the cellar; at least a dozen times I took out combs to see what they were doing.

On April 14, 1884, I took out of the cellar 148 colonies, and I never before,

nor since, have had bees so strong and sweet in the spring, and they consumed very little honey. Some colonies had natural stores, some sugar, some part sugar and honey, and about a dozen had plenty of bread, but I could not distinguish a particle of difference. The one that died had not stores enough, and was about in the centre of the tier of hives. I swept up a trifle over 3 bushels of dead bees, from November, 1883, to April 14, 1884.

I have been in about fifteen cellars, and I never yet discovered that outside noise disturbed bees. I hope that no one will misunderstand me, and think that one can go into the cellar and kick or handle the hives much as he pleases, without injury to the bees, for I believe in keeping everything as quiet as possible; but not as quiet as a bee-keeper thinks who came to see me a few days ago. While in the cellar talking to him about the bees, he stopped me and whispered, "Don't speak so loud; you will disturb your bees." I do not believe that any outside noise whatever will disturb bees in a cellar, as long as the floor upon which the hives stand, or the walls which they accidentally touch, are not jarred.

South Toledo, Ohio.

For the American Bee Journal.

The Honey-Producers' Association.

DR. G. L. TINKER.

The editor's advice on page 723 of the BEE JOURNAL for 1886, is the same that I have followed for years in selling my crop of comb honey. At present my honey is selling in this place on a commission of only 10 per cent. I find that there is no hesitation anywhere to taking it on 15 per cent., and I think that is what it should be. There are many reasons why we should pay the retailer well. I am with our solicitous and unselfish editor of the BEE JOURNAL and Mr. Baldrige in this matter, heart and soul, and I hope immediate action will be taken by honey-producers, to stem the course of commission men in forcing down the price of honey in our leading markets. Our merchants and grocerymen in the small towns and cities are guided by these low market reports in making all purchases.

Farmers and others who have small amounts of honey to sell, are compelled to almost give it away; some refusing the low prices offered, go about trying to sell direct to consumers, and the latter opine directly that there is no sale for the article in the market at the price asked, and the result is that it goes a-begging at a price below the cost of production. All this is traceable directly to the low market reports of commission men. But the fact that comb honey has sold here on our streets at 8 and 10 cents per pound, has not prevented me from selling my honey readily at 13 cents per pound. I believe that it would sell for more if it was not for

the discouraging reports complained of.

If I had more honey than I could dispose of at home, I would ship it to large towns and cities, and place it myself in the hands of retailers on commission, and keep out the middle men entirely. Such a course on the part of producers would soon change the tenor of our market reports. At all events I would fix my own price for honey, and in no case let a middle man do it for me.

I have proved this course to be a practical one, and I hope all will approve of the course suggested by Mr. Baldrige, to establish a honey-producers' association to make out our market reports, and to offer such suggestions as may be to our mutual advantage. I would further suggest that commission men be not allowed to even advertise their reports in our bee-periodicals.

New Philadelphia, Ohio.

For the American Bee Journal.

Bee-Keeping in Cuba.

A. SNYDER.

Having just returned from Cuba, I desire to give a description of that country for bee-keeping. Scorpions and flies are very plentiful; the sting of the former is very poisonous, often causing lock-jaw and death. Tarantulas (large spider) are quite plentiful, the bite of which is almost certain death. There are many large snakes, but they are not poisonous. The natives all carry a sharp-pointed knife about 8 inches long, in their belt. Their food is very different from ours, and I thought I had next to nothing to eat; not a particle of butter was to be had; no fresh meat, except for an enormous price. Their principal meat is beef cut in thin strips, made as salty as possible, and dried in the sun as hard as leather.

I have had Cyprian, Syrian and hybrid bees (all of good mettle), but they are as gentle as lambs compared with the bees that I saw in Cuba. No one can work with bees there without veil and rubber gloves, and then one's clothes are pretty well covered with stings and bees.

The climate is as fine as one could wish for. There is seemingly no end to the flow of honey, but the price is very low, only about 20 cents per gallon, or 1½ cents per pound after paying the duty, which is 20 cents per gallon. Cuban honey is of fair quality, but rather dark. I think that here at the North we can winter our bees with less labor, less expense, and less loss than they can be summered in Cuba. They need constant care during summer, there being but very little honey in the fields at that time to protect them from fighting robbers, and being destroyed by moths. Their honey harvest is from November to March. All the industries of Cuba seem to be far behind those of the United States.

Indian Fields, N. Y.

Local Convention Directory.

1887. *Time and place of Meeting.*
 Feb. 2.—N. E. Michigan, at Bay City, Mich.
 W. Z. Hutchinson, Sec., Rogersville, Mich.
 Feb. 3.—Wisconsin State, at Madison, Wis.
 F. Wilcox, Sec., Mauston, Wis.
 Feb. 4.—Fremont Progressive, at Fremont, Mich.
 Geo. E. Hillton, Sec., Fremont, Mich.
 Feb. 12.—Hardin County, at Eldora, Iowa.
 J. W. Buchanan, Sec., Eldora, Iowa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Lady Presidents.—Mrs. L. Harrison, of Peoria, Ills., writes:

Hit him again! Knock the chip from his shoulder! Mrs. Cassandra Robbins, of Indianapolis, Ind., was President of the Indiana State Beekeepers' Society for 1884; and Mr. Muth said that she was the best President they had in working up the meeting; and made the best address, although she was diffident as a presiding officer.

Bees Wintering Well.—Wm. Anderson, Sherman, Mo., on Jan. 17, 1887, says:

Very cold weather has prevailed here for some time. On Jan. 3 the mercury dropped down to 21° below zero. It was the coldest we have had for some time, though my bees had a good flight on Jan. 12 and 15, and are in good condition to stand another long confinement. Bees are doing well in this locality this winter, and if nothing adverse happens to them hereafter, we will have plenty of bees next spring.

Report.—J. D. Gehring, Parkville, Mo., Superintendent of the Park College Apiary, writes as follows on Jan. 18, 1887:

We have now 40 colonies of bees in good condition, packed with leaves and on the summer stands. We obtained 600 pounds of white comb honey, and 300 pounds of extracted, from 14 colonies, spring count, and an increase of 16. Five were queenless in May, but they held their own and built up to strong colonies, but gave no surplus.

Raising the Price of Honey.—Geo. Poindexter, Kenny, Ills., writes:

Having had some experience in selling honey, I would say that when I am in a city or town with a sample of honey in one and two pound sections, I enter a large grocery store, show the sample, and tell them that it is warranted white clover or basswood honey, as the case may be. The grocer says, "That's nice; what is that worth." I reply, 15 cents per

pound. "Oh," he says, "just step back here and I will show you Chicago prices." In a pamphlet called the *Chicago Grocer*, he finds one-pound sections quoted at 11 and 12½ cents. "We can't pay any more than Chicago prices," he says. Then I take my honey and try some other grocer, when I get the same kind of reference, and so on until I have no honey sold at 15 cents. What shall I do? Wait in the town until the price of honey raises, or sell it at 11 to 12½ cents per pound? Or would it be better to go home and wait until the honey all freezes and cracks, then sell it in the spring with a loss of leakage, and at a lower price? I would like to join an organization that would raise the price of honey, and I would give a little money and all my influence to help make it a success. But with a big crop of fruit of our own, and California fruits lasting all winter, I do not think that the organization would be a success.

Clean, White Sections, etc.—W. H. Kerr, Waynetown, Ind., writes:

Is there any surplus honey case made, that will only allow the bees to touch the inside of the sections? The time has come when we *must* place our honey on the market in clean, white sections—sections that bees have not crawled over, and that have not been covered with propolis. I commenced last May with 25 colonies, increased them to 43, and took 2,100 pounds of honey—1,500 pounds of it being in one-pound sections, and the balance extracted. I have 8 colonies in the cellar, 12 in a bee-house, and the balance packed on the summer stands.

[No; the edges of all sections are more or less exposed to the travel of the bees. You can clean them by scraping.—ED.]

Successful Wintering Expected.—S. Shoup, Coloma, Mich., on Jan. 16, 1887, writes:

The prospects are very fair so far. Bees seem to be in good condition, both in the cellar and on the summer stands, and bee-men generally, here, are feeling pretty confident that the bees will winter well, unless this cold spell remains too long. The past season was a very good one here. I have disposed of the most of my honey at a very fair price. I am holding it at 15 cents per pound. I have taken considerable pains in putting it up, and ship only that which is first-class.

Two Colonies in One Hive.—W. Mason, Fillmore, Ind., on Jan. 15, 1887, writes:

In Query, No. 359, it is asked whether it is an advantage to winter 2 or more colonies in one hive. I have 3 colonies in a bee-house now, and I will wait for the results and report. Last spring I put 2 colonies into a Mitchell long hive, putting a

division-board between them, and placing a cloth over them. On the third day I took off the cloth, put on the honey-boxes, and put both colonies together for surplus storing. To my surprise everything worked well; they worked rapidly, filling the upper story twice with two tiers of sections. I prepared 2 others in the same way, and with about the same results; but the queens must be retained in the brood-chamber, and in this way we may work as many colonies as we please in one hive, with as many mistresses, so long as they stay at home. I probably will give this matter a more extensive test next season. Up to Jan. 12, we have had very cold weather, the temperature being as low as 32° below zero. The temperature in the bee-house is 42° above.

Bees Under the Snow.—Stephen Gillson, Eureka, Mich., on Jan. 14, 1887, says:

I am wintering 4 colonies of bees. The hives are packed on top with cushions, and protected by a wind-break all around, except the east side. The hives are full of honey. Last night we had a blizzard that covered them entirely with snow. I am keeping them merely to study their nature, and as a pleasant pastime.

Good Results.—Chas. Solveson, (50-90), Nashotah, Wis., on Jan. 16, 1887, writes:

White clover began to bloom on June 1—about 15 days earlier than usual—and my 50 colonies were hardly prepared for so early a harvest; yet from 48 colonies worked for honey, I obtained 2,500 pounds of comb honey, and 3,000 pounds of extracted honey, nearly all being from white clover, as we had but a one-fourth crop of linden honey. We hardly ever have any fall honey, but the past season, however, the bees gathered a lot of dark, bitter stuff, which I presume is what is called "honey-dew;" although I removed large quantities of this "stuff," much still remained amongst their stores for winter. I hope, however, that it was mostly consumed before they were placed in their winter quarters. On Nov. 24, I carried into the cellar 78 colonies, while 12 remained on the summer stands packed with chaff. All appear to be doing well so far, although it has been 40° below zero.

Gasoline Stove for Heating Bee-Cellars.—Dr. A. B. Mason, Auburn-dale, O., writes:

Dr. Tinker, on page 825 of the *BEE JOURNAL* for 1886, says "There is nothing impracticable about raising the temperature of a bee-cellar by means of an anthracite coal stove." Where would the Doctor put the stove-pipe, if there was no chimney for the cellar? My "better half" helped me out of such a dilemma two years ago. Our cellar was getting too cold to suit me, and I could think

of no way to warm it. We burned coal, so I had no live coals to use, but we have a gasoline stove, and she suggested that we try that, and it worked to perfection; for in a very few minutes the temperature was all right. Now I hope no one will ask me what I would do if I had no gasoline stove or chimney, for I should at once say, get a gasoline stove, especially if you have a wife, mother, or sister that has to swelter over a hot stove in preparing you something to eat, or when ironing your "Sunday-go-to-meeting shirt." I have been using that same stove again this winter, and with lots of comfort too, to keep the cellar at the right temperature.

The Priority Question.—Dr. C. C. Miller, Marengo, Ills., says:

And now it is Mr. L. N. Tongue, on page 24, who sets up the priority question in order to knock it down. Has Mr. Tongue not yet found out that nobody ever asked for, or hinted at wanting legislation on the priority question?

Results of the Season.—John P. Wylie, Prairie Centre, Ills., on Jan. 14, 1887, says:

I started last spring with 15 colonies of bees in healthy condition. The first swarm issued on May 22, and the total increase was 36 swarms. I sold 3 first and 2 second swarms when they issued; I now have 46 colonies. I secured 2,600 pounds of comb honey. Some of the second swarms did not yield more than 20 pounds. The drouth cut the crop considerably shorter than it would have been, as the white clover plants dried up and did not yield much honey.

Partly-Filled Cases on Hives.—J. F. Benner, New Lisbon, O., on Jan. 12, 1887, writes:

I commenced last spring with 16 colonies, part Italians and part hybrids. Ten were good colonies, 4 medium, and 2 weak. The spring was late, but with care they built up rapidly, and commenced to swarm about May 15, earlier than I had known bees to swarm for 40 years. I increased them to 35; I could have increased them to many more, but not wanting them, I put back and doubled up quite a number. I took about 1,500 pounds of fine comb honey in one-pound sections, and 100 pounds of extracted. I could have taken perhaps 200 pounds more in partly-filled cases, but as honey was low in price, and of dull sale, I concluded to let the bees have it. I know many of our best apiarian writers condemn the practice. My bees are all in chaff hives, packed away about Nov. 1, in excellent condition.

Dr. Miller's Book, "A Year Among the Bees," and the *BEE JOURNAL* for one year, we will club for \$1.50.

BEE JOURNAL

Issued every Wednesday by

THOMAS G. NEWMAN & SON,
PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL.
At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

We Keep this Notice standing all the year round: "Always give the name of the Postoffice to which your paper is addressed. Your name cannot be found on our list unless this is done," and yet many ask us to change their address without even mentioning to what Postoffice it has heretofore been sent. It often costs us more to find their old address than they pay for the BEE JOURNAL for a year; as we may have to examine our subscription lists in every State, Province and Territory in North America. Please be more careful in the future, and never omit your name, Postoffice, county and State.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1 00	1 00
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 25	1 25
Bee-Keepers' Guide	1 50	1 40
The Apiculturist	2 00	1 70
Canadian Bee Journal	2 00	1 75
Rays of Light	1 50	1 35
The 7 above-named papers	5 25	4 50
and Cook's Manual	2 25	2 00
Bees and Honey (Newman)	2 00	1 75
Binder for Am. Bee Journal	1 60	1 50
Dzierzon's Bee-Book (cloth)	3 00	2 00
Root's A B C of Bee-Culture	2 25	2 10
Farmer's Account Book	4 00	2 00
Guide and Hand-Book	1 50	1 30
Heddon's book, "Success"	1 50	1 40
A Year Among the Bees	1 75	1 50

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

Premium Worth Having.—The **New York World** and the **AMERICAN BEE JOURNAL** (both weekly) will be sent for one year to any address in North America for \$2.00. And in addition **PRESENT** to every such **CLUB SUBSCRIBER** a "History of the United States," containing 320 pages and 22 fine engravings, bound in leather and gilt.

This "History" will be sent **FREE** by express at the subscriber's expense; or will be mailed for 10 cents extra to any place in the United States or Canada.

It is arranged chronologically by years, from 1492 to 1885. Every event is narrated in the order of its date. These are not confined, as in other works, to political matters, but embrace every branch of human action.

This premium is worth the whole of the money sent for both periodicals, and should induce thousands to subscribe, and thus get two unrivalled weeklies for nothing.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

All New Subscriptions will begin with the year, and until further notice we will send the back numbers from January 1, unless otherwise ordered.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a **DEMAND** for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Our Book Premiums.—To encourage all our present readers to get one or more additional subscribers we will present 25 cents' worth of books for every new subscriber (accompanied with \$1 for one year's subscription), sent direct to this office. Thus for five new subscribers with \$5, the getter up of a club gets \$1.25 in valuable reading matter, to be selected by himself from our list on the second page of this paper. It will pay you to devote a few hours to the interests of the BEE JOURNAL. Every one who keeps bees ought to take it. We will furnish sample copies **free** in any quantity to those who intend to get up clubs. We expect to get 5,000 new subscribers for 1887.

The Report of the Indianapolis Convention is now published in pamphlet form, uniform with that of last year. It will be sent postpaid for 25 cents to any address.

We have also bound it up with last year's, together with the History of the Society; this we will mail for 40 cents. Or if you send us one new subscriber (with one dollar) besides your own renewal, we will present you with a copy by mail.

System and Success.

All who intend to be systematic in their work in the apiaary, should get a copy of the Apiaary Register and commence to use it. The prices are reduced, as follows :

- For 50 colonies (120 pages).....\$1 00
- " 100 colonies (220 pages)..... 1 25
- " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

As a premium to the second largest club we will send my mail, postpaid, a copy of the "Farm Account Book," worth \$3. The postage is 20 cents.

A New Crate to hold one dozen one-pound sections of honey.—It has a strip of glass on each side, to allow the honey to be seen. It is a light and attractive package. As it holds but one tier of sections, no damage from the drippings from an upper tier can occur. We can furnish the material, ready to nail, for 9 cts. per crate. Glass 1½¢. per light, extra.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have just gotten up a lot of these Labels, and can supply them at the following prices : 100 for \$1.00 ; 250 for \$1.50 ; 500 for \$2.00 ; 1,000 for \$3.00 ; all with name and address of apiaarist printed on them—by mail, postpaid.

There will be a Rush for supplies needed in the apiaary after awhile, and we cannot do better than to urge all to look over their stock, ascertain what will be needed, and get it on hand before it is necessary for use—thus avoiding the perplexity consequent upon its possible delay in reaching them in time.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for reference and examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

It is No Longer an Open Question whether newspaper advertising pays. What a business man now considers in this connection is how, when and where it can be done to insure the best returns on the investment. Have something of value to sell; then select the paper which sends the greatest number of copies to those who should use the article. Use as few words as possible, and let them be printed in large type, so as to catch the eye. These are some of the secrets of successful advertising.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax :

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey ; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12½@13c. No demand for extracted, and very little for comb.
BEE SWAX.—22c. R. A. BURNETT,
Jan. 19. 161 South Water St.

NEW YORK.

HONEY.—We quote prices as follows : Fancy white in 1-lb. paper boxes, or glassed, 13c.; same unglased, 12c., and in 2-lb. glassed sections, 10@11c.; off grade 1 to 2 cts. per lb less. Calif. comb, 8@10c.; fancy buckwheat 1-lb., 8½@9c., and 2-lb., 7½@8c. Extracted white clover, none in the market. Calif. ext'd., 40-lb. cans, 5@6c.; buckwheat, in kegs and barrels, 4@5c.
BEE SWAX.—21@23c.

Dec. 7. McCAUL & HILDRETH BROS.,
34 Hudson St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 13@14c.; 2-pounds at 11@12c. Extracted, 5@7c.
BEE SWAX.—24 cts. per lb.
Jan. 1. BLAKE & RIPLEY, 57 Chatbam Street.

DETROIT.

HONEY.—Few aules are reported. Best white comb, 12½c.; Fall comb honey, 10@11c. Extracted is offered for 6@8c.
BEE SWAX.—Firm at 23c.
Jan. 10. M. H. HUNT., Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote for extracted, 3@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way.
BEE SWAX.—Good demand, 20@22c. per lb. for good to choice yellow.

Jan. 11. C.F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, in 1-lb. sections, sells at 13c.; second quality white, 12c. dark 1-lb., 10c.; white 2-lb., 11@12c. Extracted, 6c. Market dull.
BEE SWAX.—25c.
Jan. 14. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 12@12½c.; 2-lb., 11@12c. No call for dark. White extracted, in barrels and kegs, 6@8½c.; in small packages, 7@8c.; dark, in barrels and kegs, 5@5½c.
BEE SWAX.—25c.
Jan. 19. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote : Comb, extra white, 12@13 cts.; amber to white, 8½@11. Extracted, white, 4¼@4½c.; amber and candied, 3¼@4c. Trade is quiet.
Jan. 10. O. B. SMITH & CO., 453 Front St.

HONEY.—We quote good to choice extracted at 4¼c., and comb honey firm at 6@12c.
BEE SWAX.—Active at 14@21c.
Jan. 10. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lb., 8@10c.; white clover 2-lb., 10@11 cts.; dark 2-lb., 7@9c. Extracted, white clover, 6c.; dark, 4@5c.; white sage, 5@5½c.; amber, 4¼@5.
BEE SWAX.—20@23c.
Jan. 13. CLEMONS, CLOON & Co., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 3¼@4c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4@5. in cans, 5@6c. Market dull.
BEE SWAX.—Firm at 21c. for prime.
Jan. 19. D. G. TUTT & CO., Commercial St.

Advertisements.

READY TO SHIP.—Langstroth Brood-Frames, prepared to nail, at 90 cents per 100 ; 500 for \$4.00. I have several thousand of these Nice Brood-Frames in the flat, which, if ordered before Apr. 1, may be had for \$4 per 1,000, freight prepaid by C. W. DAYTON, Bradford, Iowa.
2E1F

EVERGREENS.

FOREST TREES.—11,314,000 sold in 1886. Ten times as many ready for 1887. I offer the largest stock, greatest variety and lowest prices to be found in America. Wholesale lists free.
Geo. Pinney, Evergreen, Door Co., Wis.
2E2T

CAN YOU RESIST THIS ?

THE BEAUTIFUL, instructive and amusing **CHROMO CARD,** designed especially for Bee-Keepers. It has a decided happy effect wherever shown. This CARD will not be thrown away. When the articles represented upon it are explained, the story will be repeated many times, educating people and extending your reputation. **Bees, Flowers, Children and Implements** elegantly printed in eight colors.

Sample package, 10 cts.—One sample and Price List of some old things, some new things, and all to profitably aid bee-keepers.

Address, **J. H. MARTIN,**
4Atf HARTFORD, N. Y.

FOR SALE.—FARM—splendid location for Bees or Fine Stock.—Address, WM. STEPHENS, Chetopa, Labette Co., Kans.

1A17t

Bee-Keepers' Supplies

of all kinds kept in stock, at low rates.

THE QUINBY SMOKER a specialty.

Send for Illustrated Price-List.

W. E. CLARK,
Successor to L. C. Root,
Oriskany, Oneida Co., N. Y.

JESSIE.

We are the introducers of the **Jessie Strawberry**, and the only firm that can supply plants to the trade. It is the most remarkable new fruit of the age. Send for particulars and colored plate; also for copy of Green's Fruit Grower, and our illustrated Fruit Catalogue.

TREE SALESMEN WANTED.

You can make money selling our trees, and get your own trees free. Green's Guide to Grape Culture, 25c. Green's Guide to Strawberry Culture, 25 cents. Green's Fruit Grower, 50c. per year, and Green's "How to Propagate and Grow Fruit," 50c, all to one address for 50c. Green's Tree Agent's Guide, 15c. Green's Books, (3) combined with 15 colored plates, gilt cover, 75 cents. Green's Descriptive Catalogue, with 5 colored plates and two back copies of Fruit Grower, 10c. Address,

GREEN'S NURSERY CO.,

DRAKE & SMITH,

Successors to A. E. Manum, Bristol, Vt.

MANUFACTURERS OF THE BRISTOL Bee-Hive, the Standard Hive of Vermont,

SECTION HONEY BOXES,

made from white poplar, (the best timber in the world for honey-boxes), Clamps, and a **Wood Thumb-Screw** for Clamps. Separators and Wood Sides. **LIGHTNING GLUERS,** Shipping-Crates, Bee-Escapee, Bee-Feeders, and

MANUM'S BEE-SMOKERS,

all made of the best material and in a workman-like manner. Send stamp for Sample SECTION and Price-List. 2E12t

WE WANT Agents everywhere to travel and distribute circulars. **ON SALARY** in every town and village they pass through. Men and women, boys and girls, who do not wish to be away from home over night, have a grand opportunity to make **Hundreds of Dollars** in their own vicinity. All who wish to distribute circulars for us will be required to have samples of our goods on hand to exhibit to whoever may call on them to see the goods which they are advertising for us. A sample package of our goods and full particulars will be sent with circulars **FREE.** Write and secure an agency before it is too late. **Send 15 CENTS ONLY** to help pay postage, packing, etc., etc., and we will forward to you at once, together with a contract for you to sign. This contract explains how a salary is paid monthly, and the **EXPENSES IN ADVANCE.** You can have your name and address printed on the circulars if desired. Address at once,
The National Supply Co.,
BRADFORD BLOCK, CINCINNATI, OHIO.

What Mr. Beyer says: "Please best thanks for the splendid seeds received from your firm. It would be a rather lengthy list if I should name all, but will say that amongst 35 first, and 3 second premiums awarded me at our fairs in Northern Indiana and Southern Michigan, 25 first premiums were for vegetables raised from your seeds. What firm can beat this?"
 Seed of this quality I am now ready to sell to every one who tills a farm or plants a garden, sending them FREE my Vegetable and Flower Seed Catalogue, for 1887. Old customers need not write for it. I catalogue this season the native wild potato.
JAS. J. H. GREGORY, Seed Grower, Marblehead, Mass.

A Year among the Bees,

BEING

A Talk about some of the Implements, Plans and Practices of a Bee-keeper of 25 years' Experience, who has for 8 years made the Production of Honey his Exclusive Business.

BY DR. C. C. MILLER.

Price, 75 cents, by mail. This is a new work of about 114 pages, well-printed and nicely bound in cloth. Address,

THOS. G. NEWMAN & SON,
 923 & 925 West Madison St., CHICAGO, ILL.

THE BRITISH BEE JOURNAL

AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published every week, at 1/6d Shillings and 10d. per annum, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited by T. W. Cowan, Esq.

The British Bee Journal and the AMERICAN BEE JOURNAL, one year, for \$3.00.

HUMPHREYS' HOMEOPATHIC SPECIFIC No. 28

In use 30 years. The only successful remedy for Nervous Debility, Vital Weakness, and Prostration, from over-work or other causes. \$1 per vial, or 5 vials and large vial powder, for \$5. SOLD BY DRUGGISTS, or sent postpaid on receipt of price.—Humphreys' Medicine Co., 109 Fulton St., N. Y. 45A12t

THE HORSE,

By B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents—in English or German.

THOS. G. NEWMAN & SON,
 923 & 925 West Madison Street, Chicago, Ill

 P.S.—Send 10c. for Practical Hints to Bee-Keepers

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$30.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$3.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x18 "	8 00
For 3 " 10x18 "	10 00
For 4 " 10x18 "	14 00
For 2 frames of any size, 13x20 "	12 00
For 3 " 13x20 "	12 00
For 4 " 13x20 "	16 00

The NEW Heddon Hive.

We have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

The engraving gives a good idea of the hive. The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cover, bottom-board, and top and bottom of each sectional case has one-half of a regular bee-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

A SAMPLE HIVE includes the bottom-board and stand; a slatted honey-board, and cover; two 6-inch brood-chambers, each containing 8 frames; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separators, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

It is absolutely essential to order one nailed hive as a pattern for putting those in the flat together correctly.

HIVES READY TO NAIL.—In filling orders for these hives, in the flat, we make 6 different combinations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers:

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 frames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—interchangeable, but not reversible.—Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus stories as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-chambers. Price, \$2.50 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deductions from the above prices: Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at 1/2 cent each, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives, 5 per cent. discount; for 25 or more hives 7 1/2 per cent.; for 50 or more, 10 per cent.

THOMAS G. NEWMAN & SON,
 923 & 925 West Madison St., CHICAGO, ILL.

AMERICAN
ESTABLISHED
1861
BEE JOURNAL
OLDEST
BEE PAPER
AMERICA

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Feb. 2, 1887. No. 5.

Another bee-paper is to be started in Canada to be called "The Canadian Bee-Keeper," to be published monthly at Brantford, Ont.

An English Horticulturist, who is a careful observer of insect life, has noticed that honey-bees rarely go near those flowers which humble-bees seem to like best.

The Bee-Keepers' Advance is the name of a new bee-paper published by James B. Mason & Sons, Mechanic's Falls, Maine. It contains 16 pages, and is published monthly at 25 cents per year.

Died.—Mrs. J. T. Wilson, of Nicholasville, Ky., died of pneumonia on Jan. 20, 1887, at 1 a.m. This we learn from the afflicted husband, who is known to our readers as an apiarist, who adds: "She was a faithful Christian, a loving wife, and a devoted mother." We condole with Mr. Wilson in his bereavement.

Three Colonies of bees were found, about the middle of January, occupying comfortable quarters in different hollows of the trunk of one tree. Mr. Berl Matteson, of Bingham, Mich., was the one who was thus surprised when cutting down a tree. He sawed out the part containing the bees, took it to his home, and will endeavor to winter them. They appeared to be well provisioned with honey.

A Correspondent sends us a printed slip, stating that a family in New Jersey had been "made ill by poison in their honey," and asks: "What will be the effect of these frequent reports upon our pursuit?" As this is a case where the poison was put into the honey for the base purpose of injuring others, it will have no more effect upon the pursuit than it would upon the dairy interest if it had been put into milk. Evil minded persons may put poison into anything, if they are intent upon injuring others.

Home Markets for Honey.—We have for years been trying to impress upon bee-keepers the necessity of working up their home markets—creating a demand for honey. Now that prices are low is just the time to think. Bee-men have themselves contributed largely in depressing the markets in large cities, by glutting them with honey, and then the prices there reduced on that account are made the standard for the country towns. Now the only cure for this is to prevent the bulk of the honey from being sent to the large marts of trade, and have it consumed at home. This can be done, if every person interested will but labor with this end in view. To illustrate this idea, we ask attention to the following from an exchange, which is "right to the point:"

One characteristic of success is close and wide-awake attention to the work in hand, such, for instance, as marked a New York driver on the line of stages which have recently been withdrawn from Broadway. He had a genius for driving a stage, and was noted for keeping his stage full of passengers, and for taking in more fares than any other driver on the route. His success was not accidental. His eyes were forever on the lookout, both on Broadway and in the side streets, so that he never failed to see a distant nod nor a slight gesture.

A similar alertness for business is noticeable among the fruit-venders. Three carts full of bananas and other fruit may be seen standing close together by the sidewalk. The man in the middle cart will work every moment—standing up calling attention to his stock, and alert to grapple with any one who comes up with the slightest intention of buying.

But the other vendors will be seated and half-dozing, or reading a newspaper, carelessly waiting for a customer to ask for fruit. Before noon the appearance of the wagons shows the inevitable result. By night, the middle wagon is empty, while the other vendors wheel home a good part of their stock to keep until the next day, and complain of "bad luck" and "hard times."

To follow the example of the "hack-driver" and "fruit-vender" is a sure cure for the "slow sale" and "low prices" of honey. If you cannot do the selling, you can easily hire some one to do it. There are a plenty of men who would be glad of the chance to do it for a commission.

Ex-President I. N. Cotton, of the Indiana State Bee-Keepers' Association, wants to add the following to the remarks heretofore made about lady presiding officers at bee-conventions:

I see that the question of ladies presiding at bee-keepers' meetings has been raised. The Indiana State Bee-Keepers' Association, in 1884, elected Mrs. Irvin Robbins President, and she served for one year with honor to herself and credit to the Society. Are not the Indiana bee-keepers ahead?

Catalogues for 1887.—Those on our desk are from

Paul L. Viallon, Bayou Goula, La.—20 pages—Bees and Apiarian Supplies.

E. S. Hildemann, Ashippun, Wis.—4 pages—Bee-Keepers' Supplies.

Frank A. Eaton, Bluffton, O.—6 pages—Italian Bees and Queens.

E. C. Long, Williamsville, N. Y.—4 pages—Bees and Apiarian Supplies.

Iowa Seed Company, Des Moines, Iowa—36 pages—Seeds, Plants, etc.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1887, will richly repay every apiarist in America.

Honey Sold on Commission.—We have for years urged bee-keepers either to sell their honey in their home markets, or, if they must ship it, to be sure to sell it for cash, rather than to leave it to be sold by commission men. In this issue of the BEE JOURNAL, Messrs. F. I. Sage & Son give their views on this subject in very strong language. They wind up by saying "either the cash buyers or the commission men must go." They present many good reasons for coming to this conclusion, and we hope their remarks will be read carefully, and considered thoroughly.

While we have sold considerable honey in Chicago, we always buy it of the producer and then it is our own, to sell at such prices as we may deem best, and many times have we sold it at a less figure than we gave for it. We have now on hand about fifty thousands of pounds of white extracted honey, and should be glad to sell at any day for less than it cost us. If it was held on commission by some men, it would no doubt be sacrificed so as to get the commission; but now, while nothing could be gained by an immediate sale, much may be realized by holding it for a rislog market.

It is never right to give the control of your property out of your own hands; and to ship honey to be sold on commission by unreliable parties, is the greatest of foolishness, entailing loss to the owner, and breaking down the market for all other producers. It is always safe to find out whether those to whom you ship goods are reliable, before entrusting them with your property.

The Canadian Honey Crop.—In his annual report, the Commissioner of Agriculture for Ontario, remarks as follows:

"The reports from the apiarists of the Province are extremely contradictory as to the success of their industry during the past season. Some correspondents state that the honey yield has been an unusually large one, that bees have swarmed well, and are in fine condition for winter, while others in the same township complain that the very opposite condition of things prevails. Taking the Province as a whole, however, the favorable reports are in a decided majority, and the yield of honey may be described as from fair to good. The area of apiculture appears to be extending in the Province, notwithstanding that some old apiarists have given up the industry, owing to the fatality of recent winters, and the fact that the low price of honey—8 to 10 cents per pound, a figure frequently quoted—is generally complained of."

It is said that bees can predict the weather. They do it with their little stings, and, curiously enough, they always make it warm.

The Capital of the United States has not a very ancient history, but its early days are worth recalling, when done as interestingly as W. Edgar McCann has done in the February number of FRANK LESLIE'S POPULAR MONTHLY. As if in contrast we are then taken from pictures of Old Washington to the "Domesday Book," that monument of the political sagacity of William the Conqueror. Dr. Joseph Simms, in an article on "The Forehead," combats some popular ideas, and shows that genius has often lurked under a receding brow, and idiocy or crime under a well-developed one. "The Man Outside"—"An Incident of the Sao Gabriel Valley" and "Our Sweetheart" are all worth reading, and the illustrations unusually good.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Feeding Bees in the Spring.

Query, No. 368.—When feeding bees in the spring, that were wintered on the summer stands, at what degree of Fahrenheit should the weather be to make it safe to open the hives to feed the bees?—C. L., Iowa.

Almost any spring weather will do, if you do not leave the hive open unnecessarily.—DADANT & SON.

If the sun shines, at 50° and above. If the day is cloudy, it had better be 60° and above.—G. L. TINKER.

If they need spring feeding, you can do it any bright sunny day. Close the hive as soon as possible.—H. D. CUTTING.

I should choose a "warm day," say with the temperature not below 55° or 60°. I do not think, however, that this is important.—W. Z. HUTCHINSON.

If in the morning, 60° to 80°, according to clouds and wind. If late in the evening, any temperature will do. The main point is not to excite the bees to fly out to become chilled to death.—C. W. DAYTON.

I do not like to open the hive to take out frames, etc., at a lower degree than 60° in the shade. But why disturb the brood-nest in feeding? It is not necessary.—G. M. DOOLITTLE.

Just that temperature when the bees can fly out with safety. At least that is my opinion, and it works well with me, in carrying it out in practice.—J. E. POND.

I place the feeder above the cluster, and I can feed at any temperature. This is why I like the Smith feeder, as described in last editions of my book.—A. J. COOK.

Sixty to 70° and upwards. Much depends upon whether or not the sun strikes the hive, as it should. I always reckon degrees on a thermometer that stands in the shade.—JAMES HEDDON.

It is best to give enough feed in the fall. About 50° I think is best. If in great need of both, I would quickly raise the quilt and lay sticks of candy between and across the frames over the cluster. As soon as warm enough, feed sugar syrup in atmospheric feeders over the cluster. If they will take it up, keep on until they get enough to last until they can gather from natural sources, then stop "tinkering."—J. P. H. BROWN.

I feed them soft candy or candied honey on top of the frames at any time, if I know they need feeding.

Of course I do not keep the hives open but a moment of time, and cover the bees up warmly after the feed is placed in position. If it is a mere question of handling bees in the spring, I do not disturb them unless it is warm enough for the bees to fly in the open air. I do not handle them when it is so cool that the bees are likely to be chilled if they are dropped from the combs. You cannot always tell when this would occur, by the degree of Fahrenheit.—G. W. DEMAREE.

You cannot go altogether by the thermometer. On a clear, dry, bright sunshiny day, a lower temperature will do than on a cloudy, damp day. You had better not disturb bees much when they cannot fly freely. Still, if they are likely to run out of stores, you can put some feed where they can get at it even when quite cold.—C. C. MILLER.

It is quite unnecessary to open the hives in order to feed the bees. If you must open the hives, let the temperature be at 50°, Fahr., if it is a bright day; or more, if it is cloudy.—THE EDITOR.

Ventilating Bee-Cellars, etc.

Query, No. 369.—1. If bees are wintered in a cellar that is kept at a temperature of 40° to 50°, is other ventilation than is ordinarily given a fruit and vegetable cellar, essential? 2. In such a cellar is absolute darkness essential?—B., Iowa.

I think not.—JAMES HEDDON.

1. No. 2. No.—H. D. CUTTING.

1. No. 2. Yes. There are exceptional instances, though.—C. W. DAYTON.

I think that your cellar is all right as it is. It is better to be dark.—J. P. H. BROWN.

No; but I would prefer a little ventilation in mild weather, and darkness at all times.—G. M. DOOLITTLE.

1. In my opinion, no. 2. I think that absolute darkness is an essential requirement for cellar wintering.—J. E. POND.

If there are many hives it will need more ventilation than if there are only a few. Absolute darkness is not essential, but it is *far the best*, as fewer bees will try to go out.—DADANT & SON.

I cannot comprehend why an abundance of pur air should be objectionable; neither do I know that any more ventilation is needed than that ordinarily given a fruit and vegetable cellar. I do not think absolute darkness objectionable; neither am I certain that it is essential.—W. Z. HUTCHINSON.

No; my cellar is 25x30, and 7 feet deep. It is closed up as tight as I can make it, so that no perceptible current of air comes in anywhere. Notwithstanding, there is an active circulation of air in the cellar, owing to the presence of a fire in one of the rooms overhead.—G. L. TINKER.

1. Yes. 2. Not as long as the bees are quiet. Bees in the best condition

are not likely to be disturbed by full daylight, but when they get uneasy, darkness will, I think, keep bees in the hive that otherwise would come out. On the whole, I prefer to have my cellar perfectly dark, generally.—C. C. MILLER.

I do not think that any other ventilation is required for a few bees. For many, I should like sub-earth ventilation, so as to be sure of the right temperature and good air. I would have the cellar perfectly dark.—A. J. COOK.

Other ventilation is not necessary. Though "absolute darkness" may not be positively essential, it is generally desirable.—THE EDITOR.

Why did the Bees Perish?

Query, No. 370.—Late in the fall of 1884 I had 3 light colonies of bees that I fed sugar syrup by putting it in combs and placing one hive (American) on top of another, for the bees to carry the syrup down. But within 24 hours it became intensely cold, and remained so for about 20 days. When I opened the hives I found them nice and clean, but to my surprise the bees were dead, with plenty of honey within reach. The hives were packed from 3 to 4 inches on all sides, but not on top. They had a screen 6x6 inches in the bottom-board, and the top was on each hive. 1. Can you account for the bees perishing? 2. Will bees freeze when all the conditions are right?—S. B., Ind.

1. No. 2. No.—JAMES HEDDON.

In all probability they starved. When bees become very cold they will not leave the cluster for food, but remain and starve.—H. D. CUTTING.

I guess they starved to death. It was so cold that they could not leave the cluster to get the honey.—C. C. MILLER.

The bees starved to death. Next time put the food where the bees can get it—at the cluster—and not away off, separated from the bees by a barrier of freezing atmosphere.—J. P. H. BROWN.

The bees were not able to reach the honey, and starved. If bees can get to their stores they are not liable to freeze.—G. L. TINKER.

Bees will not freeze when all the conditions for successful wintering are right.—G. M. DOOLITTLE.

The bees may not have gotten their stores in proper shape for so long-continued and severe cold. I do not think that bees will freeze "when all the conditions are right."—W. Z. HUTCHINSON.

The cold was so intense that functional activity ceased. The bees perished with the cold. This is why I prefer cellars to packing or chaff hives.—A. J. COOK.

Twenty days of intensely cold weather without any let-up would perhaps wear out the constitution of almost any colony of bees, situated as you describe the colony in question. I have frequently had the opportunity to learn that bees in the cluster can endure intense cold for a few days at a time, but this does not argue that continued cold will not wear them out.—G. W. DEMAREE.

1. I should guess that they froze to death, being in such a condition that they were unable to economize the heat of the cluster. 2. If I should find a colony of bees frozen, I would know that at least one of the most essential conditions was wrong, namely, ample protection.—C. W. DAYTON.

In all probability the extreme cold weather came on before the stores could be brought down in quantity sufficient for the bees to live on, and as they could not break from their cluster, they simply starved because their stores were not within their reach.—J. E. POND.

1. Not being able to reach the honey on account of the length of the "cold snap," the bees probably starved. 2. No.—THE EDITOR.

Correspondence.

Explanatory.—The figures BEFORE the names indicate the number of years that the person has kept bees. Those AFTER, show the number of colonies the writer had in the previous spring and fall, or fall and spring, as the time of the year may require.

This mark ⊙ indicates that the apiarist is located near the center of the State named; ⊙ north of the center; ♀ south; ⊕ east; ⊖ west; and this ⊕ northeast; ⊖ northwest; ⊙ southeast; and ♀ southwest of the center of the State mentioned.

For the American Bee Journal.

Legislation for Bee-Keepers.

DR. C. C. MILLER.

I have read carefully Mr. Heddon's article on page 775 of the BEE JOURNAL for 1886, and would give 17 cents to sit down in a room all alone with him and talk it out. I have also spent some time looking up the articles written on "Priority of Location." In the first three paragraphs of his article on page 775, I am in entire accord with him, excepting the first sentence of the second paragraph. There are matters of right that do not come within the province of legislation. He thinks that bee-territory is one of them. Just at this point our views diverge. As I look at it, for the farmer as well as the bee-keeper, it is best that the territory be distinctly marked out, and this by legal enactment. I think the time would never have been taken up in the discussion of priority of location if there had been legislation. That whole discussion was based upon the belief that for the most successful prosecution of bee-keeping, control of territory was necessary, and as there was no such thing as legal right in the case, the next best thing was to try to hold it by other means. That very discussion showed the need of having the matter settled in some way, in the opinion of at least part of the writers.

The question as to the prior right of the first comer need cut no figure

in the present case. If we can hold peaceable possession of our territory, I should even be willing to have a fresh deal made, and pay full price for a deed to my territory. If I believed that one person has the same natural and moral right as any other, I certainly should want the territory divided up by law. In the generality of cases, I believe in the priority right, but the man who has the fullest confidence in his moral right to the territory he first occupies, needs to feel that he has a legal right.

Mr. Heddon thinks that "whoever will present this proposed legislation to an able lawyer, will first receive a smile in return." Quite likely. Probably a large majority of persons, at first thought, will feel like smiling at such a proposition, but after a little thinking the able lawyer might think differently.

Mr. Heddon asks if I get the "idea of the relation between a condition of bee-keeping that will result in the greatest good to the greatest number, and the question of the survival of the fittest." Yes, I think I do, but that is not what we were talking about. I said I did not see "how he reconciles the idea of a natural exclusive right of the prior occupant with the 'survival of the fittest.'" Neither could I, with my idea of what was involved in priority of location.

But in the article in question, Mr. Heddon says that "priority of location gives one a natural right, *provided he is fitted to hold that location.*" (Italics are mine.) Now, look here, is not that rather a new departure? Narrowed down to few words, does it not mean just this—the man first on the ground has the right to hold it, *provided* he can keep everybody else away? Never mind, we will not quarrel over that part of it, but I will try to show what seems to me the need of legislation in either case. If I am not mistaken, Mr. H. advises that in case any one invades my territory I shall increase my number of colonies, and by thus overstocking the ground make it so unprofitable that he will abandon the project. He mentions that he has practiced this, and that three or four persons who have already tried, in as many instances, to occupy some of his territory, have learned by sad experience the un wisdom of their attempt; and his words imply the possibility that now and then some person may do the same thing again. Now the sad experience of those three or four persons was a bad thing *for them*, wasn't it? It cost them something in dollars and cents, to say nothing of the mental damage resulting from the feeling of failure. For their sakes, would it not have been better if he could have saved them their loss by saying, "This territory I hold in fee simple as my own, and you must go elsewhere if you want to keep bees?"

But leaving their loss out of the question, did their experience cost Mr. H. nothing? I wish we had the exact figures in the case, with full details. But without having them, let us make a little estimate, and I will try not to be unfair. Suppose a

given locality occupied by A, with 100 colonies, and any number beyond that will overstock the ground. B starts up on the same ground. The number of colonies kept by him may vary from 1 to 100 or more. It is not likely to be the larger number, but whatever the number, we will suppose that A, being the fittest to survive, increases his number, thus overstocking the ground so badly that B, with his bad management, gets little or no surplus, and gives it up as a bad job, with a total loss of his whole investment. Of course the more bees he has, the greater will be his loss.

Let us see how it is with A. If 100 is his maximum number of colonies for greatest profit, and can gather all the nectar within reach, if he increases one colony more he loses just the amount that colony consumes for its own use—say 50 pounds of honey—and for every additional colony that he increases, he will lose the same amount. He will also lose at least the same amount for every colony B keeps.

I can hardly see any way to figure, that A will not lose nearly as much as B, and if B has only a small number, A is likely to have much the heaviest loss. Now is it right that A shall undergo this tax now and then, even if he does hold the ground by it? The farmer pays so much, and owns his territory without fear of intrusion; why not the bee-keeper?

Another thing: Can any one tell how far from an established apiary it would be right for a new man to start? Opinions will probably vary upon this point for years to come, and, in case of clashing, who is to settle it?

Again, we have supposed thus far that the field is fully occupied, and that the occupant will have no difficulty in overstocking it. This is hardly true in the majority of cases. C has 50 colonies, and depends mainly upon his bees for his bread and butter, having nothing ahead. If D starts in with 25 colonies on C's ground, it may be some years before C can "freeze him out," especially if C has the same disaster some of us have had in wintering bees.

Still again, the intruder may keep a number of colonies for a series of years, even if it is a losing game, hoping the tide may turn, and as he has other business upon which he depends for a living, and as he gives little time to his bees, he can go on continuously from year to year, with 5 or 10 colonies, and 5 or 10 such men in a field may spoil it for any man. No one need tell me that a man's self-interest would prevent him from doing this. It is *done*. I know of cases, and probably others do. On all accounts, then, should not every man have a legal right to his ground?

Marengo, ♂ Ills.

The Wisconsin State Bee-Keepers' Association meets at the Capitol in Madison, Wis., on Thursday, Feb. 3, 1887, at 9 a.m. All progressive bee-keepers are earnestly invited to attend, and supply-dealers are requested to exhibit their best implements and inventions. The State Agricultural convention will be in session at the same time, commencing on Feb. 1 and closing on Feb. 4, which will be an additional inducement for many to attend. Hotel rates are from \$1 to \$3 per day. Return tickets will very probably be given over the principal railroads at reduced rates.

F. WILCOX, Sec.

The Marketing of Honey.

J. H. ANDRE.

I am pleased to see that this leading part of bee-keeping is being thoroughly discussed. The business at the present time looks more like a regular stock-gambling affair than one of the legitimate branches of sustaining a livelihood.

I expressed my opinion some time ago, that the producer and consumer were both at the mercy of the retail dealers. They usually pay in trade 10 cents per pound, which is equivalent to about 8 cents; and retail honey for 12 to 15 cents per pound. In this vicinity some are selling splendid comb honey for 7 cents per pound, and I do not doubt but some has been sold as low as 5 cents.

What we need is a dealer in every city of 10,000 inhabitants, or upward, who will take all honey that comes to market, and handle it honorably; if it cannot all be sold in his home market, let him ship it to some larger city. In order to do this I do not see how it can be done without a regular "Union," and prices published weekly, each member of the Union to be furnished with price-list. Of course it would have to be backed up by funds, but let each member pay 50 cents or one dollar annually.

This business of selling must become a regular trade, or we may as well stop bee-keeping. It needs a dealer in every city that will give it the same attention that a butter-dealer gives his trade. There would be no need of running the business alone in a small city; poultry, butter or fruit dealing could be united with it, but let the honey trade take the lead. When the honey trade is recognized as a regular business, this 5-cents-a-pound business will stop. People will have some confidence in it then.

I am not at all afraid but what the minds of those who have undertaken the matter will set it to rights; for it has become a public necessity, and such has been quickly righted in all ages.

The Ohio State Convention.

The Ohio State Bee-Keepers' Association held its annual convention at Columbus, O., on Jan. 11, 12 and 13, 1887. The first day only an informal meeting was held.

The morning session of the second day was called to order, with Dr. H. Besse in the chair. The minutes of the previous meeting, and the Treasurer's report were read and approved.

The election of officers resulted as follows: President, Ernest R. Root, of Medina, O.; Secretary-Treasurer, Frank A. Eaton, of Bluffton.

By request of the convention, President Root gave the following talk on

FOUL BROOD.

The disease first broke out in his apiary about the first of last July. He was not certain as to how it originated, but thought it was started by robber bees gaining access to a few kegs of honey, which had been purchased some time before. He said that the incipency of the disease was difficult to describe. A few affected cells appeared at first; the larvæ were of a light coffee color, and as the disease advanced the larvæ changed to a dark coffee-color, like the coffee berry, and finally dried up in one side of the cell. If a tooth pick be inserted into an affected cell, the diseased matter will adhere, forming a sort of string.

He stated that during the past season they had sixty cases of it. Each, as soon as discovered, was treated as follows: All the combs of the affected colonies, after the bees were shaken off into a clean, new hive, were consigned to the boiler furnace. He thought it cheaper to give the bees a clean, new set of frames filled with foundation, than to extract the old diseased comb, render out the wax, and boil the frames for use again. The diseased hives were then scalded out with steam. He was not sure but that the disease might appear again the coming season, but in no colonies so treated did the disease re-appear.

Dr. Besse said that he did not think it was necessary to go to that great waste of expense of burning the frames, comb and honey. Why not extract the honey, render the wax and boil the frames, and in that way save that which would otherwise be wasted?

President Root thought that there would be more or less risk attending such a practice; and that robber bees might gain access to the diseased honey and wax while so working. After some further discussion of the subject, the convention adjourned to meet at 1 p.m.

AFTERNOON SESSION.

The convention was called to order at 1 p.m., with President Root in the chair. A discussion of questions then followed. "How should a house be constructed to keep honey best, both in winter and summer?"

Dr. Besse—Keep it in a dry house, where it never reaches either extreme of heat or cold.

F. A. Eaton—Keep it in a honey-house that gets quite warm in the summer and fall, then remove it to some room where the temperature does not go down to freezing.

"Is comb honey injured, or made unsalable, by its freezing?" After some discussion it was generally agreed that the quality was not injured by freezing, but combs cracked by the freezing and thawing would cause the honey to drip.

"Which is the best method of controlling or preventing swarming?"

J. W. Newlove—I use single-tier crates, and give the bees plenty of room by tiering up. Put a case of sections on the hive about ten days before the honey-flow starts. When the bees are thoroughly at work and

have filled the sections about half, raise the case and put under it an empty one, and so on, giving plenty of room. I find that by this plan they seldom swarm.

F. A. Eaton—It is an easy matter to control swarming when running for extracted honey, as a liberal use of the extractor will greatly aid. But the difficulty is when working for comb honey. I have practiced very successfully extracting from the side combs in the brood-chambers, and placing them in the centre. If the colony is very populous I remove one comb, placing in the centre an empty frame with only starters, thereby giving the queen plenty of room; at the same time I put on one tier of sections, then tier up as fast as the honey-flow will warrant.

"Which is the best to give to a swarm, frames full of foundation, or only starters?"

Dr. Besse—I use starters only. President Root gave W. Z. Hutchinson's plan.

J. S. Ricketts said that Mrs. Jennie Culp used full sheets of foundation, and much preferred them.

The convention then adjourned until the following day.

THIRD DAY—MORNING SESSION.

C. E. Jones gave a talk on the production of fine comb honey. He said, in brief, that he does not want a colony very strong with bees, preferring a hive of 6 or 7 frames only. He does not put the sections on too early, but waits until white clover is fairly started, and gives starters only in sections, placing the sections the same way as the brood-frames, so as to insure straight combs. He recommends removing the sections early, and does not aim to secure the most honey, but the best.

"Does it pay to feed back partly-filled sections to finish others?"

It was not considered profitable.

President Root then gave a detailed description of the Heddon hive and its management.

Mrs. Culp—I do not think it profitable to change the hives in an apiary of 50 or 60 colonies, for any new hive, discarding the old ones. She then gave an interesting account of her management of an apiary without help. She works an apiary of 60 colonies; keeps her queens' wings clipped; her report for the past season was 5,600 pounds of comb honey, for which she received 18 cents per pound; and 2,400 pounds of extracted, for which she received 15 cents per pound. Her bees are hybrids. She prefers them for honey to any others.

AFTERNOON SESSION.

The discussion of questions was continued as follows:

"Does the queen determine the sex of her progeny at will?"

Mr. Miller—I have been taught that the sex of the bee is determined by compression, owing to the size of the cell.

C. E. Jones—I think that she has the full power of determining the sex.

F. A. Eaton—I have seen the queen lay eggs in queen-cells only

slightly started; also in foundation that was not drawn out more than $\frac{1}{4}$ of an inch.

Moisture in bee-hives in winter was discussed at some length. Dr. Besse said that moisture in hives is caused by the moisture in the air condensing by the warm air in the hives coming in contact with the cold air from outside, the same as the frost forms around house-doors in winter.

Mr. J. S. Mock stated a new use for broad frames for division-boards. Nail thin boards on each side, filling the space with dry sawdust, forest leaves or some light material. They are good for winter or summer use.

The committee on exhibits reported as follows: Frank A. Eaton, section-case and skeleton honey-board combined; adapted to the tiering-up system and removing sections with ease. Earl Clickenger exhibited a section-case, a case of fine comb honey, jars of extracted honey, Bingham smoker and honey-knife, and an Eaton bee-feeder. J. W. Newlove showed a combined shipping and honey crate; also well adapted to tiering up.

The convention then adjourned, *sine die*. F. A. EATON, Sec.

The Cappings over Honey.

W. Z. HUTCHINSON.

I have always enjoyed a discussion with Mr. C. P. Dadant, but, from reading his last article on page 794 of the BEE JOURNAL for 1886, I fear I shall be deprived of the pleasure of controversy to a large extent, as his assertions are so well qualified; but I will do the best I can.

If I understand Mr. Dadant correctly, he admits that all honey-cappings may not be impervious, but his position now is that the majority of them are impervious; and, in stating his position, he gives a line or two from Mr. Frank Cheshire. As he has quoted Mr. Cheshire, I will "follow suit," giving the paragraph preceding the one from which Mr. Dadant quotes. It commences on page 173 of Mr. Cheshire's new book, "Bees and Bee-Keeping," and is as follows:

"Liquid dyes kept within worker or drone cells for weeks, have not, in any case, stained water lying in the surrounding ones, which I have never found other than perfect, notwithstanding the extreme thinness of the walls. The bees labor at both sides of the latter, not only scraping the shreds, but rubbing them into complete union with their maxillæ, and this will account for their freedom from faults; but observation has led me to form a different opinion of the sealing of honey-cells, which, in former years, I described as air-tight. Most bee-keepers have noted that snow-white sealed honey, if kept in a damp place, changes color, the sealing appearing to grow transparent, and the honey itself not infrequently weeping. By experiments and microscopic examinations, I have made evident that former ideas were

inaccurate, and that not more than 10 per cent. at most of the sealing of honey is absolutely impervious to air. To extract honey, it is necessary to shave off the sealing; and if this be done skillfully, the wax is removed so free from honey as to show at once that the covers have never been in contact with the cell contents.

"The horizontal position of the cells prevents their being perfectly filled first and covered afterwards; but the bees, when the cell is approaching fulness, cap its lower part, then add honey, and increase the cover, placing shred upon shred, after the manner a turf wall is built, until the process is complete; no smoothing by the burnishing action of the maxillæ on the inner side is possible, so the air intervening between the irregular tape-like shreds cannot escape, and at the close forms a layer between the honey and its cell-lid, giving increased whiteness to the cover, and preventing also immediate leak, even should a fault remain. The air being cut through in uncapping, the caps are removed dry. Steeping in water for three days a well finished super containing about 780 cells, all but 49 revealed that they were defective, by losing their opaque whiteness; for the honey had absorbed water, and was now in contact with the inner wall."

I might bring forth more facts and arguments in support of my position, but it seems as though the above is so complete an answer to Mr. Dadant, that it is unnecessary to say more.

Cash Buyers vs. Honey on Commission.

F. I. SAGE & SON.

M. M. Baldrige calls the commission men a "curse" to the honey producers. Our opinion is that truer words were never written, and we are pleased to see that some are getting bold enough to speak their minds plainly. That the reader may understand our position we wish to say that for the past eight years we have bought and sold comb honey. In 1884 we purchased 72 tons of honey for "spot cash" at the highest price we could afford to pay; many tons of this honey was bought in the country at from 13 to 15 cents per pound (to pay freight, breakage, traveling expenses, etc., it ought to sell for 2 cents per pound more in the cities), but very soon we found that commission men were underselling us, and in the end we sold considerable honey for less than it cost us in the country. Later we found we could buy honey of the commission men for considerable less than we had been paying in the country. Notwithstanding we sold at a loss, the commission men beat us right along, and informed the wholesale and retail grocers throughout our routes that it made no difference at what price we offered honey, they would discount it, and they did so! The indications are that we shall be compelled to buy of the commission

men, who have free use of the different bee-periodicals, and can so work their cards that they can sweep the board every time.

We know honey can always be bought at less than their quotations in the papers, which are given as an advertisement, to induce shipments of honey. After they get the honey, how easy it is, when making returns, to say that it did not come in good order; was a little off in color or quality; we had an unexpected rush of honey from California or elsewhere, and were forced to sell at lower prices, etc.

We have handled more honey than any three houses in New England, during the past eight years, have paid "spot cash" for it, and defy any man to say we owe him for a pound of honey; yet if we wish to insert an advertisement in the bee-papers in search of honey, it costs us from \$15 to \$40; while the commission men who risk nothing, but are sure of a good commission, are given a full column of the best kind of advertising. We do not object to paying for our advertisements, but do believe it to be in the interests of the honey producers that the commission men's quotations should not be published even if they pay for it!

Some may say that cash buyers have helped to lower the price of honey. To prove that this is not so, we shall in the future, no doubt, buy more honey of commission men than ever before, because we can buy it at less figures than we have the face to offer in the country for the same quality of goods. Starve out—kill off your commission men, and your honey will sell for a higher cash price! The more commission men, the lower the price; the more cash buyers, the higher price you will get!

Our remarks are not wholly aimed at those who quote honey in the bee-papers, as there are a number of them who are entire strangers to us, but at this method of doing business, whereby the bee-keeper is entirely at the mercy of the commission men! Let us look at it in a common-sense way. Would any business man be likely to continue to go into the country and invest "hard cash" in honey by the car load, that he may bring it to the cities to sell in competition with men who are selling goods in which they have not one penny invested? Who could do so, and compete with them? We have had enough of it, and shall look to the commission men before investing very heavily with the bee-keepers hereafter, unless the bee-keepers form some scheme by which the commission men will be shut out, and forced to become cash buyers!

We hope this matter will be thoroughly ventilated through the JOURNAL of journals, and if it shall be decided that the cash buyers of honey, who go into the country with their money, are a detriment to the bee-keeper, then let the producers use their best efforts to kill them off, by encouraging the commission men to their utmost. Either the cash buyers or the commission men "must go."

Wethersfield, 8 Conn.

For the American Bee Journal

Helps in Bee-Keeping.

EUGENE SECOR.

Every business or trade has its trade secrets. Every person "well up" in his business knows something of those trade secrets. (I mean by "trade secrets" the knowledge which has naturally grown up and developed in every department of thought and labor, especially valuable to that department.) Possibly they may not have been learned from books or class periodicals; but, if not, they are acquired by long and patient study and observation—by a thorough mastery of the trade, and by personal contact with superior minds in the same line of work.

All knowledge is not necessarily learned from books. Experience, observation, conversation—these are all teachers. We all know the old adage, "Experience is a dear school, but fools will learn in no other." Observation and conversation, too, are dear schools.

Life is too short to glean all that ought to be known through the sense of sight or hearing alone. Knowledge gained only from personal experience or the face-to-face method is too slow for the age of railways and telegraphs. It did better in Plato's time. Now, it smatters too much of the "from-hand-to-mouth" way of providing for one's physical wants, *i. e.*, work only when hunger compels. That is just the way the man does, who, when he needs any information, has to hunt a neighbor to impart it, or go without. The better way would be to lay by a store for future use, like the thrifty colonists whose interests the BEE JOURNAL represents.

The above is prefatory to what I wish to say as to *helps* in bee-keeping. Langstroth, Quinby, and their contemporaries in the pioneer work of building up the business of apiculture in this country, labored under the great disadvantage of a lack of literature on the subject. What they accomplished was the work of a life time—laborious, unremunerative work too. Every bee-keeper cannot afford to go through the same experience they did, in learning the A B C of bee-culture. It is easier to get our experience largely at second hand. We can now learn in a week what it took them a quarter of a century to find out.

First, then, in the matter of helps, read the standard authors on bee-culture. Do not be stingy about it either. Follow the same plan recommended by a noted Divine regarding the family library: "For every child born, add \$10 worth of books." For every colony of bees, you can afford to get one standard work on bee-culture. Keep this up till all the best works on the subject are in your library. If your management of the bees is not enough better to pay for these books, you may well conclude that bee-keeping is not your *forte*.

Having 10 colonies of bees, more or less, and having procured and read

some of the many valuable books, if you wish to succeed, and to keep abreast the times, some of the many bee-papers are indispensable. The best students of the age are giving their ideas and observations through the columns of these papers. Some of the best writers have never published their experiments in book form. Much that is interesting and instructive is found nowhere else. They are the guide-boards along the way—yes, better than that, because we can carry these with us. Through them we can talk with the best authorities from Maine to California. Even the advertisements are entertaining—showing the *status* of the art. One bee-paper is not enough, either. All that is valuable is not confined to one. "The liberal soul shall be made fat." If the farmer never enriches his land, he must be content with small returns. If the bee-keeper never fertilizes his brain, he must be content to "play second fiddle," or twang on an old jew's-harp, while the procession is going by.

We cannot learn everything from books and periodicals, but as all men are wiser than one man, we shall be very dull students if we do not get more information out of them than we had in the outset. It is easier to *absorb* the experience of others and verify it, than to originate everything ourselves, and prove it afterward. In bee-talks, whether neighborly or at conventions, we find another source of acquiring knowledge. I never knew a bee-keeper who was not ready to tell all he knew at any time of day or night. Bee-keepers' societies are useful to the learner. And a neighbor who is well "up" in the "secrets" is a well-spring of delight to a beginner, if he knows how to apply the "pump."

Forest City, 3 Iowa.

For the American Bee Journal

Bees Carrying out Brood, etc.

W. H. SMITH.

The author of Query, No. 344, has had an experience similar to my own. In 1884 I had a colony that commenced carrying out brood in all stages, from the smallest larvæ to nearly matured bees. They commenced on July 1, and were still carrying out brood on July 11. How much longer they continued this work I do not recollect, but I remember that after I was completely baffled I called on several neighboring bee-keepers to get some light on the matter, but I failed, until Mr. Wm. Bingham, of Aylmer, Ont., suggested that it was possible they were doing this to make room for the rapid flow of honey that was so plentiful, and as I had already put on surplus boxes which they refused to enter, he recommended drumming them at night until they ceased carrying out, which I did, commencing early in the evening and continuing until about midnight.

The following morning I found that they had carried out only a very few

during the night, so I concluded that if that was the treatment they needed, I would give them enough of it, so I continued the drumming for two nights more. I then discovered that they had commenced working in the upper story, and had ceased carrying out brood. They did not trouble in that way any more.

The problem, to my mind, was then fully solved. They had from some unknown cause objected to work in the surplus boxes (a freak peculiar to bees), and had determined to store the honey in the brood-chamber, even at the sacrifice of brood.

BEEES STEALING EGGS.

Last year I gave an account of egg-stealing by bees; this year I have another, which is as follows: I had a young colony of Italian bees which I had made by division, giving them comb and honey, with no eggs or brood, but I gave them a queen-cell which in due time produced a fine Italian queen. In the course of time I discovered eggs and brood. I was of course satisfied that all was well, but judge of my surprise when I found that the young bees were black!

My theory is that the Italian queen got lost on her wedding tour; the bees had entered a hive of a black colony and stole an egg from which they reared a black queen.

Mt. Salem, Ont.

For the American Bee Journal

Joint Bee-keepers' Convention.

For mutual and individual benefit the bee-keepers of the counties of Butler, Floyd, Chickasaw and Bremer formed the joint bee-keepers' association of Nashua, Iowa, on Jan. 12, 1887.

The meeting was called to order by Mr. George Stocks, of Chickasaw county, upon whose motion Mr. Thos. Tracy, of Bremer county, was elected President; G. H. Potter, of Chickasaw county, was elected Vice-President; and C. W. Dayton, as the Secretary. After transacting the preliminary business of the association, a lively discussion of the important questions of the present time was entered into, lasting two days. As to the profitableness of bee-keeping, it was decided that under good management it would pay economical living expenses.

Should queens be superseded at the age of 3 years? Not unless they showed signs of failing productiveness. The bees will usually attend to the superseding of queens.

How can we get the best quality of honey? Leave it in the hive until it is "dead" ripe.

What has been the average net price of the honey crop of 1886? Eleven cents per pound for comb and 8 cents per pound for extracted.

Can any location be overstocked with bees? It was thought that our location was overstocked by bee-keepers, or else each bee-keeper must be overstocked with bees. It was thought that planting bee-pasturage was essential.

Is it profitable to use foundation in the sections? Yes. How much? A small amount if thick, and more if it is very thin.

What is the best height from the ground to place hives? For the accommodation of the bees, 4 inches. For the accommodation of the operator, 2 feet. It would also be varied by the exposed or windy location.

Is it advantageous to use the sections of old comb left over from the previous year? Not always.

Will the clipping of queens' wings affect their progeny? No.

What about the large reports in the bee-papers? It was observed that they are of sudden appearance and of short duration, often misleading, and a damage to the pursuit.

Thirteen hundred colonies were represented, and 72,000 pounds of honey had been produced in the apiaries of those present.

The convention then adjourned to meet again before the time for procuring supplies for the apiary for the coming season, according to the orders of the Executive Committee.

C. W. DAYTON, Sec.

For the American Bee Journal.

Our Neighbors and our Bees.

DR. A. B. JASON.

In reading Rev. W. F. Clarke's article on the Canadian bee-lawsuit, on page 823 of the BEE JOURNAL for 1886, I notice the following from Mr. Harrison: "So you may judge in some measure what sort of people I have had the misfortune to live among. It is a deplorable state of things for the 19th century." This reminds me of something I read when a boy, and I often tell it as I remember it, although it may not be as I read it. It is as follows:

A man was moving from one region of country to another some distance away, going from "Down East" to "Out West," I believe, and spending the night at a public house, was telling "mine host" what *bad* neighbors he had, and how glad he was to leave them; and the "good man of the house" told him he would find just such neighbors where he was going.

In a short time another man was moving from the same neighborhood left by the other, and going to the same neighborhood the former had gone to, stopped at the same public house for the night, and his only or greatest regret at moving was, that he had to leave such *good* neighbors. But he was told that he would find just such good neighbors where he was going.

Mr. L. C. Root cut the grass for his neighbor, to prevent his getting stung by Mr. Root's bees. I wonder if Mr. Harrison ever offered to help make that objectionable pig-pen any less offensive. I do not believe that it is necessary to have trouble with our neighbors about our bees. Last season I helped to gather the asparagus near my bees for a neighbor gardener, and occasionally sent them honey to put on their warm biscuits, and they

did not "kick up a fuss" about being stung, but laughed at their own swollen cheeks.

At a bee-convention recently, I told how a bee-keeper in Cincinnati got the "right side" of a neighbor. Their lots joined, and there was likely to be trouble about the bees, and the bee-keeper came to me for advice. It being near swarming time I advised him (unknown to his neighbor) to try and get one of his swarms to cluster on one of his neighbor's trees, and see that they found it there. It worked "like a charm," and the bee-keeper *lent* them a hive to put the swarm in, and the trouble was over.

Try some such way, those of you who are likely to have trouble with your neighbors; keep them sweetened up, and see if it does not pay.

Auburndale, O.

For the American Bee Journal.

Disposing of the Honey Crop.

J. W. BITTENBENDER.

I do not think that we can get complete control of the honey market, as all have a perfect right to keep bees, and in this way we get a class of bee-keepers that we cannot control or influence. If we organize under a law that every one who wishes to keep bees must get a license and give a bond for the faithful fulfilment of his agreement, then we could elect a board to make our prices, and all bee-keepers would have to sell at one price. But in these days we have too many second-class bee-keepers who keep a few colonies of bees; this is the class that injures our honey market, as they have not enough honey to bother with, and as a general thing they have a poor grade of honey, poorly gotten up, in large boxes, or in untidy packages. They think that it does not pay to be so particular, and do not have time to care for their bees properly. This class is also equally slow and careless about creating a market for honey.

As a rule, a first-class bee-keeper aims particularly to get his honey up in nice shape, has the honey trade of the city, and the merchant and the consumers look to him for honey, if he has enough to supply them.

Now what will the second-class bee-keeper do? He has not enough honey to trouble with it much, and he has no money or credit, or other produce to sell. Now what will he do? He is compelled to sell his honey. He takes it to town and offers it at a price which the merchant sells his, but gets no buyer. He puts the price down, down, down, till he gets some one to buy it. This is generally at a very low price. He then succeeds in getting a crowd around his wagon, and he is doing a large business on cheap honey.

In a day or two a customer calls at a store to buy a pound of honey. He asks the price, and is told 15 cents. "Why," he says, "the other day a man sold a wagon-load at 15 cents per pound." He leaves the store, and soon another customer enters with the

same story. Now, if the store-keeper is a commission merchant, he will drop the price down, and the producer will be the loser. If he bought the honey, he will hold the price up until the cheap honey is all consumed, then he will generally get his price. Now, to whom shall we sell, the commission men, or the retailers?

Knoxville, O. Iowa.

For the American Bee Journal.

Selling the Honey Crop.

O. N. BALDWIN.

We cannot afford to do it, nor is it right to give the commission men free what those in other branches of industry have to pay for. It seems to me that the publishers should publish the correct quotations for honey in all the principal markets, and then charge commission men the same rate they charge others for advertisements.

I went to St. Louis last year and sold honey at 18 cents per pound, when the commission merchant quoted it at from 10 to 12 cents. I also shipped honey to Kansas City, and obtained through the commission merchant 13 to 14 cents per pound. While I was satisfied with the returns, how do I know but what he sold it at 20 cents per pound, and still got his commission out of my 13 to 14 cents? By having the markets reported by disinterested parties, it may be possible to realize a better price; at any rate, I believe it would give better satisfaction.

As regards class legislation, especially for bee-keepers, I do not think that we could do anything that would reward us for the trouble of obtaining it. We, as a class, ought to rejoice that we have already so many privileges, and still our bees are not subject to the tax imposed on other property from which we receive a less proportionate income.

I would like to have a bee-keepers' honey-association to keep up the price of the products of our labor, but you might just as well try to make wheat bring \$1, or corn 50 cents a bushel. It all depends upon how badly a man wants a thing and the quantity in market, what he will pay for it. We now get, on an average, 12½ cents per pound for white clover comb honey, and we can buy the best granulated sugar for 6¼ cents per pound; and every thing else, or nearly so, is in proportion. Ought we not be able to produce honey as cheap as the best grades of sugar, by using the same capital, energy and skill in production? The time is not far distant when the apiarist must accomplish the most with the least labor and expense, and be faultless in the way he prepares his packages of honey for market, or his competitors will leave him with the sack to hold, while they are reaping the harvest.

Clarksville, O. Mo.

Local Convention Directory.

1887. *Time and place of Meeting.*

Feb. 3.—Wisconsin State, at Madison, Wis.
F. Wilcox, Sec., Mauston, Wis.

Feb. 4.—Fremont Progressive, at Fremont, Mich.
Geo. E. Hilton, Sec., Fremont, Mich.

Feb. 12.—Harden County, at Eldora, Iowa.
J. W. Buchanan, Sec., Eldora, Iowa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bees Flying.—Chas. Smith, Plum Tree, Ind., on Jan. 24, 1886, says:

I have 10 colonies on the summer stands, not packed, but with plenty of honey. Bees have been flying for the last few days. I sold all my honey at 15 cents per pound. I agree with Mr. Joel Helsler, as to price of comb honey being 16 cents per pound.

Stormy Weather, etc.—David Jantzi, Crosshill, Ont., on Jan. 15, 1887, writes:

We have had very stormy winter weather so far, and the roads are all blockaded with snow. Last season I had 10 colonies to start with, and I had during the season 27 good swarms, making 37 colonies, of which I have sold 7. The honey season was very short, on account of the drouth; but my bees gathered 850 pounds of honey, 750 pounds of it being extracted, which I sold for 12½ cents per pound in my home market, and the balance being comb honey I sold for 18 cents per pound. Comb honey sells best in this locality. I have packed my bees on the summer stands with flax chaff, and all are in fine condition now.

Reporting Honey Yields, etc.—A. D. Stocking, Alma, Mich., on Jan. 24, 1887, writes:

Last spring, at Ligonier, Ind., where my bees are, I had 8 colonies of bees in prime condition. They were wintered on the summer stands, with chaff cushions 2 inches thick over the brood, and the hives raised from the bottom-boards by a rim 2 inches deep put under the hives; the entrances were left open full width, and protected from the storms by leaving a board against the front of the hive. I had no loss. I increased them to 17 colonies; sold 1, and 2 absconded. I obtained 1,020 pounds of honey in one-pound sections from 15 colonies, an average of 68 pounds per colony. The largest amount from any one colony was 121 pounds in one-pound sections; the smallest was 4 pounds in one-pound sections. The hives were heavy with spring stores (I do not extract from the body of the hives), and I prepared 16 colonies for this winter the same as I did for the winter previous, and I have no fears

of the outcome, as I have never had 6 per cent. loss in any winter, except 3 years ago when I lost all, which was caused by impure stores, and lack of proper attention in the fall. I think the usual way of reporting the honey yields, as the average per colony spring count, is wrong and misleading. My yield by that rule would be an average of 127½ pounds; whereas I obtained mine from 15 colonies, and I think that the highest and the lowest amount should be given. This is the only true way of reporting.

Will Bee-Keepers Unite?—W. B. Thorne, Glenn, Kans., writes as follows:

Honey producers are no easier to induce to combine than are the farmers who, from past experience, have proven that any extensive organization for mutual protection is very improbable. If the unorganized producers determine on any one industry, supposing it to be profitable, that industry is "fated." The raising of cattle, for instance, was supposed to be among those industries that could never be overdone; yet the past fall has witnessed a collapse of that great industry at Kansas City. Honey, or, in fact, any article of daily consumption, is liable to share the same fate when once it attracts the attention of the masses. As honey producers, can we unite with profit in arresting the downward tendency of the honey trade? I say emphatically, yes! Will they unite? I say, no!

Price of Honey—Reversible Hives.—Fayette Lee, Cokato, Minn., on Jan. 6, 1887, writes:

I, for one, am not willing to produce honey and let commission men set the price on it. I have produced a great many thousands of pounds of it, and have always set my own price on it. But it looks as if the large producers were trying to drive all the small producers out, and they will do it if honey becomes any lower in price. I say, let comb honey sell for 15 cents a pound, and extracted for 9 cents a pound. This is my price. Every bee-keeper in the United States ought to know what the price of honey should be, and I do not know of any better way than to send extra copies of bee-papers to every subscriber to give to those who do not take them, and let such copies contain the proceedings of the producers' association, when it meets, and what the price of honey shall be. I should like to hear reports from those who have been using reversible hives; whether they get any more honey or not. It is 30° below zero this morning.

Organization for Bee-Keepers.—A. Cox, White Lick, Ind., writes:

I am in favor of a honey-producers' association, if gotten up in a proper manner. But how to do this, is quite an item. The low price of honey is attributed to a great many causes by different correspondents. There are

a great many causes, and we have no right to lay the blame on any one cause in particular. For instance, the man that has a few bees in a fence-corner is not to be blamed for all this, by no means. For in this town the cause is quite different. There has been honey shipped here that was said to be produced in the East, but on a close examination it was found to be the product of a large honey-producer in the West, and shipped to the commissioners of the Eastern cities. He was no fence-corner bee-keeper. How all this can be done with a profit to the bee-keeper is a mystery to me. The conveniences for producing honey in the West must be a great deal better than they are here in Indiana. I would suggest that all the bee-keepers' associations in the United States call a meeting for the purpose of discussing this matter, and send delegates to a national convention, at some central point; then they would be fully prepared to organize a society, if need be. I would further suggest that the new organization be consolidated with the Bee-Keepers' Union, if such a thing could be done. Then the bee-keepers would become a power. Otherwise so many different organizations for the same purpose would amount to nothing.

Results of the Season.—Daniel Whitmer, South Bend, Ind., on Jan. 19, 1887, writes:

On Nov. 20, 1885, I placed in the cellar 118 colonies, leaving 62 on the summer stands. All were in excellent condition. I lost one in the cellar, and 11 on the summer stands, principally by spring dwindling. By uniting I had 150 colonies to begin the season with. The spring was favorable, and they built up to fair working condition. On Monday, the first week in June, 25 swarms issued. They might have done better in surplus gathering had I been at home. The season was fair up to July 15. They stored 53 pounds per colony, spring count—or 7,000 pounds of comb and 1,000 pounds of extracted from unfinished sections. I have now 207 colonies in the cellar in a temperature of 45° the most of the time, and 36 colonies on the summer stands, all having an average of 40 pounds of honey per colony. All are pure Italians except 36 colonies of hybrids. About 10 swarms absconded. I sold 5, and gave 2 to friends.

Preparing Bees for Winter.—L. Reed, Orono, Mich., on Dec. 23, 1886, writes:

It was so dry here the past season that bees did but little from July 1 till Aug. 15. After the rains came we had a good fall yield. Bees swarmed but little, and they began the winter in splendid condition, strong in bees, and having plenty of honey. There was no "bug juice" the past fall. The colonies that I had expected to lose last winter, came out all right, and built up to strong colonies; some of

them stored some surplus. I began last spring with 35 colonies, and increased them to 54, by natural swarming. I sold about 1,000 pounds of honey in one-pound sections at 12½ cents per pound. I put my bees into the cellar on Nov. 15, 1886; the temperature in it has been from 38° to 50°, so far. All of my hives have loose bottom-boards, and on these boards I nail strips 1 inch by 2, just the size of the hive. When I put them into the cellar I invert the bottom-board and place the hive on the strips, which leaves the frames 2 inches from the bottom-board, so all dead bees fall down clear from the frames. When put out I reverse the board, when the hive is clear of dead bees and dirt. In winter, I leave a case on the hive filled with woolen cloths or clean rags. I leave the entrances open full width. If a colony is very strong in bees, I give it a little ventilation at the top of the hive. If my bees have good honey they will come through all right prepared in this way.

Good Shipping-Crate.—C. W. Dayton, Bradford, ♂ Iowa, writes:

Having purchased considerable honey in crates that hold 12 one-pound sections each, I have become convinced that that size of crate is a decided improvement over all other sizes. With honey in that size of package I have been enabled to make sales of whole crates instead of 1 or 2 sections, as heretofore. I do not confine this to a single instance or several instances, but that has been my experience right and left, far and near, during the whole of the past season. I can sell one-half more honey in a given time, and obtain a better price for it, than with any larger size of crate.

Favorable Winter for White Clover.—W. S. Taggart, Barton, ♂ O., on Jan. 20, 1887, says:

I began two years with 4 colonies of bees in boxes, transferred them to Victor hives, and increased them to 6 colonies with which to commence the season of 1886. I bought 4 colonies in box-hives, transferred them, and increased them to 21 colonies, by natural swarming. My apiary averaged 82 pounds of comb honey per colony, nearly all in one-pound sections. Bees are wintering well here. They are all wintered on the summer stands. The winter has been favorable for white clover, and of course this looks well for another season.

Swarming—That "Chip."—Dr. C. C. Miller, Marengo, ♂ Ills., writes:

On page 42, Mr. Hutchinson asks if I have read Mr. Simmins' book on the prevention of swarming. Now, look here, W. Z., do you call that a square blow struck at that chip? I don't. Let me ask you, have you tried Mr. Simmins' plan and succeeded? To answer your question, however, I have read the book and found it interesting, but I have not tried his plan.

Neither have I tried the non-swarming hive invented by Jasper Hazen before you were out of dresses, or perhaps before you were born as a bee-keeper; nor any of the non-swarming hives invented since. I am so much of an old fogy that I must be fairly convinced that a thing will be successful before I try it. Of course I believe, and so do you, that a colony may be prevented from swarming, or even from having a desire to swarm; as for example, taking away its brood constantly, so as to keep it a mere nucleus; but what we want is to keep a strong colony booming right through the entire season, working in sections without ever showing any inclination to swarm. That's the chip you're to aim at. Nothing would delight me more, than to come off second best in the fight; and I think it among the possibilities that we may yet master the problem; but for the present I want you to understand, Mr. H., that "that chip" lies in peaceful security on my shoulder!

Full of Information.—O. B. Barrows, Marshalltown, ♂ Iowa, on Jan. 22, 1887, writes:

I commenced keeping bees about 15 years ago, but I had a very discouraging time of it for several years. In the fall of 1884 I attended our State and County Fairs, and found I was away behind in apiculture. In January, 1885, I sent for a sample copy of the AMERICAN BEE JOURNAL, and I got more information on modern bee-culture from that one copy than I had gotten in ten years before. I subscribed for it, and in the two years that I have been taking it I have never seen anything that I wanted to conceal from any one; and whether the market reports are published or not, I presume I shall continue to think it the best BEE JOURNAL in the world! It reaches me each Wednesday before noon, and is read with great interest.

Bee-Keeping in Nebraska.—D. M. Imlay, Seward, ♂ Nebr., on Dec. 22, 1886, writes:

There was only about half a crop of honey in this locality last season, while 25 miles west of here there was a large crop. I began the season with 78 colonies (nearly all in poor condition), increased them to 128, and obtained about 4,000 pounds of extracted honey, 800 pounds of comb honey, and 35 pounds of beeswax. The extracted honey will average about 9 cents per pound, and the comb honey about 15 cents per pound, while beeswax brings 25 cents per pound. I have kept bees since 1881, beginning in a small way. I have advanced a little in the business; but if I could, with my present experience, return and correct my mistakes, I could make \$2 where I have made \$1. The past was a peculiar season. Local showers during the summer made a very material difference in the honey crop. This is a very poor place to rear queens, as the honey-flow comes in the fall; but we are not bothered with swarming

during the honey-flow, as it is so late that the bees begin to prepare for winter, and will not swarm unless they are very strong and have no room to store honey. There is plenty of goldenrod, but our bees seldom notice it; our crop is from heart's-ease, buckwheat, and the late red clover bloom. My bees are in the cellar, and the only trouble seems to be to keep the temperature low enough; it goes up to 50° with only the outside door shut. They make a low hum; should they be perfectly quiet?

[Regulate the temperature of the cellar so as to prevent restlessness.—A "low hum" shows happiness.—Ed.]

Bees Removing Brood, etc.—L. M. Foster, Friend, ♂ Nebr., on Jan. 17, 1887, writes:

Concerning my query (No. 344), I also think that the trouble (bees carrying out brood) was caused by the bees being determined to load the brood-chamber with honey. The colonies mentioned were in 10-frame Langstroth and Simplicity hives, each of the hives having 9 frames almost entirely filled with brood. There was no lack of food, as some of my colonies had already stored several pounds of honey in the surplus boxes. I had 5 colonies, spring count, increased them to 11, and one absconded. I obtained 400 pounds of nice comb honey, notwithstanding the drouth. The most of our honey is obtained from heart's-ease, or as some call it, black-heart. My bees are wintering well out-of-doors, with chaff cushions on the top stories, and a passage over the frames under the cushion.

My Management of Bees.—J. R. Gailey, Avery, ♂ Iowa, on Jan. 21, 1887, writes:

My knowledge of bees is drawn mostly from observation and experiment. I used comb frames before the war, and one-pound sections in 1867. I have had the best success with the Langstroth brood-chamber containing from 10 to 16 combs, with division-boards and the bottom-boards clamped on the lid with a 2 or 3 inch rim. (Both can be dispensed with in tiering up the hives in the cellar for winter.) I have supers (with rabbit in the side-board of the hive dispensed with), slatted honey-board, and the hive with an additional story high enough to hold 1¼-inch sections, with a flange of light hoop-iron nailed on the lower outer edge to shut on the hive like a band-box. These hives can be tiered up to any desired height. I put on a super, spread a cloth over it, and as soon as it is pretty well filled with honey take it off, place an empty one in its place, and put it back to be finished. Seven and a half inches is too shallow for caps, as only one case of sections can be placed under it at a time. I consider it important to give room in the honey season, without waiting for all the sections in one case to be finished.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

All New Subscriptions will begin with the year, and until further notice we will send the back numbers from January 1, unless otherwise ordered.

We will Present Webster's Dictionary (pocket edition), and send it by mail, post-paid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1 00..	1 00..
and Gleanings in Bee-Culture	2 00..	1 75
Bee-Keepers' Magazine	1 25..	1 25
Bee-Keepers' Guide	1 50..	1 40
The Apiculturist	2 00..	1 75
Canadian Bee Journal	2 00..	1 70
Rays of Light	1 50..	1 35
The 7 above-named papers	5 25..	4 50
and Cook's Manual	2 25..	2 00
Bees and Honey (Newman)	2 00..	1 75
Binder for Am. Bee Journal	1 60..	1 50
Dzierzon's Bee-Book (cloth)	3 00..	2 00
Root's A B C of Bee-Culture	2 25..	2 10
Farmer's Account Book	4 00..	2 00
Guide and Hand-Book	1 50..	1 30
Heddon's book, "Success"	1 50..	1 40
A Year Among the Bees	1 75..	1 50

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the **Apiary Register** and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages)	1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

The Report of the Indianapolis Convention is now published in pamphlet form, uniform with that of last year. It will be sent postpaid for 25 cents to any address.

We have also bound it up with last year's, together with the History of the Society; this we will mail for 40 cents. Or if you send us one new subscriber (with one dollar) besides your own renewal, we will present you with a copy by mail.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

The Western World Guide and Hand Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides his own, with \$3.00, for one year, we will present a copy of this valuable book.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

Honey and Beeswax Market.

following are our very latest quotations for honey and beeswax :

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c. No demand for extracted, and very little for comb.
BEE SWAX.—22c. R. A. BURNETT, Jan. 19.
 181 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10@12c.; in 2-lbs., 9@10c.; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8@8½c.; in 2-lbs., 7@7½c. Extracted, California, 5@5½c.; buckwheat, 4@4½c. Supply of comb honey is large, and demand for all kinds is improving.
BEE SWAX.—21@23c.

MCCAUL & HILDRETH BROS.,
 Jan. 21. 34 Hudson St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 13@14c.; 2-pounds at 11@12c. Extracted, 5@7c.
BEE SWAX.—24 cts. per lb.
 Jan. 21. **BLAKE & RIPLEY,** 57 Chatham Street.

DETROIT.

HONEY.—Few sales are reported. Best white comb, 12½c.; Fall comb honey, 10@11c. Extracted is offered for 6@8c.
BEE SWAX.—Firm at 23c.
 Jan. 22. **M. H. HUNT,** Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote for extracted, 4@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way.
BEE SWAX.—Good demand, 20@22c. per lb. for good to choice yellow.
 Jan. 22. **C. F. MUTH & SON,** Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, in 1-lb. sections, sells at 13c.; second quality white, 12c.; dark 1-lbs., 10c.; white 2-lbs., 11@12c. Extracted, Sc. Market dull.
BEE SWAX.—25c.
 Jan. 14. **A. C. KENDEL,** 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 12@12½c.; 2-lbs., 11@12c. No call for dark. White extracted, in barrels and kegs, 6@6½c.; in small packages, 7@8c.; dark, in barrels and kegs, 5@5½c.
BEE SWAX.—25c.
 Jan. 19. **A. V. BISHOP,** 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8@11. Extracted, white, 4½@4¾c.; amber and candied, 3½@4c. Trade is quiet.
 Jan. 10. **O. B. SMITH & CO.,** 453 Front St.

HONEY.—We quote good to choice extracted at 4½c., and comb honey firm at 8@12c.
BEE SWAX.—Active at 18@21c.
 Jan. 10. **SCHACHT & LEMCKE,** 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lbs., 8@10c.; white clover 2-lbs., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 6c.; dark, 4@5c.; white sage, 5@5½c.; amber, 4½@5.
BEE SWAX.—20@23c.
 Jan. 13. **CLEMONS, CLOON & Co.,** cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 3½@4c. Extra fancy of bright color and in No. 1 packages, ½ advance on above prices. Extracted in barrels, 4@5.5c. in cans, 5@5.5c. Market dull.
BEE SWAX.—Firm at 21c. for prime.
 Jan. 19. **D. G. TUTT & CO.,** Commercial St.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have just gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x18 "	8 00
For 3 " " 10x18 "	10 00
For 4 " " 10x18 "	14 00
For 2 frames of any size, 13x20 "	12 00
For 3 " " 13x20 "	12 00
For 4 " " 13x20 "	16 00

The NEW Heddon Hive,

We have made arrangements with the inventor by which we shall make and sell Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

It is absolutely essential to order one nailed hive as a pattern for putting those in the flat together correctly.

HIVES READY TO NAIL.—In filling orders for these hives, in the flat, we make 6 different combinations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers:

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 frames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—interchangeable, but not reversible.—Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus stories as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-chambers. Price, \$2.30 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deductions from the above prices: Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at 1/2 cent each, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives, 5 per cent. discount; for 25 or more hives 7 1/2 per cent.; for 50 or more, 10 per cent.

THOMAS G. NEWMAN & SON,

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Feb. 9, 1887. No. 6.

Locating the Paraffine Combs!—The stupid advocates of the "Wiley lie" about the manufacture of comb from paraffine, filling it with glucose and sealing it over with a "hot iron," are still industriously engaged in trying to find the place where it is said to be manufactured—but each time are foiled in the attempt! Bro. Root, in the last issue of *Gleanings*, gives the result of another "hunt," in the following language:

A short item appeared in the *Pittsburgh West-End Bulletin*, to the effect that there was an establishment in Pittsburgh making comb honey, etc. Our good friend W. H. Ferguson, of Bloomsdale, O., while in the above city, took the pains to follow it up. The editor of the paper declared there was no mistake about it, and gave the street and number. When our friend got there they said it was a fact, but that it was off somewhere else, up three flights of stairs, and so on. What do you think they found? Why, a man who makes cement and sealing-wax; and it happened that this worthy tradesman also put up very neat little cakes of wax for the sewing-table—just that, and nothing more.

The persistence of these scoundrels would be praise-worthy in any laudable undertaking, but when trying to defend that lie of Wiley's, by finding an apology for its utterance, is very disgusting. Poor fools! they will always have "their labor for their pains!"

The Bee-Lawsuit against Mr. C. C. Richardson, mentioned on page 691 of the *BEE JOURNAL* for last year, has terminated. The suit was dismissed by the judge. The attorney's fees amount to \$20, of which the Union pays one-half and Mr. Richardson the other half.

This is another triumph for the Union, which backed up the defendant in such a way as to show that the pursuit cannot be attacked with impunity.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Rat-Tat-Tat!—Rattle the drums! for we have received the following positive Order from a self-appointed Supreme Dictator:

ROSSVILLE, Jan. 29, 1887.

EDITOR OF AMERICAN BEE JOURNAL:—Stop "bee-legislation" in the *BEE JOURNAL*. It is no matter for discussion. It is undebatable—unsensible—unnecessary—un-American—tending to anarchy. Now stop it, and let "the survival of the fittest" settle the subject forever!
M. F. TATMAN.

Isn't that sublime? Who appointed him a dictator to the three hundred thousands of bee-keepers of America? By what authority or law does he decide for hundreds of thousands that the subject shall not be debated? Who appointed him a dictator to issue the Order—"Now stop it"?

The only excuse that can be offered for such sublime assurance is the thought that our would-be dictator is a crank! No one in a sane condition would assume the prerogative so boldly claims! His friends should seek some quiet retreat where he may regain his mental equilibrium!

We have had nothing to say as yet on the merits of the question of "bee-legislation," but when we have anything to communicate we shall not think of asking permission of the would-be Dictator for our doing so. And if our correspondents desire to "discuss" the subject, that fulmination cannot shut them out of the *AMERICAN BEE JOURNAL*.

The Union Convention at Albany, N. Y., a condensed report of which will be found in this issue of the *AMERICAN BEE JOURNAL*, was a decided success, and a very harmonious body. The *Bee-Keepers' Magazine* speaks thus of it:

The convention at Albany was quite a success. There were present bee-keepers from Virginia, Pennsylvania, New Jersey, Vermont, Massachusetts, Ohio, Michigan, and several other States. The one notable feature was the entire absence of any friction between the members—everything moved in such perfect harmony. Under the exceptionally able guiding of President W. E. Clark, not a clash occurred, and every proceeding was carried on with order and decorum. Mr. Clark, to our mind, makes a most capital presiding officer, being impartial, dignified and decided.

There were present on the platform at the time the presidents of four different bee-keepers' associations, viz: New York State, Eastern New York, New Jersey and Eastern and the Philadelphia Association. We do not remember of such a thing having occurred in the annals of bee-keepers' conventions in America. Perhaps our statistical friend, Editor Newman, will correct us, however, on this point.

We have no desire to criticise nor "correct" the *Magazine*, but being called on we will say that there were four or more "presidents" on the platform at the Detroit and Indianapolis meetings. At the Cincinnati convention of 1880, there were three editors of bee-papers, five presidents of bee-societies, and three ex-presidents of the society on the platform. We rejoice to notice such harmony, and hope it may long continue.

Concerning another visitor the *Magazine* remarks as follows:

We had with us at the meeting on the second and third days, Mr. Jas. A. Abbott, of Southall, England, who, up to a late day, was in partnership with his brother in one of the largest bee-keepers' supply businesses in England, but who is now about to start another house himself. This gentleman is a man of close observation, and when he talks "bee-business" he knows what he is talking about.

The Union has Lost None!—Of all the suits against bee-keeping in the United States, which the National Bee-Keepers' Union have deemed expedient to defend, not one has been lost!

The "Freeborn" case in Wisconsin was presented in such a manner, backed up by the Union, that the judge kicked it out of court!

In the "Bohn" case in California, the united resistance of the bee-keepers of the Nation was too much for the fruit-growers—and that trouble, which was proclaimed by a Nebraska apiarist to be "too much for the Union to compete with," is now all conquered! the 'raisin growers' admitting that they were mistaken!

The "Darling" case in Connecticut was dismissed as soon as it was discovered that he was "backed up" by the National Bee-Keepers' Union!

Now, the "Richardson" case in Indiana has been dismissed by the court! This is the "case" which was so badly misrepresented at the Indianapolis convention, by an officious neighbor, and it is with much satisfaction that we are now able to say that the "Union" was too much for the enemies of the pursuit of bee-keeping!

Several "suits" have been allowed to go by default in justices courts, so that we could "appeal" them, and thus have the decision from the higher courts. This plan has been eminently successful, and productive of good.

The four cases enumerated in the foregoing matter are all that have been finally decided, and it is a record for every member to feel proud of—not one case has been decided against the bees!!!

This shows the value of united action, and the moral weight of the "backing" of the National Bee-Keepers' Union! Cannot all now see that the Union should have thirty thousand members, instead of three hundred!

Catalogues for 1887.—These on our desk are from

Dr. J. P. H. Brown, Augusta, Ga.—18 pages—Apiarian Supplies, Bees, Queens, etc.

J. W. Bittenbender, Knoxville, Iowa—8 pages—Bee-Keepers' Supplies.

John A. Thornton, Lima, Ills.—Bees, Queens, etc.

George Pinney, Evergreen, Wis.—10 pages—Forest Trees and Tree Seeds.

A. C. Nellis, 64 Cortlandt St., New York.—Seeds.

If One has a Good Thing, which the people really need, the more widely he makes it known, the larger will be his sales; he will gain nothing by economizing in this matter, provided he advertises with good judgment.

Just as the forms of this issue of the BEE JOURNAL are ready for the press, we learn that the Canadian bee-lawsuit, mentioned on page 35, has been decided against Mr. Harrison. This was a neighborhood quarrel about the removal of a pig-pen, and bad temper was very evident on all sides. The Canadians raised a fund of \$50 to defend the suit, but what action (if any) was taken for its defense, our correspondent does not state.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Bees Absolutely Quiet in Winter.

Query, No. 371.—Ought bees to be absolutely quiet when wintering in the best condition? I have placed some of my colonies in the cellar this winter, for the first time, and I can always hear a gentle hum by placing my ear near the entrance. Is that an alarming condition?—H. C. P.

Not absolutely so.—J. P. H. BROWN.
I should not be alarmed at it.—C. C. MILLER.

This gentle humming is not an objectionable symptom.—W. Z. HUTCHINSON.

The low hum that you hear is not a bad sign.—DADANT & SON.

It is very seldom that bees are "absolutely" quiet. A gentle hum is not an alarming condition.—H. D. CUTTING.

No. Bees always make a gentle humming noise if alive, no matter how quiet.—G. M. DOOLITTLE.

This gentle hum is usually heard when bees are in just that hibernating (?) condition most desirable. You may rest in peace, so long as it is thus.—A. J. COOK.

I have never been able to discover a colony that did not hum more or less. The gentler the hum the better are they enjoying their nap.—C. W. DAYTON.

Quietude is the natural condition of bees while in winter quarters. A low, gentle hum indicates high temperature in the hive. When the temperature falls a little, they will quiet down to perfect silence.—G. W. DEMAREE.

Bees hibernate when wintering in the best condition. In this state they are absolutely quiet as far as the eye can detect, except at feeding times. The imperceptible respiration is accompanied by a faint murmur that is more distinct where many colonies are placed close together, as in a cellar.—G. L. TINKER.

No. Sometimes they make a great deal of noise, and come out in nice condition. Much depends upon what causes them to make that noise. Disease causes restlessness, but restlessness does not always, nor usually, cause disease. Your bees are as quiet as is usual.—JAMES HEDDON.

My own opinion is that the nearer the bees can be kept to an absolute state of quietude, the better they will winter. In practice, a state of "absolute" quietness cannot be maintained. I apprehend, however, that

the "gentle hum" spoken of, will be found in every hive, in every winter, and that the same is not evidence at all of unfavorable conditions.—J. E. POND.

No. A "gentle hum" indicates contentment.—THE EDITOR.

Effect of Water in Bee-Cellars.

Query, No. 372.—1. Can a cellar be too dry for wintering bees? If so, can it be too wet? 2. Will a body of water on the floor of a well-cemented cellar increase, or diminish, the moisture of the air in the cellar?—F., Wis.

1. I do not think that it can. 2. It will increase the moisture.—J. P. H. BROWN.

1. Dryness or dampness have less to do with wintering than temperature. If the temperature can be kept from 43° to 47°, I should worry little about the other conditions.—G. M. DOOLITTLE.

I do not know that a cellar can be too dry or too wet. I should suppose that the water in the cellar would make the air more damp, but I may be wrong.—W. Z. HUTCHINSON.

We do not think that it can be too dry, but we think that it can be too wet. A standing body of water, if colder than the cellar, will absorb moisture.—DADANT & SON.

I should prefer a very dry cellar for bees. Yet I have known cellars to have 2 to 3 inches of water and yet the bees came through in good condition. 2. It will increase it.—H. D. CUTTING.

1. If the other conditions are right, I think that bees will winter in spite of humidity. 2. If the air and water are of the same temperature it will have no effect. But make the water the warmest, and saturation of the air will take place.—J. P. H. BROWN.

1. I hardly think so, if ventilation and temperature are all right. 2. I think it can. It depends upon the ventilation. Our cellar with its sub-earth ventilation has water in it all the time, but it is not unpleasantly damp. Some of the pleasantest and sweetest cellars I know of have large cisterns in them.—A. J. COOK.

1. A cellar cannot well be too dry or too wet for bees, if the temperature is suitable. 2. It would increase the humidity of the air; but heat and cold has so much to do with the relative humidity that much depends upon the temperature as to the degree of moisture in the air.—G. L. TINKER.

No; moisture will do no harm if the temperature is kept in harmony with it. Water thrown on the floor of my cellar would increase the humidity of the atmosphere therein, because it would soon dry off.—JAMES HEDDON.

1. I think not; bees always generate more or less moisture; I question also, whether it is possible, without using heat, to have a dry cellar. 2. Ordinarily it will; much will depend, however, upon other conditions, such as ventilation and warmth. The usual and ordinary effect of the water will be to keep the air warmer, and thus

tend somewhat toward making the temperature more equable.—J. E. POND.

1. Different persons hold different theories, but after all, do they really know anything about it? 2. Under some circumstances the water on the floor would certainly increase the moisture, and I can hardly think of any circumstances in which it would diminish it. There have been cases of successful wintering of bees in which a stream of running water in the cellar was believed to be helpful.—C. C. MILLER.

As temperature (not humidity) is the essential point in the cellar wintering of bees, let that be kept at from 45° to 50°.—THE EDITOR.

Extra Combs for Extracting.

Query, No. 373.—The coming season I will work 75 colonies for extracted honey, but I have no extra combs. 1. How shall I proceed to get combs built at the least expense? Should full sheets of foundation be used, or starters only? 2. Should the frames to be filled be placed above or beneath the brood-nest? If below, would there not be less drone comb built?—W. Va.

I should use full sheets of foundation placed beneath the brood-nest.—J. P. H. BROWN.

I use full sheets of foundation placed above the brood-chamber, and I have no trouble with drone comb.—H. D. CUTTING.

In a short and abundant honey-flow foundation is worth \$1 per pound. If it is light and continued you might extract often from fewer combs, and gradually work in frames with starters.—C. W. DAYTON.

In my locality I cannot get combs built in the natural way for extracting purposes, without sustaining very great loss in the way of surplus honey. 1. It pays well to employ full sheets of foundation to get a supply of extracting combs. 2. They should be placed above the brood-nest all the time.—G. W. DEMAREE.

I should use comb foundation, and I should not care where the frames were placed. We can secure many frames of comb in the spring before the season opens, by placing foundation right in the brood-chamber.—A. J. COOK.

1. In such a case I should use full sheets of foundation, placing them in the upper story when the honey harvest arrived, and raising a frame of brood to this story so as to secure immediate work there. 2. I should place them above.—G. M. DOOLITTLE.

I would use full sheets of foundation. I put it in above; you might try both ways. I would advise you not to prepare to produce extracted honey, but to work for comb honey, unless most of your surplus crop is dark.—JAMES HEDDON.

1. I do not know. The higher the price you get for honey, the more you can afford to use foundation. I think that there is more inducement to use foundation where the honey-flow is profuse and of short duration, than

during a long-continued and moderate flow. 2. I think that I would place them above.—C. C. MILLER.

I fear there would not be time to get a full set of combs built before the harvest, without using foundation. I may be mistaken. Some recent experiments lead me to hope that I am. It is my opinion that comb built under the brood-nest in the spring would be at once filled with brood, and whether drone comb would be built would probably depend upon the age of the queen and the amount of drone comb already possessed.—W. Z. HUTCHINSON.

1. I would use full sheets of foundation. 2. As soon as the colony is strong enough to build extra combs, I would place frames of foundation between the frames of brood, and add the frames as fast as they could be used. The foundation would not be wired. The super should be of the same size as the body of the hive, and the frames interchangeable. Use a queen-excluder between the cases, and continue to add frames below, and raise up the frames of brood until as many combs as needed are built.—G. L. TINKER.

1. This is a mooted question. I apprehend, however, that it will depend upon location. Mr. Hutchinson favors the "starter" idea; I have found full sheets to work better in my own case. Test the matter and report. 2. Place them above by all means; at least that is my own opinion. I do not think that any difference would be found in the amount of drone comb built, whether placed above or below.—J. E. POND.

Use full sheets of comb foundation in or above the brood-chamber.—THE EDITOR.

For the American Bee Journal.

The Honey-Producers' Association.

M. M. BALDRIDGE.

Is there anything *practical* in the idea of an association of honey-producers to fix and control the prices on honey? Mr. Caldwell, on page 808 of the BEE JOURNAL for 1886, says "No, most emphatically." And why? Because "honey is one of the products of the farm, and, as such, it must be placed upon the market in precisely the same manner as any other product."

Well, let us see about this. Butter, I believe, is also one of the products of the farm. Now, is not the price of gilt-edge butter fixed and controlled

to a great extent, by an association of butter producers? If you do not think so, then study the proceedings of the butter producers, who, through their representatives, meet every Monday in Elgin, in this Fox river valley, and be convinced. This association not only regulates the price on all the butter made in factories, by its members, but likewise, to a great extent, that made by the farmers themselves—they who do not patronize the factory system. And how do we know this? Because all the dairy butter sold to consumers, in this Fox river valley, and elsewhere wherever these factories exist, goes up or down in price, according to grade, in perfect harmony with that of factory butter as given from week to week by the Elgin Board of Trade. Well, what is the present price of factory-made butter? For Monday, Dec. 20, the price per pound, at wholesale, as given officially, was 30½ cents, and that for Monday, Dec. 27, was 32 cents. And was much butter sold at such "extravagant" prices? I should say, yes. For Monday, Dec. 20, the sales, as given officially, were 68,794 pounds, and for Dec. 27, the sales aggregated 232,532 pounds!

Now, if butter producers can, through their representatives, fix and control the price of their farm product, why cannot honey producers, through their representatives, do likewise on gilt-edge honey? I say they can if they will it so. Yes, and they can do this with far less friction, and more successfully than butter producers. And why? Because the supply of butter never ceases—being produced every day in the year. Not so with honey; for when we once ascertain the supply of honey, at the close of each honey harvest, we are then assured that no more can be produced, with rare exceptions, until there comes another honey harvest. Then, by knowing the supply, ascertained mainly through the members of the honey-producers' association, and the probable demand, its committee can approximate pretty closely to the proper prices to fix upon it in the fall of the year, and without a weekly meeting as butter demands.

But, says Mr. C., we must place our honey "on the market" in precisely the same way that we do any other farm product, and not as you desire, to-wit: In the hands of retailers to be sold by them at fixed prices and *only* on commission.

Let us investigate this *must* idea. Because our parents and grand-parents used straw hives, brimstoned their bees, and took their honey to market in wash-tubs, is that any reason that we *must* do likewise? And because farmers generally sell their produce to middle men in order to reach consumers, is that any reason that honey producers *must* do so? As yet I have seen and read nothing that convinces me that honey producers cannot organize and agree among themselves to adopt new methods of dealing with consumers. It so happens that we live in an age of progression, and that we have the power, if we will it so, to adopt new methods

of doing business that might appear to some to be impossible and impracticable innovations. But we do not always know what we can do until we try. Then let us try, for awhile at least, what appears to me, and to many others, to be a very simple, practical, and common-sense method of disposing of our honey, to-wit: Have it sold at *our* prices to consumers, through retail agents, and by them *only* on commission.

"I am 'sorry," says Mr. C., that our honey "has gone down in price as it has this season." Well, whose fault is it? Mainly the fault of the honey producers! If they will not organize—if they will not pull together, if they will not quit flooding our large cities with honey, and if they will not stop patronizing the wholesale commission men, then they have no one to blame but themselves.

Mr. C. attributes the present low prices on honey to the good honey season; "one of the best" he has seen in his "14 years experience." Now, because the honey crop has been extra good perhaps, in his neighborhood, or in his county, or in his State, Mr. C. evidently infers that the honey yield has also been extra good throughout the United States! Honey producers should remember that the general crop of honey was not last year any above the average, and that when it is extra good in one locality, or in several localities, that there are still many other localities where it may be poor or be below the average. This has generally been the case, in the past, and will undoubtedly be the case in the future.

"Most bee-keepers," says Mr. C., "when their product is ready for the market, want the money for it, or its equivalent." That is true, but do they now get what they want? Do bee-keepers now get their money when they ship their product to the wholesale commission men? Not often, I can assure you. Then if not, why bring up this as an objection to an association of honey producers whose chief purpose is to fix a fair, honest price on honey to consumers based on supply and demand, and to hasten the disposition of it by having it placed and kept on sale by retailers everywhere and at all times. When every proper place for retailing honey in country, village, and city, is kept properly supplied with choice honey at all times, and at a reasonable fixed price, why should not the entire crop be disposed of each year even more readily than now?

"Now suppose," says Mr. C., that "the crop has been a good one," and the price of choice comb honey "is placed at 20 cents per pound, and the market price is only 10 cents." What is to be done? Why, my dear sir, you are supposing something that would not exist! How could "the market price" on honey be 10 cents when the universal price, in every State in the Union, is fixed by the honey producers of the United States at 20 cents?

And "what are we going to do," says Mr. C., "with the farmers and small honey producers?" Now, do not worry over that problem. The

farmers and small producers will not be slow in finding out that the large producers have adopted new tactics, and have quit fooling their honey away for less than its true value. They will not then be so anxious to hasten to market and sell the "stuff" at any price as now. The trouble at present is, they are afraid the large producers will flood the markets, and thereby cause low prices, and this simply makes them try to anticipate such a state of things. Another thing: Unless their honey is in small packages, of good quality, and in good condition, it will do no more harm to the wide-awake honey producer than the poor or unsightly butter made by farmers does to the gilt-edge commodity made in factories. But when the farmer and small producer adopts the one-comb sections, and has his honey in proper condition for the retail trade, and we find that their prices will do harm to large producers, then we had better buy their product. We can then place it upon the market and have it sold for us, by and through our agents, and at a profit.

Mr. C. seems to be afraid that the farmers may turn their attention to rearing bees and producing honey when they find they can sell the honey at good prices, and this will "crowd an already overstocked market." Such as his perhaps may be. This he thinks will make matters worse than they are at present. Now the overstocking of the markets with honey seems to be a great bug-bear to many, but not so to me. I have been too long in the honey trade to have any such fears. I do not believe that we can very well overstock the markets of the United States with choice comb honey, in case we distribute it properly, and see that it is kept on sale and in sight at all times, and in a presentable shape. The chief trouble at present is, as the Editor says, *unequal distribution*—coupled with the fact that the majority of retailers are entirely out of it nearly one-half of the time.

"There is," says Mr. C., "but one practical" way to accomplish "the desired end," and that is for a few rich bee-keepers to form a syndicate, buy all the honey, and make a "corner" on it. No, sir, we want no "corner" on honey, in the sense he indicates. Nor do we need a Vanderbilt. When our large honey producers once make up their minds to organize and pull in one direction, there will then be members enough in each and every honey-producing locality to buy out the mischief-makers therein, or to report such to head-quarters, when a way will be provided for protecting its members everywhere. I do not apprehend much trouble in that direction—still I may be mistaken. Suppose we give the plan a trial and find out! Reader, what say you?

St. Charles, 3 Ills.

For the American Bee Journal.

Northern Illinois Convention.

C. M. HOLLINGSWORTH.

The regular annual meeting of the Northern Illinois Bee-Keepers' Association was held at Rockford, Ills., on Jan. 18 and 19, 1887, and the writer was appointed to prepare for the BEE JOURNAL a summary of the discussions on topics of general interest. Dr. C. C. Miller was present, and was constantly called upon for his views and experiences, which he gave in an entertaining and instructive manner.

BEEES AND PLANTS.

Mr. A. J. Swezey first read a well-prepared essay on the agency of bees and other insects in the fertilization and cross-fertilization of plants. Mr. S., who is a fruit-grower, had formerly believed that bees do some harm to fruit-growers, without being in any way beneficial. But investigation of the subject by reading and observation had convinced him that the harm they do is very trifling compared with the good they do to the fruit interests.

Dr. Miller asked if there was any plant which was known to depend solely on the visits of the hive-bee for its fertility.

Mr. Hollingsworth cited Darwin's experiments with white clover. In one case a number of heads that had been protected by a net produced but few seeds, and in another case, no seeds; while heads outside the net, in both cases, which bees had been seen to visit, seeded abundantly—bees being the only insects mentioned by Darwin as having been seen on the plants. But experiment has also shown that, even with plants which are capable of self-fertilization, the crossing of one individual with another by the agency of insects is of great benefit, causing them to produce more and better seed, larger and sounder fruit, and more vigorous plants in the succeeding generation.

Dr. Miller said that he felt sure that even bee-keepers themselves were not fully aware of the importance of the office which bees perform in this way. If it is a fact that white clover depends as much upon the presence of hive-bees as red clover does upon the presence of bumblebees for the production of seed, the fact is of the first importance to farmers and dairymen. To take away the bees would be to take away the white clover from their pasture fields.

ITALIAN VS. BLACK BEES.

It was admitted that the black or German bees go more readily into the sections and produce a fancier article of comb honey. But Mr. Lee thought that they carried too much of the honey into the supers, leaving the brood-chamber poorly supplied for winter. He preferred to keep Italians only, if for nothing else, on account of their better disposition.

President Whittlesey said that the Italians would gather the most honey in a poor season.

Dr. Miller, without attempting to establish or maintain any particular strain of bees, makes a practice of buying, each year, one of the best imported Italian queens that can be had, thus constantly securing the advantage of fresh blood, and the farther advantage of pure blood, if there is such a thing in bees.

MARKETING AND SHIPPING HONEY.

Mr. Highbarger had this season sold 5,000 pounds near his home, by taking it around in a wagon through the country, and to the nearest villages. He sold comb honey at from 10 to 12 cents, and extracted at 8 cents per pound. Mr. Hollingsworth, in the village of Winnebago, had, by advertising with postal cards, sold 1,500 pounds at the apiary, besides 600 pounds at the village stores, which was a large increase over the home sales of last year.

Dr. Miller discovered a few years ago that commission men in the large cities made a practice of under-quoting the market, so that their customers would be the better pleased with the price obtained for shipment. This often had the effect of fixing the price in the country markets below what it should be. He further showed that some producers make the mistake of always putting the local price at the price in the large markets less the cost of shipment to those markets. But in localities where there is a deficiency, the local price should be the city price plus the cost of shipment. The idea that producers could combine to fix the general price of honey met with no support whatever.

With regard to the shipment of comb honey, the views brought out were, that when sent by express it is apt to be damaged by hurried and careless handling; when sent by freight and transferred on the way, it is liable to suffer from improper packing in the car by those who make the transfer; and when properly loaded and sent by freight without transfer, there is very little risk. Thus a large shipment can be sent more safely than a small one.

In an essay on "Bee-Keeping as a Pursuit," Mr. Fuller said that he had only followed it in connection with farming, but considered it, when well-managed, as profitable as other pursuits.

HIVE BOTTOM-BOARDS.

A distinction was made between loose bottom-boards and those that are not loose but movable. A vote showed a large majority against having the bottom-board nailed on the hive. In moving hives with loose bottom-boards, Mr. Gammon used a large U-shaped iron clamp with a set-screw at one end to clamp the hive and bottom together. Mr. Rice used two ropes and sticks and a wedge for the same purpose.

Mr. Hollingsworth had Langstroth hives with bottom-boards that were removable, but not loose. The bottom of the portico is nailed on like the top, and the two give the hive stiffness. In its back edge are two small auger holes to receive project-

All New Subscriptions will begin with the year, and until further notice we will send the back numbers from January 1, unless otherwise ordered.

ing headless-nails driven into the front edge of the main bottom; and two long wooden buttons with square notches on the back end of the hive, hook on projecting nails in the back end of the bottom-board.

REVERSIBLE HIVES.

Dr. Miller had tried an invertible hive last summer. It had some good points, but with all his inverting and re-inverting he failed to make the bees understand what was wanted of them; they would not work in the sections.

Mr. Gammon had last summer tried a sectional hive; but when he undertook, by interchanging the parts, to have the honey carried from the brood-department into the sections, he failed entirely. He had never had a hive become so clogged with honey to the restriction of the queen. He had also fitted a set of ordinary frames for reversing. When he first reversed them, he found one capped queen-cell, which he removed, and others started. A day or two later he found the bees had destroyed the latter, and was much elated, thinking that he had found an easy preventive of swarming. But about the time the first queen-cell should have hatched, out they went, and they kept on swarming, and at last killed their own queen.

ALSIKE CLOVER.

From ten years' experience, Mr. Lewis pronounced this one of the very best grasses for hay and pasture, especially on low ground. For hay it should be sowed with timothy, which helps to hold it up. Sow 1 bushel of seed to 16 acres. It makes but one crop of hay, does not turn dark in curing, and stock eat it up clean. It will re-seed itself indefinitely.

Dr. Miller had not succeeded in getting it to grow, and it did not re-seed itself for him.

Both Mr. Lewis and Mr. Highbarger gave good reports of the Alsike as a honey-plant. They thought that it was better than white clover, and less affected by drouth.

The President of the association for the ensuing year is Mr. L. Highbarger, of Adaline, Ills.; and the Secretary is Mr. D. A. Fuller, of Cherry Valley, Ills.

Winnebago, § Ills.

For the American Bee Journal.

Bees in Winter Quarters.

V. W. CLOUGH.

Winter quarters should exclude light, and from the time they are put away in the fall until removed in the spring, the room should remain dark. This will keep them quiet, even during warm days. After being prepared for winter, I do not want my bees to have any flight.

The repository should be so constructed that the variations of temperature will be gradual. Sudden changes should be avoided. Cold

weather is not injurious to bees, but the mischief lies in the rapid change of temperature. Any old shed, coal-house, or in fact any building that can be darkened answers the purpose. Noise does not disturb the bees, if the hives are not jarred.

To those who have large numbers of colonies I recommend for winter quarters a building on the plan of an ice-house—the walls being packed with sawdust, perfectly air-tight at the bottom, with a small ventilator at the top, without any light-holes as windows, so that when the door is closed the bees will be in a perfectly dark room.

Geneseo, ∞ Ills.

Vermont Convention.

The Vermont Bee-Keepers' Association met at Burlington, Vt., on Jan. 13, 1887. President P. C. Abbot occupied the chair, and congratulated the association on having started from the humble position of a small Addison county association and risen to the dignity of a State organization, so that every bee-keeper in the State might have the benefit of associated effort and experience.

The first essay read was by J. H. Larabee, on "In Embryo," which contained valuable advice, intended especially for beginners in apiculture.

A. E. Manum discussed the subject of "The brood-chamber from April 1 to Aug. 1," giving his methods of strengthening weak colonies in the spring, preparations for the collection of surplus honey, and extending to the close of the honey harvest, preparation for winter, etc. The subject was fully discussed.

"Cellar vs. out-door wintering" was the subject of a discussion, led by Dr. F. Bond, of Cornwall, who favored cellar wintering, although he thought it best to be governed by circumstances. His apiary was located in a windy place, so that he used a cellar. It was well to economize heat to save honey. He put his colonies in the cellar just after the ground froze, and took them out about April 10, or when the weather was warm enough for the bees to work. He did not pay much attention to ventilation.

F. M. Wright, of Enosburgh, found it necessary to ventilate, and recommended upward ventilation from the floor. He did not put his bees out until about the last of April. He placed a quilt over the frames and raised the hive off from the bottom-board.

The question was further discussed by Messrs. Leonard, Manum and Crane, the weight of opinion being in favor of wintering in the cellar. Mr. Crane gave his views on the condition of the temperature as governing the amount of moisture held by the atmosphere. A cubic foot of air at 10° would hold in suspense about one-fifth of a grain of water and a rise in the temperature will largely increase the amount of moisture that will be held.

Adjourned until evening.

"Shall we feed sugar or honey when hives are deficient in winter stores?" was discussed by Messrs. Crane, Bond, Leonard, Davis and others, the weight of opinion favoring honey as the best and cheapest.

Miss M. A. Douglas, of Shoreham, read an essay on "How shall we market our honey?" She admitted that she was undecided whether it was better to sell individually or through an association. She was strongly in favor, however, of placing a first-class article on the market in preference to adapting the quality of the supply to the demand. This essay took the first prize, and will be published later.

Mr. Leonard led the discussion on "What is the best method of re-queening colonies?" From the best colonies he took sealed queen-cells in the swarming season, and put them into a cage in the middle of a queenless colony to hatch. A frame with divisions both ways covered on one side with wire cloth, and on the other with a board or slats was used for this purpose. He introduced the queens into the hives in an introducing cage.

Mr. Manum favored the introduction of fertile queens, which he placed in a cage over a frame of unsealed honey and unhatched bees. He then cut a hole in the frame and placed it in the colony, and the bees would work their way through to the queen. Sometimes the bees would seal the hole up, when the hatching bees and queen could feed on the unsealed honey, and the queens could lay in the cells deserted by the young bees. The discussion was continued by Messrs. Holmes, Hall and others.

Adjourned until 9 a.m.

The first business of the second day was the report of the Secretary, which showed that the expense of the present convention amounted to \$13.27, of which \$3 had been received. The Treasurer's report showed \$7.27 in the treasury, leaving a deficiency of \$3. The above reports were accepted and adopted, and a contribution taken at the time was sufficient to defray all expenses and leave a balance in the Treasurer's hands.

The following were elected officers of the association for the ensuing year: President, P. C. Abbot, of Essex; Vice-Presidents, F. M. Wright, of Enosburgh; D. S. Hall, of South Cabot; J. E. Crane, of Middlebury; Secretary, R. H. Holmes, of Shoreham; Treasurer, J. E. Crane, of Middlebury.

An essay by J. H. Martin, of Hartford, N. Y., entitled "The exhibition of honey at the county fairs," was read by the Secretary. He noticed the fact that the eastern bee-keeper finds a sharp competitor in the western producer, as there they have a longer honey-flow and a cheaper mode of living, so that they can put their crop on our eastern markets at what seems to us ruinously low prices; he thought we should advertise by exhibiting at our county fairs, and push our business with the same enterprise that the dry-goods merchant does his, and, in order to maintain living prices, high-pressure methods would have to be resorted to.

E. O. Tuttle, of Bristol, presented the subject of "How to conduct conventions," etc.

A. E. Manum presented the claims of the Chapman honey-plant.

Prof. W. W. Cooke, the State chemist, presented a valuable essay on "Honey-production by plants."

After the adoption of some resolutions, the convention adjourned to meet at the call of the executive committee.

Union Convention at Albany, N. Y.

The New York State, the Eastern New York, and the New Jersey and Eastern Bee-Keepers' Associations convened at Albany, N. Y., on Jan. 11, 1887, with President Clark in the chair. After the routine business, an essay by C. M. Goodspeed was read on

ALSIKE CLOVER AS A HONEY-PLANT.

He said that Alsike comes in before basswood, and is in its prime by July 10. It blossoms very freely, and yields more honey than white clover, and as much as basswood. He esteemed it next to basswood. The amount of Alsike honey in his whole crop was variable; sometimes all the white honey was tinged with Alsike; at other times only a portion of the lower part would be. As feed for stock there was no better. His first crop was sowed late, and wet in curing, yet his cattle ate it in preference to his best-cured hay. It should be sowed with other grasses, and cut late. It seeds rather poorly, and does not do well on light soil, but on moist land there is an immense yield of rich fodder and fine honey.

A. I. Root had eight acres of Alsike on rather dry soil near Columbus, and from it obtained a rich crop of honey when his neighbors had none. It makes fine forage, especially for milch cows, and a small amount goes a great way. As pasture it is excellent, increasing the flow of milk.

John Aspinwall had seen it growing in St. Lawrence county, and was told by the farmers that it did better than other grasses.

T. F. Bingham said it was much raised for sheep in his State, and to some extent for cows. He had fed it to three horses, and they did better on Alsike and a little grain than on the best timothy or herds-grass and more grain. For bees he preferred it to either white or red clover.

H. N. Waters had raised it for 10 or 12 years, and found it succeeded best on wet soil.

L. C. Root said that good farmers like Alsike because it attracts the bees, and so a more perfect seeding is obtained. A farmer told him that his cattle would eat weather-stained Alsike in preference to his brightest and best-cured hay. He had secured honey from his clover by the ton, and it cannot be surpassed; the flavor is of the finest—better than that from basswood, though not as white. In Herkimer county it grows by the roadside as common as white clover. On dry soils it will not last long, but on moist it becomes permanent. In

growing Alsike, the interests of farmer and bee-keeper were identical.

R. Bacon said that farmers near Oneida Lake were growing Alsike to a large extent. Their subsoil was clay. His honey had been greatly improved by Alsike.

Secretary Knickerbocker said the yield was from two to three tons per acre.

M. D. West sowed two acres to Alsike, with one-third timothy. The hay was as described, and had a remarkably rich odor when put in the barn. The Alsike remained in land three years. The bees did not work upon it. Afterward he saw bees on roadside Alsike.

A member said that Alsike secreted more honey on light soils than on heavy. Five years ago he persuaded a number of farmers to try Alsike. The store-keeper was then selling 15 bags of red clover seed. Last year he sold 20 of Alsike and 4 bags of red clover.

President W. E. Clark sowed a piece, 12 years ago, to Alsike and timothy. Had cut good crops every year, and that of last year was the best of all. Last spring, when other grasses were heaved, Alsike was not, and after rolling, it was a perfect mat. Cut it July 22, and the bees worked on the aftermath until October.

Hiram Chapman spoke at length on the honey qualities of a perennial, known as *Echinops sphaerocephalus*, or the "Hedge-hog-plant," which is fully described on page 28 of the BEE JOURNAL.

RENDERING OLD COMB INTO WAX.

Ira Barber uses a large kettle, holding 25 pails of water, and melts up the old comb from 20 to 25 hives at once, putting in only a few combs at a time; keeps a good fire, but not to boil; takes out with an 8x10 inch basket; strains as fast as dipped, and cools in large dishes.

A. I. Root said the solar wax extractor was for small bits of wax thrown in from time to time and melted by the heat of the sun. If thrown in each day there would be no accumulation of rubbish. Old, hard combs were tried, the thermometer run up to boiling point, and all the wax taken out. It will work in January under cover.

COMMISSION MEN.

An essay by C. F. Muth was read. Mr. M. is one of the largest dealers in honey at the West, and a practical bee-keeper. He regarded the middle man as a necessity, a benefactor to the producer, and not a leech, working up a demand for bee-products which the producer usually had not time for, and often not the ability. Their interests are sympathetic, and they should be in full agreement.

A. I. Root said that some men could retail their honey profitably, while others could not. The latter need the middle men. He said that Mr. Muth had had great success in selling honey, and was honorable in his dealings.

R. Bacon said that the market was injured by small growers, who trade off their honey early in the season for

what the store-keeper will pay, and then this price is used to beat down the larger growers.

J. Aspinwall said that the market quotations for honey were wrong, in that the large dealers' figures govern the small sales.

H. Segel said that the price of honey was governed by the price of other sweets. When the latter recover from their depression, honey will also improve.

A. I. Root said we must educate the young bee-keeper in marketing his products. He often bought up the small lots to prevent their depressing the market, selling them afterwards at a slight advance, or even at the same figure, to a customer who wanted a cheaper article, and holding his price on his best goods. Had sold some of these lots at 15 to 18 cents. We need better acquaintance with each other, and better education in business methods.

MARKETING HONEY.

H. R. Wright, a wholesale dealer of Albany, said that there was an over-production of honey because it had not yet become a staple article. There was a great need of a uniform style of comb and package. The pound comb was too large for this market, a $\frac{3}{4}$ -pound comb being enough for an average family at one time, and he favored selling by the comb instead of by the pound. A package that could be sold at 10 cents would be in steady demand. The several hundred styles of boxes and cases interfere with quick sales. He showed a sample of a box that he preferred—a plain case 4x5 $\frac{1}{4}$ inches, holding 11 ounces. The oblong is more salable than the square, and people do not wish to pay for extra wood or glass. As the selling season is before the holidays, glass is not needed, unless the honey is to be carried over. He urged the convention to adopt a uniform package. The odd styles had to be sold separately and slowly. He thought extracted honey was improperly named. Liquid honey was a better term. The public associated the word with other "extracts" of commerce, in which there is often adulteration.

L. C. Root said Mr. Wright's talk was another evidence that when we try to help others, we always help ourselves. We were getting at facts which would help both producer, dealer and consumer. It was evident that our markets were far apart. Mr. Wright was the first man he had heard advocate unglazed boxes. In New York they require them glazed, and prefer one and two-pound sizes.

Thomas Pierce, of Gansevoort, and several others, thought sales should be by weight and not by piece. Buyers were used to the pound method, and would expect a given weight in the small packages.

Mr. Wright explained that there was no deception in selling by the comb. People bought the small combs as they did canned goods, and understood it. The weight of honey in combs was variable, and the so-called one and two pound boxes would not run evenly.

A. I. Root said that this discussion was one of the finest features of the convention. As the introducer of the one-pound package, he well remembered the opposition it encountered from dealers and others, but that was overcome. In managing a general store, he had found 10-cent packages and articles very salable and profitable, even at small margin; and there was no reason why the 10-cent honey package should not be equally popular.

J. A. Abbott, of England, said the sales there were in proportion of 1,000 one-pound to 300 two-pound boxes.

DEPRESSION IN THE HONEY MARKET.

L. C. Root said: In early days when the five to ten-pound boxes were in use, the honey was well sealed and of better character than that produced by the new methods. But they could not be divided without waste and trouble. When the single comb came into use consumers were willing to pay for glass on each section. Then bee-keepers got enthusiastic about extracting honey by centrifugal force. But gradually the price of the latter went down because of inferior quality and adulteration. Honey handled in large cities by unskilled persons has hurt the market, and we have failed to secure the attendance and co-operation of dealers at our meetings. The cost of production must be reduced and better packages devised. Liquid honey must be shipped in sealed packages; combs perfectly capped and sealed.

J. W. Porter laid the chief cause of depression in general, as well as that in the honey market, to limited coinage, sustaining his point with many financial and historical facts.

R. Bacon said our people were not educated in honey-eating; not one in twenty uses it. If every person would consume but a pound a year, the demand could not be supplied. Strikes were making a great difference in our sales; the thousands out of work have no money to buy honey or anything else.

RELATIVE VALUE OF EXTRACTED HONEY.

An essay by Dadant & Son was read. As compared with comb honey, the extracted takes the lead for use as a syrup on cakes, etc., and is more in general use than the comb. The beauty of the latter has kept up the price. Where dark honey abounds the extracted is more used. Would rather produce extracted at 6 cents than comb honey at 12 cents.

BEE-KEEPING IN THE FUTURE.

An essay by A. E. Manum was read. Fifteen years ago one ton of honey was a large shipment for a bee-keeper; now a carload is not noticed. Fifteen years ago the price was 30 cents a pound; now it is 15 cents, and likely to go still lower. But as an offset, we have an increase of consumption and a lessening of the cost of production.

We must become specialists; one devote himself to comb, another to extracted, another to brood-rearing. In

this way failure will be reduced to a minimum, and the future will depend upon the amount of brain power exerted.

L. C. Root said that economy was the word for the hour, even though the most economical people of the world are refused a place on this continent. Bee-keepers are restive because they have to sell low. Luck is a good word when *p* is put before it.

VENTILATING BEE-CELLARS.

L. C. Root said that pure air was a necessity, but if let in through tubes it produced disturbance. He preferred to withdraw the impure air, and did it by pipes attached to the stove-pipe. The colder air will press in whether there are ventilators or not.

R. Bacon's first ventilators were of plank nailed together, which brought in air from the outside. Next he used pipes carried under ground 100 feet. Now he makes his walls as tight as possible, and has closed up the sub-earth air-pipes, using a 5-inch pipe to conduct the impure air off. He finds a strong pressure of air in this pipe. He keeps the temperature at about 40°; hives are set close, with inch holes in the bottom-board. He has 80 hives in a space of 10x17 feet.

Mr. Adams, of Troy, has lost many bees, and does not use cellars any more. Has lately built a house costing \$300. The room above is only clap-boarded; that below is of brick, plastered; heats with a stove, and bees are wintering well. Put them in Nov. 13, and has not had over a quart of dead ones. Bees need more ventilation than they now get. He gives one-inch holes to hives. The proper temperature is 50°, which will drop to 40° at night.

OUTLOOK OF BEE-KEEPING.

L. C. Root—The trouble with our business is *under-consumption*, not *over-production*. In the future honey can and will compete successfully with all other sweets.

J. H. Martin read some census statistics showing the annual production of butter to be 107,873,000 pounds; maple sugar, 9,272,000; eggs, 3,000,000, and honey, 1,149,000 pounds—a mere taste if fully distributed. If the producers of each county would combine and put their products on the home market, there would be none left for export.

F. L. Smith said: We are behind the times. When I was at Toronto, three years ago, I saw over fifty tons of honey on exhibition. Who has seen two tons at any of our State or county fairs? ("Twenty pounds at the Utica State Fair," remarked L. C. Root.) Let us stop talking about low prices, educate the people and educate ourselves.

BEEES IN LAW.

A member said that his neighbor, a retired banker, had brought a lawsuit against him for not removing his bees. The distance was 85 feet. The neighbor on the other side (distant 75 feet) was not troubled. He has 145 colonies, but the banker claims that one colony is as bad as one hundred.

Mr. West had hives in a neighbor's mowing field, and he used to mow around the hives, until the neighbor himself brought his team after sundown and cut it. He also helped his neighbor put up the hay.

L. C. Root would avoid all litigation if possible. Would show objectors the necessity of the business, and would rent their land if it could be had.

F. L. Smith once had a similar trouble with a neighbor; but the neighbor had a daughter and he had a son, and they settled the whole thing so satisfactory that he and his neighbor had been good friends ever since.

The report of the committee on exhibits was severely criticized because it passed over all patented articles, and the meeting sent it back to the committee for correction.

The officers for the ensuing year are: President, W. E. Clark, of Oriskany; Vice-President, Ira Barber, of De Kalb Junction; Secretary, Geo. H. Knickerbocker, of Pine Plains; Treasurer, J. L. Scofield, Chenango Bridge.

Adjourned to meet at Utica, in 1888.

Colorado State Convention.

The State association met at Denver on Jan. 17, 1887.

The society was reorganized, a new constitution and by-laws adopted, and the Secretary ordered to take steps for incorporation.

On the Secretary's list there are over 200 bee-keepers who own 3,500 colonies of bees. He thinks there are over 6,000 colonies in the State, owned by 500 bee-keepers. Two Greeley men have 150, and sell over 12,000 pounds of honey annually.

The following officers were elected: President, Dr. D. W. King, Boulder; Vice-President, at large, E. Millison, Denver; Secretary, S. C. W. Shiff, Denver; Treasurer, William Davis, Denver.

County Vice-Presidents: W. L. Porter, Weld; V. De Vinney, Jefferson; W. K. Sinton, El Paso; C. C. Lounsbury, Larimer; G. W. Swink, Bent; D. S. Grimes, Arapahoe; W. E. Pabor, Mesa; E. J. Post, Huerfano; Miss Matie Sternberg, Boulder.

There was considerable discussion over the enemies of bees. Toads were considered the worst. The President said he had experimented with them; he had taken the toads and marked them so that he should know them if they returned. These toads were carried across a creek 1,000 feet away and 15 feet wide, yet in a short time they had returned. It was best to have the hive a few inches above the ground, with a sloping board, so that they could get up to it on returning home at times when they could not fly well.

Adjourned to March 3, 1887.

The next meeting of the Hardin County Bee-keepers' Association will be held in Eldora, Iowa, on Feb. 12, 1887, at G. W. Ward's office, at 10 a.m. Our monthly meetings are very interesting, and we hope for a large attendance.
J. W. BUCHANAN, Sec.

Local Convention Directory.

1887. *Time and place of Meeting.*
 Feb. 12.—Hardin County, at Eldora, Iowa.
 J. W. Buchanan, Sec., Eldora, Iowa.
 Mar. 3, 4.—Pan-Handle, at Wheeling, W. Va.
 W. L. Kinsey, Sec., Blaine, O.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Working up Home Markets.—J. H. Martin, Hartford, Conn., N. Y., says:

It seems to me that bee-keepers are away behind other trades in their methods of pushing their products upon the market. If honey goes begging for a market, it is because too many adopt the sit-down-and-do-nothing policy. If bee-keepers would commence with their county fairs, and work them up thoroughly, and then after the fairs work up every town near them, there would be but little honey to be sent to commission men. I think that I know about this, for I speak from experience.

Bees in Splendid Condition.—S. Valentine & Sons, Hagerstown, Md., on Jan. 24, 1887, write:

It now has been nearly 3 months that our bees have been without a flight, but on Saturday, Jan. 23, the weather was pleasant, and the bees had a good flight. On Sunday morning it continued pleasant and they were out early. Through the day the mercury rose to 62°, and the bees had a splendid opportunity to clean up their hives; they made good use of it, and were ready for gathering before the day was past. Bees have wintered nicely so far; in fact we never saw them in better condition. Colonies have lost very few bees since they were prepared for winter, and the hives seem as clean and sweet as they were in the fall. We have lost 3 colonies out of 310, but in every case it was our fault. We let them get out of honey, and very naturally death must be the result. We shall try to be more kind hereafter.

Superiority of Italian Bees, etc.—15—L. G. Purvis, (48-75), Forest City, Mo., on Jan. 24, 1887, writes:

I commenced the season of 1886 with 48 colonies, some very weak, a few very strong, and the rest of medium strength. I obtained 5,450 pounds of extracted honey, and 150 pounds in sections, and increased my apiary by natural swarming to 75 colonies. Honey sold at an average of 10 cents per pound for extracted, and 15 cents for comb honey. This is rather a favorable location for the bee-business in some respects. I am 28 miles northwest of St. Joseph, Mo. We have an abundance of willow,

soft maple, cotton-wood, elm, a great deal of fruit bloom, and later, honey locust; then white clover and linden. In the fall we have heart's-ease, goldenrod and Spanish-needle, the latter being the most important. We also have a great variety of other flowers that yield honey more or less. Our market is handy. I sell $\frac{3}{4}$ of my honey from my wagon in Kansas and Nebraska. From my experience of 15 years I am fully convinced of the superiority of Italian bees. One correspondent, I believe, said that the Italians were more inclined to rob than the blacks. His experience is exactly the opposite of mine, for in nearly every instance in my experience the black bees are the ones that are thieving, or trying to. When honey is abundant in the flowers, there is not much difference in the quantity of honey stored; but when honey is scarce, the Italians and hybrids will be gaining a little when the blacks are at a stand-still or going backwards.

Not Overstocked with Bees.—Andrew Craig, Empire, Dak., on Jan. 17, 1887, says:

The past summer was one of unusual drouth and heat, and unfavorable for bees, and so far the winter has been unusually severe. I had one colony last spring which cast a swarm on June 15, and I had to feed both of them for winter. They are packed with prairie hay. I hope they will winter, although I have some fears for their safety. They have not had a flight since Nov. 5. There is not a bee-keeper within 30 miles of here; so I have to learn the business alone, by reading and experimenting. I have made some mistakes, one of which was in the width of the top-bars of the brood-frames, which I made too wide; but I intend to remedy it in the spring.

Bees Wintering Well.—Dr. H. Besse, Delaware, Ohio, on Jan. 31, 1887, writes:

My bees are wintering well so far. Last October I built a bee-house for them; it is 20x24 feet. On Nov. 18 I put 161 colonies into it. I keep the temperature at 44°, on an average; the lowest has been 38°, and the highest 56°. I use no artificial heat, but govern the temperature by ventilators. At some future time I may give you a full account of my bee-house. It is a "daisy."

Selling Honey.—Daniel Whitmer, South Bend, Ind., writes:

Were it not for some injudicious bee-keepers the market in this locality would be much better than it is at present. Two years ago I got 17 cents for comb, and 12 $\frac{1}{2}$ cents per pound for extracted honey. But suddenly there appeared a man who was very deficient in wisdom, from Michigan, and sold his at 12 $\frac{1}{2}$ cents per pound, and finally as low as 9 and 10 cents. Now where is my profit? The mar-

ket is ruined in this place, and it has been done by men that understand the bee-business—men that produce honey by the ton. In several instances I have instructed men in apiculture, and as a remuneration for the information given, they have in every instance undersold me in the disposition of their crop of honey. I do not fear the slipshod, and old-fashioned honey-producers, but men that know something; some that even have farms, and are dealers in live stock; men who are making money out of farm products. But what do they care for the bee-specialist, or their own honey crop, just so they get it disposed of is what they are after. Some may think that I am severe, but I mean business! I have become disgusted at the movements of some who ought to know better!

Only an Average Season.—I. N. Rogers, Jackson, Mich., on Jan. 31, 1887, says:

The past season was only an average one in this county, although commencing two weeks earlier than usual. I never had bees build up to overflowing so early since I have kept them. One colony of hybrids cast a large swarm on May 8, and another on May 10. A colony of black bees cast 2 swarms in May, and stored 48 pounds of comb honey in sections by the middle of June, when the drouth came and continued until the middle of August. During this drouth bees hardly held their own, some of them having to be fed. Basswood was a failure. Fall flowers yielded a good harvest.

Commission Men Ought to be Our Friends.—Dr. C. C. Miller, Marengo, Ills., on Jan. 29, 1887, writes thus:

If I understand it correctly, what is complained of on page 57, is the remarks made about putting certain lots of honey on the Kansas City market. Now I can see nothing objectionable in the matter of telling what is put on the market and when; indeed, what we want is the fullest information about everything pertaining to the business. If there is any thing stated that is not correct, of course the correction should be made, just as any incorrect statement in any part of the columns of the BEE JOURNAL should be corrected. What we want is the full truth. Let us not be unreasonable with the commission men. They are our friends, or ought to be. Simply let them know that if incorrect reports are given they are likely to be looked after.

Bees in a Cave, etc.—John Turnbull, La Crescent, Minn., on Jan. 13, 1887, writes:

I began with 19 colonies last spring, and I now have 59, all by natural swarming, except 5 nuclei. I had 2 colonies the combs of which melted down on July 5. Bees did well during white clover, but very little in the fall. Some of my late swarms were

short of stores. I took 1,000 pounds of comb honey in 1 and 1½ pound sections. My first 150 pounds of honey I sold for 15 and 16 cents per pound. Afterward honey was crowded into the city, so that it was sold as low as 8 and 10 cents per pound, and in trade at that. I have sold the most of mine for 14 and 15 cents per pound. I think that I can sell what I have left for that price. I built a bee-cave in the side of a hill. I put up boards in front to keep up the bank, and then put logs on for a roof, laying the logs close together. I then put 2 feet of straw and 2 feet of earth on the logs, then a shingle roof over all. It is 10x16 feet, 7 feet in the clear, with a hall 6 feet leading into the cave, with two doors. The temperature is from 20° to 30° below zero outside; in the cave it is now 40° above zero. I have a box in it 3x4 inches, inside measure, for a ventilator. The bees are very quiet. I had always wintered my bees in the cellar. There is nothing to disturb them in the cave.

Dry Season in Missouri.—J. W. Johnson, McFall, Mo., on Jan. 26, 1887, writes:

The past season was a poor one here for bees. I have nearly 40 colonies in the cellar in good condition. We are hoping for a good season this year, for we need honey, and that means money. I think that only a few bees will winter, because it was so dry last season, and the most of the bees are kept in logs or box-hives, and their keepers robbed them too close in the forepart of the season. My health is so poor that I cannot tell whether I will get any honey or not next season, although it may be a good season for the bees. It is said by some that bee-keeping is a good thing for invalids. I was in the late war, and I sometimes wonder whether any of my old comrades keep bees.

[Yes; hundreds of them are engaged in keeping bees and producing honey.—ED.]

Severe Weather, etc.—S. W. Rich, Hobart, N. Y., on Jan. 31, 1887, says:

We have had some very severe weather here this winter, but as our bees were in excellent condition in the fall, I predict that they will winter well, as they appear to be doing nicely now. Last season was very unfavorable here, as the crop was very light and of poor quality. We hope for a better crop next season.

Fixing the Price of Honey.—Wm. H. Balch, of Oran, N. Y., writes:

A year ago last fall a well known egg-buyer told me that he had found a few hundred pounds of honey in a back place that he could buy for a small sum for cash. He wrote to a certain prominent commission merchant in New York city, telling him what honey could be bought for in central New York. One of my fel-

low-bee-keepers wrote to this same commission merchant, asking him what honey was worth. He named a mere pittance, and referred him to what the egg-buyer said that honey could be bought for in central New York. Again, a man with a few pounds of inferior honey, and in bad shape, will take it to town, and haul it around and shout, "What will you give for honey?" Still another, with a few colonies of bees will have his honey in proper shape, and take it to the grocer and say, "I must have some groceries; give me what you can for my honey." The grocer is in direct communication with the New York commission house; of this I have had them tell me, in the better days of bee-keeping. I think that Mr. B. H. Standish, on page 25, is about right.

Clipping Young Queens' Wings.—Jno. D. Gehring, Parkville, Mo., writes:

In all the bee-books which I have read, and in all the bee-papers to which I have had access, I nowhere have found any noticeable mention made of this most important fact, viz: Queens' wings clipped before they are fertilized, are utterly worthless! Old bee-keepers may laugh at this statement, so strongly made, until they reflect that there was a time when they, too, had to learn this from expensive experience; but it seems to me these same old bee-keepers were a little dull when they forgot to caution beginners not to clip a queen's wing before she has begun to lay.

Young Bees Hatching.—J. A. Buchanan, Holliday's Cove, W. Va., on Jan. 22, 1886, writes:

Bees are having a grand "romp" in the open air. The temperature is 65° above zero in the shade, with the sun bright and warm. The bees are in splendid condition. I opened a few hives and found that the queens were all laying, and in a few instances some 1887 young bees were hatching. Clover is not yet injured by the winter, which makes good prospects for the coming season.

Extracted Honey in Glass Pails.—John Rey, East Saginaw, Mich., on Jan. 21, 1887, writes:

For selling extracted honey I would like to have every bee-keeper in or near a city, try glass pails. It is a nice way to put up extracted honey, and it will almost sell itself. Of course a label with the bee-keeper's address should be on every pail. It is the best way for me to handle choice extracted honey in my home market, and it brings the price of extracted honey up from 12 cents to 14 cents per pound. I use pails holding 1½ pint, ½ pint, and 1 pint. The 1½ pint pail holds 10 ounces; the ½ pint pail holds 1 pound, and the 1 pint pail holds 1½ pounds. There is no daubing, no waste, and no dipping honey

out of a can, for the store-keeper, but it is all clean work, and the glass buckets make a nice appearance. I always have them placed in a showcase, or where they may be easily seen. The pails have bails, and are handy to carry. I also put up honey in pint fruit-jars, but I sell five dozen glass buckets where I sell one dozen of the fruit-jars. I sold more than my entire crop of extracted honey last year in this way. My crop for 1886 was 4,000 pounds of extracted and 2,000 pounds of comb honey, from 118 colonies. Last fall I was in Detroit, and I did not find one store that had extracted honey put up in glass pails. O, how I wished that East Saginaw was as large as Detroit! It is a little hard at first to work up a trade, but if I found a store-keeper that I could not sell to, I would let him take one dozen of each kind of pails and tell him that when the honey was sold I would call for the money for them; and in this way I worked up a nice home market. In order to hold the market, I would always exchange other honey for that which was candied; for if it stands any length of time it will get hard and not sell well. Do the fair thing with your customers, and you can always sell your honey.

Bee-Cellar Lined Overhead.—Frank A. Eaton, Bluffton, O., on Jan. 26, 1887, writes:

I notice in the answers to Query, No. 365, that it is generally conceded that the lining overhead in a bee-cellar is not necessary. My experience is different. I consider it very necessary, not only to prevent noise, but to help regulate an even temperature. Lath the joist overhead with common plastering-lath, and pack it as it is lathed with good oat-straw; this will absorb the moisture of the cellar and help to regulate the temperature. I have wintered over 100 colonies without any loss (except from starvation), in this sort of cellar for the past four winters.

Bees Playing in Mid-Winter.—Jonas Scholl, (70-72), Lyon's Station, Ind., on Jan. 29, 1887, writes:

Bees have come through the long cold "snap" in fine condition. After six weeks of confinement to the hives they had a good flight on Jan. 22. It is quite a satisfaction to see the bees play in the sunshine in mid-winter. In the last ten years I have made no material change in the manner of wintering bees, because it has been so satisfactory. This winter one-third of the colonies have "Hill's device" over the frames instead of square sticks. This gives the bees room to cluster more compactly under the blanket, and easy access to their stores. For convenience and utility, but few inventions have been given to the bee-keeping public that excel this simple arrangement.

☞ The Pan-Handle Bee-Keepers' Association will meet at Wheeling, W. Va., in the K. of P. Hall, 1138 Main St., on Mar. 3 and 4, 1887.
W. L. KINSEY, Sec.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for 1887, will richly repay every apiarist in America.

Continuous Advertising brings much larger returns, in proportion to the outlay, than periodic or spasmodic advertising. Keep this point before the people.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal 1 00..	1 00..
and Cleanings in Bee-Culture 2 00..	1 75
Bee-Keepers' Magazine 1 25..	1 25
Bee-Keepers' Guide 1 50..	1 40
The Apiculturist 2 00..	1 70
Canadian Bee Journal 2 00..	1 75
Rays of Light 1 50..	1 35
The 7 above-named papers 5 25..	4 50
and Cook's Manual 2 25..	2 00
Bees and Honey (Newman) 2 00..	1 75
Binder for Am. Bee Journal 1 60..	1 50
Dzierzon's Bee-Book (cloth) 3 00..	2 00
Root's A B C of Bee-Culture 2 25..	2 10
Farmer's Account Book 4 00..	2 00
Guide and Hand-Book 1 50..	1 30
Heddon's book, "Success" 1 50..	1 40
A Year Among the Bees 1 75..	1 50

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the **Apiary Register** and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages) \$1 00
" 100 colonies (220 pages) 1 25
" 200 colonies (420 pages) 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have just gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

By Using the Binder made expressly for this **BEE JOURNAL**, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Sample Copies of the **BEE JOURNAL** will be sent **FREE** upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the **BEE JOURNAL**. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the **BEE JOURNAL** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

Dr. Miller's Book, "A Year Among the Bees," and the **BEE JOURNAL** for one year, we will club for \$1.50.

The Western World Guide and Hand-Book of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides his own, with \$3.00, for one year, we will present a copy of this valuable book.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the **Weekly BEE JOURNAL** for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the **AMERICAN BEE JOURNAL** for one year, will be clubbed for \$1.25.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax :

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12½@13c. No demand for extracted, and very little for comb.
BEE SWAX.—22c. R. A. BURNETT, Jan. 19. 161 South Water St.

NEW YORK.

Four-fifths of the Combs are drawn out from Foundation in wired frames; all Queens reared in the swarming impulse, & except a few superseded in full colonies. With the largest order (not less than 10) I will give an Excelsior Honey-Extractor; with 2nd largest (not less than 5), an Excel. Wax-Extractor and Uncapping-Knife—provided I sell my Bees. Bees shipped as ordered, and in the order they are in bee-yard. Remit by P. O. Money Order, or Draft on New Orleans. Correspondence & offers solicited. Address, W. T. MADDOX, Alexandria, La. 6A1f

DON'T GET LEFT!—Nothing extends reputation equal to the brilliant Chromo Bee-Card. See page 77, or address, J. H. MARTIN, HARTFORD, N. Y. 6W(3tm)40t

WANTED.—To confer with a reliable married man who has a good knowledge of Bees, with a view of establishing an Apiary near Boston. Address, BOX 151, MILTON, MASS. 6A2t

WANTED, an active, reliable man in every city and town in the State of Illinois to work up Councils of the American Legion of Honor, an insurance organization now having 60,000 members, and we are willing to pay liberally in cash for services rendered in this work. It can be performed at odd and leisure hours without interference with regular business, and is an occupation affording much pleasure to those engaged in it. For full explanation how to go to work and what to do, address THOMAS G. NEWMAN, 925 West Madison St., CHICAGO, ILLS.

WANTED.—I cannot give my bees the attention they should have, and I am therefore anxious to obtain the services of a competent, reliable apiarist, to aid me. I want a single man. For further particulars address, E. C. JORDAN, 6A1f JORDAN SPRINGS, Fred Co., VA.

CLOVER SEEDS.

We are now selling Alsike Clover Seed at the following prices: \$8.00 per bushel, \$2.25 per peck, and 25 cents per pound. Also, Melilot or Sweet Clover Seed: \$6.00 per bushel, \$1.75 per peck, and 20 cents per pound, by express or freight. All orders promptly filled upon arrival, THOS. G. NEWMAN & SON, 923 & 925 West Madison Street, CHICAGO, ILL.

OLD TIME PRICES!

UNTIL further notice I will accept orders for FOUNDATION as follows—to be shipped in April: Dunham Brood, per lb. 35c. Vaadervort Thin, per lb. 45c. All fresh made. Also the best FOUNDATION FASTENER in the market. WAX worked—Dunham 8 cts. and Vaadervort 15 cts. per lb. No Circulars. Seven years experience in the business. J. V. CALDWELL, 6A1f CAMBRIDGE, Henry Co., ILLS.

Chapman Honey-Plant Seed

(*Echinops sphærocephalus*.) We can supply this seed **POST-PAID** at the following prices: One-half ounce, 50 cents; 1 ounce, \$1; 2 ounces, \$1.50; 4 ounces, \$2; ½ pound, \$3; 1 pound, \$5. One pound of seed is sufficient for half an acre, if properly thinned out and re-set. THOS. G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL.

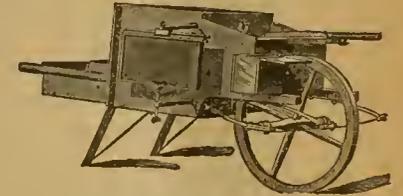

APIARY FOR SALE

HAVING other interests which claim my attention, I wish to sell my apiary of 138 Colonies, in the village of **Winnebago, Ills.**—7 miles from Rockford, and 100 miles west of Chicago. The location is first-rate, and no other apiary near. The past season, 82 colonies increased to 138, and gave 7,000 lbs. surplus—nearly all white clover, and 4-5 of it comb; 2,300 lbs. sold at home for cash without peddling. Langstroth Hives, with good Combs, Tiering-up Section-Cases, Division-Boards and Feeders, Extractor, and good Honey-House. (Rented place of one acre.)

If not disposed of before April, it will be sold at auction.

C. M. HOLLINGSWORTH, 6E3t WINNEBAGO, ILLS.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " " 10x18 " " " " " "	8 00
For 3 " " " " 10x18 " " " " " "	10 00
For 4 " " " " 10x18 " " " " " "	14 00
For 2 frames of any size, 13x20 " " " " " "	12 00
For 3 " " " " 13x20 " " " " " "	12 00
For 4 " " " " 13x20 " " " " " "	16 00

The NEW Heddon Hive.

We have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

It is absolutely essential to order one nailed hive as a pattern for putting those in the flat together correctly.

Hives, nailed and painted, \$4.00 each.

HIVES READY TO NAIL.—In filling orders for these hives, in the flat, we make 6 different combinations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers:

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 frames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—interchangeable, but not reversible.—Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus stories as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-chambers. Price, \$2.30 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deductions from the above prices: Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at 1/2 cent each, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives, 5 per cent. discount; for 25 or more hives 7 1/2 per cent.; for 50 or more, 10 per cent.

THOMAS G. NEWMAN & SON,
923 & 925 West Madison-St., CHICAGO, ILL.

JESSIE.

We are the introducers of the Jessie Strawberry, and the only firm that can supply plants to the trade. It is the most remarkable new fruit of the age. Send for particulars and colored plate; also for copy of Green's Fruit Grower, and our illustrated Fruit Catalogue.

TREE SALESMEN WANTED.

You can make money selling our trees, and get your own trees free. Green's Guide to Grape Culture, 25c. Green's Guide to Strawberry Culture, 25 cents. Green's Fruit Grower, 50c. per year, and Green's "How to Propagate and Grow Fruit," 50c., all to one address for 50c. Green's Tree Agent's Guide, 15c. Green's Books, (3) combined with 15 colored plates, gilt cover, 75 cents. Green's Descriptive Catalogue, with 5 colored plates and two back copies of Fruit Grower, 10c. Address,

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Feb. 16, 1887. No. 7.

Flowers.—We acknowledge the receipt of a bouquet of flowers from Mr. J. W. Winder, of New Orleans, La., which came by mail on Feb. 7. With it was two stems of white clover in bloom, the stems being a foot long. This shows what a varied climate we possess—flowers in bloom there while here the land was clad in a mantle of snow and ice, and the thermometer indicating 20° below zero.

Mr. W. T. F. Petty has sent us samples of his new queen shipping-cages. They are 2x1½ inches by 1 inch high. There are places for the bees and food separately, with an entrance to each in the side, which is covered by a sliding door—the whole weighing less than half-an-ounce. The ventilation is unexcelled, and the whole thing is neat, light, strong and cheap; it can easily be filled with bees and food, and can be sealed up by simply attaching the necessary one-cent stamp. The grain of the wood of the thin top and bottom runs crosswise of the cage, making it very strong and light.

Robert, son of C. H. Lake, of Baltimore, Md., died on Jan. 22, 1887, aged 11 years. This is the third child Mr. Lake has lost within the past two years. He buried his only daughter, aged 12 years, two years ago, and his oldest son a year ago, 21 years old.

Referring to an item on page 67, about another bee-paper for Canada, a correspondent in the *Canadian Bee Journal* says:

I sincerely trust this is a mistake, but if the project is really under serious consideration, I hope the projectors, whoever they may be, may re-consider the matter. Instead of two or more inferior, half-supported bee-journals in Canada, let us have one good one.... Two papers cannot, in my opinion, thrive and succeed.

Now, we can inform our Canadian friends that a **third bee-paper** is projected in Canada—to be called "The International Bee-Master." Of course all cannot prosper—the only possible result is dismal failure and loss to the projectors, as well as to those who subscribe for some of them.

Down-Right Dishonesty.—In the Berryville, Va., *Courier*, we find the following which was sent to us by a correspondent from Maryland:

Recently a bee-keeper of Berryville, Va., sold to a merchant in York, Pa., about 500 pounds of honey. Instead of receiving a check, he received a letter from the merchant's son, saying the honey was almost worthless, and would be sold for what it would bring. Mr. D. promptly took a train for York and dropped into the store he had shipped to. Upon inquiry he found that he was in the presence of the young man who had written the letter which took him to York, and he asked if he had any honey for sale.

"Oh, yes," was the reply, "I have a fine article just from Virginia, and will show you a sample of it," and thereupon stepped back and in a few minutes returned with some of the beautiful honey. "Is it all like this?" "Yes, sir," said the young man. "How much have you?" was next asked. "About 500 pounds." "Are you sure the lot is as good as that?" he next asked, "as I am a good judge of honey." "Just walk back here and see for yourself," said the young man. "Well, I am glad to hear you say so, and now I'll introduce myself. I am Mr. D. to whom you penned this letter"—producing the letter—"and the next time you undertake to play a sharp game be sure of your man first." If a thunderbolt had shaken the house the young man could not have been more startled at the manner he was confronted by the person he sought to victimize with raciality, and he was compelled to hang his head in shame.

Mr. D. demanded his money, and after a few words a check for it was issued.

Our Maryland correspondent suggests that, "in order to obtain fair prices for honey, the time will come when private routes, similar to the 'city milk routes' will have to be established in order to sell the honey produced!"

Of course it must be borne in mind that the above is an extract from a local paper, and may not be quite correct in detail, and we hope, for the sake of our confidence in humanity, that it is an exaggeration.

The honey routes have been tried in this city, and were very profitable until Perrine (the "boss" adulterator) ruined the business with his glucose abomination! Now, it would be impossible to do anything in that line, for almost every customer remembers the Perrine wagons and their trash!

It might be made successful where such experience is unknown, and such methods unthought of. Perrine boasted that the business brought him thousands of dollars every year, until he ruined it by his avariciousness and dishonesty!

Eugene Secor was elected Vice-President of the Iowa State Horticultural Society at its late annual meeting at Charles City. We learn the above from the *Winnepago Summit*, which also contains the following about wind-breaks in prairie country:

The society offers liberal premiums for new seedling fruits that are desirable, and also for the planting of forest trees. The evergreens recommended for general planting are, white and Scotch pine and Norway spruce, and red cedar and arbor-vitæ for hedges. Evergreens make the best wind-break, and their cheapness ought to induce a more liberal planting of them. He says, by the thousand, they can be got for about a cent apiece, large enough to plant out where wanted. European and American larch (tamarack), and 30 or 40 other varieties of deciduous trees are perfectly at home here in Iowa, and should be more largely planted. They beautify the landscape, break the force of the wind, and add to the money value of every farm where planted.

Legislation Against Bee-Keepers.—Mr. M. H. Hunt, of Bell Branch, Mich., writes as follows:

I have just read a copy of a bill introduced in our legislature making it unlawful to keep over 5 colonies of bees within 25 rods of the public highway or dwelling house not owned by the owner of the bees. Should this bill pass it will be a serious matter for a large number of our friends. I advise the bee-keepers in every legislative district to send in remonstrances signed by every bee-keeper and his friends in this State; also let the member from each district know how they feel on the matter.

A similar matter is reported in California, where a petition to the legislature is being signed in San Diego county, asking to have the bees removed from the lands adapted to the production of raisins.

"Class legislation" is to be regretted at all times, and we seriously doubt whether it should ever be enacted. In the cases cited, it would be a grievous burden upon apiarists, and should be energetically opposed.

The National Pure Food Convention was held in Washington, D. C., on Jan. 19, 1887. The President's address contains the following:

This is an unselfish movement, as broad in its character of beneficence to present and future humanity as the cerulean vaults of heaven. Its benefits are truly unselfish, for its foes as well as its friends shall receive its blessings. Its virtues, like rain from heaven, shall fall upon foe and friend alike. We have begun action, and we will not cease until we have accomplished all it is possible to accomplish. To every foe who turns up to discourage us we shall find a hundred friends to cheer us onward in this battle, for pure sustenance, the foundation of happiness, prosperity and good government. The people shall know their enemies, those who for gain would give an encouragement to elevate their race to that state of true happiness that comes from the vigor and virtue of good health. This nation cannot exist many years without protecting its people from fraudulent and injurious adulteration. The time is here, and now we vow eternal steadfastness to this work, until the commerce, the health and life of the American people be as fully protected as are the same of the people of almost all foreign governments.

Some Years Ago, in central Illinois, Mr. H. Thayer had several colonies of bees, but they all winter-killed. Not caring to re-stock the hives he destroyed all but one of them; that one he left just where it stood when the bees in it died. Last summer, says a correspondent, he noticed a lot of bees busily cleaning out that hive, and the next day a swarm came and occupied it. In about 15 minutes after that another swarm came from the opposite direction, and also went into it—the two swarms uniting peacefully. They are now in winter quarters doing well.

Catalogues for 1887.—Those on our desk are from

- G. M. Doolittle, Boredino, N. Y.—4 pages—Bees and Queens.
- J. D. Goodrich, East Hardwick, Vt.—1 page—Bee-Keepers' Supplies.
- M. Richardson, Port Colborne, Ont.—16 pages—Bee-Keepers' Supplies.
- J. W. K. Shaw & Co., Loreauville, La.—4 pages—Italian Queens.
- A. D. Wood, Rives Junction, Mich.—8 pages—Bee-Keepers' Supplies.
- Geo. E. Hilton, Fremont, Mich.—3 pages—Apiarian Supplies.
- F. M. Atwood, Rileyville, Ill.—7 pages—Apiarian Supplies.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Feeding Syrup to Bees.

Query, No. 374.—Ten pounds of granulated sugar will make a little over 16 pounds of syrup. If this syrup is fed to a colony having empty combs, so that the bees will have to store it in the combs, how many more pounds will the colony weigh at the end of a week, providing other colonies are neither losing nor gaining in weight; the bees to have their liberty all the time.—H.

Try it and tell us through the BEE JOURNAL.—G. M. DOOLITTLE.

It would depend upon the time of the year the feeding was done.—G. L. TINKER.

On the average, about 10 pounds, providing there is no combs built. That was my experience with pure honey, and I do not see why it should not be so with syrup.—C. W. DAYTON.

Experiments seem to show that the loss in storing about equals the water in the syrup; so that we must allow only for pounds of sugar. In the above case there would be about 10 pounds of stores. It is curious about this loss; but the fact still holds.—A. J. COOK.

Mathematically, the question cannot be answered. Bees, when fed a given quantity of sugar syrup, always fail to store the same quantity in the combs. This is why all the projects of feeding back honey, sugar syrup, etc., have failed in a pecuniary sense.—J. P. H. BROWN.

Yes, 10 pounds of granulated sugar will make a little over 16 pounds of syrup, more or less, according to its density, and considerably less if it is as thick as it ought to be. In a week after you feed it, you will find that it has not increased the weight of your hive more than 8 or 10 pounds. The proper way is to feed combs of sealed honey.—G. W. DEMAREE.

It is hard to tell without actually trying it. Even then the next trial might show a different result. Would not 16 pounds of syrup from 10 of sugar be pretty thin? At a rough guess I should say there might be a gain of 5 pounds, but it is only a guess, and as before intimated the results might be very different at different times.—C. C. MILLER.

My tests in this direction have shown me that a loss in weight will be found; that is, the weight will not be as much as the food itself before being given; and I find, too, that there is a variation in different colonies, and at different times as to the loss in weight.—J. E. POND.

If you feed such thin syrup as that, what you feed will weigh but 13 pounds, as soon as it is evaporated or ripened to the consistency of ripe honey. I use 3 pounds of water to 10 pounds of granulated sugar, when feeding late. Whether there will be much further loss in weight, will depend upon how much breeding, robbing, etc., is going on.—JAMES HEDDON.

Because the loss is so great, feeding back extracted honey to the bees to make comb honey has been a failure. Only the sugar will count—the colony will probably only increase 10 pounds.—THE EDITOR.

Producing Extracted Honey.

Query, No. 375.—Having 30 colonies of hybrid bees in 10-frame Simplicity hives, can I produce more and better honey by extracting directly from the brood-chamber, or by placing extracting supers on the hives, and using the tiering-up plan? Would it be advisable to place Simplicity brood-chambers, with wired frames and full sheets of foundation, underneath the brood-chamber already in use?—W. P., Wis.

Place extracting supers above the brood-chamber.—DADANT & SON.

By placing extracting supers on the hives, and using the tiering-up plan.—G. L. TINKER.

1. Use the tiering-up plan. 2. Should prefer to place them on top.—G. M. DOOLITTLE.

I think that I should prefer to tier up. I would hardly put anything below the brood-chamber.—C. C. MILLER.

I should prefer extracting supers and tiering-up; but if you resort to an extra brood-chamber beneath the one already in use, you will need no extra supers on top.—J. P. H. BROWN.

I would adopt the tiering-up system, by all means, and put the super over the brood-nest.—W. Z. HUTCHINSON.

Tier up and extract from the surplus department. Put on tiers of combs "under" the brood-chamber proper.—JAMES HEDDON.

I should prefer to put on a super and tier up. It will not give you any satisfaction to put a full size frame under your brood-chamber.—H. D. CUTTING.

I prefer the tiering-up plan; not to get better honey, but for convenience. *Honey is honey*; and well-cured honey from the same kind of bloom is equally excellent however secured.—A. J. COOK.

1. By using supers and tiering up. 2. With this method, excluding honey-boards must be used to confine the queen, and one or two combs of brood should be placed in the lower story, and then watch that young queens are not reared in the upper story. Under these conditions it is all right.—C. W. DAYTON.

The quality of the honey will be all the same whether you extract from the brood department or from supers, but to take the honey from supers, on the tiering-up plan, is much the best way. There is nothing to be gained

by putting the supers under the brood-chamber.—G. W. DEMAREE.

1. Put on upper stories and adopt the tiering-up method, by all means. The number of stories to use will depend upon the honey crop; enough should be used to catch all the nectar the bees bring in, and also to allow of full evaporation or ripening before extracting. 2. I think not; I should place them above, by all means.—J. E. POND.

Place the extracting supers above (not below) the brood-chamber. The honey will not be better, but the plan more convenient. Whether the quantity of honey will be much or little will depend upon the season.—THE EDITOR.

Management for Comb Honey.

Query, No. 376.—Next season I shall work my apiary for comb honey, and this is the course I am thinking of following: First, I shall get the bees to breeding as early as possible, and keep all combs full of brood by contracting, uncapping honey, and giving only enough comb for the queen to keep filled with brood, striving thus to have all the honey put into the boxes. Next, I shall permit one swarm from each colony; shall hive it on 4 or 5 frames with starters of foundation, and with a large case of sections filled with comb foundation. Now as to the old colony that has cast a swarm: It is without a queen, and for two weeks the bees will put the honey into the brood-frames, thus getting the start of me. I propose to set aside, early in the spring, a few colonies to rear queens, placing these queens in nuclei until wanted. Four days after a colony has cast a swarm, I shall cut out all signs of queen-cells and introduce one of these young queens, which I will expect to keep the honey out of the frames by keeping them filled with brood. Does the above plan seem feasible?—A. L., Mass.

Yes.—DADANT & SON.

Yes; all but the waiting four days. Give the queen in 24 hours, and for me I should as soon have a virgin queen for this purpose as a laying one.—G. M. DOOLITTLE.

Theoretically, your plan is perfectly feasible, but practically it will be attended by a few objections, such as too many swarms, and too much laborious "tinkering," particularly in a large apiary. Besides, a constant disturbance of a colony of bees during the midst of a honey flow is objectionable.—J. P. H. BROWN.

I believe your plan to be a good one, for a lengthy and light honey flow; but in many locations we must get the honey from an old colony that does not swarm. The honey flow is too short for such manipulation and building up of the colonies after swarming. It needs a cheap assistant with a sharp eye, to find and cut out queen-cells.—C. W. DAYTON.

Your theory is all right. Let us know just how it turns out in actual practice.—H. D. CUTTING.

The above plan is feasible, but it is doubtful if the best one that may be pursued. The rearing of the young queens as proposed would cost the use of several colonies, and result in a loss of the honey they would produce, with only a trifling gain; for,

after a colony or two has swarmed there will be queens enough costing nothing for all purposes. Again, if the flow of nectar is short, as is the rule, it seems best to prevent increase by hiving the swarms into hives of brood which may be readily prepared for the purpose where there are many colonies in an apiary.—G. L. TINKER.

Yes, and it would be even if queens were not introduced. The old hive will be full of brood when a swarm leaves, and there will be but few bees left; so that the new queen will be in time. I should not go to the trouble to rear the queens, but rear one from each colony. I think it will pay best.—A. J. COOK.

The plan you suggest will work very well. In its main features it is much like my plan for preventing increase, and utilizing the swarming energy. I do not cut out the queen-cells at all, for the reason that I shake nearly all the bees off of the frames on the seventh day in front of the hive containing the swarm, and this so weakens the old colony that the first queen that hatches, or any virgin queen turned into the hive, will destroy all the queen-cells, and prevent after-swarms. I prefer to introduce virgin queens to colonies just after casting a swarm.—G. W. DEMAREE.

It is worth trying. As the plan is one of your devising, you will be more likely to succeed with it than if any one else devised it, but the longer you keep bees the less you will feel certain about what any plan will do till fully tried by the bees. You might try one or two colonies by giving the new queen, without waiting four days.—C. C. MILLER.

Theoretically, the plan is not only feasible, but it is the plan to work after. In practice it will be found difficult to follow it, owing to the many "snags" that will be found to run against. My advice is, to follow this plan as nearly as possible, as it is the general plan used by all experienced apiarists.—J. E. POND.

For the "first two weeks" not very much honey will be gathered by the old colony. There certainly will not, if the Heddon method of preventing after-swarming is practiced; and even if there is, the bees will "elevate" it to the sections just as soon as the young queen begins to be crowded for room. The colonies run for queen-rearing will, in this case, be worse than wasted. Do not do it.—W. Z. HUTCHINSON.

Much of your proposed plan is practical with a small number of colonies. I would let the old colonies supply the new queens, and you need have no fears of the old brood-chambers becoming clogged with honey, for as soon as the young queens need the room, it will all be changed to brood.—JAMES HEDDON.

Your plan will doubtless succeed in an apiary of medium size. Try it with a few colonies, and then you can better judge its practicability.—THE EDITOR.

Feeding Bees for Winter.

DR. A. B. MASON.

Nearly every fall since I began bee-keeping, 18 years ago, I have had to feed some of my colonies so that they might have plenty of stores for winter. Previous to last season I had worked for extracted honey almost exclusively; extracting all the white clover, basswood, and sweet clover honey, relying upon the yield from fall flowers for winter stores; and the fall honey being often a minus quantity, has obliged me to do a large amount of feeding, sometimes as many as 70 colonies, and it has always been a dreaded task.

On removing sections and the supers used for extracting, the first of last October, I found that most of my colonies would require feeding in order to have plenty of stores for winter, and I proceeded as follows, and the work was so readily and rapidly completed that I shall never dread feeding again:

The frost having previously killed the honey-producing flowers, and the bees being quiet and closely clustered, on Oct. 6 I weighed every hive and its contents, and noted the number of spaces occupied by bees, and the number of frames, etc. Towards evening the weather became warmer, so that the bees were flying quite lively. I shook the bees from several hives, and found their weight. I also weighed several empty combs, and empty hives, and by a brief calculation I found the amount of stores each colony had, and when one needed feeding, I raised the front end of the hive about 2 inches, and nearly closed the entrance, so as to prevent robbing while feeding. Having on hand a quantity of well-ripened unmarketable honey on the morning of Oct. 7, it being warm and the bees flying I commenced feeding. Having a quantity of tin boxes holding about a pound of honey each, I had them filled, and going to the hives where food was needed, I removed the cover and turned up the back end of the quilt and poured from one to five pounds of honey into each hive.

But few colonies were fed before the bees of the whole apiary seemed to have found out that there was honey to be had, if they did have to fight to get it, and I had to suspend operations. But not wishing to be out-generated, I prepared for an evening entertainment, and as soon as the bees had nearly ceased flying I again commenced operations. But not wishing to repeat "Novice's" experi-

ence, so graphically described a few years ago in *Gleanings*, when he tried working at the bees at night with "Mrs. Novice" holding the light, and the bees doing a large amount of crawling. I did not raise the quilts, but raised the front end of the hive still higher with one hand, and poured in the honey rapidly, and so kept in all the bees. When too dark to see well, a light was held for me. The next morning every thing was quiet, and in "apple pie" order. This operation was repeated for two evenings, and my bees were ready for winter quarters, so far as I was concerned.

When I commenced feeding there was an average of 9 1-5 pounds of honey to each colony, and I fed an average of 6 pounds per colony, and the average loss in weight for the three nights and two days while feeding was 1 1/2 pounds. A colony that was not fed any, lost 1 3/4 pounds, and others not fed lost in weight. One colony that was fed 6 pounds gained 3 3/4 pounds more than was fed; and there was no robbing.

On Nov. 13 all were placed in the cellar with an average loss in weight from Oct. 9—the date of the last feeding—of 1 5-7 pounds.

The above is a portion of my essay read at the Michigan State Beekeepers' Convention, held at Ypsilanti recently, and at which I am reported as saying that the loss in feeding 6 pounds of sugar syrup was 1 1/2 pounds. I did not feed sugar syrup, but fed as stated above, well-ripened honey, and I was surprised at the loss in weight, and should have expected greater loss in feeding syrup.

For the American Bee Journal.

Securing a Uniform Price for Honey.

J. F. LATHAM.

The general gist of the articles and remarks that appeared in the closing numbers of the BEE JOURNAL for 1886, and thus far this year, embodying suggestions relative to concerted action by apiarists in regulating the sale of their honey, seem about "pat" to the call of the times; particularly those of the Editor on page 771, and Mr. Baldrige on page 774 of the BEE JOURNAL for 1886. Although the slip-shod, back-woods-go-as-you-please bee-men mentioned by the Editor, and the "wholesale commission dealers" and "up-with-the-times mischief-makers" mentioned by Mr. Baldrige, may be quite prominent in their spheres, they fail to complete the list.

But little fear need be entertained in regard to the "slip-shods," as their shadows, now scarcely discernible, are fast relegating to—nowhere. If the "real mischief-makers" described by Mr. Baldrige as "running around," etc., disparaging their good fortune, and "forcing grocers and everybody else to take the 'stuff' at their own price," are serious obstacles to a brisk demand for honey at paying rates,

there is also another class who may be added to the list and described as "running around" among producers offering "spot cash" for their whole crop at the apiary; relieving them of all trouble in finding a market, costs of transportation, and as often viewed by the bee-keeper, commissions; but the actual "runner around," when making calculations of his sales, needs no prompting to anticipate which side of "profit and loss" will be augmented by the commission; illustrating very fully that Mr. Baldrige, who represents himself as an old honey dealer, is well posted in what he is writing about. Notwithstanding the many facts in his statements, the "white sheep" of the flock ought not to be blackened by inappropriate appellations. Scape-goats often fail to fill the bill of the immolator!

Eight and 10 cents per pound, at present costs of production, for a good quality of comb honey at the apiary, does not invariably result in pushing things the right direction, when the same honey costs the consumer 15 and 20 cents per pound; neither will a second-hand purchase of a ton or more of the same honey in light-weight packages, and disposing of the same at a price per section that was paid per pound, list among the "business-like methods" that always result in securing to all *bona-fide* producers "a fair, honest and decent price for their honey."

But what is a fair, honest and decent price for any commodity but the medium rate that represents the equilibrium of value in exchange—the expositor of supply and demand? If a bee-keeper makes the production of honey wholly or partially the means of a livelihood, the exigencies of his avocation require an exchange of the fruits of his labor for other commodities that the calls of life demand. A brisk exchange on satisfactory terms, results in "business prosperity." A lethargic call for the staples of life results in "business depression." When an excess of production is forced upon the market the consumer gets the advantages of low prices; while a "lean" market and high prices favor the producer. When a large surplus of corn is produced in the West, the Eastern consumer gets his supply at a comparatively low cost; while a deficient crop increases the price. In either case the exigencies of location lead the consumer to comply with the fluctuations of the market, which he can neither "bear" nor "bull"—local production not being sufficient to aid him in influencing "trade rates."

It is not apparent that a diction of sale rates can be made *radically* applicable in establishing a uniform price for a product derived from an area so variant as those from which the honey crop is obtained. When apiculturists in California, Texas or Florida can produce honey, transport it to the Eastern markets, and sell it for less than what would be remunerative for honey from the apiary of the bee-keeper to whom the Eastern markets are home markets, how is the difference to be equalized? Surely, not by

any "robbing of Peter to pay Paul" edict from a local association; or Board of Trade that would monopolize the sale of all the honey within its reach. Monopolies are expensive luxuries. The less tribute a product pays to useless handlers, the more satisfactory will be the negotiations of those who may be the most directly interested in its movements.

With the foregoing incomplete summary of the subject, it seems that the main features of an association for honey producers need be no more or less than a systematic centralization of ideas based on information representing the true *status* of the honey crop each season; the requirements of trade, demand and supply, in the different localities of our apicultural area; and a central body distributing the rays of its satellites—instead of the reverse—by a genuine, *bona fide* market report, coupled with such suggestions as the movements of the markets from time to time demand. The Cappings over Honey.

C. P. DADANT.

On page 71, Mr. Hutchinson speaks of my incidental quotation from Mr. Cheshire's writings, as though it was the main argument of my article. I would ask him to read the article over and answer my question: Why is the honey in the sound, sealed cells liquid while the other is granulated? I would offer to send him a sample of that honey, free and prepaid, but I suppose he has seen the same thing.

I also wish to state that I quoted *only* Mr. Cheshire's *conclusions* on the imperviousness of the cappings, which Mr. Hutchinson does not give. My reasons for quoting so little from Mr. Cheshire were, that the part of his writings given by Mr. Hutchinson is rather contradictory in itself since he says that "*the air intervening between the irregular tape-like shreds cannot escape*" (italics mine), which would mean, if it means anything, that the cell is air-tight. Moreover, Mr. C. calls the honey-cells air-tight.

These contradictions in the most thorough and most scientific work on bee-anatomy, in a book that has corrected gross errors, that we all believed as truths, in the writings of our leading teachers, only show that this question of imperviousness is a thorny one.

I would add only this: I have repeated, on some of the honey mentioned in my former article, the tests made by Mr. Cheshire, of steeping it in water for weeks, and the result in my case was *entirely negative*, for not a single cell of it absorbed water. True, this does not disprove Mr. Cheshire's test, but it proves that different circumstances cause different results. I would ask Mr. Hutchinson to make this test himself on different grades of comb honey.

Hamilton, 10 Ills.

For the American Bee Journal.

A National Honey Company.

SAMUEL RAU.

After reading Mr. J. V. Caldwell's article on page 308 of the BEE JOURNAL for 1886, I thought a good deal about the honey "corner" he slightly hinted at, but as the "corner" business has heretofore been manipulated, I confess the idea was rather unsavory to me.

Since then I have read of the cattle men of the West, who complain of the middle men robbing them of all the profit in the business, and are moving towards forming a gigantic cattle pool. They contemplate forming an association with a capital of \$100,000,000 in 1,000,000 shares of \$100 each. Now, it seems to me that we honey producers of this country, "flowing with milk and honey," could get something feasible and tangible out of this movement to help our own case.

Why could not the bee-keepers of North America form an association with 100,000 capital in 10,000 shares of \$10 each? Or, if this amount is inadequate, increase the capital to \$1,000,000. Some of the weak-kneed ones may, at first sight, be almost scared, and in amazement wonder where all this money is to come from, but hold your peace and see. The company would have to be organized upon the most substantial basis possible; be under the management of a certain number of directors to be elected by the stock-holders; these directors should be no weak-kneed or hesitating men, but the most practical, substantial, energetic, influential and pushing men in the whole fraternity; they should be men of experience and unquestionable honor! They should be men of pluck and the ability to organize—such men as the Western Union Telegraph Company, and the Standard Oil Company have at the helm. Do not say that we do not have them; we have the material out of which to make them. The opportunity and the occasion almost invariably produce the men.

Let each bee-keeper take one share of the capital stock, for say every 40 colonies of bees, or fraction thereof that he owns. I am writing without any statistics at hand, and this is made merely as a suggestion, and might be improved upon. These shares might be made payable in several different annual payments, bear 6 per cent. interest, and be secured by first mortgage on the bees represented. On these mortgages any amount of capital necessary to carry on the business could be raised. Middle men could be entirely dispensed with, thereby increasing prices to the producer without increased cost to the consumer.

The company should sell stock only to actual bee-men and honey producers, and control the entire honey interest of this continent. It could soon guarantee to its stock-holders better prices than they are now receiving, as well as guard against any

further depreciation of prices. They would of course have to establish honey depots in all the principal cities and towns of this country, and perhaps eventually open up markets in foreign lands. Then let no honey be sold at any price except through, or by the consent of this company, and each member be allowed to ship in honey in proportion to the amount of stock he has.

You can call this a "corner," pool, or what else you please, but I am convinced that if rightly organized and ably managed, a company of this kind could not fail to be of immense advantage to the bee-keepers of this country, without working to the detriment of any one. The railroad companies pool issues; the great manufacturing and mining companies organize and combine for their own financial safety and protection, and why not we? No doubt there would be obstacles to remove and difficulties to surmount, and many a "Doubting Thomas" to silence. It might even take several years to fully organize and equip a company of this character, but perseverance and persistent effort would in due time accomplish the desired end, and lift the vast honey interests of this country out of the slough of despondency and place them upon the solid basis of permanent prosperity. The hour is ripe—the opportunity of a life-time is before us. Will we improve it? What say you, fellow bee-keepers?

Columbiana, 6 O.

For the American Bee Journal.

How to Sell Honey, etc.

W. J. CULLINAN.

As to fixing the price of honey, I think it would be difficult to do, although much might be done toward keeping up the price. I am of the opinion that if bee-keepers would organize themselves into commercial unions in every State, gather up the honey of their specified territories, grade, crate, and offer it in attractive shape and at stated prices, it would be a big stride toward success.

In the meantime, each individual honey-producer should thoroughly canvass his (or her) own neighborhood, and thus build up a trade of their own. There is no apiarist but who has lots of customers all around him, and he will surprise himself if he will but make an effort to bring them in contact with his product and solicit their patronage.

Tell them (your customers) that honey is good for the lungs and liver; that they will not cough so much nor be so bilious; that it is a blood purifier, a mild laxative, in fine a thorough and harmless renovator of the whole system; that they will live longer, feel better, be more at peace with themselves, their Maker, and with mankind; die happier, and leave a greater legacy to their children, if they will but consume honey in lieu of other sweets. Remember, "you know not what you can do until you try!"

On Nov. 27, 1886, I carried 16 colonies of bees into the cellar, the temperature of which I have tried to keep as near 42°, Fahr., as possible, although at one time it sank to the freezing point. I find that the bees keep the most quiet at from 38° to 42°. On Jan. 20 I carried 3 colonies out of the cellar, and found, upon examination, that they were in splendid condition, with scarcely a dozen dead bees to the colony, and hardly any perceivable diminution in their stores. I never saw bees look cleaner, brighter and happier at this season of the year. It is too soon to crow, but I must say that I am highly pleased with cellar wintering, so far!

Mt. Sterling, Mo. Ills., Jan. 27, 1887.

For the American Bee Journal.

Effects of too Much Ventilation.

C. W. DAYTON.

Though I have always argued in favor of ventilation, I did not always find it entirely satisfactory. Many of the readers probably know that I practiced suspending the colonies in "mid-air" in the cellar.

When I began keeping bees I thought if I could get the bees safely through the winter I should be satisfied. This was only partly the case. While I was pleased to find the colonies strong and healthy it was less pleasing to see them entirely destitute of brood. By experiment it was found that the nearer the condition of the colonies approached the "mid-air" suspension method of ventilation, the more certain was the preservation of the lives of the bees, and their ability to rear brood was proportionately lessened.

My cellar is contrived so that any degree of temperature between 40° and 50° can be easily maintained. The colonies were put into the cellar from Nov. 12 to Nov. 25, and taken out from April 12 to April 25 in every year. Sometimes 100 colonies wintered entirely without loss, and when put out they were found without so much as an egg to indicate the presence of a queen.

When they were put out late in April it would be late in May before young bees could be reared to take the place of those that were fast disappearing on account of old age. As a consequence, strong colonies that continued a month without replenishment, became weak, and consisted almost entirely of young bees. Had the colonies come from the cellar weak in bees they would have been very likely to have dwindled entirely away; but the colonies that were wintered on the suspension principle were almost without exception very strong and healthy when put out, so they built up again after the dwindling season was over.

Having the colonies in their weakest condition (in number of bees) about the middle of May, and the white clover coming into bloom from June 10 to June 20, it made lively business getting the weakened colo-

nies in good working condition in the short space of time. Under these conditions have I reported successful wintering of the bees, and that they were not ready to sip from the clover when it came into bloom.

By the suspension method I have wintered strong colonies in all temperatures ranging from 30° to 50° above zero, and maintained all the winter, and it was a rare case if the colonies were not well supplied with healthy bees when taken out in the spring. In wintering very small colonies at a temperature of 50°, they gradually dwindled away, yet not so fast but that some bees remained to protect the queen until taken out of the cellar. This experiment was tried many times, and it was seldom that the colonies came through the winter in good condition.

When the temperature for the small colonies was at 50°, they came out tolerably well, but as they needed warmer and closer packing in the spring, and close attention all the time, I gave up their care as too "puttering" business. I think 60° would be about right for 2-frame nuclei in the forepart of the winter, and 75° or 80° the proper temperature to start brood-rearing in March and April. Ten degrees lower than that would do if their brood-chambers were tightly sealed above, but I find where the brood-nests are tightly sealed all winter, moisture accumulates and disorders the colonies so that 99 out of a 100 are in a deplorable condition long before spring comes to their relief. The abundant ventilation and consequent conditions seems to restrict the bees so that they remain tightly clustered for the economizing of heat.

Bradford, 6 Iowa.

For the American Bee Journal.

Prevention of Swarming.

J. H. ANDRE.

The general opinion of those who have spent a life-time with bees, is that there is no sure way to prevent swarming, unless the colonies are kept weak by dividing, and then one must use care or the hatching of young queens will frustrate his plans. But if one does not want natural swarms, he will hardly want to divide colonies. My way of preventing swarms (remember, I do not say it is infallible) is to feed the bees in the spring until the apple blossoms furnish nectar; if there are no blossoms, feed the bees later, but discontinue the feeding at least a week or ten days before white clover blossoms; this will get the colony strong in bees, and enough should be fed so that 10 pounds will be stored in the hive.

There is usually a short honey drought between apple bloom and white clover, and if the bees have been fed liberally previous to this, it will be quite natural for the queen to cease laying. This will give a strong colony of bees, and of the right age to gather honey instead of swarming, and when

the harvest of white clover comes these colonies will not be overstocked with eggs or brood. Give them a chance to work on surplus, and if you take off the cases entire, do not wait for them to fill the last sections, but put the unfinished ones in the next case. This is a good plan to try, and one that does no damage.

Lockwood, ♀ N. Y.

For the American Bee Journal.

U. S. Honey-Producers' Association.

J. F. HAYS.

In his suggestions to honey producers in regard to selling their honey in home markets, Mr. M. M. Baldridge says: "Pay retail agents a good commission; if they disobey instructions, take away the unsold honey and refuse to supply them with any more until they comply with your wishes."

I do not look upon this plan in such sanguine light as does Mr. B., for in 99 cases out of 100, instead of the dealer complying with the producer's wishes, he would be supplied with an inferior quality of honey, likely enough built by the bees in a soap-box inverted on an old-fashioned box-hive, while the producer with his first-class honey would be left in the lurch. This is a very important point to consider in this matter of controlling the price of honey, and for which I can see no remedy.

Mr. B. next informs us that 20 and 25 cents per pound is none too much for honey, on the principle of "live and let live." Now let us look at the inconsistency of this. A few years ago honey was in demand at 25 cents per pound; then honey producers were almost "tickled to death." They boasted that they were making from 200 to 500 per cent. on their investments, and boasted so long and loud that they attracted public attention, and the people were not slow to take hold of a business requiring such small capital and with such paying results. Naturally enough, there are now more than fifty honey producers to where there was one then; consequently prices for honey have fallen on account of over-production. Now there is quite a change in the tune. Instead of boasting of enormous profits there are pitiful whims about not getting former high prices, on the principle of "live and let live."

Mr. B. next proceeds to berate the commission men. He says that commission men are to a great extent responsible for the prevailing low price of honey. Will any bee-man admit such misanthropic nonsense? His remedy for the evils commission men have wrought, is organization. By what means he expects honey producers to better their condition when organized, he leaves his readers in blissful ignorance. So did the leaders of the Grange movement a few years ago. That word "organize" possesses a magical power that is generally sufficient to cause men to jump without considering where they may alight.

The farmers were made to believe that they were suffering terrible things at the hands of "middle men;" and the cry was, "organize," and organize they did, but they ignominiously failed to better their condition one whit. Does Mr. B. expect honey producers to make themselves a laughing-stock, as did the Grangers, by demanding a high price for their honey on the ground that they are organized?

A United States honey-producers' association with its members so widely situated must, of necessity, not only fail of its object, but make matters a great deal worse. Simply because a little handful of flour-producers on Fox river can control the price of a staple commodity, it does not follow that the bee-men of the United States can likewise control the price of an article that is not a staple, and with a steady increase of its production to contend with besides. Bee-men should be warned by the sad experience of others.

Maccomb, +o Ills.

For the American Bee Journal.

Warming Bee-Repositories.

EUGENE SECOR.

During our coldest weather it is often desirable to heat our bee-repositories. The cheapest way in which this can be done, and at the same time produce the desired result in health and comfort to the bees, is worthy of consideration. Some use a hard-coal stove, and some, I believe, an open fire in a cellar fire-place. In large rooms where it is practicable to use either of these, I see no reason why they might not be economical and satisfactory. Others carry a hod of live charcoal into the cellar at every "cold snap." This I think can be improved upon by the use of an oil or gasoline stove. I have not used the latter, but I am using for the second winter, the former. I am inclined to the opinion that a common kerosene-oil stove, such as are used in a great many summer kitchens, is good enough for all practical purposes. So far, this winter, I have had to light mine only a few times. The temperature out-doors has dropped several times to about 30° below zero, but the cellar has been kept at as near 45° above zero as possible. When it gets below 40° I light the oil-stove. In a few hours the temperature of a room 12x20, and 7 feet high, will be raised 10°.

The cellar under my house is 32x40 feet, divided into four rooms. The partitions are studded, lathed and plastered. The house is heated with a soft-coal, hot-air furnace. The northwest room is occupied by that. The southeast room, cornering with the furnace-room, is the bee-cellar. It has no outside windows nor doors. It is Egyptian darkness from November until April. The heat from the furnace affects it but little, except that the whole cellar is kept dry by it. (Seed-corn is kept in the cellar.) As

the grounds slope to the north, and the outside entrance and several windows are on that side, and as I do not try to keep any of the rooms from freezing except the bee-room (which is also the vegetable apartment), when the fluid in the thermometer gets to playing "ho-peep" down among the thirties, and continues those antics for two or three days, the bee-room will sometimes get a little too cold. Then the oil-stove is lighted. I find it so simple, so cheap, so easily controlled, so perfectly adapted to the needs, that I ask nothing better.

Improving the Honey Market.

GEO. W. PENN.

I think that it is time for the bee-keeping fraternity to wake up, and do something to better the condition of the honey markets. What injures our honey market more than anything, is the small producers. Take my location for an illustration, which will compare well with the whole country. A certain per cent. of all trades and professions in this town and country keep bees; the per cent. will run about as follows: Doctors, 3 out of 5; merchants, 2 out of 18; lawyers, 1 out of 15; shop-keepers, 4 out of 9; hotel-keepers, 1 out of 5; laborers, teamsters, etc., 12 out of 40; and farmers, 2 out of 5. Now but a small per cent. of all these people will pay any particular attention to their bees; so if they happen to get any honey it will be in bad shape for market, and they will almost give it away to get rid of it. Farmers sell broken lots of honey for 8 cents per pound, and take it in trade; and in large boxes, to be cut out as sold, they may get 10 cents per pound. So I am compelled to hold mine until all these lots are sold.

The merchants say to me that they would rather pay me from 3 to 5 cents per pound more for my nice one-pound sections of honey, but they are compelled to take it off the farmers' hands or lose their trade. So they cannot afford to pay much for it, and hence they sell it cheap, although I have been getting 12½ cents per pound in cash for my comb honey.

Of course it sells slowly as long as so much cheap, broken stuff is on the market. In making a delivery recently, of over 4,000 pounds to about 40 stores, I learned some new ideas. One was that the finest and nicest honey put up in the best shape has to take a "back seat." I called at one store, just after delivering 5 cases of one-pound sections, to tell them about the empty cases, etc. Not seeing any of my honey in sight, I began to wonder what had become of it so quickly. They told me that they did not know when the cases would be empty. In looking at it they concluded that it was such a nice lot of honey, and in such nice condition that they had thought best to keep it out of sight until all the other lots were disposed of. Of course I could not

say anything, for they had paid me for my honey, and they had a perfect right to do as they liked with it.

Comparing the sale of extracted honey with that of comb honey, I have sold each year 5 pounds of extracted to 1 pound of comb honey. I always carry a sample jar, and fill it out of my bulk of honey, so I can truly say it is an exact sample of all of my linden honey, or white clover, or what variety it represents.

Our merchants are generally shrewd business men, and one can expect them to ask some questions; hence one must be posted, and have an answer ready for every question. When you once have a trade established with a merchant, and the merchant with his customers, on your brand of extracted honey, you will have no difficulty in selling.

In this manner I have sold, this season, 25 barrels of nice extracted honey. I have sold just about one-fourth as much comb honey. About the only way to successfully control the honey market, in my opinion, is to have one buyer in each market, and every store in that town or city to buy honey only from that one buyer.

In that way all stores can avoid being overstocked with a lot of broken and inferior lots of honey. These mess lots can be bought cheap by this buyer, and sold to some factory so as not to ruin the general market. In this part of the country there is too large a percentage of the people generally keeping a few bees, to make it profitable for any one.

For the American Bee Journal.

The Season of 1886.

J. M. HAMBAUGH.

In the fall of 1885 I put into winter quarters 101 colonies of bees in my home apiary, and 17 in another apiary. My home apiary contains 85 Simplicity hives, and 16 Quinby hives, *a la* Dadant; the other apiary has all Quinby hives. I wintered all on the summer stands, removed all surplus combs from the sides, and confined the bees on from 5 to 9 combs; removed the burlap on the top of the combs, and placed strips $\frac{3}{8}$ of an inch thick every 3 or 4 inches crosswise of the brood-frames, to admit the bees over the top of the brood-frames, which gives free circulation of air, etc. I then tucked side burlaps close and snug around the outside frames, letting them lap over the top of the brood-nest; and packed dry, hard maple leaves at the sides, and filled the cap. I also put long slough-grass around each hive, being careful not to obstruct the entrance.

Quite a number of my colonies were so strong that I could not confine the bees on less than 8 or 9 frames, in which instance I would place the division-board on the north side of the hive, and simply fill the caps with absorbents. I should have said before that the rear end of each hive

was raised 2 or 3 inches higher than the front end.

The winter, though quite rigorous, was not so severe on bees as the one previous. There was intervals of moderation, that gave the bees a chance for flight. On Feb. 8 and Feb. 22 they had good flights; also on March 6 and March 15. I removed the wind-breaks, packing, etc., from March 15 to March 17, and found 6 dead colonies out of 101; generally speaking, I found the bees in splendid condition. Those that had gone into winter quarters strong in numbers, were in the best condition. Quite a number were found very scant of stores, and had to be fed. Two had died of starvation, 2 from being robbed in my absence, and 2 were too small numerically, and succumbed. One was in a Quinby hive, and 5 in Simplicity hives; the one in the Quinby hive was a merenucleus when it began the winter.

The 17 colonies at my out apiary were simply prepared by putting the division-board on the north side of the hive, until the bees covered the combs fairly. I put $\frac{3}{8}$ -inch sticks under the burlap, and filled the cap full of dry leaves. These 17 came through in splendid condition. I equalized each and every hive with from 15 to 30 pounds of stores, according to their strength prior to packing, and I noticed, when overhauling them after all packing was removed, that while some of the colonies seemed to have an abundance of stores, I could scarcely notice any difference in their weight, many being scant and some destitute. Can any one give a reason for this (to me) strange phenomenon?

Early in the spring I removed the 15 colonies in Quinby hives to the out apiary, a distance of three miles, making an apiary of 32 colonies in Quinby hives; I kept each kind separate as nearly as I could. During fruit-bloom I bought 17 colonies of bees in box-hives, and transferred them to movable Simplicity combs. These 17 additional colonies I added to my out apiary, making 49 colonies in all, spring count. Vegetation was from a week to 10 days in advance of the previous two years. From April 25 to May 7 bees built up rapidly and gathered some honey from willow and fruit-bloom. White clover bloom made its first appearance on May 7, and bees gathered honey from it on May 12.

I worked the out apiary for extracted honey, and during the season I took 5,700 pounds from it, and increased the apiary to 56 colonies by natural swarming. The average per colony was 116 16-49 pounds, spring count.

Our fall harvest was almost an entire failure. My home apiary did not produce nearly as much as the out apiary, from the fact that within a radius of three miles it is surrounded with over 500 colonies of bees, and, besides, linden pasturage is not so good, and the bees in the Simplicity hives did not build up to the strength of those in the larger hives. This much has been gained from practical experience, and my conclusions are

irresistible, that a hive is not perfect in its construction that does not give the queen her full capacity of egg-laying, and uninterrupted power of reproduction; and the surplus department must be made to accommodate the needs of the most populous colonies, or contracted to meet the requirements of the smallest.

The production of my home apiary was 3,416 pounds of extracted, and 400 pounds of comb honey in 1 and 2 pound sections. I worked 66 colonies for extracted honey, 11 colonies for comb honey, and 3 for queen-rearing. The increase was made by division and natural swarming, and amounted to 92 colonies.

Spring, © Ills.

Special Legislation for Bee-Keepers.

N. N. BETSINGER.

When Dr. C. C. Miller introduced this subject in the International convention held at Indianapolis, to the most of us it was a surprise that a man of so much thought and study should take the position of the desirability of obtaining special legislation for bee-keepers. Without premeditation, I found myself on the negative side of the question, staunchly denouncing such a course; but, upon reflection, and after reading all that has been written on this subject, I am conscious of the feasibility of such legislation, for the following reasons:

1. Because it is just and right, and we should demand protection from the Government.

2. We are public benefactors, producing a sweet by means of our profession that cannot be excelled for its usefulness, for the sustaining of both body and mind.

3. The production of the honey crop would be much larger, and could be produced at a less cost than at the present time.

4. The price of our product would be more uniform and more easily regulated, not by monopoly, but by the amount produced, and thus be more remunerative to us.

5. Bee-keeping is a science, and should therefore be upheld by our Government, which would encourage the attainment of perfection in our pursuit.

Marcellus, © N. Y.

For the American Bee Journal.

Results of the Season.

S. VALENTINE.

In the vicinity of Hagerstown and southwest of it, the bee-keepers are jubilant over the results of the past season, whilst north and east of this place it was another failure. In the fall of 1885 my bees were put into winter quarters weak in numbers and very short of stores, and came out weak in the spring; but April being warm and pleasant, they built up very fast. May brought with it an

abundant crop of all kinds of bloom, but very little honey, the weather being too wet and cold. On June 1 I had to feed 110 pounds of sugar in one of my apiaries, and to have done justice it should have been a barrel of sugar. About June 18 the honey-flow commenced, and continued until July 25, when the heavy rain-storms cut it short. After this we got no honey. I had plenty of fall bloom, but scarcely any honey was gathered after Aug. 1. The honey flow was not much over half its usual length, yet it was a good yield.

In the spring of 1886 I commenced at my out apiary with 68 colonies, 12 to 15 were weak, and the balance in fair condition. From this yard I took 2,000 pounds of honey in sections, and 3,000 pounds of extracted honey, and put into winter quarters 173 colonies.

In this apiary I took 2 colonies of Albino bees in April and worked them to see what could be realized from them; the one I worked for comb honey, and the other for extracted. The one worked for comb honey (counting it in honey and increase) netted me \$112.30; the other, \$56, although the latter was the most promising in the early part of the season.

I put into winter quarters 20 colonies from the stock worked for comb honey. They are all in good condition. If I live and my bees live, I shall keep a record of those 20 colonies, and report next fall. At my home apiary I used most of the colonies for queen-rearing, so I took only 2,000 pounds from it, most of it being comb honey.

Hagerstown, Md.

For the American Bee Journal.

That Organization for Bee-Keepers.

JNO. A. BUCHANAN.

If it can be made to appear that the interests of bee-keepers would be best subserved by forming a compact for the purpose of sustaining the price of their product, the sooner they organize the better. This course has been hinted at quite frequently since honey has been sold by so many at prices that have not justified or paid cost of production. It is claimed that this unhappy state of affairs should not of necessity exist; and that by legislation, or by the organization of an association for the purpose of holding up the price, would be the remedy for the existing trouble. As to the foolishness of any attempt at securing legislation in the interest of the pursuit, I would say such folly is unpardonable.

As to a "honey-producers association," and the possibilities of its power ever becoming so great as to be able to control prices, I have grave doubts. Mr. Baldrige says that producers should know what is a fair price for honey compared with that of other commodities, and then demand this price. He also intimates that this association of honey producers shall fix a price at which their

product must sell. I would prefer to be left free to buy and sell in the open market of the world. I do not like the idea of being cramped or in any way hemmed in or dictated to.

"Fix a price" that would fairly compensate the producer. How could this be done? In one State the average yield of surplus honey may not be more than 25 pounds per colony, in another State the average would be 50 pounds. In this one case the honey sold at 20 cents per pound would be \$5 per colony, which might satisfy the producer. In the other case, 15 cents per pound might be considered good enough. How would an association proceed to fix and regulate prices for each locality, and for the different grades offered for sale? Speculators would upset all the arrangements every time. No, this is not the way out.

Still another plan has been proposed, and that is to establish storage-houses where all honey produced shall be stored, then graded and held until the offers would justify, or rather satisfy the producer. In order to enable producers to hold out for the best prices, the association is to advance money to the *needy ones* on their consignments. If any bee-keepers are willing to go into such an arrangement, it appears to me that they have no confidence in their own business capacity, and therefore give their business into the hands of others to manage for them.

Some years ago a wool-growers' association was organized in this neighborhood. A wool-house was established first in Steubenville, O., and subsequently removed to Philadelphia, Pa., where a great many farmers sent their wool to await better prices—which they generally failed to get. A man in whom great confidence was placed was selected to manage affairs, and this he did so adroitly that he cheated them out of the whole business, the concern being left in such a shape as to entirely ruin financially a great many excellent men of this and other neighborhoods. Here the proceeds of a life-time of toil and struggle for a competency was swept away—all for lack of confidence in men to transact their own business.

Talk about the middle men and the commission men taking all the profits! This is the way I treat them: Last fall I drove into a town a few miles distant with a load of honey, and went to the principal dealer in honey and stated my price. Said he: "I can buy just as nice honey as that for 10 cents." "And you retail it for 20 cents do you." "Yes, and have no trouble to get it." "Well," said I, "you will have trouble in the future." So at the house adjoining his store I commenced selling nice comb honey at 18 cents, and extracted at 12½ cents, or 10 pounds for \$1. I visited this town once a week while my honey lasted, selling on each trip an average of 50 pounds of comb honey, and 450 pounds of extracted. It is needless to say that the sales of honey by middle men in that town was completely ruined.

My crop this season from 70 colonies was 2,000 pounds of comb honey, 5,100 pounds of extracted honey, and \$30 worth of beeswax. About 15 days were spent in selling this honey from a peddling-wagon direct to consumers. The average price obtained was 18 cents for comb, and 12½ cents for extracted honey. By the time all my honey was sold the demand was just booming.

In conclusion I want to say that we will hear no more wails from bee-keepers about dull sales, low prices, and the need of a honey-producers' association, if every one who has honey to sell will go to work, and by a persistent effort sell his honey to his neighbors, and to all within a reasonable marketable distance. Let all pursue this course, and *keep it up*, and I will guarantee that in less than six months from to-day, they will be offered a paying price for their honey by commission men who will then be willing to pay for space in our newspapers for the privilege of quoting the markets, or be left out.

Holliday's Cove, W. Va.

Local Convention Directory.

1887. *Time and place of Meeting.*
Feb. 23-24.—E. Iowa & W. Ill., at Davenport, Iowa.
J. Wadsworth, Sec., Moline, Ills.
Mar. 3, 4.—Pan-Handle, at Wheeling, W. Va.
W. L. Kinsey, Sec., Blaine, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bee-Keeping in Idaho.—F. H. McDonald, Star, Idaho, on Jan. 31, 1877, writes:

My bees wintered well last winter on the summer stands without any protection. I had one swarm on May 3, and a second swarm on May 13. This winter so far has been favorable. My bees have a flight every week. So far the lowest mercury has been was 6° above zero, and we have not had an inch of snow at one time, and but very little freezing.

Good Honey-Flow.—Henry Hohnadle, Chadwick, Ills., on Jan. 31, 1887, says:

I put out 30 colonies last spring, 3 of which were very weak, and I increased them to 46. We had a good honey flow, and I secured 2,000 pounds of white clover and basswood honey in 1-pound sections, about 1,000 pounds of fall honey, and have 1,000 pounds of unfinished sections. I sold my comb honey at from 12 to 13 cents in my home market, and 500 pounds of extracted at 10 cents per pound. My bees are in a bee-house in straw hives packed with straw under a shed.

My Experience with Bees.—K. H. Fell, Bloomington, Ill., on Feb. 4, 1887, writes:

I left 30 colonies on the summer stands in the fall of 1884, in what I thought good condition. In the spring of 1885 I had 3 weak ones left. In the fall of 1885 I had increased them to 8 good ones. In the spring of 1886 I found them all right, and during the season I increased them to 26 colonies, which are on the summer stands in good condition, and I took as surplus 600 pounds of comb and extracted honey, about an equal quantity of each; nearly all of which I have sold at 16 $\frac{1}{2}$ and 10 cents per pound. I still have considerable surplus to feed and build up my apiary with in the spring.

Benefiting Honey-Producers.—A. L. Leach, Dwight, Ill., says:

I believe that honey producers would be much more benefited than in any other way, by controlling swarming as much as possible, and uniting to ship their honey to a single wholesale dealer in each city, who would be governed by a national committee, and give security to do honest work. Then let each ship what honey he cannot sell at home.

Basswood in Illinois.—J. P. Faurot, Hope, Ill., writes:

I would like to ask the readers of the AMERICAN BEE JOURNAL, whether or not basswood ever yields much honey in the State of Illinois. Mrs. L. Harrison, of Peoria, said in a communication that it did not. I have no means of telling, as I live in a prairie country, but I thought of moving my bees to the timber if the basswood would yield so as to make it pay. My 33 colonies, spring count, yielded 3,300 pounds of white clover comb honey, with an increase of 20 swarms.

Bees Doing Nicely.—P. L. Gibson, Muscatine, Iowa, on Jan. 21, 1887, says:

My bees are doing nicely. They are in a cave with the temperature at 40° to 41° above zero, inside, while it ranges from 10° to 30° below outside. I have 40 colonies, and although I think the cave is a little cool, it is perfectly dry; but my bees are not entirely quiet at that point. I received 40 pounds per colony, spring count; but on account of a dry summer I obtained no fall crop.

Glassed and Unglassed Honey.—B. E. Foster, Utica, N. Y., writes:

I was pleased to see Mr. Crandall's article on glassed and unglassed honey, on page 57. I have kept bees for 10 years, and if I should keep them 50 years no one would find a section of my honey on the market without glass; for if glass is put on clean it makes the honey look better. For my glassed honey I get about 3 cents a pound more than for the unglassed,

because the latter leaks more, and when a case is opened it is all daubed up. I have kept store for 10 years, and the more nice honey I could show on the counter the more I could sell. I never had a complaint about glassed honey. About 14 to 15 cents is the right price for comb honey at wholesale. Extracted honey should never be sold for less than 10 cents per pound. Honey at 6 to 7 cents per pound is cheaper than "black-strap," the cheapest grade of molasses.

Bees Refusing Food.—Geo. W. Plinke, Louisville, Ky., writes thus on Feb. 5, 1887:

I have two colonies wintering in a cellar; the temperature being about 40°. They are very quiet, and seem to be doing well, although they had only about 10 pounds of honey when I put them in the cellar. I gave them liquid honey, but they would not store it away. 1. What was the reason for their not doing so? 2. Would it not be best to raise the temperature in the cellar? 3. Would it be advisable to put them on the summer stands on March 1. 4. If not, would it do to put them out on some warm day, and put them back again in the evening?

[The reason your bees did not take the feed you gave them was because of the too low temperature, and besides this, they had natural stores within reach. I would not raise the temperature or make any changes, nor put the bees out until settled weather, as long as they are quiet, provided they can get at all of the 10 pounds of stores that their combs contained. In the condition you describe, they have stores enough to last until it is due time to put them out, when you can feed them readily. Whether or not they can get at all of their stores depends upon the shape of their hives, narrow, shallow hives with fewer combs are best. If, upon examination, you find they are out of available stores, I think in your latitude your fourth, and last proposition, might be expedient. — JAMES HEDDON.]

Bee-Keeping in Minnesota.—I. W. Rollins, Elgin, Minn., on Feb. 8, 1887, writes:

I have kept bees in a small way for about 10 years, and have increased my apiary from 1 colony to 60. I commenced with the box-hive made of rough boards. I now have 8-frame Langstroth hives, and use two-pound and one-pound sections with wide frames. When I commenced to keep bees there was no white clover, and but little basswood within 5 to 10 miles, and bees had but little to gather honey from except wild flowers, and did rather poorly. There

is a large amount of clover when the winters are favorable, and also a large amount of Alsike, and some buckwheat. From 50 colonies last spring I had 2,200 pounds of comb honey, 1,800 pounds of which was clover, and the remainder from fall flowers and buckwheat.

My Success in Bee-Keeping.—Milo George, Bowling Green, O., on Feb. 9, 1887, says:

I commenced the season of 1886 with 18 colonies, which I transferred from Gallup frames to American frames. I did not get my bees until the last of May, and had the hives and frames to make after that. I put 32 colonies into winter quarters, and they are all right so far. I got about 800 pounds of extracted and 100 pounds of comb honey. My bees are all in chaff hives.

Moving Bees a Long Distance.—John H. Shelt, Spearville, Kans., on Feb. 7, 1887, says:

I came to Kansas last November from Ohio, and carried a small colony of bees with me on the cars, 900 miles, and brought them through all right. They have had two good flights since I have had them here. I keep them in a cave, and they are doing well.

Association for Honey Producers.—James Heddon, Dowagiac, Mich., writes:

I believe that we owe a debt of thanks to Messrs. F. I. Sage & Son (page 71), and Mr. M. M. Baldrige (page 85) for their able articles on the subject of our interests as honey producers. Just compare Mr. Baldrige's article, on page 85, with the report of the decision of the members of the Northern Illinois Convention, as found on page 86, the middle of the last column. The report of their decision occupies three lines, and contains no argument or reasons; Mr. Baldrige occupies three columns, every paragraph of which is brimful of both. Whether or not we can stop a "comet," "corner" the honey market, or accomplish any other desirable purpose, after having held a hundred conventions devoted to the best ways and means to produce more honey in the United States, do you not think that we can profitably hold just one to discuss methods of disposing of it, at a living price, and prevent others from "cornering" us?

Convention Notices.

The annual meeting of the Eastern Iowa and Western Illinois Bee-Keepers' Association will be held in Moore's Hall, 110 East 3rd Street, at Davenport, Iowa, on Wednesday and Thursday, Feb. 23 and 24, 1887, commencing at 10 a.m. Bee-keepers and those interested in bee-culture are invited to be present. Those wishing to exhibit be-fixtures or honey, will please bring the same for inspection. J. WADSWORTH, Sec.

The Pan-Handle Bee-Keepers' Association will meet at Wheeling, W. Va., in the K. of P. Hall, 1138 Main St., on Mar. 3 and 4, 1887. W. L. KINSEY, Sec.

Issued every Wednesday by

THOMAS G. NEWMAN & SON,
PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL.

At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12½@13c. No demand for extracted, and very little for comb. **BEE SWAX.**—22c. R. A. BURNETT, Jan. 19. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10@12c.; in 2-lbs., 9@10c.; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8@8½c.; in 2-lbs., 7@7½c. Extracted, California, 5@5½c.; buckwheat, 4@4½c. Supply of comb honey is large, and demand for all kinds is improving. **BEE SWAX.**—21@23c. **MCCAUL & HILDRETH BROS.,** Jan. 21. 34 Hudson St.

SAN FRANCISCO.

HONEY.—Extracted is firm at 4@4½c., and comb at 7@12c. per lb. **BEE SWAX.**—19@21c. Jan. 31. **SCHACHT & LEMCKE,** 122-124 Davis St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 13@14c.; 2-pounds at 11@12c. Extracted, 5@7c. **BEE SWAX.**—24 cts. per lb. Jan. 21. **BLAKE & RIPLEY,** 57 Chatham Street.

DETROIT.

HONEY.—Few sales are reported. Best white comb, 12½c.; Fall comb honey, 10@11c. Extracted is offered for 6@8c. **BEE SWAX.**—Firm at 23c. Feb. 11. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote for extracted, 4@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way. **BEE SWAX.**—Good demand, —20@22c. per lb. for good to choice yellow. Jan. 22. C. F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, in 1-lb. sections, sells at 13c.; second quality white, 12c.; dark 1-lb., 10c.; white 2-lbs., 11@12c. Extracted, 6c. Market dull. **BEE SWAX.**—25c. Jan. 14. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 12@12½c.; 2-lbs., 11@12c. No call for dark. White extracted, in barrels and kegs, 6@6½c.; in small packages, 7@8c.; dark, in barrels and kegs, 5@5½c. **BEE SWAX.**—25c. Jan. 19. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8½@11. Extracted, white, 4¼@4½c.; amber and candied, 3¼@4c. Trade is quiet. Jan. 10. O. B. SMITH & CO., 453 Front St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lb., 8@10c.; white clover 2-lb., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 6c.; dark, 4@5c.; white sage, 5@5½c.; amber, 4½@5. **BEE SWAX.**—20@23c. Jan. 13. CLEMONS, CLOON & CO., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 8½@4½c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4¼@5c.; in cans, 5@6c. Market dull. **BEE SWAX.**—Firm at 21c. for prime. Feb. 3. D. G. TUTT & CO., Commercial St.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscribers for one year and the binder for \$1.50.

Sample Copies of the BEE JOURNAL will be sent **FREE** upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Aplyr Register and commence to use it, the prices are reduced, as follows:

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 25
" 200 colonies (420 pages)..... 1 50

The larger ones can be used for 5 few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

The Western World Guide and Handbook of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides his own, with \$3.00, for one year, we will present a copy of this valuable book.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

As there is another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Mr. Geo. Pinney established the ever-green business in Sturgeon Bay, Wis., nearly 25 years ago. He now claims to have the only nursery of the kind in the State, and to do a business in that line second to none in America. His advertisement appears in another column.

Advertisements.

WANTED.—Three live men to work in an Apiary and Nursery.
7Atf. S. J. FREEBORN, Ithaca, Wis.

PRACTICAL Bee-keeper wanted for four months. Correspondence solicited.
7A3t. P. BALDWIN, Independence, Mo.

100 COLONIES of BEES For sale cheap. Reason, too many.
7A8t. H. NEUHAUS, Burlington, Racine Co., Wis.

HOW TO RAISE COMB HONEY. Price 5 cents. You need this pamphlet, and my free bee and supply circular. 7Atf.
OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

PURE Italians. Tested Queens, June, 1.25 each. \$12 per doz. Full colony & tested queen, June, \$6.
5A17 O. N. BALDWIN, Clarksville, Mo.

FOR SALE.—100 Full Colonies of Italian and Hybrid BEES, in 2-story Standard Langstroth Hives, at \$10 per Colony. Four-fifths of the Combs are drawn out from Foundation in wired frames; all Queens reared under the swarming impulse, except a few superseded to full colonies. With the largest order (not less than 10) I will give an Excelsior Honey-Extractor; with 2nd largest (not less than 5), an Excel. Wax-Extractor and Uncapping-Knife—provided I sell my Bees. Bees shipped as ordered, and in the order they are in bee-yard. Remit by P. O. Money Order, or Draft on New Orleans. Correspondence & offers solicited. Address, W. T. MADDOX, Alexandria, La. 6Atf

DON'T GET LEFT!—Nothing extends reputation equal to the brilliant Chromo Bee-Card. See page 77, or address.

GREGORY'S ALL SEASONS CABBAGE AND CATALOGUE

My vegetable and flower seed catalogue will be sent free to all who write for it. It is full of fine engravings, with over forty of the best of all the new vegetables. It contains among its vast variety a larger number of home grown seeds, I have reason to believe, than can be found in any other catalogue published in this country. Farmers who make money from valuable new vegetables are those who, being the first to raise them, get a monopoly of their markets. Such will plant largely of this kind of all the early drumheads, the All-Season Cabbage; for, my friends, it has come to stay! **JAMES J. H. GREGORY,** Marblehead, Mass.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. Feb. 23, 1887. No. 8.

Eggs-actly.—Our good friend, Dr. C. C. Miller, of Marengo, Ills., has sent us a box of the nicest of fresh eggs. His thoughtfulness is only exceeded by his generosity.

Mr. Harry, of Cisne, Ills., has sent us a new queen-cage for shipping and introducing. It is a wire tube inclosed in a wood block, which is well ventilated; and when received, the tube containing the queen may be introduced without handling the queen.

Does Extracting honey cause foul brood? Is a question sent to the BEE JOURNAL by Mr. Skinner. He asks us to state the question, and let any one answer it who desires to do so. It is now stated. Let the "wise ones" reply.

The Harrison Case in Canada stands in about this condition, says our correspondent: "It had been argued before it came to the notice of bee-keepers generally, and no further evidence could be given until the judge had given his decision, which he had reserved—and when given, that was against us." Whether it will be appealed or not is not yet decided.

E. R. Newcomb's catalogue is a very unique and tasty pamphlet, and is a credit to him as well as the printer. The "catalogues" which the supply dealers are issuing now are about as much of a credit to the pursuit as those issued ten or fifteen years ago were a disgrace to it. This is very praise-worthy.

Frank Leslie's Sunday Magazine for March is above the average of magazines. Illustrated articles on "Russian Schools," "Some Memories of the Tulleries," "A Buried Greek City in Egypt," and "Famous English Literary Women," give variety and interest to this number. There is an abundant store of short papers, poems, sketches, etc. The illustrations are numerous and beautiful.

That Legislation which we mentioned last week as being sought to be made in Michigan is stirring up the bee-men there. Mr. S. Shoup, of Coloma, Mich., has sent us a copy of the bill. It was introduced by Mr. McCormick, and recommended by the committee on Roads and Bridges. It reads as follows:

A bill to prohibit the keeping of bees in large quantities near any public highway or dwelling house not owned or occupied by the keeper or owner of such bees.

SECTION 1. *The People of the State of Michigan enact*, That it shall not be lawful for any person to keep to exceed five stands of bees within 25 rods of any public highway, or less than 25 rods of any dwelling house not occupied by such keeper or owner of bees.

SEC. 2. Every keeper or owner of bees neglecting or refusing to comply with the provisions of the preceding section after due service of written notice shall be subject to a penalty of \$5 for each day's neglect or refusal, which may be enforced and collected before any court of competent jurisdiction.

Mr. Geo. E. Hilton, President of the Michigan State Bee-Keepers' Association, writes thus:

This bill, should it pass, would be a great calamity to our pursuit, and to the State as well. As it is almost a necessity to have our bees reasonably near both, and it simply means the extinction of the honey-bee, and a terrible calamity to the horticulturist, I feel it my duty to urge every bee-keeper in the State to write to their Senators and Representatives, asking their assistance in defeating any such bill. Just deluge them with letters. Use the best arguments at your command to prove that our rights are being infringed upon, and that we are alive to our interests, and demand our rights.

Mr. Shoup says: "I hope you will do all you can to help us defeat it. It seems strange that any soe man would undertake to get such a bill to become a law."

Mr. Charles Walker, of Bravo, Mich., writes thus:

While we have been talking of forming an Association, and of "Legislation," a bill has been stealthily framed and introduced into our legislature which will be of great detriment to us, and unless we send in a prompt and vigorous protest, it may become a law. This bill aims a blow at our homes. The warning note has been sounded from Bell Branch, and we should now get up a remonstrating petition and send it to Lansing *at once*. The officers of our bee-associations should take the matter up, and every district should send in a petition against the Bill *at once*. Such an array of names should be sent as would surprise our legislators. The injustice of the Bill may be seen in the fact, that 5 colonies of bees can be kept close to the highway, but 30 or 40 colonies must be moved back 25 rods, whether the owner has land enough to do it or not! I will spend both time and money to defeat this Bill, and hope all other bee-keepers in our State will do the same. "To be fore-warned is to be fore-armed."

Prof. Cook is the man to look after the interests of bee-keepers. He is near the State Capitol, and knows just how to manipulate matters to prevent any injustice being done to bee-keepers. He also has the will as well as the sense of justice and right. Above all others in Michigan, he is the bee-keepers' friend. We commend the whole case to him.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook. This is the title of a new pamphlet of 40 pages, published by A. I. Root, of Medina, O. It is nicely printed, and profusely illustrated. It is intensely interesting, and should be read by all who are engaged in the production of maple sugar. Price, 40 cents. It may be had at this office.

More of the Wiley Lie.—Mr. John Crawford, of Pleasant, Ind., on Feb. 13, writes us the following:

I send you a copy of the *Scientific American*, which has some more of the Wiley scientific pleasantries. I think it is really too bad, for a paper of the standing of the *Scientific American* to publish such falsehoods—doing an injury to an important industry. The article referred to is said to be the report of a conversation between Health Commissioner De Wolf, of Chicago, and an *Evening Journal* reporter. Bees have wintered well so far, and have had a good fight for several days past.

From the article in question we quote the following, containing the allegations about comb honey:

"There is no such thing in this city as the adulteration of articles of food, as a sanitary question," said Health Commissioner De Wolf, of Chicago, to an *Evening Journal* reporter.... "I have heard, also, that honey was found in the comb in beautiful cuts, where neither the comb or the contents had ever seen a bee-hive. The comb was manufactured out of paraffine, and the cells were filled with glucose, but that is not a sanitary violation. It is a commercial fraud, for honey is glucose."

Mr. S. D. Webster writes thus:

Mr. Editor, this is from your own neighborhood, and you had better get your Health Commissioner set right on the comb honey question, as he has evidently been taken in by the Wiley lie. I send it to you because I suppose you cannot see all the progeny of that pestiferous publication.

While a slander travels faster than lightning, a correction goes along like a snail. The damage done by that Wiley lie never can be repaired, or its influence counteracted. No matter what is said to the contrary, it will be regarded as true by thousands, and be quoted by them, as though Wiley was "authority"—instead of being convicted by his own confession of lying without the least shadow of an excuse. Dr. De Wolf is another of the victims of quoting his so-called "scientific pleasantries."

Mr. Henry Cripe introduced a new "queen" into his hive at North Manchester, Ind., on Jan. 29, 1887. The BEE JOURNAL wishes the bride and groom a long and happy life, and hopes that "the queen" will ever enjoy the love and esteem of her present admirer; that the "hive" will never "run short of stores," or be overtaken by any calamity! Now is a good time to enjoy "the honey-moon;" for soon "the flowers that bloom in the spring" will call them to the labors and toils of the apinary! Then they as well as the bees must work for a good harvest.

Catalogues for 1887.—Those on our desk are from

- Henry Cripe, North Manchester Ind.—18 pages—Apiarian Supplies.
- John Nebel & Son, High Hill, Mo.—8 pages—Bees, Queens, and Bee-Keepers' Supplies.
- B. J. Miller & Co., Nappanee, Ind.—16 pages—Hives and Apiarian Supplies.
- James M. Hynes, Stewartville, Ind.—12 pages—Bees, Queens, and Bee-Keepers' Supplies.
- J. C. Vaughan, 146 West Washington St., Chicago, Ills.—72 pages, large quarto—Flower and Garden Seeds.
- Charles F. Uhl, Millersburg, O.—4 pages—Bees and Queens.
- Joseph E. Shaver, North River, Va.—16 pages—Bee-Keepers' Supplies.
- Edward R. Newcomb, Pleasant Valley, N. Y.—34 pages—Bees, Hives, and Bee-Keepers' Supplies.
- Oliver Fuster, Mt. Vernon, Iowa—12 pages—Queens, Bees, and Supplies for the Apinary.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Building up Colonies in Spring.

Query, No. 377.—What method do you pursue in the arrangement of the combs in the brood-chamber in building up colonies in the spring? In other words, in spreading the brood do you pay any attention to the relative position of combs containing bee-bread, with those containing eggs or hatching larvae? If so, how do you arrange them when putting in the extra combs?—W. C., Ill.

I simply add frames as needed, placing them next to the brood.—A. J. COOK.

Move the combs outward and put an empty comb in the centre. Leave the pollen where it belongs, on the outside frames.—DADANT & SON.

I aim to have the combs containing the least amount of brood on the outside, and that usually includes the combs containing pollen.—C. W. DAYTON.

I do the most of my spring work in the fall, before bees go into winter quarters. I pay no attention to the bee-bread; the bees will attend to that.—H. D. CUTTING.

I put the empty combs in the centre of the brood-nest, which keeps the bee-bread in the same relative position to the brood as before. However, I think it matters little where the bee-bread is.—G. M. DOOLITTLE.

The combs to be added should be placed between those having the most sealed brood, and those having much bee-bread kept close to those having the most unsealed larvae. If the colony is not very strong it is always best to add the needed combs at the side.—G. L. TINKER.

By commencing at page 11 of "A Year Among the Bees," you will see that I do not do very much spreading, and when extra combs are added they are generally added outside the brood-nest.—C. C. MILLER.

I do not "spread the brood," because I believe my bees build up more rapidly by being allowed to follow their own instincts, which leads them to concentrate and pack closely the brood in the early season. If the brood-nest has been contracted, I simply add combs at the side of the brood as fast as the bees can cover them.—G. W. DEMAREE.

If your colonies are in good condition, with plenty of stores, and with prolific queens, the "let-alone method" you will find to work the best in the end. Years ago, the "spreading brood" furor consigned many colo-

nies to the shades. In no cases should the brood be spread faster than the bees can cover it. The frames containing pollen should be placed on the outer border of the brood-nest.—J. P. H. BROWN.

I do not approve of the so-called spreading of the brood in the spring. If extra combs were needed early in the spring, I would put them at the side of the brood-nest; later, if the colony were storing, I would put the combs (not too many at a time) in the centre of the brood-nest. Judgment must be used in this matter. With a sectional brood-chamber hive, the brood-nest can be safely enlarged by placing a section beneath that already occupied.—W. Z. HUTCHINSON.

I do not practice spreading brood. With the brood-chamber made in two horizontal sections, when the queen needs more room I add the second section below, which is in the direction the queen naturally extends her brood-nest, but can have no tendency to cool off the brood already in the other half of the brood-chamber.—JAMES HEDDON.

I do not think it will make any real difference how the frames are placed as regards the matter of bee-bread. I do not use the "spreading" at all; my plan being to build up by adding frames of brood taken from colonies that can spare them. The main point with myself is to keep the brood in the centre of the cluster, so that it will have all the heat possible.—J. E. POND.

Frames as needed can be placed in the centre of the brood-nest, or at the outside. "Spreading the brood" is often disastrous, especially unless practiced by an expert.—THE EDITOR.

Number of Frames in a Hive.

Query, No. 378.—Will it do to work 9 frames in a bee-hive only 11½ inches wide, inside measure? If so, what would be the proper width of the frames?—H.

Seven-eighths of an inch would be the proper width.—W. Z. HUTCHINSON.

No. Such a hive should not contain over 8 frames.—DADANT & SON.

I use 13½ inches for 9 frames, and I prefer it to any other distance. I do not think that you would be successful with the distance you propose.—G. M. DOOLITTLE.

You can get the 9 frames in the 11½ inches, with a ⅜-inch frame, but it will be close work. It will give you better satisfaction to use 8 frames.—H. D. CUTTING.

I should prefer only eight. Nine would necessitate too much crowding. I always have my frames ⅝ of an inch wide.—A. J. COOK.

I have never tried 9 frames in 11½ inches. Seven frames in 9 inches worked well when they hung very true. They did not always hang true, so the bees occasionally removed the brood and cells from the side of a comb.—C. W. DAYTON.

Yes. If by width you mean depth, I would say 13 inches; but, then, such a frame would be very inconvenient to handle—too deep.—J. P. H. BROWN.

I have failed to see any advantage from spacing brood-combs closer than 1½ inches from centre to centre, and I do not believe there exists any.—G. L. TINKER.

It will make very close work, but if everything is very true and straight you may succeed with it. From ⅝ to 1 inch for the top-bar is the proper width.—C. C. MILLER.

How large your brood-chamber should be depends upon the style of the hive, character of your location, and your proposed plan or system of management.—JAMES HEDDON.

By shaving the combs to ⅝ of an inch in thickness as advised by Mr. J. E. Pond, 9 frames can be worked in the space you mention, but the combs should be wider apart for wintering. When combs are worked "close" to crowd the honey out of the brood-chamber into the surplus cases, it is handy to work a division-board at one side of the hive to facilitate the removing of the combs, when there is a necessity for removing them.—G. W. DEMAREE.

I think it would be impossible to so work, as great difficulty would be found in removing and replacing the frames. I am in favor of working with ⅝-inch wide frames, spaced just bee-space apart. I work 10 frames in a 14½-inch wide Langstroth hive, and use a dummy to fill in the extra space. This allows me, by removing the dummy first, to take out and replace frames with ease to myself and safety to the bees.—J. E. POND.

The proper width of brood-frames is ⅝ of an inch. From centre to centre it should not be less than 1½ inches.—THE EDITOR.

Tin-Rests in Surplus Cases.

Query, No. 379.—What are the objections, if any, to the use of tin rests, folded T-shape, for supports to the sections in surplus cases?—J. R., Ind.

If made properly out of heavy tin-plate I see no objections to them.—J. P. H. BROWN.

They are very good.—DADANT & SON.

I do not know of any.—A. J. COOK.
I do not know of any serious objection if the supers are made right. See page 38 of "A Year Among the Bees."—C. C. MILLER.

The objection to T-shaped tin-rests with me would be that it leaves a space between the sections, and could not well be used with side-opening sections.—G. L. TINKER.

The only objection of any account that I know of, is that the sections will be largely covered with propolis, and require a vast amount of labor to properly clean them. This, to me, has been a serious objection, and has prevented me from using such supports.—J. E. POND.

They are very liable to get bent out of shape. I dislike to adjust the sections to them—it requires so much care in doing it. They have other disadvantages and some good points; but not enough to offset their bad ones.—JAMES HEDDON.

It is a mere matter of taste. The tin **T** supports answer every purpose. I have used them in some of my section-cases for several years. By their use separators can be worked between the rows of sections, the separators resting on the stems of the inverted **L**'s. And if an invertible case is wanted, another set of the tin **T**'s can be secured between the cross-rows of the sections at the top of the case, thus securing the sections in a central position in the case, and holding them firmly, no matter which side of the case is up.—G. W. DEMAREE.

Their liability to bend is the greatest objection to their use.—THE EDITOR.

Handling Cross Bees.

Query, No. 380.—Can very cross bees be successfully handled without getting many stings? If so, how would you proceed with the fiercest kind of hybrids?—L.

Smoke them until thoroughly subdued before the hive is touched.—W. Z. HUTCHINSON.

Yes. Use a good bee-veil and smoker.—A. J. COOK.

Have a cheap boy to handle a good smoker while you handle the bees.—DADANT & SON.

Take the fight out of them by an application of plenty of smoke before you open the hive. Use a bee-veil.—J. P. H. BROWN.

Provide yourself with a very large smoker; then remove the queen and introduce one that would give less trouble.—H. D. CUTTING.

This requires too long an answer for this department. I have treated it to my own satisfaction. See my book, under the head of "Subduing Bees."—JAMES HEDDON.

I always got lots of stings with such bees, and when too cross I pinched the queen's head off. A late number of the *British Bee Journal* recommends oil of winter-green rubbed on the hands to prevent stings. This is from no less authority than Mr. Frank Cheshire.—C. C. MILLER.

I never had any bees that I could not subdue, except the Cyprians. Blow smoke into the entrance, at the same time gently jarring the hive by pounding on it with the fist. Wait two minutes and proceed to handle them as you please.—G. M. DOOLITTLE.

I think they can. It should become second-nature to always face the breeze when in the apiary with the face thrown forward and downward. Use smoke for a protector. I approach a hive very suddenly, blow the smoke in at the entrance a few times to scare the guards, then get

off the covering as quickly as possible, and as I always get the first shot, three whiffs of smoke there sends them pell-mell down into the hive. While they are getting over their scare and coming back to the top of the hive, I manage to get one or two frames out. The main point is to move deftly, gracefully and surprisingly swift under cover of the smoke.—C. W. DAYTON.

I can manage such bees without being often stung. Having them in a properly adjusted hive, I would leave them to themselves except to adjust the surplus cases, and to remove the honey, doing the work when the bees were busy at work in the fields. With the "fiercest kind of hybrids" my plan would be to pinch off the head of the queen and change the strain of bees.—G. W. DEMAREE.

I think they can. Use Scotch snuff in a roll of cotton cloth in the smoker, or tobacco in any other convenient form with shavings. If there is a liability of robbing, the smoking should not be done until towards evening. There is little danger of smoking them too much, as during the night following they will fully recover so as to defend the hive in the morning, and will be good bees for about a week after. I have seen nothing that will take the fight all out of bees like tobacco, and it does one good after being stung to use it.—G. L. TINKER.

My experience has been that very cross bees will sting when handled, and I have never found any means of preventing them from so doing. To handle them I use gloves and a veil; this does not prevent the stinging, but does protect me from their stings. I know of no other way to protect one's self, other than, don't keep such "fellers."—J. E. POND.

A good veil and a large size smoker are the essentials. The best way is to get rid of irascible bees.—THE EDITOR.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Correspondence.

This mark \odot indicates that the apiarist is located near the center of the State named; \oslash north of the center; \ominus south; \oplus east; $\omin�$ west; and this \odot northeast; $\omin�$ northwest; \oplus southeast; and $\omin�$ southwest of the center of the State mentioned.

A Screen-House for the Apiary.

JAMES M'NEILL.

As all thrifty bee-keepers are laying plans and making preparations for the coming season during the leisure of winter, I will offer a few suggestions in regard to a screen-house, and advise every bee-keeper to get one ready for use the coming season. I got my idea of the screen-house from Mr. Heddon's book, "Success in Bee-Culture." And here let me suggest to those who hesitate about spending 50 cents or a dollar for bee-literature, that there is no investment from which they are so likely to receive a big return. This one idea from Mr. Heddon's book was well worth ten times the price of the book to me the past season.

Owing to the drouth the honey-flow ceased entirely about the middle of July last season, and the bees of my out apiary became so demoralized that I could do nothing at all with them in the way of taking off honey. Work as quickly as I might I could not go through more than two hives without having a desperate case of robbing on my hands; and if there is anything in this world which is down-right aggravating, it is trying to take honey from the hives when the air is full of robber bees.

In my despair I thought of the screen-house, and soon had one modeled after Mr. Heddon's description with some modifications. His house is a stationary affair with a board roof, and all his hives have to be carried to it for manipulation. Mine is made much lighter, so that it can be moved along to suit my convenience, ten or a dozen hives being manipulated at one place. My screen-house is 5x6 feet on the ground, and 6 high. I would have made it 6x6 feet square but for lack of room among my hives. The two sides are covered with wire cloth, the upper half being double according to Mr. Heddon's directions. But if I were making another one I would have the lower half double instead of the upper, as the manipulated hive, being placed on the ground, the outside bees are attracted to it, and cluster on the wire-cloth as near to the hive as possible, while the bees inside are attracted by the noise of those outside, and cluster opposite them on the inside, so that if any honey is passed out, it is done through the lower half of the screen.

The two ends of my screen-house are covered with thin muslin, and the top is also of muslin fastened to two

light sticks 6 feet long, and kept taut and in place by a pin through the ends of these sticks into the upright side-pieces. A door which swings on hinges is placed in one end. The sides of the house are, of course, separate, and are held together by two Van Deusen hive-clamps at each corner.

No implement for the apiary which I have ever made—not even excepting the solar wax-extractor—has proved its usefulness so completely as this screen-house. When robber bees are rampant, and stings are as plentiful as huckleberries outside, all is serene within. I have an idea that the bee-keeper is stung more by robber bees than by the bees of the hive which is operated upon, though of course they are more savage when robber bees are ready to pounce into their hive as soon as it is opened. One can work all day in the screen-house and scarcely receive a sting, and this I regard as a great, though incidental, recommendation. The fact that we can go right along with our work during a dearth of honey, when without it all operations would have to be suspended, is what makes the screen-house so valuable. Hence I advise every bee-keeper to build a screen-house for next season's use.

Making Honey-Vinegar.

T. F. BINGHAM.

Long ago I was requested to describe my plan of making honey-vinegar. To simplify the whole understanding of the matter, it is well to state just how much honey is required to make a gallon of the best vinegar made. One pound of honey and one gallon of water will just make the article required. That is, 29 pounds of honey will make—water being added to it enough to fill a regular 32-gallon barrel—one barrel of the best vinegar. The vessels I use to make it in are common alcohol barrels, which I find at drug-stores. I saw out one of the barrel heads and paint the outside to prevent the iron-hoops from being destroyed by the vinegar.

The barrels and vinegar are kept in my house-cellar, so covered with burlap as to keep the dust out and let the air in. One year converts this water and honey into the choicest vinegar. More age will make it sharper or more acid, but at one year old it is fine enough for any use.

Of course sweetened water from washing honey-cappings is the most common waste of the apiary, and to utilize it is presumed to be the desirable matter in connection with honey-vinegar. Still, with the low price of honey bee-keepers may find a reasonable outlet for some of their poor honey, such as is unfit to sell as an article of delicate luxury for table use.

To know how sweet water slowly sweetened and constantly fermenting

should be, is one of the difficult features of converting the washings of cappings into vinegar. An instrument used by brewers known as a Saccharometer, would, of course, show the amount of honey in the water, even if the taste did not fully determine the increasing sweet in the water as it was souring. I have made a few cheap instruments to be used by those who wish to know how sweet water should be for vinegar, and may be relied upon as permanently accurate for such test.

Vinegar made of honey may be evaporated, and the honey will candy in the residuum, and may be so reclaimed when honey is more prized than vinegar. So it will be seen the honey still holds its place, even though it has previously been the most perfect vinegar.

I trust that the above may enable many to obtain the one article of universal use, in its known pure state. Abronja, 9 Mich.

For the American Bee Journal.

The Question of Bee-Legislation.

J. E. POND.

Dr. C. C. Miller is undoubtedly honest in his opinion that the question of who may and who may not keep bees in a given locality, should be settled by legislation, but he fails as yet to point out the legal remedy in the form of an enactment. For myself I fail to see just how any statute could be framed that would work justly, or that could be so applied as to prove equitable. In the first place, bees are only property so long as they are within the immediate control of their owner. Secondly, there is no way by which bees can be kept within such control, except by becoming the absolute owner of all the land within such a radius from an apiary, that no flight could be extended beyond the territory actually held in fee by the bee-keeper. Thirdly, bees as foragers are neither respecters of persons or property, and cull or pillage nectar from any spot where it can be found by them.

Taking the above points into consideration as factors in the problem, how can it be possible to enact a just and equitable law to govern the matter? To say that one man may keep bees to forage on another's territory, while that other shall not keep them to forage on his own land, would most certainly not be democratic, and most positively would be un-republican. The law made applicable to keeping bees, should certainly not differ from the law applicable to other property, and any law that tends to reduce competition tends also to the production of monopolies.

I think, as does Mr. Heddon, that the law of the "survival of the fittest" is the only law that can be applied equitably; and if some one meets with a loss by reason of his inability to work as easily, cheaply and understandingly as does another, that it is a matter that is common to all

lines of business, to all trades and to all professions; the weaker must go to the wall. As well might a law be enacted to protect some lawyer, doctor or merchant who had not sufficient ability to protect himself, as to protect a bee-keeper from competition.

Again, where shall we begin, and where shall we end? For myself I believe that we have laws enough now, and that instead of making more it would be far better to wipe out entirely many of those that now exist. Who can draft any law in regard to bee-keeping, that is better than the law of honest competition?

The Honey Market in California.

M. SEGARS.

I have read with great interest the articles regarding a national organization for the purpose of obtaining better prices for our honey. For one I must say that if such a union can be formed to work harmoniously for the interests of all sections of our country, it would doubtless do much good. But what is the prospect of being able to secure such co-operations? Surely, the present membership of the "National Bee-keepers' Union," especially from this State, does not appear in the least encouraging.

Our fellow-bee-keepers here are sadly demoralized by the low prices of honey and other obstacles, and seem to prefer the slumber that reduces their property to naught, rather than labor for their own welfare. I have been exclusively engaged in the honey business for the past twelve years as a producer and shipper. My own crop for 1886 was about 40,000 pounds, most of which was extracted. I shipped to various markets about 350,000 pounds; most of this honey was extracted, of the best quality and sold here, on the car, for the pitiful prices of $3\frac{1}{8}$ to $3\frac{3}{8}$ cents a pound. Deduct from these prices the cost of packages and labor, and what an insignificant profit remained! This may explain the demoralized condition of bee-keeping in California, and why Italian bees in movable-frame hives can be purchased for less than \$1.50 per colony.

The frequent suggestion of making a market at home for our honey, is good, but in that regard I will say that honey is no luxury in California households. We can do but little in placing our large productions in home markets in this thinly settled country. The production of this county for 1886 was about 540,000 pounds of extracted and 130,000 pounds of comb honey, taking the third rank of counties in this State. We were obliged to sell, and the bulk of our crop had to be exported. The many bitter experiences of making consignments to commission houses have quite destroyed our confidence in that class of mankind, and we are no longer lured by their tempting quotations.

The market reports of commission men have proven themselves to me to

be *glaring falsehoods*. In shipments of honey, covering a period of twelve years, I have never succeeded in a *single instance* in getting the prices appearing in the market reports. I have known commission houses to make returns of all prices under quotations as low as to bring the consignor *in debt* \$1.90 on a shipment of nearly 5,000 pounds of extracted honey, which sold for \$8.10 above the freight and commission, and bill rendered for melting, having candied, \$10.

If there is no way to secure better prices, and with some degree of certainty, send us some *still*, enthusiastic brother, and he can become the king bee-keeper upon a small investment. San Bernardino, Calif.

For the American Bee Journal.

The Nebraska State Convention.

The Nebraska State Bee-Keepers' Association met in Lincoln, Nebr., on Jan. 12, 1887. The convention was called to order by Vice-President J. G. Hodges.

Owing to the slow arrival of members, the regular order of business was postponed until the next day, and the meeting then listened to an essay by Mr. A. D. Reller, on "Wintering Bees," which was followed by a discussion.

Mr. Muir said he had found it to pay to ship honey to city markets to be sold on commission.

The members present were requested to make to the Secretary a special report of their success and failures for 1886.

SECOND DAY.

Called to order by the Vice-President at 9 a.m. The finance committee, having reported favorably the reports of the Secretary and Treasurer were read and accepted.

The committee on foul brood, appointed at the last meeting, reported that Mr. Henry, of Filmore county, whose bees were thought to have foul brood, had destroyed his bees by fire.

After the enrollment of members, Prof. Bessy, professor of botany at the State University, delivered an address, showing how bee-keepers and botanists could work to each other's mutual benefit; and extended an invitation to the members to visit the University, which was accepted and appreciated.

Mr. E. Kretchmer, of Coburgh, Iowa, gave an instructive address on the past and present apiculture in the West.

President W. F. Wright's resignation having been offered by letter and accepted, Mr. R. R. Ryan, of Bradshaw, was elected president of the association. The remainder of the day was spent in discussing the following subjects: The solar wax-extractor and wax rendering; best method of increase; what time in the year is it best to exchange queens; what strain of bees is the best for business; and the best method of creating a honey market.

THIRD DAY.

Called to order by President Ryan at 9:30 a.m.

The session was devoted to special business, and considerable wrangling and personal feelings cropped out by some member, who was modestly rebuked.

The association then adjourned to meet in Lincoln on Jan. 11, 1888, for their next meeting, and then proceeded in a body to visit the State University.

Legislation for Bee-Keepers.

W. J. CULLINAN.

This subject is one of considerable importance. However, I am of the opinion that it would *not* be feasible to secure such legislation, from the fact that it would be *impossible*. As well ask Congress to give to some certain man in each of the counties of the different States of the Union, say the pioneer sheep-raiser of each respective county, the whole, sole-right to that county as a territory in which to rear sheep. It would certainly be very agreeable to the one securing the set-off, as he would have a good local demand for his wool and mutton. But would not the thousands "left out in the cold" by such a law soon "rise in their might" in opposition to such unjust legislation? And yet the passage of such a law could, in my opinion, be as easily obtained as the passage of one giving to certain bee-keepers an exclusive right to the territory which they happened to occupy.

Were one greedy enough to wish it, it would certainly be very "desirable" to have a township or two set off to him as his exclusive territory in which to pursue his chosen occupation; you might then go just a step further and say that no one else should sell honey within the same territory; another step and say that no one living within its limits should purchase honey outside that territory—in fact, it would be difficult to draw the line, when once well started, as to where to stop "legislating." And about the time one got everything "fixed up" to suit his select exclusive ideas, the thousands of bee-keepers who did not happen to be among the pioneers of their localities, would raise such a howl with their congressmen, I think, that it would soon become altogether "feasible" as well as extremely "desirable" to have that law rescinded.

For years Congress has been endeavoring by appropriate legislation to check the great cattle companies of the West from monopolizing large areas of that vast domain to the exclusion of actual settlers. Every honest-minded man will uphold the Government in the course it is pursuing. And now should we bee-keepers, who are supposed to possess in a somewhat unusual degree the noble traits of honesty and fair-

dealing, as well as a brotherly regard for members of the craft, ask Congress to foster and sustain that which it has long been trying to quash, viz: monopolies? For a bee-monopolist, while he might not be as big a man, would come under the same head and be in every way as bad a man as the sheep-monopolist, the cattle-monopolist and the land-monopolist. And so, I say, away with the idea of monopolies of every kind and class!

Let every one keep bees who wishes to; and make them pay if he knows how. And when the crop is shortened by over-stocking, and the prices lowered by over-production, the weakened and wavering will forsake the field to those who have an abiding faith in the pursuit, and the perseverance to stay with it.

Mt. Sterling, Ills.

For the American Bee Journal.

The Honey-Producers' Association.

J. V. CALDWELL.

Mr. Baldrige's article, on page 85, needs, in my judgment, a brief answer. He says that the Elgin factory-men meet each week to control and fix the price on butter. But it seems to me in this he must be mistaken. In the general market, the law of supply and demand must be the ruling power. He says that for Monday, Dec. 20, 1886, the price of butter, as fixed by the factory men, was 30½ cents. Very well; this price was no doubt for the finest grades. Now suppose they had put the price at 40 cents, does Mr. B. think that they could do so and still hold their trade? I have to-day a price-current from a Chicago commission firm, and I notice that creamery butter is quoted at 28 to 30 cents per pound, and that, too, with no mention of Elgin butter; and I have no doubt but what good butter shipped from any point brings that price, thus showing conclusively that the market will bear that figure whether it should chance to be made in Elgin or Rockford, or any town in the country.

But again, butter is one of the necessities in every family in the land, while the finest honey is relished by comparatively few. Honey is a luxury, and in my opinion it will continue so to be, and we may just as well face this fact one time as another. My experience in my own market confirms me in this. When it sold in years past at 18 to 20 cents per pound, a certain amount was consumed, while now with nice comb honey selling at 11 cents I cannot see that the demand has increased a particle. When a man enters a store his inquiry is for staple articles—butter, sugar, coffee, etc. If he chances to see the honey he may say "That looks nice, don't it?" and that usually ends it.

Now in this matter I do not wish to discourage any real practical suggestions. If a society can be formed to distribute our product evenly throughout the country; to keep us

informed as to the yield in general; and to benefit producers in any real practical manner, I should certainly give it my hearty sympathy and cooperation.

But, says Mr. B., "When our large honey-producers make up their minds to organize and pull in one direction," etc., then his one price object may be accomplished. Well, whom does he call "large producers?" Suppose one party producing 20,000 pounds becomes a member, while in the same place are 20 small bee-keepers producing each 1,000 pounds who do not join the association, would his 20,000 pounds have the effect of raising the price any more than the same amount in the hands of the small bee-keepers would in lowering it? I think not.

Now, in all candor, Mr. B. had better leave this matter of a fixed price to the inexorable laws of supply and demand.

Cambridge, Ills.

For the American Bee Journal.

Winter Quietude of Bees.

JOHN CRAYCRAFT.

I think there need not be a doubt but what at a season of cool or cold weather, with no flowers and no brood-rearing, bees take on a state of quietude even in this warm climate of South Florida. It was warm on Christmas day, and the temperature was 72° in the shade, yet I noticed very few bees flying, and not having examined or even opened any hive for some four weeks at a time, I went over them, equalizing the stores of the colonies as to their individual wants; so that all would have plenty until the flowers come again.

I opened the hive of a fine colony of Italians, and found them in a state of quiet, almost a death-like stillness, but in a few moments they were in an active state. I continued the examination on other colonies, and found them in almost the same state of quietude, although at the same time there were a few bees around the entrances, occasionally one passing out and in. At this time there is very little brood, there being no source of honey, and from this I am led to think that even in a warm climate like this, when brood-rearing is stopped, and no honey in the fields to gather, even though it may be warm and very pleasant, the bees will take on this repose and remain so at intervals of several days at a time, and then come out on a general cleansing flight, return to the same quiet until instinct tells them that it is time to commence their preparations for the propagation of their race.

To further confirm my examination, I know of a very strong colony of the common small yellow-jackets that make their home on the ground. I went to it to learn something of them, and I found a few at the entrance, as it were, on guard, but none passing in or out. I thought I would stir them up a little and see if they were at home. I did so, and I found

in a few minutes that there were more at home than I desired!

So it is with the toad; it could hop every day in the year, but it does not. They can be found in some quiet place taking a little rest. It is the same with the snake, lizard, and all the small reptiles; even the so-much-talked-of alligator will spend several weeks, and some say here several months in quietude, after obtaining a square meal on a few pine-knots to keep his stomach from collapsing. I think that we need not doubt but what bees do hibernate, but I think they do so only at times when there is no brood-rearing going on, or very little, at least.

Altoona, Fla.

For the American Bee Journal.

Apicultural Patents.

A. N. CLARK.

In the article on "Apicultural Progress," the writer says: "Whoever looks back over the great progress of apiculture during the last two decades, will not fail to discover that inseparably connected with this progress is the one of mechanical inventions. Perhaps I might well have said that this invention constitutes the major portion of that progress."

To the above we may heartily answer, yes. But are we to suppose that we would now have all these mechanical conveniences without patent laws to protect the inventor? I think that a great many of our labor-saving devices would be unheard of in the absence of governmental protection; for, in the first place, there would be less inventing, and, in the second place, many inventors would try to keep their inventions a secret in order that they might more easily compete with others in the same business. But with proper protection the inventor advertises his new or improved utensil. So that every one has an equal chance with his neighbor. Again, the proper protection of the inventor induces mechanical knowledge to spread very rapidly; hence, it acts as a great civilizer.

It is quite generally understood that a great many apiarists are strongly opposed to any one who will protect his property with a patent. There is an indirect and a direct reason for this opposition. First, manufacturers of apiarian supplies, who manufacture more than they originate, advise people not to patent their inventions; and these probably really considered it unfair to take out a patent, for, as Faraday said, "The force of the temptation which urges us to seek such evidences and appearances as are in favor of our desires, and to disregard those which oppose them, is wonderfully great." "It consists in the tendency to deceive ourselves regarding all we wish for." This error of judgment affects the anti-patent bee-keepers not only through the manufacturers, but in a direct manner also.

For those who oppose the patent system on the ground of monopoly,

we have the authority of ex-commissioner of patents, Benjamin Butterworth, M.C., of Cincinnati, who says: "Not to exceed 10 per cent. of the patents issued by the Government of the United States prove valuable to the patentee. So that besides the expense of time, labor, material and cost of patent, the inventor runs a great risk for which he should when successful be substantially rewarded."

Mr. Heddon suggests an "Honorary Inventor's Rights System." But does it not appear to the reader that he has too much faith in the honesty of bee-keepers? Would it not leave the honest apiarist to compete at a disadvantage with the rogue?

My attention has been forcibly called to this subject of patents, by the appearance before Congress of a bill known as "Bill H. R., No. 4458," which, if passed, will strike a death-blow to inventors of apiarian implements.

East Le Roy, Mich.

For the American Bee Journal.

The Use of Comb Foundation.

H. M. CATES.

"Does it pay to use foundation?" is often asked, so I will give my experience with it. My way of increasing my number of colonies is by natural swarming, and I hive the swarms that issue in June on empty frames. If it should be a good season they will just about fill the brood-chamber of a Langstroth hive. Where I hive swarms on old combs or foundation, each colony will store from 40 to 60 pounds of fine honey, and leave plenty in the brood-chamber for winter. Counting the surplus honey at 20 cents a pound (I never sold a pound for less), I have from \$8 to \$12 per colony; and deducting from 80 cents to \$1 for foundation, leaves me a nice profit per colony. I have used foundation in sections in half sheets and ½-inch guides on the top-bars, and I found that it pays just the same in proportion.

The past season I placed from 1 to 2 frames of foundation in the centre of the brood-chamber, and as soon as I dared to spread the brood apart, I took out the outside frames that had little or no honey or brood in them, using them to hive swarms on, and getting the foundation drawn out better and more even in that way than in any other. I then hived the swarms on but 2 frames of old combs for the first 24 hours, placing at the same time on the top (using division-boards, of course), from 8 to 24 two-pound sections; this forced the bees to occupy the sections immediately. In this way I find that it is best to use only ½-inch guides in sections.

One thing that I have often noticed in hiving swarms on full sheets of foundation is, that in the centre of a hive, especially at the top of the frames, they will often build new comb on top of the foundation, instead of drawing out the cells to the proper length. This led me to try

getting it drawn out in the early spring, and using old combs gave the queen a chance to commence laying at once, and forced the majority of the bees to use their wax in comb-building in the sections. This plan may be old to most bee-keepers, but I learned it by hard study and close watching, and I shall do the same thing this season. All the bees seem to be wintering exceedingly well so far, in this locality.

Shideler, O. Ind.

For the American Bee Journal.

The Marketing of Honey.

T. H. CANTY.

On page 70 it states that the producer and consumer are both at the mercy of the retail dealers, as they usually pay in trade 10 cents per pound for honey (which is equivalent to about 8 cents), and retail it for 12 to 15 cents per pound. In this vicinity some are selling splendid comb honey for 7 cents per pound, and I do not doubt but some has been sold as low as 5 cents.

This reminds me of some honey I bought of a bee-man to retail at 15 cents per pound, and in a day or two the bee-man was around selling to my customers at 12 cents, so I was compelled to come down to his price. If bee-keepers want to keep up the price of honey they will have to get the retail dealers of their towns to help them sell their honey. Make prices with the dealers so they cannot afford to send after honey, and do not undersell them, for if they have any grit they will make you regret your promise. Sell all you can in home markets, and do not glut the large markets that make the prices on all produce.

The commission men, as a rule, do the best for their customers that they can, for that is their bread and butter, and on their name rests their business, just like the producer; if the latter's name becomes associated with adulteration, and it is said that he sells glucose for honey, his honey is not sought for.

Canty, ♀ Dak.

For the American Bee Journal.

Can Bees Hear?

D. BRIMMER.

I think the idea that bees cannot hear is erroneous, for many reasons, and a few of those reasons I will try to state. One is, they do not emit the same sound in the act of flying at all times. For instance, an angry bee can be distinctly distinguished from one not angry. Some will say that is caused by their wings. Then I would ask, how do a few bees lead a large colony in a straight line to some tree previously selected a mile or more away?—a fact that I have known for a long time; also that a swarm can be stopped by creating sounds above that of the swarm and the leaders; but it must be continuous to be effective.

This I know, for I have stopped many swarms after they had gotten well under way for the woods. If they cannot hear, how is it accounted for?

I have had swarms so intent on going that they tried it two days in succession, and were brought back and the queen's wing clipped before they would stay. Then, it is well known that a swarm will not leave unless the queen is with them. How is the knowledge of her presence communicated through the swarm, if they cannot hear?

Who has not heard the young queens piping as soon as the first one is hatched, and answering each other in quick succession, one a sharp, shrill sound, and the other a muffled sound—evidence that one is in confinement? After an experience of over 47 years in handling bees, and being a bee-hunter longer still, I am convinced that the faculty of hearing in bees is very acute—a thing, I think, that can easily be demonstrated.

Hoosick, O. N. Y.

For the American Bee Journal.

Bee-Keeping in Cuba.

H. E. HILL.

Bee-culture, with the improvements of modern times, is a thing entirely unknown in this portion of Cuba, and our method of handling bees has created quite a sensation among the natives. One native, after watching the proceedings for a few minutes, called a friend, saying, "Come and see what strange people these are—how they play with bees!" Some of them say that "bees cannot do well when they are disturbed and handled in such a way." Another says when he discovers our secrets he will make "millions;" then a more enlightened brother informs him that the secret lies in "that kind of whistle (the smoker) that is worked with the hands;" saying that "he knows how to make them come or go with that thing."

I should like to give a description of a Cuban apiary, but to convey any idea of the appearance of those that I have visited, I fear is beyond my skill. I think of no better way, however, than to ask the reader to imagine a pile of hollow palm and cedar logs varying in length from 3 feet to 6, and in diameter from 5 inches to 2 feet, that have been laid around by a cyclone. Without regard to "position of the entrance," they lay to all points of the compass; but all occupy a horizontal position, with an occasional exception where one is seen laying with one end upon another log, and the other end resting on the ground. I can assign no reason for this position, unless it has been thoughtfully placed in this way by the apiarist to save his bees the annoyance of carrying water for the brood in rainy weather. In each of these hollow logs is a colony of bees, or else the remainder of one that has been destroyed by the moth or flown to some place more in accordance with its idea of a suitable home.

A Cuban honey-extractor and wax-extractor are very much alike, both being a piece of coarse linen. For extracting honey, the combs (that are taken from the end of the hollow log, or from under it) are placed in the linen sack and squeezed until no more honey (and dirt) can be obtained. Then the sack is placed into boiling water until the wax is as nearly all extracted as can be under such a process.

In transferring nearly 100 of the above-referred-to colonies from the logs to the Langstroth hives, I did not find one that was not affected more or less with the moth; some of which were completely destroyed by its ravages. It is not uncommon to see a colony of bees festooned outside of the log where there is a tree near the end, or anything else for them to attach their combs to; having moved out for the convenience of the moth and roaches which out-number the bees. Where a colony has been long in this condition and established business outside, the combs get weather-beaten, and have the color of a hornet's-nest.

My apiary is located at La Gloria, about three miles from the city of Cienfuegos, among the hills and fields that are now "a perfect sea of bloom;" and the bees are working from morning until night upon the *Companea*, and another plant which I should pronounce mother-wort. These plants grow here in great profusion, and yield large quantities of honey and pollen. The palm, coconut and banana also furnish some nectar now.

La Gloria, Cuba.

For the American Bee Journal.

A Case for Open-Side Sections.

H. W. FUNK.

I am in hopes that we will welcome a better surplus case for pound sections than any of those now in use. The fraternity is always on the alert for improvements, hence it surprises me that the new style of sections with side-openings do not attract more attention. I have just finished a case adapted to their use, of which I will try a number the following season. I think they will do. This case consists of a rim just as high as the section, and just long enough to admit 4 rows of sections easily; cross-wise it is about $\frac{3}{4}$ of an inch wider than the 8 sections. (This size is for the 10-frame Langstroth hive.) Into this space a $\frac{3}{8}$ -inch board is dropped as large as the inside of the case; between it and the case wedges are driven down tight with a hammer. Perhaps thumb-screws would be an improvement on wedges. Care must be taken to have the sections all of the same width.

Separators with little legs to stand on till the case is wedged, could be used very conveniently; it would take only three separators to put one in every alternate space. If the bee-space between the cases is desired, the rim need only be made bee-space wider. I think the sections could be

wedged tight enough so that they would not sag in the centre of the case. A slotted board has been invented, cut to correspond with the openings in the bottom of the sections, to be used where no bee-space is desired below the first section-case.

I think with these open-side sections bees will be less liable to swarm, as a string of them will be more like the large frames used in extracting supers than disconnected sections with divisions between. Next fall I expect to know more about the matter. All the above is mere theory, and the true bee-keeper believes in his theory until experience or common-sense teaches him better.

Bloomington, \odot Ills.

Local Convention Directory.

1887. *Time and place of Meeting.*
 Feb. 23-24.—E. Iowa & W. Ill., at Davenport, Iowa.
 J. Wadsworth, Sec., Moline, Ills.
 Mar. 3, 4.—Pan-Handle, at Wheeling, W. Va.
 W. L. Kinsey, Sec., Blaine, O.
 Mar. 16.—St. Joseph Inter-State, at St. Joseph, Mo.
 E. T. Abbott, Sec., St. Joseph, Mo.

∇ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

First Pollen for 1887.—Z. A. Clark, Arkadelphia, ρ Ark., on Feb. 10, 1887, says:

My bees brought in the first pollen on Jan. 21, fifteen days earlier than last year. They have worked 6 days this year on elm and maple. It is 72° in the shade to-day, and the weather is balmy. Last year was a sorry honey year with us; it was too dry.

Bees Quiet.—D. Q. Roberts, Hollansburg, \circ O., writes:

My first experience with bees was last spring. They did well through the summer, both in swarms and honey. I stored them away in my cellar in November. They seem to be very quiet in their winter quarters. I use Langstroth hives. There are many dead bees thrown out of the hives. Why is this?

[They are old bees, and, when dead, are thrown out.—Ed.]

Clover Chaff for Winter Packing.—S. J. Youngman, Cato, \odot Mich., on Jan. 26, 1887, writes:

Those that have bees have rather abandoned cellar-wintering, and those with experience are more successful than formerly. Some have decided that they have killed their bees with kindness, having in many cases packed them too heavy and tight. I have used both oats and wheat chaff, but I

have discarded both, and I am now using clover chaff, which I use quite heavy on the sides, but lighter on top of the frames, and leave it quite loose with plenty of air over the top. I find the chaff always dry; I think it is the best material to carry off dampness, and at the same time retain the heat furnished by the bees inside the hive. I have also tried forest leaves, and I find them far inferior to the chaff; if leaves are used they should be packed or pressed down but slightly, as the moisture does not pass readily up through, but will condense and drip down upon the bees. When I examined my bees the other day, considerable water and dampness was found inside the hives, while those packed with the clover chaff were perfectly free from dampness. All the colonies were alive on Jan. 20, and some took a flight in a light rain, with the temperature at 50° above zero, while the others remained quiet. All seem to be wintering well. Extracted honey is in good demand; I sold all of mine at 10 cents per pound.

Sundry Questions.—Hallett & Son, Galena, \circ Ills., ask these questions:

1. What proportions of honey and water will make the best vinegar; and what time is necessary to make good vinegar from honey?
2. How long have bees been kept in a cellar during winter and come out in good condition?
3. Why sow Alsike clover for bee-pasturage when it blossoms the first time with white clover?
4. Will black bees gather honey from the second crop?
5. Will a swarm of bees be any more likely to settle south of the hive, for the reason that the entrance is towards the south?
6. How close may hives be put for safety and convenience?
7. What shape and how large a piece of foundation should be put into sections?

[1. See page 118. Mr. Bingham is a good authority on honey-vinegar.

2. Five months.
3. Cut it, and have it bloom later.
4. Yes.
5. There is a little more likelihood of it, but no certainty.
6. From 2 to 4 feet; but they touch in some apiaries.
7. Fill them.—Ed.]

My Way of Selling Honey.—A. D. Stocking, Almena, ρ Mich., writes:

On page 58, Mr. George Poindexter, after giving his experience with his honey, asks, "What should I do?" I would say, try the plan I did. At first, every time I went to town I took a small case of nice one-pound sections of honey in my hands, and showed it to all whom I met, and sold some and took what orders I could, and left some with a few good men to be sold on commission. I set the price at which it was to be sold, paid no attention to any market reports

given; and I have never asked any one what they would give for honey. If they thought that my prices were high, I would say that the honey was mine, and that if they did not sell it they would lose nothing. Honey was selling for 5 to 8 cents lower than my price, but it was in a very different shape. I established my reputation for the quality of my honey, and in the style in which I put it up. My honey was always of first quality; if I had any that was inferior I sold it for what it was, or kept it at home, and I never had any trouble in selling my honey at my own price.

Sending Comb Honey by Freight.—Capt. Charles Regnier, Saarlouis, Prussia, asks:

What is the best way to pack comb honey in sections, to be sent 150 miles by railway?

[Pack it in crates which show the honey through glass, to ensure careful handling. Have it packed with the combs parallel with the rails, and if tiered up, let it be secured so it will not be thrown down by the cars' "bumping."—Ed.]

Early Brood-Rearing.—T. A. Daniel, Wewahitchka, \circ Fla., writes as follows on Feb. 5, 1887:

We have had some fine weather for the last 3 weeks. Bees are bringing in pollen in quantities, and building up rapidly; they average from 2 to 3 frames of brood to the hive. Maples have been in bloom for some time.

Reversible Extractor.—A. J. R., of Windham, \circ N. Y., asks:

Would it pay to obtain a reversible honey-extractor in an apiary of 200 colonies?

[It would pay, if you obtain a good one.—Ed.]

Wholesale and Retail Prices of Honey, etc.—T. M. Coleman, Glendon, \circ Iowa, on Feb. 9, 1887, writes:

There is one thing that I have not seen mentioned in the discussion on controlling the price of honey, that I think could be remedied to some extent, and that is, the great difference in wholesale and retail prices. On page 8 a writer says that prime extracted honey is 5 to 7 cents per pound in Chicago, and 3 to 4 cents in other cities. I infer from his article that he is pleased at the prospect of honey becoming an article common on the tables of all classes. But I am told that this cheap honey from our hands goes on the tables of consumers at 12 to 15 cents per pound, and often higher. I shipped a lot of extracted honey to a grocer in a distant town, and it cost him about 10 cents; and I have positive proof that he sold it at 20 cents a pound. There are so many men in the grocery business that they

are claiming too large a profit on our labor. They wanted me to sell my honey to them at 10 cents per pound, and let them retail it at 15 cents the past season, but I would not do it. My honey was in one-pound sections, in nice cases each with a glass side, and I determined I would not go to all the trouble necessary to put it on their counters, and let them merely hand it out to their customers, and take one-third as their share. As to bee-legislation, I do not think we need much if any more than we have. My bees did well last winter in a cellar with the temperature at 34° above zero much of the time; and this winter they seem to be doing finely when it runs down to 30° above zero. My home is lonely this winter; my wife, after going with me for 35 years of life's journey, has gone on before me, to "the better land." May be I ought not to say anything about it here, but the Editor's words about his mother, last October, spoke to my heart in such a way, and called out such sympathy from bee-keepers, that I feel nearer to all of them.

Food for Shipping Bees.—Jacob Alpaugh, St. Thomas, Ont., asks:

1. What is the best food to put in with queens while being shipped, or with bees shipped by the pound? 2. How is it made?

[1. The "Good" candy. 2. Ask I. R. Good, of Nappanee, Ind.—Ed.]

My Report.—John B. Tully, Wyoming, Ill., on Feb. 11, 1887, says:

I commenced the spring of 1886 with 3 colonies of bees, and increased them to 8, by natural swarming. I obtained 900 pounds of honey in one-pound sections, besides plenty for the bees to winter on.

Patented Bee-Hives.—W. G. Hayen, Pleasant Mound, Ill., says:

Please answer this question through the BEE JOURNAL: If a person sells me a bee-hive, and some one else has a patent on it, who would be responsible?

[If you did not know that it was patented, you would be an innocent purchaser.—Ed.]

Bees Breeding Early.—John Nebel & Son, High Hill, Mo., on Feb. 14, 1887, write:

We have had some very changeable weather lately. The temperature has fallen 50° in 18 hours. On Feb. 10 it was 70°; on Feb. 11, 20°. Bees that are on the summer stands have had several good flights since Jan. 20. The winter has not been very severe on bees here, so far; but they have consumed more of their stores than usual, and as they are breeding very rapidly now (the weather being quite warm), they will need a good deal of attention to supply them with enough stores until fruit blossom. Jan. 24

being a warm day, we opened a hive, which was very strong with bees, in which we found brood in all stages, even to capped cells, occupying a space of about 6 inches square in two frames. We are inclined to think that our bees have begun breeding too early, and on too large a scale for the changeable weather that we are having. Two hundred colonies wintered in the cellar are doing nicely.

Shipping Bees and Keeping Honey.—H. M. Moyer, Hill Church, Pa., asks the following:

1. Is it safe to ship full colonies of bees by express in Langstroth hives, by fastening only the top-bars of the frames? Or will they swing too much on the bottom-bars so that it will pinch the bees?

2. Will extracted honey keep as well during the summer if it was in a freezing room the winter previous—say in a room whose temperature was a good many times at zero—as it will when it was in a room which did not freeze?

[1. It is better to cut pieces 1x $\frac{5}{8}$ inches, and as long as the depth of the frames, and put one between each end-bar, wedging the last one. This is perfectly safe, unless the combs break.

2. Yes.—Ed.]

Bees at Work on the Maples.—R. J. Mathews, Riverton, Miss., on Feb. 8, 1887, writes:

My bees were wintered on the summer stands, and are doing well. They commenced bringing in pollen on Jan. 23, and are still doing so; they seem to be very strong in numbers, and I think they are working on maple and spice-wood. It is earlier than usual, but we are having very warm weather for this season of the year. My apiary is in Arkansas, west of the Mississippi river, and near its banks.

Spring Weather and Bees Flying.—G. L. Rankins, Weston, Ky., on Feb. 8, 1887, writes:

My bees had a nice flight on Jan. 13, and now on the 4th to the 8th of February we are having spring weather, and the bees are humming as if it was April. I wintered my bees on the summer stands, and lost one colony; it was a late swarm, and it froze on Jan. 1; the mercury was 8 below zero.

My Experience with Bees.—Wm. Cleary, Algona, Iowa, on Jan. 21, 1887, writes:

Two years ago I obtained 2 colonies of bees, and secured a few pounds of honey from them, and increased them to 4 colonies the first year. A year ago last fall I got 16 colonies more and put the 20 in the cellar in the fall, and last spring I took out of it 19, some of which were very weak. I in-

creased them to 33, sold 3, and doubled up some, so that I now have 23 in the cellar and 4 in a tenement house outdoors, in which they winter well. We had a very poor season for honey last year, as it was so dry. The clover did not last long, and we got very little basswood honey, and no fall honey. I had to feed sugar to some of the late swarms before putting them away for winter. I weighed and marked each hive as I put them away, so I will be able to tell how much it requires to winter a colony of bees. The cellar is about 40° Fahr., and the bees are dry and all right.

Making Wax-Sheets.—J. F. S., of Charles City, Iowa, asks the following question:

In making wax-sheets for foundation, how can they be dipped to make both ends of even thickness?

[Dip twice, reversing the ends of the board.—Ed.]

Bees in Splendid Condition.—Henry Cripe, North Manchester, Ind., on Feb. 11, 1887, writes:

Bees in this locality had a good flight on Feb. 9 and 10, and seem to be in splendid condition. My bees were all on the wing except 5 colonies that are buried in a clamp, and they will have to stay in where they are until the latter part of March. I have wintered some in this manner for four winters, and never lost a colony, except several that starved.

Good Weather for Bees.—John Rey, East Saginaw, Mich., on Feb. 10, 1887, says:

Bees are having a fine time, as the weather is warm and just right for bees to have a cleansing flight. They are spotting the snow some, but it is in a dry state. Every colony in my yard came out in strong force, and in a healthy condition. I notice a good many young bees and a few drones from some of the strongest colonies. I think that fully 80 per cent. of the bees will winter in northern Michigan.

Clover in Nebraska.—N. W. Aflerbaugh, Cameron, Nebr., on Feb. 8, 1887, writes:

I have 37 colonies of bees on the summer stands, packed all around except the front, and they have plenty of honey. Bees have been flying every month this winter; the weather is mild. I had a good yield of fall honey. As soon as we get clover here I think that Nebraska will produce more honey than any other State, as clover blooms in June and heart's-ease in the fall until frost. I am in favor of a bee-keepers' union to regulate the price for honey. One thing I am afraid of is, that the California honey will regulate the prices here.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c. No demand for extracted, and very little for comb.
BEESWAX.—22c. R. A. BURNETT,
 Jan. 19. 181 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10@12c.; in 2-lbs., 9@10c.; of grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8@8½c.; in 2-lbs., 7@7½c. Extracted, California, 5@5½c.; buckwheat, 4@4½c. Supply of comb honey is large, and demand for all kinds is improving.
BEESWAX.—21@23c.
 MCCAUL & HILDRETH BROS.,
 Jan. 21. 34 Hudson St.

SAN FRANCISCO.

HONEY.—Extracted is firm at 4@4½c., and comb at 8@12c. per lb.
BEESWAX.—19@21c.
 Feb. 9. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively.
BEESWAX.—24 cts. per lb.
 Feb. 11. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Few sales are reported. Best white comb, 12½c.; Fall 60mh honey, 10@11c. Extracted is offered for 8@8½c.
BEESWAX.—Firm at 23c.
 Feb. 11. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote for extracted, 4@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way.
BEESWAX.—Good demand, —20@22c. per lb. for good to choice yellow.
 Jan. 22. C.F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, in 1-lb. sections, sells at 13c.; second quality white, 12c.; dark 1-lbs., 9@10c.; white 2-lbs., 11@12c. Extracted, 6c. Market dull.
BEESWAX.—25c.
 Feb. 15. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 12@12½c.; 2-lbs., 11@12c. No call for dark. White extracted, in barrels and kegs, 5@6½c.; in small packages, 7@8c.; dark, in barrels and kegs, 5@5½c.
BEESWAX.—25c.
 Jan. 19. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8½@11. Extracted, white, 4½@4¾c.; amber and candled, 3¾@4c. Trade is quiet.
 Jan. 10. O. B. SMITH & CO., 453 Front St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lbs., 9@10c.; white clover 2-lbs., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 6c.; dark, 4@5c.; white sage, 5@5½c.; amber, 4½@5.
BEESWAX.—20@23c.
 Jan. 13. CLEMONS, CLOON & CO., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 3½@4½c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4½@5c.; in cans, 5@6c. Market dull.
BEESWAX.—Firm at 21c. for prime.
 Feb. 3. D. G. TUTT & CO., Commercial St.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

The Western World Guide and Handbook of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides his own, with \$3.00, for one year, we will present a copy of this valuable book.

There is no Mistake in insisting that—as in all other things, so in advertising—the best is the cheapest, no matter what its first cost may be.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

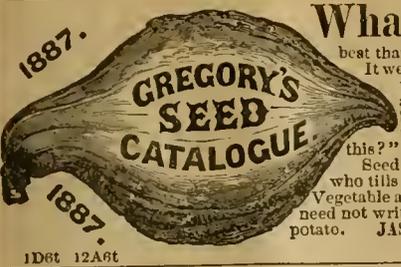

E. Duncan Sulffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Convention Notices.

The annual meeting of the Eastern Iowa and Western Illinois Bee-Keepers' Association will be held in Moore's Hall, 110 East 3rd Street, at Davenport, Iowa, on Wednesday and Thursday, Feb. 23 and 24, 1887, commencing at 10 a.m. Bee-keepers and those interested in bee-culture are invited to be present. Those wishing to exhibit be-fitures or honey, will please bring the same for inspection. J. WADSWORTH, Sec.

The St. Joseph Inter-State Bee-Keepers' Association will meet in the Lecture Room of "Unity Church," at St. Joseph, Mo., (9th between Felix & Edmond Sts.), on Wednesday, March 18, 1887, at 7 p.m. All are invited. E. T. ABBOTT, Sec.

The Pan-Handle Bee-Keepers' Association will meet at Wheeling, W. Va., in the K. of P. Hall, 1138 Main St., on Mar. 3 and 4, 1887. W. L. KINSEY, Sec.

What Mr. Beyer says: "Please best thanks for the splendid seeds received from your firm. It would be a rather lengthy list if I should name all, but will say that amongst 34 first, and 3 second premiums awarded me at our fairs in Northern Indiana and Southern Michigan, 23 first premiums were for vegetables raised from your seeds. What firm can beat this?"
 AUGUST BEYER, So. Bend, Ind.
 Seed of this quality I am now ready to sell to every one who tills a farm or plants a garden, sending them FREE my Vegetable and Flower Seed Catalogue, for 1887. Old customers need not write for it. I catalogue this season the native wild potato.
 JAS. J. H. GREGORY, Seed Grower, Marblehead, Mass.

FOR SALE CHEAP, for cash, 1 to 100 Colonies: Bees by the pound, of either Italian or Albino Bees, and QUEENS. — Address, OTTO KLEINOW, (Opp. Ft. Wayne Gate), Detroit, Mich. 8Et

FINE ITALIAN QUEENS for sale, reared from Imported and Home-Bred Mothers. In April, Untested Queens, \$1.25 each, or \$13 per doz.; May to Nov., \$1 each; per doz. \$10. Tested Queens \$1 more; Select Tested, \$1.50 more. Address all orders to, J. P. Caldwell, San Marcos, Hays Co., Tex. 8A3t

WANTED.—Three live men to work in an Apiary and Nursery.
 S. I. FREEBORN, Ithaca, Wis. 7Atf.

PRACTICAL Bee-keeper wanted for four months. Correspondence solicited.
 P. BALDWIN, Independence, Mo. 7A3t.

100 COLONIES of BEES
 For sale cheap. Reason, too many.
 H. NEUBAUS,
 Burlington, Racine Co., Wis. 7A8t.

HOW TO RAISE COMB HONEY.
 Price 5 cents. You need this pamphlet, and my free bee and supply circular. 7Atf.
 OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

PURE Italians. Tested Queens, June, 1.25 each. \$12 per doz. Full colony & tested queen, June, \$6. 5A1y
 O. N. BALDWIN, Clarksville, Mo.

FOR SALE.—100 Full Colonies of Italian and Hybrid BEES, in 2-story Standard Langstroth Hives, at \$10 per Colony. Four-fifths of the Combs are drawn out from Foundation in wired frames; all Queens reared under the swarming impulse, except a few superseded in full colonies. With the largest order (not less than 10) I will give an Excelsior Honey-Extractor; with 2nd largest (not less than 5), an Excel. Wax-Extractor and Unclipping-Knife—provided I sell my Bees. Bees shipped as ordered, and in the order they are in bee-yard. Remit by P. O. Money Order, or Draft on New Orleans. Correspondence & orders solicited.
 Address, W. T. MADDOX, Alexandria, La. 8Atf

DON'T GET LEFT!—Nothing extends reputation equal to the brilliant Chromo Bee-Card. See page 77, or address.
 J. H. MARTIN, HARTFORD, N. Y. 6W(3tm)40t

WANTED.—To confer with a reliable married man who has a good knowledge of Bees, with a view of establishing an Apiary near Boston. Address.
 BOX 151, MILTON, MASS. 6A3t

WANTED.—I cannot give my bees the attention they should have, and I am therefore anxious to obtain the services of a competent, reliable apiarist, to aid me. I want a single man. For further particulars address,
 E. C. JORDAN,
 6Atf JORDAN SPRINGS, Fred Co., Va.

READY TO SHIP.—Langstroth Brood-Frames, prepared to nail, at 90 cents per 100; 540 for \$48.00. I have several thousand of these Nice Brood-Frames in the flat, which, if ordered before Apr. 1, may be had for \$8 per 1,000, freight prepaid by C. W. DAYTON, Bradford, Iowa. 2Et

SECTIONS.

WE make a specialty of the manufacture of DOVE-TAILED SECTIONS of the White Poplar, the whitest and best wood for the purpose. We make all styles and sizes, but recommend the Side-Opening Sections as superior to any other. The great accuracy and fine finish of our Sections are the admiration of everybody. Sample 3 cents. Price-List of Supplies free.
 Address, DR. G. L. TINKER,
 NEW PHILADELPHIA, O. 8Et1

OLD TIME PRICES!

UNTIL further notice I will accept orders for FOUNDATION as follows—to be shipped in April:
 Dunham Brood, per lb..... 35c.
 Vandervort Thin, per lb..... 45c.
 All fresh made. Also the best FOUNDATION FASTENER in the market.
 WAX worked—Dunham 8 cts. and Vandervort 15 cts. per lb. No Circulars. Seven years experience in the business.
 J. V. CALDWELL,
 6Atf CAMBRIDGE, Henry Co., ILLS.

CLOVER SEEDS.

We are now selling Alsike Clover Seed at the following prices: \$8.00 per bushel, \$2.25 per peck, and 25 cents per pound. Also, Melilot or Sweet Clover Seed: \$6.00 per bushel, \$1.75 per peck, and 20 cents per pound, by express or freight. All orders promptly filled upon arrival.

THOS. G. NEWMAN & SON,

BEES for SALE, Cheap.

100 Colonies of American-reared Italian Bees, best strain, strong, and in 10-frame wired Simplicity hives; for sale at \$8.00 per Colony. Z. A. CLARK,
 SEtf ARKADELPHIA, ARK.

Alley's Drone and Queen Trap.

Price, by Express, 50 cts.; by mail, 65 cts.: 12 in the flat, and one nailed (13 in all), \$3.50; 50, in the flat, \$12.00. Address.

THOS. G. NEWMAN & SON,
 923 & 925 West Madison St., CHICAGO, ILL.

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published every Week, at Ten Shillings and 10d. per annum, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited by T. W. Cowan, Esq.

The British Bee Journal and the AMERICAN BEE JOURNAL, one year, for \$3.00.

APIARY FOR SALE

HAVING other interests which claim my attention, I wish to sell my apiary of 138 Colonies, in the village of Winnebago, Ills.—7 miles from Rockford, and 100 miles west of Chicago. The location is first-rate, and no other apiary near. The past season, 82 colonies increased to 138, and gave 7,000 lbs. surplus—nearly all white clover, and 4 1/2 of it comb; 2,300 lbs. sold at home for cash without peddling. Langstroth Hives, with good Combs, Tiering-up Section-Cases, Division-Boards and Feeders, Extractor, and good Honey-House. (Rented place of one acre.)

If not disposed of before April, it will be sold at auction.

C. M. HOLLINGSWORTH,

Wooden Pails for Honey!

WE can furnish regular Wooden Water-Pails—well painted on the outside, and with 3 iron hoops and a tight-fitting wood cover, at \$2.25 per dozen. They will hold 25 lbs. of honey, and when empty, can be utilized for use as an ordinary household pail.

THOS. G. NEWMAN & SON,
 923 & 925 West Madison Street, CHICAGO ILL.

THE "BOSS" ONE-PIECE SECTIONS.

Patented June 28, 1881.

WHILE attending the North American Bee-Keepers' Convention at Indianapolis, we learned there was a rumor afloat that the Patent on the ONE-PIECE SECTION had been set aside—circulated by unprincipled parties, to mislead bee-keepers. We would say in regard to this, that such is not the case. It is now before the U. S. Supreme Court, at Washington, and will probably be decided before a great while, when we will notify all through the Bee Journal. Until then pay no attention to rumors.

Before ordering write us for prices. We will furnish you Sections as cheap as the cheapest. Let us hear from you before you order. Address,

J. FORNCROOK & CO.,

1Atf Watertown, Wis., Nov. 1, 1886.

Thos. G. Newman & Son, of Chicago, sell the one-piece Sections manufactured by us.

Extracted Honey For Sale.

We have a large quantity of CHOICE WHITE EXTRACTED HONEY, in kegs holding from 200 lbs. to 225 lbs. each, which we will deliver on board the cars at 7 cents per lb. Orders solicited.

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

GIVEN AWAY!

THE AMERICAN APICULTURIST

A 32-page magazine, published monthly, by Henry Alley, Wenham, Mass.

Terms, \$1.00 per annum. To each new subscriber we will send FREE, by mail, one of our latest improved "Drone and Queen Traps," the regular price of which is 65 cents. Send for sample copy.

Make Postal Note and P. O. Money Orders payable at the Salem, Mass., P. O., or enclose the \$1.00 at our risk.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. March 2, 1887. No. 9.

Mr. M. F. Tatman, whose letter appeared with our comments on page 83, writes an explanation and apology. He did not *intend* quite as much as his words implied, and he meant it more in jest than in earnest. His explanation is quite satisfactory.

Fayette Lee, of Cokato, Minn., has sent us a model of a tin bottom (like a pan) for crates, to prevent the leakage from daubing grocers' counters. It is a very nice thing, but we fear would be too expensive for general use.

The Costs in the case of McIntosh vs. Harrison thus far amount to about one thousand dollars. If the case were carried to the Supreme Court, the costs would be an additional twelve hundred dollars. So says the *Canadian Bee Journal*.

The Great Subject of the Day for the American people, is the exposed condition of our great seaports, in a dozen of which one-fourth of the wealth and resources of the whole nation is accumulated. Destruction of a great port would spread ruin to all parts of the country. Mr. Joseph Nimmo, Jr., in his article, "Our Unprotected Seacoast," gives a lesson that all should read in *Frank Leslie's Popular Monthly* for March.

Bees on Shares.—We have several inquiries as to the terms of such contracts, and in order to answer them all at once we will state the usual terms of such contracts. It is usual for one party to furnish the bees, and the other the care and labor. The expense of new hives for swarms, comb foundation, sections and crates for comb honey, kegs or barrels for extracted honey, extractors, smokers, queens, etc., to be equally divided. At the end of the honey season the honey and increase of bees are equally divided—leaving each to take all chances of marketing as well as wintering the bees. A written contract, stating the whole agreement in full is always desirable to prevent misunderstandings.

Passed Away.—Speaking of the "death record" of the most renowned apiarists of Europe during 1886, the *Bulletin* of our friend Bertrand, of Nyon, Switzerland, says:

Switzerland deplores, among others, the removal by death, of M. Mona; Italy, Mr. C. Fumagalli, the author of a hive largely in use among Italians; France, M. Jules Madare, President of the Societe de la Somme, and M. Maurice Girard, a distinguished entomologist and author of a valuable book on bees; Scotland has lost her James Anderson, a veteran of Scotch apiculture, who, in his day, was remarkably successful with the Stewarton hive; and, lastly, Russia has seen the passing away of Dr. A. Butlerow, Professor of Chemistry and of Medicine at the St. Petersburg University. Dr. Butlerow was the promoter of modern bee-keeping in Russia, and his works are considerable, among which is a Russian translation of Berlepsch's book. The deceased doctor was also founder of a school of apiculture.

We formed the acquaintance of Dr. Butlerow when attending the Austro-German Bee-Keepers' Convention at Prague, Bohemia, in 1879. The Czar of Russia had commissioned him to confer a "decoration" upon Dr. Dzierzon for his valuable apicultural services. In the presence of some 3,000 persons he conferred this great honor amidst much enthusiasm. At the banquet which followed, the editor of the *AMERICAN BEE JOURNAL* had the honor of his company, together with Herr Andreas Schmidt, (now deceased), Dr. Dzierzon, the Baroness Von Berlepsch, Herr Vogel, and some other celebrated bee-masters.

But since then a number of the prominent apiarists of the Old World have passed away, in addition to those enumerated by M. Bertrand. Among them are: Herr Andreas Schmidt, who, for nearly a quarter of a century had edited the *Bienen Zeitung* in Germany; the Rev. Herbert R. Peel, editor of the *British Bee Journal*; Mr. John Hunter, author of *Hunter's Manual*, in London, England; Prof. Von Siebold, the faithful friend of Father Dzierzon, and others whose names we do not now recall.

Peace to their dust! We shall all soon join "the silent majority!"

Referring to an item on page 67, about another bee-paper for Canada, Mr. Allen Pringle, in the *Canadian Bee Journal*, says:

I sincerely trust this is a mistake, but if the project is really under serious consideration, I hope the projectors, whoever they may be, may re-consider the matter. Instead of *two or more* inferior, half-supported bee-journals in Canada, let us have one good one.... Two papers cannot, in my opinion, thrive and succeed.

Mr. W. F. Clarke, in the same paper, on page 927, under date of Feb. 10, 1887, remarks thus:

I most thoroughly endorse Mr. A. Pringle's remonstrance against the establishment of another bee-paper in this country at present. Certainly no one who has the best interests of Canadian bee-keeping at heart will advocate the expediency of a rival bee-paper. Our friends from across the lines have committed the error of starting too many bee-papers. They are constantly springing up like mushrooms, and soon die.

There is considerable truth in the remark about there being too many bee-papers in the United States, but *three* for Canada would eclipse any showing that could be made "across the lines."

Too many bee-papers boom the pursuit, weaken prices, and destroy confidence by the premature death of the *weaklings*.

None Lost!—Just imagine the surprise of our readers who happen to have seen the *Canadian Bee Journal* of Feb. 16, upon discovering, on page 931, the following paragraph:

The "Union" in the United States claim to have lost *nine* of the suits which they have thus far defended!

In our paper of Feb. 9 we stated that the Union has lost *none* of the suits which it had deemed expedient to defend, and after placing each suit on record, by enumerating it and the decision arrived at, we added:

The four cases enumerated in the foregoing matter are all that have been finally decided, and it is a record for every member to feel proud of—not one case has been decided against the bees!!!

It would be fair to presume that the Editor of our *Canadian* cotemporary wrote the word "none," and that the printer set it up *nine*. As a vast difference in the two statements is caused by the substitution of one letter, we hope that the *Canadian* editor will make the necessary correction both speedily and cheerfully. Justice demands it, for the Union has defended only *four* suits, and of these *not one has been lost!*

We Commended that Michigan legislation matter to Prof. Cook, in our last issue (page 115), and we are well persuaded that it is in good hands. Mr. George E. Hilton, President of the Michigan State Association, writes thus:

You are right Mr. Editor. I wrote to Prof. Cook last week, and he says he will attend to it. He thinks that there will be no trouble in defeating such an unjust Bill. I have also written to the State Horticultural Society in session at Hillsdale, to pass a resolution against it. I have seen our representative, and arranged to have the matter postponed for 30 days, which he says he can and will do; in the meantime, I think our forces will be sufficiently centered to over-balance any efforts which Mr. McCormick can make.

Here follows a letter from Prof. Cook, who accepts the *trust*, and will, as he has done so many times before, see that justice is done to the pursuit of bee-keeping. He says:

The "Bill to wipe apiculture out of Michigan" (that is my title to it) will never pass, and will probably never be called up. Michigan aims to foster her important industries and not to throttle them. Such a Bill could not get a dozen votes in the Michigan legislature. Still, I hope every bee-keeper in Michigan will write to Hon. Mr. McCormick, Lansing, Mich., urging him to withdraw the Bill. It will serve to enlighten him and others as to the status of this business.

Catalogues for 1887.—Those on our desk are from

- F. A. Snell, Milledgeville, Ills.—16 pages—Aparian Supplies.
- J. W. Powell & Son, Mankato, Minn.—16 pages—Bees, Bee-Keepers' Supplies, etc.
- Smith & Smith, Kenton, O.—24 pages—Implementations in Bee-Culture.
- C. Weckesser, Marshallville, O.—16 pages—Bees, Queens, and Garden Seeds.
- David Hill, Dundee, Ills.—8 pages—Evergreens, etc.
- Esra Baer, Dixon, Ills.—8 pages—Bees, Queens, and Aparian Supplies.
- Hughes & Tatman, North Topeka, Kans.—4 pages—Bees, Queens, Chickens, etc.
- Edward Gillett, Southwick, Mass.—16 pages—Ferns, Plants, Flowers, etc.
- W. W. Rawson & Co., 34 South Market St., Boston, Mass.—24 pages—Vegetable and Flower Seeds.
- N. N. Betsinger, Marcellus, N. Y.—6 pages—Perforated Separators.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Honey Consumed in Rearing Brood.

Query, No. 381.—What amount of honey is represented in a brood-frame 12x12 inches, or a Langstroth sized frame? Or, in other words, what amount of stores have been consumed by the bees in providing for the larvæ until the cells are sealed?—S.

Twenty cubic inches of honey represent one pound in ordinary combs.—G. M. DOOLITTLE.

The amount of stores consumed in providing for the larvæ depends altogether upon the amount of brood. A frame 12x12x1½ would hold from 5 to 8 pounds of honey, depending upon the condition of the honey.—J. P. H. BROWN.

A Langstroth brood-frame, regular size, full of honey in the comb, weighs nearly 9 pounds. I do not think it would be possible to ascertain accurately how much stores, pollen and honey a frame full of larvæ would consume before being sealed. I might guess 1 ounce of pollen and 4 pounds of honey.—G. L. TINKER.

A Langstroth frame fully filled, and with comb ¾ of an inch thick, as I use mine in the brood-chamber, will weigh not far from 5 pounds of honey.—J. E. POND.

In favorable weather for brood-rearing I should judge that a frame of brood was equivalent to a frame of honey. In colder weather it takes more honey.—C. W. DAYTON.

Too much depends to warrant an answer in pounds. Larval food, and much of the food of the workers during the active season, consists of pollen or bee-bread.—JAMES HEDDON.

It is hard to say. Bees in the height of the season, when confined all day by a rain, will often lose from 1 to 3 pounds, as shown by scales. Yet so many things are to be considered that even this is no criterion. Bees often use 15 or 20 pounds of honey in the spring while filling their hives with brood. Yet we do not know how much they gathered in the same time.—A. J. COOK.

It depends somewhat upon the condition of the weather. In feeding colonies in the spring that have no reserve stores, about 3 pounds of honey for the first square foot of sealed brood; 2 pounds for the second square foot, and something less for the third square foot. I have never tested the matter accurately, but after the bees get up the proper heat by high feeding at the start, it re-

quires less food afterward to keep brood-rearing going. Feeding for brood is a pretty dear business.—G. W. DEMAREE.

No satisfactory answer can be given to the question as stated. Any one may speculate.—THE EDITOR.

Laying Worker Bees.

Query, No. 382.—How can I distinguish a laying worker-bee from other workers, or from a queen?—Kans.

A laying worker bee looks like any other worker bee.—C. C. MILLER.

The bees sometimes treat her in a manner somewhat similar to the way a queen is treated. Occasionally she may be seen laying.—W. Z. HUTCHINSON.

By the size, as compared with a queen. I know of no means of telling them from the other workers unless you catch them laying.—G. M. DOOLITTLE.

They appear exactly like the other bees, unless when depositing eggs. I have imagined other movements to betray them. They cannot be distinguished satisfactorily.—C. W. DAYTON.

They are distinguishable only by dissection. If we are right, Count Barbo, of Milan, was the first to show the condition of their ovaries by microscopic descriptions.—DADANT & SON.

You cannot unless you see them laying. They look like other workers, and so are easily distinguished from a queen.—A. J. COOK.

You cannot distinguish a laying worker from other workers; though I have observed that the underside of the abdomen of a laying-worker was fuller than that of an ordinary one. You have only positive knowledge when you catch them in the act of depositing the egg. They are distinguished from a queen in the same way you distinguish a pig from a goat.—J. P. H. BROWN.

There is no way to distinguish a laying-worker from other worker bees, unless you can detect them in the act of laying eggs. You could distinguish a laying-worker from a queen if it was possible to first identify the laying-worker.—G. W. DEMAREE.

The only way I can do this myself, is by seeing her in the act of depositing eggs, and I have never found any appreciable difference in size or form between a laying worker and any other worker-bee. It is easy enough to distinguish a laying-worker from a queen, as the queen always shows the mark of royalty, while the worker, laying or otherwise, never does.—J. E. POND.

It is not possible always to distinguish laying-workers from the other workers, though it is easy to know one (if you can get your eye on it) from a queen by the length of the latter's body, and the size. Sometimes the laying-worker can be dis-

tinguished from the other bees by the hairs being all worn off from the abdomen, so that they appear black and shiny. Where there are laying-workers there will generally be seen many such bees, but only a few of them may be developed into laying-workers.—G. L. TINKER.

You can readily distinguish any worker from a queen by the difference in size, as has been shown in engravings; but I will let some one else tell how to distinguish laying-workers from any other worker bees, unless you can catch them in the act of laying.—JAMES HEDDON.

Laying-workers are not distinguishable from other bees; if you have seen a worker lay, you can easily determine by its size that it is not the queen.—THE EDITOR.

Bees Refusing to Accept the Hive.

Query, No. 383.—I let my bees swarm naturally, often several swarms clustering together. They would not accept the hive, but crawl all over it, both inside and outside. Is it because they have no queen, or too many? I have tried doubling up the colonies, dividing the bees and putting them into several hives, and raising the hives to give them air, but all to no avail. They would finally die out. I have had single swarms act the same way.—Texas.

It is because they have no queen.—J. P. H. BROWN.

The lack of a queen causes such actions.—W. Z. HUTCHINSON.

The loss of the queen, I judge, by the bees balling her or otherwise, is the cause.—G. M. DOOLITTLE.

Such actions on the part of bees always indicates the loss of the queen.—G. L. TINKER.

I hardly know what the trouble was, unless the queen was lacking.—C. C. MILLER.

I should say that they had no queen.—H. D. CUTTING.

It is usually because the queen does not enter the hive. By practical experience in the apiary is the way to learn to overcome this class of difficulties.—JAMES HEDDON.

The fact that they "die out" suggests queenlessness. The queens were balled and killed in the cluster, or after hiving. You should find and cage a queen for them for two days. "Single swarms" might do so when honey was not very plentiful.—C. W. DAYTON.

When bees swarm, and two or more swarms cluster together, they often become demoralized by reason of the presence of more than one queen, and refuse to do any good. It pays me to remove all but one queen at the time of hiving them, if it is desirable to unite all together. Such swarms should be hived on the old stand and given one or two frames of brood, so that if the queen is killed by the mixture of strange bees, they will have the presence of brood to rear a queen.—G. W. DEMAREE.

Queenlessness, without doubt, must account for such actions.—THE EDITOR.

Distinguishing Swarms.

Query, No. 384.—I am obliged to be absent from my apiary till 3:45 p.m. each day. If, on my return, I find a swarm on a tree, what is the best way of ascertaining from what hive it came? I have tried sprinkling with flour, but with little success. Please explain fully.—F., New Jersey.

By observing the appearance of the colony. The hive that has just cast a swarm will have fewer bees than usual at the entrance; and if sections are on, they will be comparatively deserted.—J. P. H. BROWN.

If there are only a few colonies in the yard they may be examined; if there are many, the swarm may be hived, and then watch be kept to see where the stragglers finally go.—W. Z. HUTCHINSON.

Learn the condition and strength of each colony, so that you can on your return note the change, if one casts a swarm in your absence. If one has many colonies it may be impossible to tell where second-swarms have issued, unless the bee-keeper is on hand very soon after; then scattering young bees, and bees with crippled wings in front of a hive, will be the index.—G. L. TINKER.

After you have hived the swarm and taken them away from the place where they were clustered, take a bunch of the bees to a little distance and throw them in the air. In a little while you will find them ventilating at the entrance of the old hive. If floured, it is all the better. But the best way is to clip the queen's wing.—C. C. MILLER.

I have experimented considerably to overcome cases like the one here described. I have succeeded by putting some flour in a deep tin cup and dipping up some bees from the cluster, and after shaking them up, and giving them a good scare, turn them loose in the apiary. Some of them will generally go straight home and discover to the observer the hive from which the swarm issued. Once in a while the bees refuse to identify their old home in this way, and I am "swamped."—G. W. DEMAREE.

The "flour" plan is a success with me. Flour a tea-cupful after having kept them until just as the bees in your apiary cease flying, and then carry them some rods away to some warm nook, and scatter them broadcast; hurry to your apiary and you will see where they swarmed from.—JAMES HEDDON.

After you have hived the swarm you will find a few bees trying to cluster where you took the swarm from. Take a good handful of flour and throw it upon them and drive them from the place, and you will soon find them at the entrance of the hive from which they came. I do not think it ever failed me. Use plenty of flour.—H. D. CUTTING.

There is no sure way unless you can find the queen. If you remove her from the cluster, then the bees will go back to their old hive. By close attention previously, you would be able to know possibly what colony was preparing to swarm. By opening

the hives you could very likely tell by the number of bees, what colony had swarmed. If you are away, as you say, you ought certainly to clip the wings of your queens. Then the bees will show you, as they will go back, and usually you will find the queen in the hive, or in a knot of bees hard by.—A. J. COOK.

Take a tea-cupful of bees from the swarm and put them in a bee-tight box, being sure not to get the queen. Hive the swarm, placing them (as soon as in the hive) where you wish them to stand. Now open the box, and at the same time throw all the bees in the air so they will take wing, when in a moment or two they will return to the parent hive and set up the call (by fanning of wings) of "home is found."—G. M. DOOLITTLE.

You can toss a few bees in the air some distance from the swarm, and ascertain which hive they return to; or you can examine the hives and see from which a swarm has come out. Either plan is uncertain, however. Why not use a queen and drone trap, or make your swarms either on the nucleus plan or by dividing? Either way would be preferable to myself, than to have swarms issuing during an unavoidable absence.—J. E. POND.

If they have no queen with them, you ought to be able to see which hive they go into. I would search the queen out of the cluster and put her into a cage, and when the bees begin to return to the hive, remove it and put a new one in its place. As soon as they begin going into it, let the queen loose amongst them. You should know which colonies are most likely to swarm. This would aid you.—C. W. DAYTON.

By using a drone and queen trap you may prevent the queen from leaving, and the bees will return to the hive. Then you can divide the colony at pleasure. The flour would, no doubt, successfully determine from which hive the bees came, if tried just before they cease to fly.—THE EDITOR.

Convention Notices.

☞ The St. Joseph Inter-State Bee-Keepers' Association will meet in the Lecture Room of "Unity Church," at St. Joseph, Mo., (9th between Felix & Edmond Sts.), on Wednesday, March 15, 1887, at 7 p.m. All are invited. E. T. ABBOTT, Sec.

☞ The Pan-Handle Bee-Keepers' Association will meet at Wheeling, W. Va., in the K. of P. Hall, 1138 Main St., on Mar. 3 and 4, 1887. W. L. KINSEY, Sec

System and Success.

☞ All who intend to be systematic in their work in the apiary, should get a copy of the *Aplary Register* and commence to use it, the prices are reduced, as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

Restoring Good Prices for Honey.

JOSHUA BULL.

Much is being written about the low price of honey, and the consequent discouraging prospect for bee-keepers, and the blame for this state of things seems to be laid, by some writers, chiefly at the doors of the farmers and others who keep only a few colonies of bees, and who consequently have but little honey to sell, and hence it goes at any price, thus spoiling the market for others. To the careless observer this, no doubt, has much of the appearance of truth in it; for no doubt some know by painful experience that even a very small quantity of honey sold at a low price in a small town makes it very hard for the next person who may come to the same market with honey to sell, to get any more for it than his predecessor sold his for. But before we saddle all the blame upon this class of producers, let us see if the cause for this condition of things is not traceable to some other source.

It is not because those who have but little honey to dispose of are willing to sacrifice the little they may have for mere nothing—not at all; for generally those who have but little honey to sell feel the necessity of getting all they can for it, as much so as those who have more. But let us see how one of those farmers is trying to sell his small lot of surplus honey to some shrewd grocer.

The farmer says, "Mr. Grocer, can I sell you some nice comb honey today?"

Grocer: "How much do you want for it?"

"Twenty-cents per pound."

"Whew-o-o-o!! why honey is selling for only 10 to 12 cents in Chicago, and if you should send it there, when you have paid freight and commission, you would not have more than about 8 cents per pound left for your honey. But now, to be fair with you, I will give 9 cents cash, or if you will take your pay in groceries, I will allow 10 cents per pound for it."

"That is not enough; it would be too little pay for the time and labor that I have spent in taking care of my bees; allow me 15 cents, and you can have it."

The grocer (very independently) says: "O, no, no, I can get honey shipped from Chicago for less than that. You must accept my offer or we cannot trade."

The farmer goes on and visits a number of other grocers with like results, and at last is obliged to sell for

just what they choose to give, or else not sell to them at all. The man who is more extensively engaged in the business, and has established a reputation for producing an extra-nice article of honey, may stand a little better chance; yet he is very largely at the mercy of the ruling prices in the large cities.

Who, then, is to blame for the low prices which prevail in those large markets? Is it not fair to conclude that every one who sends honey to those markets, when they are already fully supplied, is responsible for the depression of prices, just in proportion to the amount which he sends in? Because when any market has a sufficient supply to meet all demands, it does not take a very great overplus to cause a reduction in prices; and when the prices are once down, it is not easy to get them up again, so long as an overplus is continually being forced upon the market. Therefore, if all would withhold their honey from these great centres of trade, until the supply is so reduced as to allow it to command a fair price, it seems to me that much better prices might then be maintained; not only in those places, but also in our home markets. Meanwhile, let every honey producer be vigilant in working up a home market, for there are thousands of people in this great country that hardly taste of honey from one year's end to another, who would buy quite freely if it was only placed where they could get it without extra trouble. Those who have never tried it can hardly realize how rapidly this home trade will grow and develop if we only furnish the germ, and then nourish it with a first-class article of honey, and square dealing.

Five years ago it was difficult to sell honey at all in this town, but now I can sell all the surplus I have without any effort, only to get it ready. To put up comb honey for private family use, I make nice, light crates to hold 12 sections each, after the Heddon pattern, only instead of nailing the cover on, I nail a thin moulding all around the edge of the cover in such a manner as to shut down over the top of the crate about half an inch, fitting closely to keep out flies, ants, and all other troublesome insects; then give it two coats of good light-green paint, and it is ready for use. When the crate is filled with nice comb honey, the snowy whiteness of the combs showing through the glass in the ends of the crate, appears in beautiful contrast with the color of the paint, and looks very neat indeed; so that almost any housewife is captivated at first sight with its inviting appearance, and is generally very willing to purchase a crate. These crates, if properly cared for, will last for years, and can be refilled as often as desired.

For the grocery-trade I made a show-case with a drawer underneath the glass part in which can be placed a quantity of sections for convenience in supplying customers without opening into the upper part where all should be kept in neat and tasty order. This case filled with nice honey is

kept standing in a conspicuous place upon the counter in one of the leading stores in this town; so that every person who enters that store will be sure to see it: and the result is that the honey sells freely, and the demand steadily increases. The fine appearance of the honey thus exhibited has often attracted the attention of strangers who have visited this place on business from Green Bay, Milwaukee and other places, so that when about to return, they have on several occasions bought some of this honey to take home with them, saying that it was the nicest thing of the kind that they had seen. By means of this show-case I have recently received a number of orders for honey from parties of whom I had never before heard. I obtained 15 cents per pound for comb, and 10 cents for extracted honey, net, for last season's entire crop; and no freight nor commission to be deducted therefrom.

Now let every person who wants to make money, by keeping of bees and producing of honey, Consider a moment of what I am telling: "Build up a home market," and do your own selling: Don't give all the profits away in commission, For that leaves your purse in a wretched condition.

It is foolishly wrong, yes more, 'tis a pity To send all your honey away to the city, When hundreds of people around you would buy it; If you don't believe this, just start out and try it.

When selling your honey, make good weight and measure; For that always gives to each customer pleasure. Don't try to get gain by fraud and deceit— Dishonesty always deserveth defeat.

An injury often provoketh resentment— Integrity bringeth true peace and contentment. Then be not repulsive through covetous blindness, But treat every one with cordial kindness. Be courteous, kind-hearted, magnetic, polite, And I think you'll succeed in the business all right.

Building up Nuclei into Colonies.

WM. MORSE.

Last spring I disposed of all of my bees and fixtures except two 3-frame nuclei, which were very weak. On April 1 I transferred them to a "dividing hive;" each had 3 frames partly filled with honey, and bees enough to cover one side of one frame, and no brood. As the weather was cold I put hot stones wrapped in paper on top of the frames every night and morning. On April 6 one queen commenced laying. On April 9 the other commenced laying, and when the 3 frames were well filled with brood and honey, I gave another, and so on until each had 5 frames well filled with brood and honey. That was June 8; I then took one frame with bees and queen and formed a nucleus, and put the others together. That gave me 1 good colony with 9 frames well filled with brood and honey.

I then put on 24 one-pound sections, and on June 13 I tiered up with 24 more one-pound sections, and on June 18 all the sections were about half worked down. I then put back the frames of brood and queen, divided them with a division-board between them, and gave each 3 empty frames and put on the sections; that gave

me, on June 18, 2 colonies, each having 5 combs of brood and honey, 3 empty combs, and 24 one-pound sections half worked down.

They kept on in the sections as though they had not been disturbed. One gave me 105 pounds of honey in one-pound sections, and the other 88 pounds. I think I can produce one-third more honey with the same strength of bees in the spring with a "dividing hive," than any other hive that I have seen, with less labor, and can control the swarming.

The Harrison Bee-Lawsuit.

WM. F. CLARKE.

The judges have given their decision on our Canadian bee-lawsuit, and bees are now virtually interdicted as a nuisance, within the limits of incorporated villages, towns and cities. No appeal has been taken by the defendant, and unless the Ontario Bee-Keepers' Association moves in the matter there will be none. I doubt the wisdom of incurring any further expense in the case. The higher court would almost infallibly confirm the judgment of the lower one.

If nothing further is done, there is a precedent established by which magistrates, judges, and courts will be guided in all future complaints. These will be made, we may be very sure. The old proverb, "Let sleeping dogs lie," applies. "All is quiet along the Potomac" while every canine in the region is locked in slumber, but let one awake, and "give voice," and the chorus of barks becomes universal. For my own part, I shall "git out" of the limits of the corporation with my bees as quickly as possible. I have been anticipating this trouble for some time past, and in re-letting my farm a year ago last October, I reserved an old saw-mill and about an acre-and-a-half of a cedar grove, one of the loveliest spots imaginable for an apiary, with right of way, and a room in the farm-house, for just the emergency which has arisen. It will be a considerable inconvenience, but there are several mitigating circumstances, viz: 1. The distance is only two miles. 2. It will take my bees that much further from an apiary now only a mile off in which there was foul brood last summer. 3. Danger of over-crowding, which was beginning to loom up here in the city, will be greatly lessened. 4. My farm neighbor opposite sowed fifty acres of Alsike clover last summer, which ought to be a bonanza for my bees. It is not often that a calamity is attended with such, and so many attendant circumstances calculated to lessen it.

This precedent will quickly be quoted far and wide through the newspapers. It will have its influence on the American as well as the Canadian side of the lines. If a fight is set up, I believe it will terminate disastrously to bee-keepers. My voice

is not for war. I think we may just as well accept the situation first as last. It will cause considerable trouble and loss to many bee-keepers, but in the long run I do not think that it will be disastrous to the interests of apiculture. Those who have disapproved of any but specialists going into bee-keeping, should hail the new *regime*, for it will cut out all the "small fry" at one fell stroke. It will go far to settle the "priority of location" dispute. Bees will be kept on "bee-farms" instead of on small lots. There will be less exposure to robber bees, foul brood, mixing of swarms, and other evils born of contiguity. Dr. Miller will now see that there is another phase to legal protection, viz: protection against bee-keepers, as well as protection among them.

Our friend J. B. Hall has long flattered himself that a special Act of Parliament would be necessary before municipalities could pass by-laws ordering the removal of apiaries outside corporation limits. He now finds another of life's illusions rudely dispelled. Alas!

Guelph, Ont.

For the American Bee Journal.

That Honey-Producers' Convention.

JAMES HEDDON.

I have read the different articles upon the subject, and pondered many an hour upon the feasibility of a special North American Bee-keepers' Convention, to be held, say early next May. For years I have written about subjects relative to such a work, and hopefully dreamed of the time when something might be done directly in the interest of the honey producer. Let us hold a meeting without a sample of or a word about apiarian supplies, or how to produce more honey. It is a grand thing to know how to obtain a maximum yield at a minimum outlay of capital and labor, but as it is also a most welcome state of affairs to know where and how to exchange this crop into that medium of all exchanges—money; and further, that we have held hundreds of conventions, nearly all of which have ignored this subject, let us hold *one* three-day convention in which we will exclude discussions directly relating to production. Let this convention be devoted to the weeding out of our pursuit many fallacies which have clogged our wheels of progress.

I have had to smile at the misconception on the part of many.

Mrs. Harrison mentions the "Pope's bull against the comet," and others talk as though we were proposing to meet for the purpose of "bucking the inevitable," and uprooting all the natural channels of trade. But all we can hope to do is to somewhat straighten some of them! When we read that Smith is readily getting 18 cents per pound for his comb honey, and Jones is selling his (equally good) for 10 cents, we know something is

wrong with the "channels." Our map shows us that these gentlemen are not transportation-cost of one cent per pound apart. We know that these "channels" have been fingered by some one, either producer through ignorance, or buyers through mischief, and we would like to "finger" it a little ourselves.

Mr. C. W. Dayton, on page 38, has presented arguments, many of which are contrary to my experience. He says that when we have produced more honey than will be consumed as a luxury, it must supersede other sweets. I say that whoever builds upon that foundation must be willing to sell extracted honey at 3 cents per pound, and I am not. I well remember years ago telling some of my friends that if they did not stop "gushing" and exciting everybody about the great profits of the bee-business, they would yet see extracted honey sell at less than 10 cents per pound; they laughed at that and said it would never be so low; that I was "scared" and that they were "working in the interest of honey production." Well, now it is down there, and they tell us they are delighted that consumers can obtain it at so low a price, and that the children of the poor can have more of it to eat. It seems they are working for consumers, and as they have had something to sell to bee-keepers all this time, it is strangely possible that in these arguments some of them were working for themselves.

True, honey production was once a profitable business. Its followers were well paid, and a well paid class of customers and subscribers (even though not so many of them) are better for supply-dealers and bee-papers than a large number of failing ones.

A truth can be told so many times that it becomes a falsehood; so may a falsehood be told so many times that it becomes true. Let me illustrate how these truths have affected our business: Certain apicultural writers said that honey production was a good paying business; that a man could become rich at it; they told this truth so many times that it has become false! Again, certain honey-dealers said that the price of honey was down in their city, and they told that falsehood so many times that it became a truth! If you could to-day make all the manufacturers, producers and consumers in this country believe that hard times was close upon us, they would come at once!

It has been intimated many times in this paper, that many local markets have been ruined by some bee-dabbler who had no means of knowing how much his little crop cost him, opening the market at a price below cost of production. The specialist can produce honey cheaper than any one else, and he alone can tell just what it costs, because he is not backing up this class of production by any other.

Do you not think, if we hold a convention in which we discuss the "average cost of production," until we settle on a figure, that a report of this discussion and settlement will have a tendency at least to lessen the

number of cases where local markets are ruined as before mentioned? I think it will; and if that is all we shall accomplish, it would be many fold more than was ever done at any previous convention. We can shake hands and get acquainted, and talk about producing honey and wintering bees, in the lobbies, the same as at other conventions; but I have not and will not mention one-tenth part of the advantage of such meeting.

We overstock our field and produce two pounds of extracted honey to get the price of one pound of comb; as Mr. Baldrige says, we sell this two pounds to a family that consumes one pound a week, and wait two weeks instead of one before we can make another sale. Exclusive production of gilt-edged comb honey is one among dozens of the ways out of our trouble.

I have scarcely touched the subject at the head of this article, and there are some very good reasons which will be brought up at that convention that will not be presented before. Depend upon it, we shall have the most intensely interesting meeting ever held by bee-keepers; one unparalleled in its promotion of the "dollar and cent" interests of honey-producers; one whose report will be eagerly sought, and of lasting benefit to our pursuit.

Necessity of Pollen for Bees.

SAMUEL CUSHMAN.

In response to Prof. Cook's article on page 742 of the *BEE JOURNAL* for 1886, I would say that in my article on page 711 of the same volume, my quotations are his exact words, as any one can see by turning to "Pollen Theory," on page 25 of the same volume, except that the printer put "nitrogen" where I wrote nutrition. I ask all interested to read the Professor's essay.

I am willing to admit that I used, on page 616, the term *nitrogen* ("elementary nitrogen exists only in the one form of gas") where I should have used *nitrogenous* (but this was not in the quotation), and that mineral salts should not have been called by me organic food. I do not question the correctness of the analysis quoted by Prof. Cook, and admit that muscle is not the greater part of it nitrogen. As the definition of nitrogenous is "Pertaining to nitrogen or containing nitrogen," the real question at issue is the same.

Albuminous or nitrogenous material is found in white of eggs and milk as albumen; in cheese, caseine; in lean meat, fibrin, and in grains as gluten. The ideas given by Prof. Cook were that the excreta of bee-diarrhea is almost always—if not always—composed of pollen-grains, while bees that had no pollen in the hive showed none in their excreta, therefore by removing pollen we could prevent diarrheal. That if bees were kept in

the quiescent state they needed only honey to serve their wants; that they have in their blood and tissue enough albuminous material to last all winter, and that pollen would not be needed. That in animals fat alone serves the purpose of *all food*, and for a time keeps up nutrition; that possibly all organic food may be converted into fat; that nitrogenous food (food containing nitrogen) can be transformed into fat by a peculiar vital process. That almost pure muscle is transformed into fat; as an example, fatty degeneration of the heart is given. That carbo-hydrates are falsely called heat-producing food! That carbo-hydrates are the best food for bees in winter quarters. That carbo-hydrates are used with other food to build up tissue. That heat is produced by vital work. That the albuminoids are absolutely essential in food to form vital tissue. That in all vital action some of this albuminous material is used up and must be restored. That active workers need pollen. That in order to get bees through the winter without diarrhea, when the temperature cannot be controlled, they should be deprived of pollen.

I hold that the nitrogen in food cannot be transformed into fat, and that muscular tissue or albuminous material cannot be entirely changed into fat. That stored fat (or otherwise) cannot as a food serve the purpose of albumen or nitrogenous material. That in fatty degeneration of the heart the fibrin or albuminous material is carried away and replaced by fat. That fat is not made into tissue, is not truly vitalized, but is merely stored in living tissue. That carbo-hydrates are heat-producing, and serve the purpose of *fuel* for the body, to carry on the vital forces and eventually produce heat. That this surplus fuel in animals is stored as fat to be drawn upon in time of need.

I would like to ask, how could bees have any pollen in their excreta, if there were none in the hive? Who believes that bees cannot have diarrhea that is not colored by pollen? Is cold or improper temperature harmless to bees if their pollen is removed? Will not excess of moisture in the air of a hive produce diarrhea? Can they be made so quiescent or inactive as to live until the hive is opened in the spring, without wearing out any tissue?

The Professor says that bees do not hibernate, are not quiet, but in the winter cluster are continually changing from the outside to the centre of the cluster, although this activity is very slight (page 87, 1886). We would infer then that they do need pollen, although but a very slight amount. Even if they do hibernate, or have hibernating spells (which I believe is all that is claimed by Rev. W. F. Clarke), they would need pollen between those spells when active. If without pollen and they do wear out nerve and muscular tissue, will not the result be an impoverished and feeble condition?

Tissue worn out must be replaced. How much of that material can the

blood and body of the bee contain? They store both carbonaceous and nitrogenous food in their combs, why do they not lay in a supply of one and not the other of these elements, if but one is needed? Animals that hibernate store up in their bodies both of these elements sufficient for winter.

Bees generally breed in the spring before the hives can be opened. How about those with no pollen? If the pollen theory is sound it will live, no matter what is said against it. If it is not sound, the sooner all find it out and turn their attention to *real causes*, the better for our pursuit.

Pawtucket, 3 R. 1.

For the American Bee Journal

A Bee-Hat for Protection.

WM. MUTH-RASMUSSEN.

If you would fain your nose protect
From bee-stings, don't a veil select;
For my experience with a veil
Is, that it is too light and frail.

When, just like some, a veil I used,
My nose was also oft abused;
On one occasion 'e'en it got
Two stings at once, which made me hot!

A veil may easily take fire,
Resulting in disaster dire,
And cause, as then perhaps you'll find,
A wall of quite a different kind.

Now, if you my advice will follow,
I'll tell you what will beat "all hollow"
The veil and such like institutions;
Then you can draw your own conclusions.

First, get a cheap hat, made of straw,
(A calico hat is even better);
Then borrow needle and thread from "ma,"
Or if she'll sew for you, why, let her.

Next, make a cylinder, to-wit,
Of wire-cloth, which your head will fit
So easy, that it won't come loose
To neck or ears, nor to your nose.

First scorch the wire-cloth o'er the fire,
Then beat the paint from woven wire;
This makes it easier on the eyes,
While bright paint off the sight defies.

Trim wire-cloth quite wide in front,
Full width of face is best, I find;
From thence decrease the width beyond
The shoulders; make it scant behind.

Join narrow ends to form the rear,
Turn in the raked edges, both,
That they may not your fingers tear.
Now make a wide fringe out of cloth;

Sew this to cylinder, below,
That it may o'er your shoulders fall.
To rim of hat you now will sew
This whole concern; and that is all.

It shades the head, protects the eyes,
Admits the air, is cool and nice,
And if the wind a little blows,
There is no danger to your nose.

Independence, Calif.

For the American Bee Journal

Regulating the Price of Honey.

GEO. F. ROBBINS.

When I hear a man talk about paying 20 per cent. commission, if a grocer will retail honey at 20 cents per pound, or about compelling dealers to sell and consumers to buy at your price, I do not know whether to laugh or growl. I would laugh to see it tried here. It is easy to say, but it is a far different thing to do.

I fancy I hear my brother, as he surveys his growing stock on some balmy, vernal day, soliloquizing thus: "Mares are worth more than horses, and steers more than heifers. It would be better for me to have my

colts all mares, and my calves all males, and that is just what I'll do." Will he? It would be about as well for him to say, I will sell all my wheat at a dollar per bushel, my hogs at 6 cents per pound, etc. The consumers have something to say about that, and it is right that they should. It is no more reasonable for me to talk about getting my price for honey. I have made most heroic efforts in that direction the past fall, and I know how it goes. It is no use to talk about keeping up arbitrary prices. Whatever may be the effects of competition and combination, supply and demand do more than all other things to regulate prices. Whether it be labor at one end of the list, or produce at the other, all are subject to the same inexorable law. Labor combinations have bent their energies during the past year as never before, to get the labor markets at their disposal, so to speak, and what have they accomplished? Nothing but to demonstrate the utter futility of any such expedients.

The farmers of this country can no more set the prices for their products than they can bridge the Atlantic! Honey producers are no better off. The season of 1885 was a very poor one. I, with about 1,100 pounds of honey to sell, had almost a monopoly of the trade. I got about 16 cents per pound for it. It was the best I could do. A few consumers would buy honey at 18 or 20 cents per pound, and a few dealers would handle it at that. The majority would not touch it. They could not afford it. The year 1886, having four times as much honey and four times as many competitors, what is the sense in thinking about keeping the price at the previous year's figures! There have been many times as much honey sold last year as the year previous, because the quantity on the market has put it down within the reach of the masses. Where one person will buy honey at 20 cents per pound, six, perhaps, will buy it at 15 cents. It naturally follows that more grocers will be found to handle it. This theory I have found to hold good in practice.

To create a home market has long been my hobby, and I have done my best to make it; consequently there are few groceries in Springfield that I have not visited. At least one man would not deal in honey unless he could get it at 10 cents, and none of them would give over 12½ cents. I worked hard to get a number of grocers to sell on commission, and succeeded with just one.

Mr. W., who has sold honey for me on the above terms for several years, persistently refused to do so last year. Some time ago I tried to sell him a lot at 12 cents per pound; he wanted it at 10 cents. He finally offered me 11 cents; if he could not get it at that he would look elsewhere. I had the honey on hand, and it was take that or ship it, and stand the chances of getting less. I had been canvassing the city, and I knew the state of the market. Another grocer wanted the same amount at 10 cents, and because I would not sell it at that I have it

yet. Perhaps some may say that here is where the advantage of a "pool" would come in; the grocer would be made to pay a *little* more at least.

I presume if the business was all in the hands of specialists, and grocers would handle it, and their customers purchase it at prices fixed, such a pool might be effectual. But those are the rubs. In the first place very few will purchase honey at any price. The Mr. W. before mentioned, told me that he had sold considerable honey at 12½ cents that he would not otherwise have sold at all. But he could see that it cut into the syrup trade.

Again, specialists cannot always control the markets, and all markets cannot be controlled alike. In Springfield is a prominent lawyer and a wealthy druggist who keep bees largely for pleasure. Together they produced nearly 2,000 pounds of nice comb honey which they sell at 12½ cents per pound in trade. That knocks me out, as I want cash, while an opulent lawyer or merchant can very easily consume that much in groceries.

Again, here is an old, retired farmer who potters with bees largely as a pastime, and he finds it very convenient to pay for his groceries in the same way. What do these men want with combinations? They take no interest in the honey business, properly speaking, and could not be prevailed upon to join any combination. And there are enough of such men to defeat any pool that might be formed in a flush season.

The Hive-Entrances in Winter.

G. M. DOOLITTLE.

A correspondent wishes to know "if the entrance of the hives should be closed while the ground is covered with snow." As I have experimented largely along this line, perhaps I cannot do better than answer this question through the BEE JOURNAL.

Soon after I began keeping bees a friend recommended closing the entrances to keep the bees in the hives at times when mild weather occurred with snow on the ground, for, said he, "if you do not do this, lots of bees will be lost on the snow, especially toward and in early spring." He also said that if plenty of upward ventilation was given, the bees would get all the air they required from above, so no harm could possibly arise from the supply of air being cut off below.

I closed the entrances as advised, all going well as long as it kept cold and cloudy. One bright, sunshiny day, although quite cold in all other places except where the sun shone on the front side of the hives, I was out in the bee-yard when I heard a little clicking noise all about me. Wondering what it was, I listened and soon found that the noise came from the hives, a closer inspection revealing that it was produced by the bees gnawing at the hive-entrances, trying to get out. Several such days occur-

red, during which I found that all was quiet in the hives until about 1 p.m., by which time the sun would so warm the interior of the hives that the cluster would be broken and unrest maintained until about 7 p.m., when the cluster would again be formed. In this way the life of the bees was being worried out, and I thought to open the entrances, for I began to realize that I should lose my bees if something was not done.

Upon opening the entrance to one hive I soon saw that such a course would not answer, for out rushed the bees *en masse*, as though they had escaped from prison, taking wing and rising above the hive. As soon as they came above the hive the cold north air struck them, when they were soon spinning on their backs on the snow or wallowing in the same, never to rise again.

The next day I was called some distance from home, and on the way I saw a man sweeping snow up about his hives. I stopped and asked him the reason for so doing. He said he had two reasons, the first of which was that in times of extreme cold the snow greatly protected the hives; and second, that at times when the sun shone brightly (yet the air was not warm enough for bees to fly in safety) the snow kept the hives cool, so that the bees had no desire to fly. I now had learned a way to obviate my trouble, as he told me that every time the snow fell he swept it about the hives, thus having snow about them when there was any on the ground.

From this on for two or three years, after every fall of snow I piled it around the hives until they were covered up, the entrances being closed all the time. All proved satisfactory, except the work part of it, until one winter nearly all of the colonies so treated seemed to get too warm, and about Feb. 1 broke cluster and went to breeding. After I ascertained this fact I took the snow away from a few hives down as far as the lower edge of the cap or corner, which caused them to quiet down, and when spring opened these few were about all I had left.

About this time I had a number of colonies to drift under some 10 feet deep, so that I lost all track of them, and after trying once or twice to shovel down and find them, I gave it up and waited until spring. When they came out, only 3 out of 12 were alive, and of the 3 alive only 1 came through to June, and that was very weak. These 12 only represent the success I have had with bees drifted in snow whether the entrance was open or closed, although others report successful wintering under like circumstances.

Not being satisfied with anything so far attained, I next left the entrance open and swept snow up against the hive as far as the brood-chamber extended. This appeared to give better results, still I kept on trying other experiments until four years ago, at which time my hives were fixed as follows:

The entrance of each hive was open 4 inches in length, and a board as

wide and as long as the front side of the brood-chamber was stood on the bottom-board out in front and away from the entrance 4 inches, and then leaned against the hive. When snow falls I only sweep it up over this board and front side of the hive, closing each end between the board and hive with snow, while the rest of the hive is left as it was. In all cases the bees are in chaff hives with a 4-inch thick cushion filled with sawdust over the frames above the quilt. In this way my bees have wintered to please me, except as dead bees sometimes accumulate on the bottom-board to such an extent as to cause the combs to mold; still the most of the old bees go out into the vacant space in front of the entrance to die, yet not all.

To obviate even this occasional trouble, I have this winter made a part of my colonies a rim 1½ inches wide, and as large as the bottom of the hive, which is placed on the bottom, and the hive placed on this; which gives room below the combs for all the dead bees that may accumulate, besides plenty of air. The colonies thus fixed seem to be in the best of condition at this writing, while some not so fixed are getting restless on account of their not having a chance to fly since the five days of last November, and our winter being unusually severe thus far.

Now about bees flying when the snow is on the ground: I find that bees can take wing from the snow as well as from bare ground, provided it is warm enough. The degree of warmth I find necessary for such successful flight is 45° in the shade, providing it is perfectly still and the sun shining brightly. If partly cloudy or the wind blowing lightly, it must be 50° in the shade, or else we suffer loss. With a high wind and cloudy a little loss will occur with it as warm as 57° to 60°. At all times not warm enough for flight the bees remain quiet if fixed as above, providing they are not restless at a temperature of freezing and below. Colonies suffering from the so-called diarrhea are never clustered quietly.

Borodino, © N. Y.

For the American Bee Journal.

Getting Extra Combs for Extracting.

JOHN REY.

In reply to the question, "How shall I proceed to get combs built at the least expense?" I will give the plan that I have been using the last three years. I always save the drone comb when I examine a hive in the apiary, or whenever I find a brood-comb that has any drone comb in it I cut it out and insert worker comb in its place. I do not allow any drone comb in the brood-chamber.

My brood-frames are the Langstroth size, in 10-frame hives; the surplus cases are only half as deep, and hold 7 brood-frames for comb honey, each brood-frame holding four one-pound sections with separator. My extracting combs I work in the same cases,

as they are the same size as the frames that hold the sections. The way I get good, strong extracting combs, I lay the drone comb on a bench, and lay on one of these brood-frames, with a thin-bladed knife cut the comb on the inside of the frame, and the comb will fit in tight. It is hardly necessary to wind a string around it to keep the comb from falling out, as the frame being so shallow, the bees will soon have it fastened to the frame all around, when it forms a strong extracting comb that will last for years.

There is not the least danger of the queen laying in these combs. After they are drawn out they are 2 inches thick, and even thicker; I have had them 3 inches thick. They are nice to uncap. The uncapping knife will reach clear across the comb, it being only $4\frac{1}{4}$ inches deep. The comb is stronger, and it will bear handling better than if it were the full size Langstroth frame; but the best of all is, if you have no reversible extractor, these shallow combs can be reversed *inside* of the extractor, and 8 of them can be put in at one time. Eight of these frames will hold more honey than 4 of the brood-combs.

My experience has been that whenever a case of extracting drone-combs were on a hive they would not build drone comb below in the brood-chamber; even if I put in an empty frame and let them build comb it would always be worker comb. It is natural for them to have drone comb in the hive, and if it is kept directly over the brood-chamber, they will not build it below. Besides, what harm is it if the queen does get up there and lay in the drone comb?

I work on the tiering-up plan. The drones will hatch out in due time, the cells will be filled with honey, and that is just the way I get them started to work in the cases. When I put the first case on a hive, I take a frame from one of the colonies that has brood in the surplus case, and put it in with the case that goes on the next hive. This is what I call a "baiter" or a "decoy," and the bees will go right to work.

East Saginaw, Mich.

For the American Bee Journal.

Northeastern Michigan Convention.

The Northeastern Michigan Bee-Keepers' Association held its fifth annual meeting on Feb. 2, 1887, at Bay City, Mich. After the reports of the Secretary and Treasurer had been read and accepted, and the members had paid their dues, President Taylor read his address.

After the address the following query was asked: "Do bees, by means of their stings, add formic acid to the honey when capping it?"

Dr. L. C. Whiting—I have, for hours, watched bees at work sealing honey in an observatory hive, and never saw any indications that the bees brought their stings into use, either to add formic acid or to use

them as "trowels." I look upon this as another ephemeral illusion. The formic acid in honey is probably a secretion that is added to it while the honey is being handled by the bees.

Dr. C. E. Rulison—I, too, have watched bees for hours, when they were sealing honey, and the work is all done with the mandibles.

INDUCING BEES TO WORK IN SECTIONS

Dr. Rulison—Use shallow brood-nests.

W. Z. Hutchinson—A good flow of honey will start them the quickest of anything; but with me they start much quicker when the sections are filled with empty combs.

President Taylor—With me comb foundation has given more satisfactory results than empty combs.

Dr. Whiting—I once saw 25 colonies very quickly started to work in the sections by raising the cover and the covering over the sections, thus allowing the warm air to pass up through the sections.

W. E. Harris—I thought reversing the brood-combs had settled this problem.

W. Z. Hutchinson—With very shallow combs but little is gained in this respect, as the combs are about as full of brood upon one edge as the other.

Dr. Rulison—The shallower the combs the less the need for inversion.

TEMPERATURE AND MOISTURE.

President Taylor—With the temperature at 40° I believe bees will winter as well, if the air is dry, as they will at a higher temperature but a moist atmosphere.

W. Z. Hutchinson—One of the recent queries in the AMERICAN BEE JOURNAL, asked if the presence of water in a cellar added to the moisture of the air.

Dr. Rulison—I once contended for a dry atmosphere in which to winter bees, and Prof. Cook replied that in the College bee-cellar the water usually was 6 inches deep, yet the bees wintered well.

Dr. Whiting—This all depends upon the relative temperature of the air and water. If the water is warmer than the air, there will be evaporation; if colder than the air, the moisture in the air will condense upon the water. Ice in a cellar will dry the atmosphere.

PREVENTION OF SWARMING.

Dr. Whiting—I had a neighbor that kept his bees from swarming by cutting out queen-cells and slicing off the heads of the drones before they hatched.

W. Z. Hutchinson—Mr. Simmins says that bees will not swarm so long as they have unfinished combs between the brood-nest and the entrances.

Dr. Whiting—In the days of box-hives I knew of a swarm being hived in a tall hive. The first season it built the combs about one-third the way down. The next season it swarmed before the hive was one-half full of combs.

Dr. Rulison—I have tried this method several times, but it is not always a success.

W. Z. Hutchinson—I have never tried the plan, but Mr. Heddon says that the Simmins' method of preventing swarming is a "fallacy." I am sorry to hear so much against the system, for now that "chip" on Dr. Miller's shoulder seems further from my reach than ever.

R. L. Taylor—I have never had any success in repressing swarming.

W. Z. Hutchinson—Unless it was in an out apiary I fail to see benefit in preventing swarming (*i. e.*, of first swarms), unless the harvest was unusually early and short. I have always secured more honey from a colony (and its increase) that swarmed than from one that did not swarm.

Honey-plants were discussed at some length, but the opinion prevailed that their cultivation was unprofitable, unless they furnished something aside from honey. Alsike clover was the favorite, and the furnishing of seed to surrounding farmers was recommended.

Quite a number of instances were mentioned to show the advantage of a space below the combs in winter.

"Old or young bees for winter" was one of the queries that came in for its share of discussion. W. E. Harris preferred to have all the bees hatched before the middle of October; W. Z. Hutchinson agreed with him. He would have them all batched sooner than that, rather than later, and have the bees prepared for winter early. President Taylor had induced late breeding by feeding the bees sugar, yet the bees wintered well.

All agreed that it was better not to unite weak colonies early in the spring.

The following officers were elected: President, R. L. Taylor, Lapeer; Vice-President, John Rey, East Saginaw; Secretary, W. Z. Hutchinson, Rogersville; and Treasurer, Dr. L. C. Whiting, East Saginaw.

The convention adjourned to meet next December, in East Saginaw, Mich., in connection with the Michigan State Bee-Keepers' Association.

W. Z. HUTCHINSON, Sec.

Bees-Legislation, etc.—James Heddon, Dowagiac, Mich., writes:

Dr. Miller has been studying the question of bee-legislation for years, and then was unfair enough to surprise us with its announcement. I did not know there was so much argument on his side; I thought it was all "jug-handle" proposition. I am not sure that any of us can successfully answer his last article, and I shall not try it, and give him the case for the present at least.

Errata.—There was a slip of my pen or the "typo," for I never place any kind of surplus receptacles "under" the brood-nest, and do not advocate it. See my answer to Query, No. 375.

[To change the word *on* to "no" will make the answer read correctly.—Ed.]

Local Convention Directory.

1887. *Time and place of Meeting.*

Mar. 3. 4.—Pan-Handle, at Wheeling, W. Va.
W. L. Kinsey, Sec., Blaine, O.

Mar. 16.—St. Joseph Inter-State, at St. Joseph, Mo.
E. T. Abbott, Sec., St. Joseph, Mo.

☛ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Bees in the Cellar.—Christian Weckesser, Marshalville, ♂ Ohio, on Feb. 16, 1887, says :

Having been very successful in wintering bees in a cellar which opened into a basement kitchen, and on account of a rather neglected condition of the apiary, I placed about one-half of my bees into another vacant cellar the past fall, and expected my usual success. I had no apprehensions in regard to their condition, until the temperature went down, and the nuclei became affected with diarrhea. I at once took them all out, letting them fly for a day or two, and packed a part of them and returned the rest to a better cellar, where, I believe, they are now faring as well as usual.

Proper Spacing of Brood-Combs.—Louis F. Burgess, North Walton, ♂ N. Y., asks :

1. What is the exact depth of the cell in which the pupa-bee is confined for development. 2. What is the exact space between combs that bees will leave on sealing cells, either brood or store? I am after the proper spacing of brood combs from centre to centre, concerning which differing statements have appeared.

[An average of thirteen-thirty-seconds of an inch; the space bees leave between their combs, varies somewhat where they build with no guide except their instincts. This is true of both store and brood combs. As it is best to adopt a system that keeps the combs the same distance apart all the year around, no doubt that distance is $1\frac{3}{8}$ inches from centre to centre.—JAMES HEDDON.]

Bees are Uneasy.—Mr. E. D. Lerch, Leeds Centre, ♂ Wis., writes :

My bees are uneasy, crowding around the entrance, and many come out in the cellar. They have quilts over the hives, and the temperature is from 38° to 42°. There is a good fire in the room above, and the cellar door leading to it is open at night. What is the matter with them?

[The description given is insufficient to determine the cause of the trouble.—ED.]

Feeding and Packing Bees.—A Subscriber desires the following questions answered :

1. When the fall flowers are scarce, so that the bees cannot gather enough honey for winter, and through some unavoidable circumstances they cannot be fed enough before putting them into the cellar, can they be fed at intervals while in the cellar, as a general thing, without injurious results?

2. It is recommended at all times when forest leaves are used, to use either sugar or maple leaves, or beech leaves, to pack bees with for winter. Will not any other kind of leaves do as well to pack bees with as the above-mentioned leaves? Will not any kind of leaves, even fruit-tree leaves, absorb the moisture as well as the maple leaves?

[There is no doubt but that under certain circumstances, with all conditions right, bees may be fed pure cane sugar syrup every day, in a cellar. But why allow such a starved condition to prevail so late in the season? I should use any kind of leaves that were the handiest.—JAMES HEDDON.]

Bees Wintering Well.—Thomas C. Stanley, Boyleston, ♀ Ills., on Feb. 18, 1887, says :

In the fall of 1885 I put into winter quarters 600 colonies, and in the spring of 1886 I had 200 poor colonies left. The past season I increased them to 400, in one way and another, and obtained a surplus of about 3,000 pounds of comb honey. So far this winter I have not lost 5 per cent., and I hope that we have seen the worst here, and that we may now have a successful season or two.

Making Honey-Jumbles.—J. W. Park asks the following question :

How are honey-jumbles made? I have been told that they will get soft in damp weather, and spoil. Is this true? What are they worth? What will the outfit cost to make 10 pounds of honey-jumbles per day?

[Will any one who can, please answer the above questions?—ED.]

Zinc Queen-Excluders.—Jos. Beath, Corning, ♀ Iowa, says :

I work my apiary for extracted honey, and use a frame 12x12 inches, 9 frames to the hive; the top story for surplus is the same size. My queens use, on an average, about $\frac{1}{2}$ of the upper story for brood in the honey season which continues during white clover, and with intermissions until the fall flowers are gone. About what per cent. of surplus would I be likely to gain by using zinc queen-excluders?

[While the zinc queen-excluders may be very convenient, they would not affect the quantity of surplus honey obtained.—ED.]

Bees Storing Rye-Meal, etc.—S. H. Rickard, West Bridgewater, ♂ Pa., on Feb. 19, 1887, writes :

My bees had a good flight yesterday. I have 10 colonies in the upper part of my stable, fixed so that they can fly out and in at will. They carried in quite a lot of rye-meal. I examined them and they had plenty of stores and quite a lot of brood in all stages; some of them had part of three frames filled with brood. The bees out-doors took no meal, but perhaps they are not breeding like those in the stable. I notice that some are agitating bee-legislation. I think that it would be a detriment to nine-tenths of the bee-keepers. Why not "let well enough alone," and not make bad worse?

Sundry Questions.—Jno. E. Heard, Pikeville, ♂ Tenn., asks the following:

1. What quantity of bees in the spring is an average good colony?

2. What is the average fair wages for one to take charge of 150 colonies, spring count, and then produce from 200 to 250 queens for sale?

3. Can old people get spectacles to wear naturally, that will magnify two or three times larger when looking over bee-frames?

[1. That depends upon how early in the spring. Say from ten to thirty thousand.

2. A practical apiarist should command between 50 and 100 per cent. more than the wages given to common laborers.

3. You can get spectacles that will aid you greatly in looking over combs for queens.—JAMES HEDDON.]

Bees Packed in Chaff.—J. O. Munson, Peruville, ♂ N. Y., on Feb. 3, 1887, says :

I put 70 colonies into winter quarters, and they had a good flight about the middle of January; they appeared all right. I winter my bees in chaff hives. I expect a good crop of honey and not a little money next season.

My Advertisement has caused a real rush, so that I have made up my mind that the AMERICAN BEE JOURNAL is an excellent advertising medium, considering the small size of my advertisement. It far exceeds my expectations.—C. W. Dayton, Bradford, Iowa.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Issued every Wednesday by

THOMAS G. NEWMAN & SON,
PROPRIETORS,

923 & 925 WEST MADISON ST., CHICAGO, ILL.
At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12½@13c. Not much call for extracted, and very little for comb.
BEESWAX.—25c. L. A. BURNETT,
Feb. 21. 181 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10@12c.; in 2-lbs., 9@10c.; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8@9½c.; in 2-lbs., 7@7½c. Extracted, California, 5@5½c.; buckwheat, 4@4½c. Supply of comb honey is large, and demand for all kinds is improving.
BEESWAX.—21@23c.
MCCAUL & HILDRETH BROS.,
Jan. 21. 34 Hudson St.

SAN FRANCISCO.

HONEY.—Extracted is firm at 4@4½c., and comb at 8@12c. per lb.
BEESWAX.—19@21c.
Feb. 9. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively.
BEESWAX.—24 cts. per lb.
Feb. 11. BLAKE & RIPLEY, 57 Chatbam Street.

DETROIT.

HONEY.—Few sales are reported. Best white comb, 12½c.; Fall comb honey, 10@11c. Extracted is offered for 6@8c.
BEESWAX.—Firm at 23c.
Feb. 11. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote for extracted, 4@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way.
BEESWAX.—Good demand,—20@22c. per lb. for good to choice yellow.
Jan. 22. C. F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, in 1-lb. sections, sells at 15c.; second quality white, 12c.; dark 1-lb., 9@10c.; white 2-lbs., 11@12c. Extracted, 6c. Market dull.
BEESWAX.—25c.
Feb. 15. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 12@12½c.; 2-lbs., 11@12c. No call for dark. White extracted, in barrels and kegs, 6@6½c.; in small packages, 7@8c.; dark, in barrels and kegs, 5@5½c.
BEESWAX.—25c.
Jan. 19. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8½@11. Extracted, white, 4½@4¾c.; amber and cased, 3¾@4c. Trade is quiet.
Jan. 10. O. B. SMITH & CO., 453 Front St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lb., 8@10c.; white clover 2-lbs., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 6c.; dark, 4@5c.; white sage, 5@5½c.; amber, 4½@5.
BEESWAX.—20@23c.
Jan. 13. CLEMONS, CLOON & CO., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 3½@4½c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4½@5c.; in cans, 5@5c. Market dull.
BEESWAX.—Firm at 21c. for prime.
Feb. 3. D. G. TUTT & CO., Commercial St.

By Using the Binder made expressly for this **BEE JOURNAL**, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Sample Copies of the **BEE JOURNAL** will be sent **FREE** upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free.
52A40t

THE "BOSS" ONE-PIECE SECTIONS.

Patented June 28, 1881.

WHILE attending the North American Bee-Keepers' Convention at Indianapolis, we learned there was a rumor afloat that the Patent on the ONE-PIECE SECTION had been set aside—circulated by unprincipled parties, to mislead bee-keepers. We would say in regard to this, that such is not the case. It is now before the U. S. Supreme Court, at Washington, and will probably be decided before a great while, when we will notify all through the Bee Journal. Until then pay no attention to rumors.

Before ordering write us for prices. We will furnish you Sections as cheap as the cheapest. Let us hear from you before you order. Address,

J. FORNCROOK & CO.,

1Atf Watertown, Wis., Nov. 1, 1886.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. March 9, 1887. No. 10.

The Minnesota Valley Bee-Keepers' Association was formed on Feb. 25, with about 20 members, who are enthusiastic bee keepers.

The February Number of the Bee-Keepers' *Advance* is a great improvement over the initial number. The type is smaller; more taste is displayed in getting it up, and the printing is more creditable. There is still much room for improvement.

Prof. G. G. Groff, of Lewisburg, Pa., is engaged to deliver a course of lectures on apiculture, open to all students, at the Brecknell University in that city, next May and June. This we glean from the annual catalogue of the University, which is on our desk.

A Section Case, to hold 30 one-pound sections, is received from J. W. Powell & Son, of Mankato, Minn. The sections are protected from the bees on all sides, keeping them clean and marketable, by a honey-board with slots to correspond with the openings to the sections. We have before received several with such protections at the bottom of the case, but none with it at the top also, allowing them to be tiered up and still kept from contact with the bees. It is placed in our Museum for the inspection of visitors.

Eastern Oregon may not be very noted for bee-keeping, but a farmer there discovered six pounds of honey in a pumpkin, as will be seen by the following item from an Oregon paper:

In the lower Rock Creek country Mr. Keene has 5 colonies of bees, and he says they did fairly well last year. He raised some large pumpkins in his corn-patch, and some of them got so ripe that they bursted open. He noticed some of his bees making regular trips to one of the pumpkins, and going in and out of a crack in it. He cut the pumpkin open and there found 6 pounds of honey. He says that before going to Oregon he had read much about the advantages of the State, but none of it ever said that he could raise pumpkins and honey on the same vine!

From England we have the following letter from our friend William Carr, Esq., who, during our last visit to England in 1879, was our constant companion. He has been a reader of the AMERICAN BEE JOURNAL for many years, and a faithful friend to Americans. He writes:

MY DEAR MR. NEWMAN:—I wish you could have come over to our Colonial Exhibition last autumn; and seen the rapid strides we had made in bee-keeping since you favored us with your company in 1879.

We made the most we could of your Canadian neighbors during the three months they were with us. They represented the "Ontario Bee-Keepers' Association," and have returned to Canada with \$4,935 which they received for the honey they brought, after deducting the expenses.

They went to see almost everything of interest in all parts of this country, and everything was thrown open to them, and highly delighted were they with their reception. You would see an account in the bee journals of some of the entertainments we gave them, and how they said they were pleased.

If you could only have come, you would have been not only a *New-man*, but a very great man amongst us, as there is nobody we should have rejoiced to honor more than your *kind and genial* self. I often show your photograph to my numerous bee-friends. Wishing you every happiness you can desire, I am Yours very truly,

WILLIAM CARR.

Newton Heath, England, Feb. 14, 1887.

We should have been delighted to have accompanied our Canadian friends; but when we make another visit we may bring a ship-load of honey from the United States, to "sweeten" the trip and "create" a British market for our honey! The 180 tons of American comb honey which was on exhibition and sale when last we visited London, soon vanished, and was as successful, we imagine, financially, as the Canadian shipment of last autumn.

We thank our English friends for the many kindnesses shown to our Canadian brethren—for "we are all Americans, you know!" Give us a chance to reciprocate, by making a visit to America—and we will try to repay the debt with interest.

At the Nebraska Convention Mr. Henry (as was reported on page 119) had burned his bees that were thought to have foul brood. By an oversight, the vote of thanks which followed this announcement, was omitted. This course, the vote stated, "saved the cost of inspection, and danger of the disease spreading." In the third paragraph the word "not" was omitted. It should have read thus:

Mr. Muir said he had *not* found it to pay to ship honey to city markets to be sold on commission.

A letter from Mr. Shier, of Sanilac county, Mich., quite agrees with Mr. Muir. He says he sent 1,200 pounds of nice comb honey to a commission merchant, who was found to be offering it at 8 cents per pound, but could not make a sale.

The Annual Review, by Geo. W. Meade & Co., of San Francisco, Calif., is received. It gives statistics of the crop for last year of dried fruit, raisins, prunes, almonds, walnuts, peacuts and honey. They say that the crop of honey has all been sold, and that the outlook for the future is bright!

Michigan Apiarists Aroused!—The Bill introduced into the Michigan legislature by Mr. McCormick, of Allegan, has thoroughly aroused the apiarists of that State. Mr. Julius Tomlinson, of Allegan, has a letter published in the *Detroit Evening News*, from which we copy as follows:

This Bill, if it should become a law and be enforced, would practically destroy the important industry of bee-keeping in this State. I venture the assertion that there is not one apiary in one hundred in this State, located 25 rods or more from the public highway. In the nature of the business, it cannot be so located. Apiaries must be near the homes of their owners, and they are so, invariably. If I had to go 25 rods to attend to my bees in swarming time, and care for them in other ways, I would be obliged to give up bee-keeping, and so would every other bee-keeper in the State.

I cannot understand the motive for this legislation. Laws should only be enacted on the demand of a general public sentiment. If there has been any demand for this law I have not heard of it. There can be but two valid reasons for this proposed law. One is the protection of the public who use the highway, and the other the protection of homes. In both of the respects it fails. Five colonies of bees near the highway may be as damaging as 50, and I apprehend that should one attack the Hon. Mr. McCormick (as well they might in retaliation for such legislation), he would speedily receive such damage as would convince him that he has made a serious mistake in his little Bill. This Bill would fail equally to protect homes. Bees enter dwellings only to obtain some unprotected sweets which they covet. They roam everywhere, from three to five miles from their hives; 25 rods is no protection at all. Three miles distance at least would be needed.

I trust that the manifest injustice of this Bill will convince the legislature that its enactment would be a grievous mistake.

Catalogues for 1887.—Those on our desk are from

Geo. E. Hilton, Fremont, Mich.—4 pages—Apiarian Supplies.

F. A. Salisbury, Syracuse, N. Y.—24 pages—Apiarian Supplies.

Samuel Cushman, Pawtucket, R. I.—4 pages—Honey.

Wm. W. Cary, Coleraine, Mass.—28 pages—Bees and Apiarian Supplies.

M. S. Roop, successor to A. B. Howe, Council Bluffs, Iowa—20 pages—Bee-Hives and Supplies.

John S. Collins, Moorestown, N. J.—18 pages—Small Fruit Plants and Trees.

J. A. Everitt & Co., Indianapolis, Ind.—48 pages—Vegetable Seeds.

C. W. Costellow, Waterboro, Maine—12 pages—Apiarian Supplies.

M. J. Dickason, Hiawatha, Kans.—16 pages—Bee-Keepers' Supplies.

Levis Roesch, Fredonia, N. Y.—12 pages—Grape Vines, Small Fruit Plants, etc.

M. H. Hunt, Bell Branch, Mich.—12 pages—Bees, Queens, and Bee-Keepers' Supplies.

Thomas G. Newman & Son, Chicago, Ills.—36 pages—Bee-Keepers' Supplies.

F. D. Wellcome, Mechanic Falls, Maine—16 pages—Small Fruit and Bee-Keepers' Supplies.

The First Number of "The Canadian Honey Producer," to be published by E. L. Gould & Co., Brantford, Ont., is on our desk. It contains 24 pages—about one-half of them being very creditably filled with matter of interest to honey-producers; the other pages are devoted to advertising. It has a healthy appearance, and we wish it prosperity. It is edited by R. F. Holtermann, who is known to our readers as a former correspondent to the AMERICAN BEE JOURNAL.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Producing Extracted Honey.

Query, No. 385.—1. Can I get as much extracted honey with a single story hive, as by the tiering-up method, using the Langstroth frame, the bees being Italians and hybrids? 2. How many frames should such a hive hold to work to the best advantage?—Kinney Co., Tex.

Yes, by making the single story so that it will hold 30 or more frames.—G. M. DOOLITTLE.

1. I think you would get more honey by tiering up. 2. I prefer 9 frames to each story.—H. D. CUTTING.

1. Probably you can, if the hive is large enough. 2. Perhaps not less than 15, and more might be better.—C. C. MILLER.

I presume you can, but it is not so convenient as the latter method. With a "long idea" hive I think that I should wish for from 16 to 20 Langstroth combs.—W. Z. HUTCHINSON.

1. While I think you can get fully as much honey from a single-story hive, I prefer to tier up. 2. Eight or 9 frames in double story—12 to 16 in one story for extracted honey.—J. P. H. BROWN.

1. With proper management I think as much extracted honey could be obtained in a single-story hive as in any other. 2. Twenty.—G. L. TINKER.

1. If there is any difference I think it is in favor of the tiering-up method. 2. Mine vary according to the size of the colony, from 20 to 50 frames.—C. W. DAYTON.

No, unless like Mr. Poppleton, you use a 25-frame hive. We prefer the tiering plan with half stories.—DADANT & SON.

I can get the best results by the tiering-up plan. But I have done very well with a hive holding 16 or 18 frames, and extracting as often as the combs are filled. I prefer the tiering plan.—G. W. DEMAREE.

1. Yes; but such hives are not as convenient, do not look as well, and are discarded by us after many years' use. 2. There ought certainly to be 20 frames.—A. J. COOK.

1. I do not think you can, at least I have never been able to do so. 2. About 8 frames in the brood-chamber, and from 8 to 10 in the upper story, depending upon the honey-flow will, I think, give the best results. I use 10 in each story myself, but I think I could perhaps get more honey by the use of only 8 frames below.—J. E. POND.

1. Yes, but not with as little labor and little exposure to robber bees

when they are about. 2. Twenty-four to 30 frames. The tiering system has always eclipsed the "long idea" one-story plan, and I have tried both extensively.—JAMES HEDDON.

1. You may; but to "tier up" is preferable. 2. Twenty.—THE EDITOR.

Prevention of Swarming.

Query, No. 386.—Why cannot swarming be prevented by keeping the brood-nest large enough during the entire season to accommodate the capacity of a queen, according to the following management: the brood-nest to be inverted at the beginning of apple bloom, put on the top storage-room, and so continue to keep plenty of surplus room, and so continue to the above plan, in following described hive with 8 frames: Outside measurement 18 $\frac{1}{2}$ x25 inches; brood-frames, 24x11 inches, closed ends 1 $\frac{1}{4}$ inches, top-bars $\frac{3}{4}$ of an inch; also side storage for about 30 pounds. The bees worked through openings on the end and side. I used the tiering-up system, and obtained 200 pounds of comb honey from one colony so treated, last year, which was double the amount of any other one of 17 colonies which gave one swarm, and whose hive was not tiered up or inverted. By referring to the record of this colony I find that it is 3 years old, and has never swarmed. On April 13, 1886, I inverted the brood-nest and put on a case of 44 one-pound sections, and the bees commenced to work at once in them, being a strong colony.—A. L. ILLS.

"One swallow does not make a summer." We do not believe in reversing, but believe in a large brood-nest.—DADANT & SON.

Very large brood-chambers do not always prevent swarming; but these in connection with inverting, tiering up, etc., go far toward its prevention.—J. P. H. BROWN.

I have had no experience in preventing swarming, aside from after-swarming, unless it be to give plenty of surplus room, shade and ventilation.—W. Z. HUTCHINSON.

Circumstances and locality make a great difference, in many cases. If you succeed so well, keep on with your system, and you will soon find out whether it is the system or the bees.—H. D. CUTTING.

If your plan works well for a term of years, then you can say you are master of the situation. Remember that "one swallow does not make a summer." Nearly double the amount of comb honey you report has been secured from a colony worked on the swarming plan, in a single season.—G. M. DOOLITTLE.

You are just the one to answer the question by actual trial. Try half your colonies this way in 1887, and report your success. A single colony does not prove much, as there is great variation in colonies.—C. C. MILLER.

I am aware that very large hives have a tendency to keep back swarming, but when bees get the swarming fever badly, they will swarm no matter what sort of hive you use. The presence of very old queens in swarming time has more to do with the desire to swarm than does the size of the hive, or perhaps any other cause. I have no faith in inverting hives for any purpose.—G. W. DEMAREE.

Such management ought to prevent swarming, but why not use regular sized fixtures and extend the capacities (for brood and honey) upward in one or more stories. I have used as

high as 6 stories, or 60 frames, and obtained 580 pounds of honey from the colony, so managed.—C. W. DAYTON.

If it works, all right. Some colonies are less given to swarming than are others. Room alone will not always preclude swarming fever. Mr. Simmins says that room in front will. Possibly room and inversion combined may solve the matter. Here is a fine field for good experimental work.—A. J. COOK.

This is purely a theoretical matter, and one that can only be tested practically on a large scale. A large brood-nest tends to discourage swarming. I question very much whether the matter of inverting will affect the matter either way. Bees will swarm unaccountably at times; and then again they will not, and cannot be made to do so. We have much yet to learn in this direction.—J. E. POND.

A colony in such a hive so manipulated and kept well shaded, would be much less apt to swarm, and your results in surplus honey are what my experience would lead me to expect. You bring about many of the same conditions that I do with my new hive. You miss the advantages of "contraction," and I greatly prefer interchanging the parts of the horizontally divisible brood-chamber, to the practice of inverting. There is still left the natural instinct of the bee to re-produce the species, and as yet I do not claim to be able to entirely prevent all issuing of swarms.—JAMES HEDDON.

After repeated trials, you are the most competent person to answer the question.—THE EDITOR.

Shippers vs. Honey-Dealers.

Query, No. 387.—A, (who is a bee-keeper, acknowledged expert and good judge of honey,) orders of B, (who is also a bee-man, and an extensive dealer in honey,) a case of California honey. B obtained the case and ships it to A. A, upon its arrival, examines the honey, and at once concludes it is one-half or nearly all glucose; he writes B to that effect, and refuses to pay for it. B replies that the honey was purchased specially in good faith for A's simple "Ipsé dixit" is something more than A's order, and unless advanced as proof of adulteration, B refuses to accept the return of the honey, and must have the amount paid; at the same time he suggests arbitration.

In such a case as the above, upon whom does the onus of proof of purity lie? And is a honey-dealer at the mercy of any customer who, on examining a shipment of honey, decides (without subjecting to any test whatever) it is adulterated? What course should a dealer adopt on receipt of accusation of adulteration?—Penn.

The *onus probandi* should rest upon A. B's course is correct, and he does wisely in suggesting arbitration.—J. P. H. BROWN.

This is a legal question, not an apicultural one. I should suppose that the accuser must prove his accusation.—W. Z. HUTCHINSON.

This is out of my line of business, but I should say that a chemical analysis should be had to decide the matter.—G. M. DOOLITTLE.

At first B should have satisfied himself as to the purity of the honey. If it is not pure then it should find its way back to the California producer. A should prove by competent judges

that it is adulterated. A honey-dealer is at the mercy of the customer, and the more so when he ships honey a long distance on credit.—C. W. DAYTON.

In this case B is simply a middle man, and should send a bill from the party from whom the honey was obtained. This would be B's voucher that it was California honey. Unless A can prove that the honey is not what he called for, "California honey," he will have to pay for the honey sent. What course should a dealer adopt, would depend upon the parties involved.—H. D. CUTTING.

I should think that B can collect of A without offering any proof, and A must prove the honey impure if he would avoid payment. I do not, however, consider those who answer queries in this department authority in a matter of this kind. We are supposed to answer questions because we have had experience in bee-keeping, and a man, especially a lawyer, who never saw a bee, could answer this question just as well or better than we.—C. C. MILLER.

The burden of proof rests with him who first claims the honey to be adulterated. If nothing more than assertion was needed to justify one in refusing goods, every fickle-minded rogue could use it to very bad purposes. Have the honey analyzed, and then you will know about as much concerning it as you do now; possibly more.—JAMES HEDDON.

Were I A, I should send a sample of the honey to other experts to secure their judgment as to its value and quality. Were I B, I should do the same. Both should be willing to arbitrate. I would never go to law, but would always try to be so fair in dealing that any person with whom I had a difference, would leave the matter to disinterested parties for settlement. Law in such cases is a poor remedy; I guess that we may safely say a "fraud and a delusion."—A. J. COOK.

This is purely a question of law, and as such has no place—at least should in my judgment have none—in this department. Opinions of those others than lawyers or men versed in the law, can but be of little value; and the gratuitous opinion of a lawyer given here, would not be justice to his brothers in the locality of "Penn." If "Penn." will write me personally, I will answer him, however, without charge.—J. E. POND.

B is right. If we had to prove our honey to be pure, every time a fool calls it adulterated, we would have to spend hundreds of dollars in chemical tests, which might be as unreliable as the fool's assertions. We do not believe that there is any adulterated California honey, although some say that they adulterate it in the East. Honey is cheaper now than glucose, especially in California, but some people suspect every one else of being dishonest, and will believe a falsehood sooner than the truth.—DADANT & SON.

When "A" received the case of honey—never having before seen it—

it was proper for him to inspect it, and he might reject it, if it was adulterated, or not what he ordered. If this was not allowed in law, the purchaser at a distance would have no show for his rights. But should B feel aggrieved, believing he had filled the order properly, he would be the plaintiff in his action for his pay, and the rights of the parties would be litigated. Just as long as glucose and sugar syrup is fed to bees we will hear of such cases as this.—G. W. DEMAREE.

It is hardly probable that the honey is adulterated, because it will not pay at the present prices of both honey and glucose. If A claims that the honey is adulterated, he should at least attempt to prove it. Arbitrate it by all means.—THE EDITOR.

Queries Waiting their Turn.

One, whose queries had been waiting for some time, wrote to us a rather "rough" letter, hinting that we were acting unfairly in not letting his queries be answered earlier. To convince him and others that the Queries are on hand, and to prevent a repetition or duplication of the questions (as well as to show the order of publication), we will here print a portion of those now in type, awaiting their turn for publication:

Query, No. 388.—What are the best packages to put up honey in for retail, before it is granulated?—J. G.

Query, No. 389.—In doubling up late swarms or weak colonies, do you think it best to kill the queen of the last bees you put into the hive, or let the bees do it themselves? I suppose we have many queenless colonies.—H. C. G.

Query, No. 390.—1.—What race or strain of bees make the thinnest cell-walls, or use the least wax in comb building, and what use the most? 2. Would you recommend a strain that built heavy combs if you had to ship honey some distance to market?—G.

Query, No. 391.—I use a hive holding 9 frames about the Langstroth capacity. After swarming I wish to reduce the number to 7 frames. Would I secure as much honey by using two dummies, one on each side of the brood-nest with a bee-space all around the dummies, or would it be best to use a close-fitting board, and shut the bees out from passing around them?—Subscriber.

Query, No. 392.—Would it be advisable to make the slots in the sections, so that when two are placed together they will be queen-excluding, and thus save the expense of queen-excluding honey-boards? If not, what would be the objection to this plan?—Ky.

Query, No. 393.—Have we what may be called gentle strains of bees that are the equal, as producers of comb honey, of some of the more ill-tempered varieties? In other words, does ill-temper and extra-working quality exist in bees as inseparable factors?—L.

Query, No. 394.—Having 6 colonies of bees, 4 of which are in box-hives, and all in the cellar (here we put them out in the latter part of April, and wishing to stimulate them for rapid increase, will it be wise or prudent to transfer them when first put out of the cellar, as I do not want them in box-hives?—A. G., Vt.

Query, No. 395.—Is there any successful method of catching swarms as they issue from a hive?—Monticello, N. Y.

Query, No. 396.—In running an apiary for comb honey, desiring no increase, and using the latest improved hives and supers, how many colonies can one man, having a good knowledge of the business, handle so as to bring the best returns for the money invested and the time spent?—J. C., Ills.

Query, No. 397.—1. Would it be advisable to move 30 or 40 colonies of bees 14 miles the latter part of July, on a spring-wagon, in order to get them in a locality where they would work on buckwheat, there being no buckwheat in this locality. 2. What would be the best way to ventilate each hive while moving them?—Pennsylvania.

Query, No. 398.—Is a cross between Caroliniana and Italiana a profitable bee?—H. W.

Query, No. 399.—Is not an unpainted hive both warmer and drier than a painted one, if not permitted to become wet?—H.

Query, No. 400.—1. Will bees work in the sections as well with a bee-space above as with a close cover? 2. Would this prevent the use of so much propolis above the sections?—W. J., Tenn.

Query, No. 401.—Do bees consume more honey when they have an occasional flight, than they do in continued cold weather?—on the summer stands?—Arnold.

Query, No. 402.—What is the best and most feasible method for "building up" colonies in the spring, in time for the white clover honey harvest?—E. B., Ills.

Query 403.—I am troubled about getting bees out of the sections when the latter are filled with honey. I use two-pound, close-top sections. I have to take the sections out of the case and brush the bees off. Can you inform me of any better way?—Wisconsin.

Query 404.—1. Ought the super or case of sections be put on the hive of a swarm at the time of hiving? If not, when? 2. Ought they to be put on the hives of old colonies before the brood-chamber is filled with brood and honey?—E. & W. M., Va.

Query 405.—What is your actual experience in regard to bees tearing down queen-cells when the cells are inverted?—Missouri.

Query 406.—Can you give any reason why bees should swarm in January, leaving honey and brood in their hives, also queen-cells and a few bees? The day they swarmed it was very pleasant, and the sun was shining.—Louisiana.

Query 407.—Recently I was skulking a steer that had choked to death, when I saw several bees eagerly sip the blood as it flowed from the several veins. 1. Did any one ever notice bees do this before, and at what season of the year? 2. Can you suggest any reason for their gathering blood, as plenty of water was near them?—Mo.

Query 408.—I use an 8 frame Langstroth hive; if I change to one having 10 frames, will I get fewer and larger swarms? Will I get more comb honey?—Y., Maryland.

Query 409.—Suppose an earth-roofed cave, half under and half above ground, frost-proof, well drained, well sub-earth ventilated, containing a trough holding 2 barrels of water, into which, and from which, by a sub-earth pipe passes 4 or 5 barrels of fresh water every morning and evening, from a well (the temperature of which water is 45 degrees Fahr.). 1. Would such a cave be a good winter repository for bees? 2. Will the trough of water be a benefit or an injury to the bees? 3. How many colonies will be safe in such a cave, the dimensions being 10x15 feet, and an average of 6 feet high?—S., Central Ills.

Query 410.—Is it essential to extract from the brood-chamber in the production of comb honey?—T. P., Va.

Query 411.—All other conditions being equal, how much more comb honey will one colony of 50 colonies of bees store in brood-frames than in one-pound sections?—Ohio.

Query 412.—Mr. A. wants to try wintering his bees in his cellar, which communicates, by a stairway, with the kitchen above. 1. Will it be in any way a detriment to the health of his family to have his bees in the cellar? 2. How large a room must be partitioned off for 30 colonies? 3. Will it be any benefit to whitewash the room before putting in the bees?—H. D. S., Pa.

Query 413.—Will bees winter better on old than on new combs?

Query 414.—How many frames of the Gallup size would be best for producing comb honey, where the honey harvest continues from the last of May until the last of July, with generally a fall crop?—B., Iowa.

Query 415.—1. Can extracted honey be put on the market as high and delicate a flavor as comb honey of the same kind? 2. If so, give the best method of securing and handling the same?—N. J.

Query 416.—1. When the standard Langstroth hive is used for producing extracted honey, is it best to use full-depth second-stories or shallow supers on the tiering-up plan? 2. How deep should the frames for the latter be? 3. What thickness should the top and bottom bars be to prevent sagging?—New Jersey.

Sections Filled with Comb.

C. H. DIBBERN.

In 1884 I wrote an article in the BEE JOURNAL strongly condemning the use of sections filled with combs from the year before, expecting to stir up a "hornet's nest;" but beyond receiving a card of thanks from several prominent bee-keepers, little more was said about it, at the time. When in recent numbers of the BEE JOURNAL I found such bee-keepers as Messrs. Doolittle and Thielmann, and Mrs. Harrison, still advocating a policy that had proved so objectionable to me, I concluded to write again. I am very glad Mr. Doolittle has finally concluded to knock this "chip" off my shoulder. I am both interested and aroused, after reading his criticisms on page 37.

Many years ago—perhaps following the advice of Mr. Doolittle, who claimed, I believe, that combs saved from years before were worth their weight in gold—I carefully saved all sections or boxes containing comb, as well as every particle of comb that could be used for surplus boxes or sections. As this was before the advent of good comb foundation, this was perhaps the best that could be done then. When I began to use sections and foundation I continued the same course, saving every section that contained comb that was at all fit to use. I soon noticed, however, that there was a marked difference between sections that contained the combs, and those filled with the Dadant thin foundation, after the bees had finished them, although side by side on the same hive. Those that had contained the empty comb would almost invariably grade "No. 2," while the honey in new sections built on foundation was just "too nice for anything," and would just as surely grade "extra No. 1."

Nor was the above the only difference, for I found that after these sections of honey built from old comb, had been on the racks a month or two, they would show a sweaty appearance with indications of souring, such as bulging off the caps, and the honey running out. This disappointed and disgusted me greatly. The room was as dry as could be, and I also noted that the sections with foundation were in perfect condition. Of course when I came to crating the honey for market, a re-grading would be necessary, and much of my "No. 2" comb-filled sections would now go into "No. 3," while some even had to be extracted to save it, and the empty

combs would again be carefully saved; for had not Mrs. Harrison said they were worth \$5 per pound?

I had this experience eight or ten years ago, and it puzzled me greatly. Still thinking that so great a bee-keeper as Mr. Doolittle could not possibly be wrong, I concluded that the fault must be mine, in removing the honey too soon after it was capped by the bees; and I then tried leaving it on the hives two or three weeks after it was finished. Of course this was objectionable in several ways, but I could see no other way out of the difficulty. I soon found that the bees themselves had trouble with it from souring, and were removing great patches of it after it had been sealed, and I was obliged to leave many sections until fall, when I had a kind of speckled honey.

Still not willing to "cut out the old combs and burn up the sections," I continued to save the best, and used them to some extent; even last year, although very dry, the result was little better.

I do not put on surplus cases until the honey-locust blooms, which with us is the commencement of the white honey harvest. I care little for fruit-blossom honey, as it is rather dark, and it is then too early to greatly increase the bee-space. I have no trouble whatever in getting the bees to take possession of the sections at once. Now, if Mr. Doolittle cannot get his bees into the surplus arrangement, without all the pattering and coaxing described by him, I would advise him to change his hives at once, or procure bees that have some "get up" to them.

Now let us examine the expense account, of which Mr. D. tries to make so much. Good white-wood two-pound sections can be had for about $\frac{1}{2}$ cent each; and the wax in the comb in a well-filled section to be cut out, will buy a nice sheet of comb foundation, so that the actual loss is only $\frac{1}{2}$ cent for each section burned. On the other hand I have a nice section of No. 1 honey, that I can sell more easily, give better satisfaction, and sell for 2 cents per pound more than the sections produced on the Doolittle plan.

I naturally conclude that I am more than $1\frac{1}{2}$ cents per pound better off; that I am not "throwing away my money at the birds;" nor that my family is likely "to come to want" by pursuing such a course. I do not advise burning all the sections; if any are nice and clean they may be used again, after cutting out the combs; but if Mr. D. can make any money scraping propolis glazed, honey-be-smear sections, his time must indeed be of little value.

I consider this subject of vital importance to producers of comb honey. I have reasons for my conclusions, which I have not the space to give now. I want all bee-keepers to produce the very best honey in the most marketable shape, and that cannot be done by using old sections filled with comb.

Milan, Ills.

For the American Bee Journal.

Forced Respiration, Bee-Legislation, etc.

G. W. DEMAREE.

Dr. Tinker's reply to my article, found on page 808 of the BEE JOURNAL for 1886, presents views so nearly in accord with my own observations that I would feel inclined to let the matter rest, so far as he and I are concerned, if he had not attempted to support that monstrous error about bees "exercising" to "warm up" when suffering from low temperature. The Doctor admits that bees do not "kick up their heels, or get on a tear," but he would have us believe that they "blow!" That is, when they wish to "warm up" they "simply begin a forced respiration, the opposing force coming from the effect of low temperature." Amazing philosophy! The fact is, a rising temperature outside of the hive is the only "force" that bees can utilize to raise the temperature in the hive, or "warm up," as the Doctor puts it. The "opposing force" to the respiration of the bees must be warmer air than that with which they are surrounded while they are clustered under a temperature too low for their safety, for an unlimited time. This fact alone explains why it is that a cellar kept at a low temperature for a great while becomes a very sepulcher to the bees.

What Dr. Tinker brings forward as evidence is the very opposite of the facts so well understood in connection with all warm-blooded animals. "Forced" or involuntary "respiration" is nature's own method of lowering the temperature of the animal body; the "opposing force" coming from the effects of cool air drawn in, and expelled from the lungs by force of respiration. Bees, as well as all warm-blooded animals respire (or "pant" as we sometimes say) with forced rapidity when "over heated," but never when they are oppressed with low temperature. The reason that I can winter my bees in single-walled hives without any loss, if the bees have plenty of stores, is because we have intervals of warmer weather which rouses the bees from their confinement in the cluster, and enables them to take food and recuperate strength for the next cold snap, and so on through the winter, until returning spring calls them to active labor.

I once thought that because bees store food for winter, and because they would starve if their stores failed, that the bees must continue active at all times. But later observation has changed my views on this subject. I have found that during very cold spells of weather my bees in single-walled hives appear like dead bees between the combs, and when the temperature begins to rise, the bees gradually feel the effects, and arouse themselves in proportion to the rising temperature. These are literal facts drawn from ocular demonstration, and are destructive of Dr. T's theory.

Bees in a cellar are in an artificial condition, and that they should remain active, or "rouse up" to take food in a temperature suitable to that condition, is not strange. It does not prove anything to the point in the present discussion. Dr. Tinker has, in his articles, brought out more interesting facts concerning the winter condition of bees than any other whose writings I have read, and therefore I was surprised to see him support—even in a modified form—the error that bees resort to "exercise" to oppose the effects of falling temperature. It is strange that Dr. T. has failed to see that this error was invented to bolster up the "pollen theory," which Dr. T. as well as myself rejected all the while.

Before closing this article I wish to call attention to some practical matters which seem to be engaging the minds of bee-keepers just now. First, in regard to low prices for honey: Past experience of other producers ought to satisfy honey producers that no good can be derived from "organization," or any other scheme in the hands of producers, to "force up" the price of their products. "Supply and demand" must ultimately prevail over all schemes. Looking at the matter as I do, we have arrived at no crisis yet. There can be no real "glut" as long as the honey market is undeveloped. It seems to me that any person of ordinary forethought should have been able to see that production of honey is likely to "out run" the development of the market. This is the only trouble now.

There is much to hold up the drooping spirits of honey producers yet. Our honey market is undeveloped—there can be no real "glut" as long as this state of things exist. "The way out" is to develop the honey market, and this must be done by individual effort. Work up a demand for honey in every corner of the country, and the "crisis" will be pushed a long ways ahead.

Another point of practical interest is "legislation," to define the rights of bee-keepers. By what authority this could be done, no one has ventured to say, though some one has intimated that the Congress of the United States might look after the matter as to whether my neighbor B or myself should yield the right to pasture the lands of the farmers of this vicinity with our bees. But we are not informed as to where the law may be found giving to Congress of the United States the right to regulate the "domestic" affairs of the States.

But to be serious, from what source could any law-making power get the authority to pass and enforce a law to prevent any man from keeping bees on his own premises? Of course this would have to be done in fact or in effect to carry out any measure settling a question of "priority of location." My "location" is my lands, and by the right of occupancy I keep my bees on my own premises. This simple statement of fact makes interference impossible. If bee-keepers will be so inconsiderate and unwise

as to crowd any one vicinity with bees until they become unprofitable, the law of success and failure will have to work out the problem just like any other business.

As to the question of "nuisance:" To ask the question, as many have done, "Is bee-keeping a nuisance?" is "kicking before they are spurred." Bee-keeping is an agricultural pursuit, and has the same protection under law that other branches of agriculture enjoys. But it should be borne in mind that the "live stock" handled by the bee-keepers is not so easily governed as some other species of live stock are, and for this reason the bee-keeper must practice extra care if he would keep out of trouble. Society is necessarily a compromise, and a nuisance law is absolutely necessary for the man who "won't budge an inch."

Christiansburg, 8 Ky.

For the American Bee Journal.

Eastern Iowa and W. Ills. Convention.

The Eastern Iowa and Western Illinois Bee-keepers' Association held its fifth annual convention in Moore's Hall, Davenport, Iowa, on Feb. 23 and 24, 1887. The meeting was called to order by President Geo. L. Gast.

Communications were read from H. Chapman, in relation to the "Chapman honey-plant," and from N. N. Betsinger, in reference to a "wire separator."

Mr. Jacobs stated how he had disposed of his own and the crop of honey of several of the members present, by traveling through the North and West, showing the superior shape in which his honey was produced; in this manner he sold about 22,000 pounds, all of which was delivered with little or no breakage. Mr. Jacobs prefers one-pound boxes for shipping, and is very enthusiastic over the way our honey compared with that of California, both as to flavor and neatness of packages.

After discussing the question, "Do bees puncture grapes?" the following resolution was read and unanimously adopted:

"WHEREAS, Difficulty has arisen between certain parties—bee-keepers and grape growers—as to bees puncturing grapes; therefore, be it

Resolved, By this convention, which is composed largely of grape growers, that in the past experience of grape-growers and bee-keepers, members of this convention, that we have not in a single instance found grapes worked upon by bees, unless first punctured by birds or insects."

The reports of last years' honey crop was taken, and 23 members reported 1,113 colonies, spring count, and 116,887 pounds of honey; also 413 pounds of wax.

In an address by the President, on the prospect for the white clover, he gave it as his opinion that as the winter has been very favorable, we have a good chance for a crop, but not one-half that of last year, from the fact of last summer being so unusually

dry, that the new seed had had very little chance to germinate; but he consolingly added that we may have a good fall crop.

Officers were elected for the ensuing year as follows: President, Geo. L. Gast, Le Claire, Iowa; Vice-President, J. E. Hunter, Wyoming, Iowa; Secretary, H. S. Dibbern, Milan, Ills.; and Treasurer, Miss Kate E. Case, of Davenport.

The convention adjourned until the third Wednesday and Thursday of February, 1888.

H. S. DIBBERN, Sec.

For the American Bee Journal.

Legislation for Bee-Keepers.

DR. C. C. MILLER.

On page 794 of the AMERICAN BEE JOURNAL for 1886, Mr. W. H. Osborne presents his views, and, as I understand it, from the stand-point of a member of the legal fraternity. He makes a change in the programme by touching lightly on the "desirability," and discussing the "feasibility" of legislation. To tell the plain truth, I do not at all feel sure of the feasibility, but I think the desirability so great that it is worth while to talk about it a good deal to find out if there is no way by which the thing can be brought about. But let me ask why does Mr. O., like several others, insist upon making priority of location an integral part of the subject under inquiry?

Referring to the minutes of the Indianapolis Convention, we find the thing to be inquired into was "the desirability and feasibility of securing such legislation as will give a bee-keeper an exclusive right to keep bees in a certain territory." Now is there any "priority" in that? I do not see why any should refer to it at all, excepting Mr. Heddon, and he very properly refers to it because he takes the ground that priority of location gives a man such advantage that he needs no legislation. Let us therefore leave priority out of the question.

In a nutshell, the matter looks to me something like this: The bee-keeper, like the farmer, cannot prosecute his business without occupying a certain amount of territory. It is for the general good that the nectar be gathered, just as it is for the general good that the ground be cultivated, and that this be done it is for the general good that each man, bee-keeper as well as farmer, have his own portion assigned to him so that there be no conflict. Take the cattle-grazing plains where cattle are running on free grass. For a time it may be well enough that there shall be no ownership of land, but will it not be the best way to have the land divided up and each man own his own territory? Does not the same thing apply to bee-keeping? As Mr. Osborne makes no objection to the desirability, only that priority right is undesirable, and as the priority right business need not necessarily

enter the question at all, we can have no discussion upon that point.

As I before said, I am not so certain about the feasibility, but I am quite anxious to believe in it, and, lawyer though Mr. O. is, there is a certain tone of candor about his article that makes me hope that he will listen with good-natured patience to one who differs from his views, even if he is entirely ignorant of Coke and Little—is it *ton* or *john*?

Mr. Osborne thinks that it would not do to use the license plan, and I think I agree with him; at any rate I think it is not the best plan. How would it do to take the plan I have already hinted at, and let government sell out the territory just as it sold out the soil for cultivation? The first thought may be that the territory has already been sold and cannot be sold over again, but a lawyer will hardly make that objection, for, so far as nectar is concerned, the territory has never been sold, and no land owner, I think, pretends to control it. Besides, the farmer, although in a general sense he owns his place and can do what he pleases with it and on it, really owns it only for certain purposes or uses. He can by no means do exactly as he pleases. For instance, some years ago I bought some hives with movable frames and put them in use. Mr. R. C. Otis called on me and told me they infringed on a patent-right owned by him, and I cheerfully paid him \$10 that I might own the 37 acres that I already had paid for and owned for some other purposes, but for the purpose of using Langstroth hives, the territory up to this time had not belonged to me.

With this plan of buying territory I think Mr. O. will not hold his objection that monopolies would be fostered, for there would be no more monopoly in bee-keeping than in farming, but the same competition.

By the plan I suggest, Mr. O's last objection, you see, will disappear, for Mr. Smith would not pasture his bees on lands of Mr. Jones, but on his own. If the objection is made that Jones owns the nectar that is on his farm, it may be taken from him if it is for the general good just as my land may be taken from me, to be used as a road, and if he is damaged thereby let the damage be paid. But I think it will easily appear that instead of being damaged he is benefited by the visits of the bees.

I think I agree with Mr. Osborne in his closing sentiment, that the well-posted bee-keeper can defy competition (under favorable circumstances), but the fact still remains that under existing laws he may be so encroached upon like Messrs. Heddon and Doolittle, that he may suffer loss therefrom.

And now, if Mr. O. thinks there is nothing unfair about it, I would like to come over on his side for awhile, to say that an objection occurs to me that he has not mentioned. Suppose we consider three miles as far as bees travel, and I own three miles in every direction from my home, putting thereon at my home enough bees to stock the ground. Whoever owns the

territory adjoining mine may put apiaries all around me close up to my territory line, and thus take the greater part of the nectar that I thought was mine. Is there any way out of this difficulty?

Since writing the above, Mr. C. G. Beitel, on page 807 of the AMERICAN BEE JOURNAL for 1886, gives us another legal opinion, and thinks that in Pennsylvania class legislation would not do. Now, in the part of Pennsylvania where I was born and where I spent many happy days, class legislation was and still is very popular, if you call it class legislation for a farmer to purchase and own his own farm. And just that same kind of legislation I think is needed for the bee-keeper. Why does Mr. Beitel, too, assume that priority of location has anything to do with legislation?

And now, on page 9, Mr. J. R. Roebuck desires legislation against cider-mills. I have had full benefit of cider-mills and sorghum mills, and wish they were away, but I do not think it would be a good plan to ask for any legislation concerning them.

The Use of Comb Foundation, etc.

W. Z. HUTCHINSON.

It is evident that those who oppose the non-use of full sheets of foundation in the brood-nest when hiving swarms do not fully understand my position.

On page 120, Mr. Cates says: "If it should be a good season they (the bees of a swarm hived upon empty frames) will just about fill the brood-chamber of a Langstroth hive. When hived upon combs or foundation each colony would store from 40 to 60 pounds of fine honey, and leave plenty in the brood-chamber for winter."

If a very large brood apartment is used, a good share of it is virtually devoted to the storing of surplus, and I have always advocated the furnishing of the surplus apartment with foundation or drawn combs. When I hive a swarm upon empty frames, or rather upon frames furnished with starters only, the brood-nest is contracted so that some of the bees must work in the sections, which are taken from the old hive and contain combs in all stages of growth. By this method I have always secured more honey than when full sheets of foundation or combs were used in the brood-nest.

Doubtless all would be glad to save the expense of foundation, and secure more honey besides; but it seems difficult to fully explain, in a few short articles scattered through the different bee-papers, so that every one will comprehend all the points that have a bearing upon this problem; and, at the suggestion of Mr. A. I. Root, I have written a book upon the subject, in which I have also touched briefly upon some other important points connected with the profitable production of comb honey.

The book is now in press, and as soon as it is published, the price and other particulars will be stated.

CAPPINGS OVER HONEY.

I would say to Mr. C. P. Dadant, that the probable reason why honey in sealed cells does not candy, and does candy in unsealed cells, is because the latter has no protection, while the former has, although the protection may not be absolutely impervious. There is also another point: Unsealed honey may not be so thoroughly ripened as sealed honey, and the more completely that honey is ripened the slower it is to candy.

If the cappings over honey are absolutely impervious. I do not understand how the honey can so increase in bulk as to ooze from the cells, as it does when we say that it "sweats."

Rogersville, δ Mich.

For the American Bee Journal.

How to Prevent Swarming.

B. F. WOODCOCK.

I have now read three reports of enormous crops of honey without any increase; others say, "I allow no increase." One man with over 150 colonies, spring count, reports the best flow of honey he ever saw, and then closes with great complacency, saying, "I allowed no increase." Will some of the brethren please tell us just how to do this thing during a copious flow of honey?

I started last spring with 69 colonies, and secured 3,450 pounds of honey, about three-fifths being comb. I wanted but little increase, but I got over 50 swarms, all the same. Yes, in spite of tiering up, ventilating, cutting out queen-cells, hiving back and driving back, out they came pell-mell, helter-skelter! My increase was 50 colonies, but how many swarms issued I do not pretend to say. I put two and three swarms together, or they put themselves together, more properly speaking. One day I had 11 swarms in about 60 minutes; while three were in the air, my assistant (a little boy 12 years old) cried out: "Here comes another one!" "Yes, and by the way, look at No. 26 kicking each other out."

When I hived a swarm back, and cut out queen-cells, they often took the sulks and would not work even when I gave them more surplus room than they could occupy. I killed the queen in several instances, and cut out queen-cells after 8 days, and yet they would not work.

I can control swarming to a very great extent by tiering rapidly and giving room a little before they need it, but imperfectly filled sections has been the result with me every time. How to prevent swarming, and at the same time sacrifice neither the quantity nor the quality, or rather the perfect finish of our honey, is with me a vital question at this time, and I will ever hold in grateful remembrance the one who shall tell me how to do it.

Pleasantville, δ Iowa.

For the American Bee Journal.

The Wisconsin State Convention.

The Wisconsin State Bee-Keepers' Association met at Madison, Wis., on Feb. 3, 1887, with some 60 bee-keepers in attendance.

The first subject introduced was, "How to sell honey?" upon which Mr. E. A. Morgan, of Columbus, read an essay. He recommended selling comb honey to grocery men by commercial travelers, in a manner similar to that in which other goods are sold. He advocated selling extracted honey in 5 and 10 pound pails direct to consumers, and for this purpose going around among consumers once a month. He took strong grounds against shipping to commission men on account of their unreliability. The discussion of this subject suggested that we should not assert granulation as a test of purity, for some kinds of honey do not always granulate. Wild bergamot honey and honey-dew were said to be of this class.

An essay on "How shall we increase our profits?" was presented by Mr. Frank Minnich, who made the following recommendations:

1. An isolated place with plenty of honey-producing plants.
2. Cheap, convenient hives.
3. Not too many bee-spaces for the bees to fill with "mountains" of wax to climb over in reaching the sections.
4. Plenty of bees in the hive.
5. Small starters, that consumers may not object to the wax-centres in the comb.
6. Tiering up sections.

The statistics of bee-keepers present, so far as collected, showed 1,866 colonies, spring count; 3,039, fall count; 41,450 pounds of comb honey, and 144,412 pounds of extracted. The average yield per colony, spring count, was 99 pounds, of which about 28 per cent. was comb honey. The amount on hand yet was 10,440, being about 6 per cent. of the crop produced.

AFTERNOON SESSION.

President C. A. Hatch read his annual address, after which Frank McNay gave a talk on "Surplus receptacles." He recommended shallow frames with separators for holding sections; also favored cases for holding sections, giving the bees but a few at first, and increasing the number as the colonies became strong and the honey flow increased.

Mr. Gammon and a few others prefer to dispense with separators, but the majority favored their use.

Dr. Vance read an essay on "The value and uses of honey—its adaptation to the human system," which will be useful if published hereafter.

Hon. George Grimm being introduced, made a few very pleasant remarks, after which he was questioned upon the subject of "Wintering bees." He said that if other conditions are all right, a cellar may be either wet or dry. Pure food, a slight upward ventilation of the hive, strong colonies, and a proper temperature are the most important conditions.

"What causes swarms to issue late in the fall?" Mr. Grimm said that it

is sometimes caused by the bees superseding their queens. Mr. Robinson said that buckwheat blooming late sometimes causes it.

Mr. E. France read an essay on "Controlling increase." He extracts once a week, destroys queen-cells if any are started, and divides the strongest colonies by taking two frames of brood with adhering bees, to form new colonies.

EVENING SESSION.

The evening meeting was a very pleasant one. The principal subject discussed was "Marketing Honey," upon which nearly every one had something to say. Dr. Vance, Rev. H. A. Winter and others advised the distribution of small tracts or leaflets calling attention to the purity, excellence and cheapness of honey as an article of food. Mr. Winter recommended peddling it near home, and showing it from house to house. Mr. Wilcox approved of peddling, provided it should not be peddled at the same price at which it is sold to retailers. If we sell small packages to neighbors at the same price that we sell it to grocery men, we shall soon destroy their retail trade.

The convention did not think that a honey-producers' association for the purpose of fixing, controlling or regulating prices of honey could ever be made practicable.

The following officers were elected: President, C. A. Hatch; 1st Vice-President, H. A. Winter; 2nd Vice-President, George Grimm; Secretary, F. Wilcox; and Treasurer, M. J. Plumb.

The convention then adjourned to meet at the call of the President, in February, 1888. F. WILCOX, Sec.

For the American Bee Journal.

Moving Bees before Wintering.

THOMAS STOKES.

The queries during the past year have been a volume of knowledge, but none of them more opportune than No. 315, where the question is asked if bees would be as likely to winter well hauled 80 rods, or be picked up and carried right into the cellar.

As I was to move to another place in the spring, I thought it best to dig a cellar and over it build a workshop, and move the bees into it where they would be ready in the spring. There is no cellar here fit for bees, and for three years I have wintered them in clamps; but in this cold climate of such severe changes, as we have several times through the winter when the mercury will go down from about freezing to from 10° to 20° below zero by morning, it is too much for anything but an underground repository, and have them in first-class condition in the spring.

On Nov. 17 it was mild in the morning, and the ground was thawed about an inch in depth. I drew them up in a light wagon, taking the 48 colonies in five loads, having first securely fastened them in their hives. In the evening I took a lantern, opened all

the hive-entrances, and the bees came rushing out, but very few flew. After opening all the entrances I darkened the lantern and waited awhile; on nearly all the hives they were hanging out in front similar to the way they do on a hot day in the summer.

A few evenings afterwards I went in again and found they had returned to the hives, but a few of the most populous were uneasy. The temperature was 47°, so I left the ventilator wide open and let it cool down to 40°, when they were all quiet. It still keeps at that temperature with the ventilator closed by filling with peastraw, although we have had much severe cold weather.

A few days ago I was in the cellar and they were all quiet, with very few dead bees scattered over the cellar bottom. So it appears the shaking did no harm in this case.

Minesing, Ont.

For the American Bee Journal.

Combinations for Honey-Producers.

J. M. HICKS.

On page 106 Mr. Jno. A. Buchanan has given us something of practical value. It seems to me, from a long experience, that as a rule all combinations and unions have proved to be of very little value to the masses, but often a bonanza to a few at the expense of the many.

We also find that for several years past the quotations of honey (not glucose) has been very low by the various commission men in many cities, and especially in Cincinnati and Chicago; while at the same time I was retailing honey of my own production at 20 cents per pound for extracted, and 25 cents per pound for comb honey. I have disposed of my 1886 crop of 4,000 pounds at 20 cts. per pound, all of which has been sold direct to the consumer, and not a pound went into a grocery-store or to a commission merchant.

I have long since found that it takes industry to produce as well as sell honey at a paying price. The value of industry is not very much known by our commission merchants, except at the expense of the producer; hence every producer should be his own salesman, provided he always desires good returns.

It does seem to me, viewing it from a practical stand-point, that we as a class of honey producers cannot afford to form an organization for the purposes as stated by Mr. Baldridge, to fix a price for honey. It seems to me to be more like a gambling scheme, and should not be tolerated by the honey-producers. But as remarked by Mr. Buchanan, I prefer to control and sell my honey, when I have it, direct to those of my immediate vicinity who know me and desire a pure article; not to sell at an exorbitant, but at a fair living price to the producer. I have now been in my present location for over 15 years, and I have never sold a pound of honey for less than 20 cents.

Battle Ground, Ind.

For the American Bee Journal.

Priority of Location and Inventions.

O. M. ALVES.

I wish to enter a protest against certain views held by correspondents of the BEE JOURNAL. Mr. Heddon thinks that the claims of "priority of location" are right in morals, but doubts whether legislative bodies could be induced to enact a law for the enforcement of the same.

Dr. Miller not only accepts the principle as right, but goes further, and gives it as his opinion that it would be practicable to make it statutory. I hardly think it necessary to debate the Doctor's latter opinion, for the reason that I think few could be found who would agree with him. I wish, however, to examine the subject with no reference to legislation. The claims of the principle rest on acquired property. There can possibly be no other basis. Its advocates will say that it has no legal rights, but that being founded upon morals, it by right should have, even though legislators fail to enact. There is much confusion here, let us attempt to dispel it.

First, upon what principle does property in general rest? Examine any standard treatise on the rights of property; consult any competent jurist, or properly analyze the subject for ourselves, and we will find that it rests upon the power to hold—upon the right of conquest, or upon public policy. Nowhere do we find an ethical principle at the bottom.

In a savage state man acquired property by occupancy or conquest, and held it by superior force. In time, as association and certain forms of civilization began to develop, the association or State said to the occupiers, pay tribute and otherwise obligate yourselves to the State, and the State will by its own power defend you in the enjoyment of your property. This is the basis upon which the rights of property-holders are founded to-day. The guarantee is from public policy, not from ethics.

It must be borne in mind, however, that there are many things neutral as to morals or ethics, but nevertheless proper, being founded in the needs of the existing state of society, and under this head lie the rights of property.

The great confusion of Dr. Miller and Mr. Heddon lies in the fact, that in this view all property is based upon ethical principles, than which there can be no greater misconception. It has been seen from the foregoing upon what property does rest. In the present state of society it is very important that property's established rights should firmly hold, but as men slowly grow less selfish, these demands of property will and are shading down this harshness. While this process is going steadily on (albeit very slowly), we are asked to acknowledge in theory at least, new and harsher views—views that even the oldest common law never contemplated. The demand seems to me almost monstrous in its selfishness.

Mr. Heddon's views on inventions, on page 22, are likewise defective. A man can have no right to an invention save that which organized society gives him, and to hold this right he must use such diligence and such prescribed methods as society requires. When he fulfils these methods, society through its holdings of public policy will give him his inventions, as so much acquired property. When he fails to satisfy these prescribed methods, the same public policy will deny him the acquirement of such property. All this is as it should be.

It is true that a man of delicacy would hardly make use of another's invention, even though unpatented, when the inventor objects. But his declining so to do, cannot be construed as an act of acknowledgement of the other's property, but rather as the concessions of an unselfish man to the demands of a selfish one.

Let us as law-abiding citizens sacredly respect all acknowledged property, but let us not for the sake of a growing nobler humanity, demand new and harsher lines of selfishness.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

The Proposed Michigan Bee-Law.
—Chas Walker, of Bravo, Mich., writes as follows on Feb. 28, 1887:

I have been circulating a remonstrance to the Bill against keeping bees in this State, now before the legislature, and I have the signatures of most of the neighbors of the originator of the Bill, not one refusing to sign it. I have sent it direct to Mr. McCormick, who introduced the Bill, and I hope that if Prof. Cook is in Lansing when this Bill is reached, he will see that justice is done. There has been no trouble with bees in this county (Allegan) that I have ever heard of, and why Mr. McCormick should take the course he has, is quite a mystery to me.

Chaff Hives for Winter, etc.—J. H. Andre, Lockwood, N. Y., on Feb. 21, 1887, says:

Bees have not had a good flight here for over three months. Those on the summer stands will be apt to winter poorly, especially those in chaff hives. I do not see how any one can advise the use of the chaff hives, for to my

mind they are nothing more than refrigerators. They will keep the colony a little warmer during a protracted cold spell, but the cold will get in for all of that, and three or four hours of sunshine will have no effect in warming through the packing; while those in a single-walled hive will get warm enough to partake of food, and will be ready for the cold again. I have tested them in the same yard, and those in a single thickness of wall came through the best. Several of those in chaff hives perished with the cold with plenty of honey and clean combs. Would it not be a good plan where colonies come through weak, and the honey is sour, to put the bees on clean combs and feed? The high price of butter has caused honey to be used as a substitute here, and the crop will be used up cleaner than it has been for years.

Young Bees.—Jno. W. Snuff, Niles, Mich., on March 3, 1887, writes:

I started last spring with 7 colonies, increased them to 18 by natural swarming, and took about 500 pounds of comb honey, which I sold at 10 cents per pound in my home market. The forepart of the season was good, but the latter part was poor on account of the drouth. I put the bees into the cellar about Nov. 20, and took them out for a flight on March 1 and 2. Several of the colonies had young bees almost ready to fly. The temperature of the cellar was at 40° to 50° all winter.

Quiet Bees, etc.—W. H. Miller, Berrien Springs, Mich., on March 1, 1887, says:

I commenced the spring of 1886 with 15 colonies, the most of them being in good condition. I increased them to 51 colonies, and most of them were put into winter quarters in very good condition. I also secured about 650 pounds of comb honey. I have my bees packed out-doors with sawdust, and I think they are doing very well so far, for they are keeping very quiet, and do not spot the hive much when they fly. They have had several chances for a flight since being packed, and I hope they will come out all right.

Wintering Bees, etc.—Alex. Rose, Sullivan, Ills., on Feb. 28, 1887, writes:

I commenced last spring with 31 colonies of bees, increased them to 63. I lost some queens, and some colonies dwindled last fall which left over 50 pounds of fine white clover honey. I sold 11 colonies, 6 died during the winter, 41 have plenty of honey, and 2 are scarce of honey. I am feeding them. They do not seem to be as strong in numbers as at this time last year. I filled the caps with dry hickory leaves, which I shall leave on until warm weather. I believe they will help to keep the brood warm. I shall feed syrup for about 3 or 4 weeks, commencing as soon as the weather gets warm enough to admit of dis-

turbing them. I heard that one man had lost all—5 colonies; another, 3 out of 50. I think that in small apiaries they are half dead. Men who had bees in good condition have lost much less. I am going to use 1-pound sections, 7 in a tier, 4 tiers to the hive, and will tier up as needed.

Using Comb Foundation.—John McKern, Dryden, © N. Y., asks:

Does Mr. Demaree give a swarm full sheets of foundation or only starters, and are those swarms apt to cast other swarms when working for comb honey? I have had swarms in 2-story hives and working for extracted honey with plenty of room, swarm out after they had been to work some time.

[By request Mr. G. W. Demaree replies as follows:—ED.]

My management depends on the the purpose I have in view. If I wish to prevent increase, I put the swarms on half the usual number of standard frames, using only starters in them, and fill up the spaces at the sides of the frames with division-boards cleated on their sides so as to make them stand $\frac{1}{2}$ -inch apart. Over all goes a metal queen-excluder, and on this sets the first "tier" of surplus cases. By this management the whole force of the new colony (swarm) is spent in producing surplus, and comes out as a mere nucleus, and is disposed of as such at the close of the season, either by uniting or letting them play out. If increase is desirable, I have the swarms on full sets of frames filled with foundation, and give the colonies an abundance of room as fast as they need it, practicing the tiering system to supply their wants. If the queens are old there will be danger of swarms issuing, but ordinarily no swarms will issue from new colonies, if the queens are satisfactory to the workers. This influence, or queen condition, gives us the key to the situation.—G. W. DEMAREE.

Good Results.—W. H. Graves, New Carlisle, © Ind., on Feb. 26, 1887, says:

I had 36 colonies, spring count, in 1886, and increased them to 70. They gathered over 2,000 pounds of comb honey in one and two pound sections, which I have sold in my home market for from 9 to 14 cents per pound, mostly for $12\frac{1}{2}$ cents.

Bees Recovering from Diarrhea.—Chas. W. Banker, Menomonee, © Wis., on Feb. 28, 1887, writes:

I put 17 colonies of bees into the cellar about the middle of November, 1886, all in good condition except 2 that were a little light in stores, but had plenty of bees; they seem to be all right as yet. When I put the bees into the cellar the temperature was 45° Fahr., and after the middle of January the mercury dropped to 35° Fahr.; it has ranged from 35° to 38° ever since, and still they are quiet and seemingly in as good condition as

need be, except one colony that I noticed on Jan. 20, had a little touch of diarrhea, but they seem no worse now than they were 10 days after I first noticed them. *Do bees after being attacked with diarrhea ever recover? The colony was very strong in bees, and heavy with stores when I put them into the cellar. My bees are all in 10-frame Simplicity hives, and I put them into the cellar with the covers on, just as they were on the summer stands.

[*Yes, after a cleansing flight.—ED.]

Happy Bees and Bee-Keepers.—Jacob Oswald, Maximo, © O., on Feb. 18, 1887, writes:

I commenced the spring of 1886 with 20 colonies of bees in chaff hives. During the summer I harvested 1,000 pounds of comb honey and increased the number of colonies, by natural swarming, to 35. Last fall my bees gathered a fine lot of honey from buckwheat and fall flowers, and I allowed them to store it all away in the brood-chamber. In November I prepared them for winter on the summer stands in splendid condition. On Jan. 23 they had a regular frolic, and now they are all alive, strong and doing well. I have now as many bees as a novice can handle, and I feel like the boy who caught the bear, "I can't hold it, I can't let it go." The bee-keepers of eastern Ohio are in good spirits, and a good report may be expected from them the coming summer.

Hand-Holes in [Crates, etc.]—J. B., of Iowa, asks the following:

[1. What is the best method of cutting hand-holes in the ends of shipping-crates? 2. Also of making holes in brood-frames for wiring?

1. The usual method is to use a wabbling-saw, that is, a saw unevenly fastened on the saw-arbor; but we use and prefer a cutter-head in place of a saw.

2. Punch the holes with a set of brad-awls operated by a treadle.—ED.]

Bees all Right.—T. F. Bingham, Abronia, © Mich., on March 1, 1887, says:

My bees are in fine condition, both those that are out-doors and those in the cellar. They have not seemed to care whether they had a flight or not, but to-day every bee that desired to do so, had a flight, and are all in good condition.

Honey-Production in California.—J. W. Johnson, McFall © Mo., writes:

On page 118, Mr. Segars, of California, wrote about honey-production in that State, and bewailing the low price of honey, but he forgets that in that country they seldom have any loss of bees, and secure twice as much honey per colony as we do here, while we lose many colonies in win-

tering, and produce much less honey per colony. A man from this place went to Arizona last fall, and when he returned he told me that bees in that Territory produced 300 pounds of honey per colony, and that at no time of the year could they not get enough for their living. Here a bee-keeper must be at the expense of making a cellar, withstand blizzards, and often lose 50 colonies of bees in one winter; so I do not think that a bee-keeper in California ought to grumble at the low price of honey, for he can count on scarcely any loss, and an almost invariable honey crop. As to organizing to uphold prices, I think that such organization would be quite ineffectual—the country is too large for that.

The Need of Frequent Flights.—

Green R. Shirer, Greene, © Iowa, on March 2, 1887, writes:

I examined my bees yesterday and found 4 colonies dead and 3 others nearly so; the rest had a good flight then, and I think they will come through all right. I had 51 colonies in the fall packed in chaff on the summer stands; they nearly all have diarrhea pretty badly. There are signs of a general break-up in the weather, and if our bees can have frequent flights they will be all right.

Frequent Flights for Bees.—D. M. Stoler, Saxton, © Pa., on Feb. 25, 1887, writes:

My bees had their first flight on Jan. 21, completely spotting hives and snow in relieving themselves. We have had five weeks of mild weather since then, bees flying every few days during this time. I saw them working on rotten apples and gathering water. I had to close the hives on Jan. 30 to prevent robbing; also one colony carried out a few dead young bees. I am wintering my bees on the summer stands, with nothing around the hives; some are in Simplicity and some in the Chautauqua double-walled hives. All are doing well so far. Twelve inches of snow fell in 4 hours to-day, with indications for colder weather.

Successful Wintering.—J. W. Sanders, Le Grand, © Iowa, on March 3, 1887, writes:

Our long cold winter is pretty well gone, and at this time, from the reports I get, bees seem to be wintering finely. I have not heard of any signs of bee-diarrhea yet. I put 61 colonies into the cellar, and with one or two exceptions all seem to be doing well; still the next four weeks may make a change. I have kept the temperature of the cellar, by close watching, from 38° to 46° . I believe the great problem in successful wintering is plenty of young bees in the fall; plenty of good honey in store; see that all are prepared late in the season for winter; and a good cellar for wintering, where the temperature is easily kept above 40° , and well supplied with pure air.

BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10¢@12¢; choice, 12¢@13¢. Not much call for extracted, and very little for comb.
BEE SWAX.—25¢. R. A. BURNETT, Feb. 21. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10¢@12¢; in 2-lbs., 9¢@10¢; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8¢@8½¢; in 2-lbs., 7¢@7½¢. Extracted, California, 5¢@5½¢; buckwheat, 4¢@4½¢. Supply of comb honey is large, and demand for all kinds is improving.
BEE SWAX.—21¢@23¢.

MCCAUL & HILDRETH BROS.,
Jan. 21. 34 Hudson St.

SAN FRANCISCO.

HONEY.—Extracted is firm at 4¢@4½¢, and comb at 8¢@12¢, per lb.
BEE SWAX.—19¢@21¢.
Feb. 9. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

Feb. 3. D. G. TUTT & CO., Commercial St.

By Using the Binder made expressly for this **BEE JOURNAL**, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Sample Copies of the **BEE JOURNAL** will be sent **FREE** upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1 00..	
and Gleanings in Bee-Culture.....	2 00..	1 75

A Year Among the Bees.....	1 75..	1 50

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the **BEE JOURNAL**. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the **BEE JOURNAL** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the **Apiary Register** and commence to use it. The prices are reduced, as follows:

- For 50 colonies (120 pages) \$1 00
- " 100 colonies (220 pages) 1 25
- " 200 colonies (420 pages) 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Dr. Miller's Book, "A Year Among the Bees," and the **BEE JOURNAL** for one year, we will club for \$1.50.

There is no mistake in insisting that—as in all other things, so in advertising—the best is the cheapest, no matter what its first cost may be.

The **Western World Guide** and **Hand Book of Useful Information**, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides his own, with \$3.00, for one year, we will present a copy of this valuable book.

ADVERTISEMENTS.

WANTED.—Three live men to work in an Apiary and Nursery. 7Atf. S. I. FREEBORN, Ithaca, Wis.

APIARY FOR SALE

HAVING other interests which claim my attention, I wish to sell my apiary of 138 Colonies, in the village of **Winnebago, Ills.**—7 miles from Rockford, and 100 miles west of Chicago. The location is first-rate, and no other apiary near. The past season, 82 colonies increased to 138, and gave 7,000 lbs. surplus—nearly all white clover, and 4 5 of it comb; 2,300 lbs. sold at home for cash without peddling. Langstroth Hives, with good Combs, Tying-up Section-Cases, Division-Boards and Feeders, Extractor, and good Honey-House. (Rented place of one acre.)

If not disposed of before April, it will be sold at auction.

C. M. HOLLINGSWORTH, 6E3t WINNEBAGO, ILLS.

A NEW HONEY-EXTRACTOR.

THE SIMPLEST and cheapest in the market. No special constructed can or vessel required. Any common molasses or whisky barrel or other suitable vessel at hand will do. It extracts as clean and fast as any other two-frame extractor. It is suitable for American or Langstroth frames, up to 13x20. It weighs only 8 lbs. ready for shipment. Price in the flat, \$2.50; set up, \$2.75. State right to make, use and sell, \$1.00. Date of patent Feb. 9, 1886. Send for circulars to the inventor and manufacturer, **J. C. MELCHER**, 10A6t O'QUINN, Fayette Co., TEXAS.

THE "BOSS" ONE-PIECE SECTIONS.

Patented June 28, 1881.

WHILE attending the North American Bee-Keepers' Convention at Indianapolis, we learned there was a rumor afloat that the Patent on the ONE-PIECE SECTION had been set aside—circulated by unprincipled parties, to mislead bee-keepers. We would say in regard to this, that such is not the case. It is now before the U. S. Supreme Court, at Washington, and will probably be decided before a great while, when we will notify all through the Bee Journal. Until then pay no attention to rumors.

Before ordering write us for prices. We will furnish you Sections as cheap as the cheapest. Let us hear from you before you order. Address,

J. FORNCROOK & CO.,

1A1f Watertown, Wis., Nov. 1, 1886.

THOS. G. NEWMAN & SON, 923 & 925 West Madison Street, CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. March 16, 1887. No. 11.

Rev. Henry Ward Beecher is dead. That he was one of the greatest men of the age, is conceded alike by friends and foes.

The Danish Bee Journal for the year 1886 is received from Mr. Alfred Rusbridge, of Chichester, England, author of "Bee-Keeping; plain and practical; how to make it pay, etc." Articles from this gentleman are translated and run all through the year. It is edited by Hans Ersler, and published at Kalundborg, Denmark.

The Bees have Wintered Well, is the general remark of all apiarists. As we are promised an early spring, if the bees have no serious "set-backs" the crop of honey will be good, and plans will have to be made to place it upon the market in the most desirable manner, and to maintain living prices.

In Florida, says H. G. Burnett, in the Dispatch, bees are swarming, and bringing in honey rapidly from the abundant bloom of the penny-royal, so that extracting is the order of the day. The hives contain about an average of 50 pounds of honey, most of which is sealed over. Prospects are good for an average of 75 to 100 pounds per colony of penny-royal honey. By the time that crop is gathered, the saw-palmetto will open up, and the bees will be kept busy at that until June.

Carelessness in writing seems to be so very prevalent that we desire to call attention to it before another season's business commences. We have to-day (Friday) received a postal card, without name, post-office, county, State, or date, complaining because the writer received no reply to one before sent—which was probably in the same condition. To all let us say be sure to write your name plainly, with postoffice, county and State before sending an order to any for goods.

Another Triumph for the Union.—McCormick's Bill to "wipe apiculture out of Michigan," as Prof. Cook calls it, was tabled on his own motion on the 4th Inst. In addition to the remonstrances from officers of the Michigan Bee-Keepers' Associations, and apiarists generally, we sent him marked copies of the BEE JOURNAL. Prof. Cook, Vice-President of the Bee-Keepers' Union, used his influence, and Mr. Heddon, at Prof. Cook's request, sent him an official letter, as President of the Union, and here is Mr. McCormick's reply:

JAMES HEDDON, *Pres. Bee-Keepers' Union*—DEAR SIR:—Yours, in regard to House Bill 89, is at hand, and in reply I will say that the Bill came up in its regular order, and was, upon my own motion, "laid on the table," and I shall let it die there! I do not wish to injure the bee-interests, or drive them out of the State. Yours, etc.,

JAMES W. MCCORMICK.
Lansing, Mich., March 8, 1887.

"Mr. Heddon says: "In this we again see the use of organization. I think it quite likely that Mr. McCormick introduced the Bill without giving it due thought, to please some disgruntled constituent, and now, upon re-consideration, is as glad to let it die as any of us."

Here we have another example of the benefits to be derived from organization and combined effort. The members of the Bee-Keepers' Union have many triumphs to be proud over, and this adds another laurel.

Bingham's Vinegar Test.—So many have inquired how to make the vinegar test, mentioned on page 118, that we here give Mr. Bingham's method, which will answer all the questions at once:

Take of clean yellow beeswax, one-half ounce, and two ordinary shot, $\frac{1}{8}$ inch in diameter. Warm the wax until it is soft, and put the two "shot" into the centre of the piece of wax, as nearly as convenient. Make the wax into a ball like a marble. Its upper surface will rise to the surface of the vinegar or water containing one pound of honey per gallon—just the amount needed for the best vinegar.

The United States Senate reinstated the special clause for apiculture in the Agricultural Appropriation Bill and passed it, but in conference, in the hurry of the last days of the 49th Congress, the House threw it out again, so apiculture will have to get along again on "short rations" for another year. This is very unfortunate, when so much ought to be done, under Governmental control, for our pursuit during the coming year.

Deaths.—We were made cognizant last month of the loss, by death, of the wives of both Mr. Ira Barber and Mr. F. C. Benedict, two well-known apiarists of this State. They have our heartfelt sympathy. Another who joined the "Great Ranks" was Mr. A. T. Blauvelt, of Blauveltville, N. Y., a veteran bee-keeper and breeder of very fine bees.—*Bee-Keepers' Magazine.*

James Harper, of Mason, Mich., who has been a subscriber to the AMERICAN BEE JOURNAL for 20 years, has just passed to the other shore. His 48 colonies of bees packed in chaff are wintering finely—having recently had a good flight. This information comes from his son.

More Lying.—C. W. McKown, of Knox Co., Ills., has sent to us the Knox County *Republican*, with an article marked, copied from the New York *Mall and Express*. In it some lying penny-a-liner has drawn upon his imagination for writing a "fancy article," which damages the pursuit of bee-keeping. It is headed, "Honey and Comb to Order," and the first paragraph reads thus:

Not only has American enterprise succeeded in manufacturing a honey-comb to save the bees the trouble of furnishing a receptacle for their sweet store, but it even threatens to do away with the services of the industrious little bee, by supplying the honey also. More than one variety of manufactured honey is at present sold in the market, as being the genuine product of the little busy bee. Some of it comes in the form of strained and clarified honey put up in glass jars. More of it is supplied in the comb in small boxes with glass on either side, through which it may be seen, looking as natural as if it had been stolen from the hive.

Such irresponsible falsifying is the more dangerous and despicable, because it will travel by lightning, and be wafted on every breeze—while the truth, as a correction, will limp along like a cripple, and be kicked by every passing crowd.

The wily part played by the originator of that so-called "scientific pleasantry," will cause his name to be execrated by honest persons all the World over. And if he should live a thousand years, and devote all his remaining life to atone for the damage he has already done to an honest pursuit, he would die an infinite debtor to it; for the multiplying tongue of slander and falsehood never can be controlled or made to cease its villainous calumnies! His name will

Go down
To the vile dust from whence he sprang,
Unwept, unhonored, and unsung."

In the Reading matter of their catalogue for 1887, Messrs. J. W. Powell & Son, of Maakato, Minn., remark as follows:

To all who wish to be in the front rank in the art of bee-keeping, we recommend the AMERICAN BEE JOURNAL, published weekly for one dollar a year by Thos. G. Newman & Son, 923 and 925 West Madison Street, Chicago, Ills. The above-named paper is a live, wide-awake journal, and will make a live bee-keeper of any one who will take and read it.

As this was unsolicited and totally unexpected, it is the more valued. Thanks.

Catalogues for 1887.—Those on our desk are from

Thomas B. Blow, Welwyn, Herts, England—60 pages—Bees, Hives, and Honey.

E. T. Flaagan, Belleville, Ills.—8 pages—Bees and Supplies.

Reynolds Bros., Williamsburg, Ind.—16 pages—Bees and Supplies.

E. R. Pierson, Tarrytown, N. Y.—96 pages—Seeds and Plants.

J. M. Hambaugh, Spring, Ills.—10 pages—Apiarian Supplies.

S. D. McLean, Columbia, Tenn.—2 pages—Bees.

E. M. Yeomans, Andover, Conn.—4 pages—Bees.

J. W. Eckman, Richmond, Tex.—4 pages—Bees and Poultry.

There is no Mistake in stating that—as in all other things, so in advertising—the best is the cheapest, no matter what its first cost may be.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Packages for Extracted Honey.

Query, No. 388.—What are the best packages to put up honey in for retail, before it is granulated?—J. G.

Glass-jars, tumblers, or small cans.—J. P. H. BROWN.

For packages (less than a gallon), glass.—JAMES HEDDON.

Probably pint and quart fruit-cans made of flint glass.—G. M. DOOLITTLE.

If the honey is to be allowed to granulate, I know of nothing better than tin pails.—W. Z. HUTCHINSON.

A jar belonging to the consumer. The second best is tumblers and raised-cover pails. The jar usually holds the most, and is emptied soonest.—C. W. DAYTON.

Different markets require different packages, and you must find out by experiment for your own market.—C. C. MILLER.

It depends upon your trade. The low prices make large packages more profitable than heretofore. Hence we would advise small kegs and cans holding from 10 to 50 pounds, although we use 5-pound cans to a very good advantage.—DADANT & SON.

I have used the Muth glass jars, 1 and 2 pounds; the objection is that they cost too much. Tin packages are cheaper, but do not sell the honey like the glass jars do. Glass packages for the retail trade are best, if we can get them cheap enough.—G. W. DEMAREE.

It will depend upon your market. Find out what the people want, then supply that want. In this locality small glass packages sell best. If you can sell granulated honey in your market, I would advise putting it in tin packages.—H. D. CUTTING.

It depends entirely upon the market. Some useful vessel of small size, which can be tightly sealed, like tin pails or jelly cups, or fruit cans are the best. Some markets prefer Muth jars, but they are of no use after the honey is out.—A. J. COOK.

The best package to put up liquid honey for retail is a glass package that may afterwards be used for other purposes. I saw recently a new sealing cap for glass jars of foreign design, introduced by Mr. James A. Abbott, of London, that must prove very valuable.—G. L. TINKER.

It will depend entirely upon the taste of purchasers. Ascertain the wants and requirements of the market, and follow them. The pound

package is usually the most salable, as it is compact in form, of convenient size for use, and what is of some consequence, reasonable in price. The style of package will depend upon the taste of customers.—J. E. POND.

Glass jars, tin pails or kegs, according to the requirements of your market.—THE EDITOR.

The Best Bees for Comb-Building.

Query, No. 389.—1.—What race or strain of bees make the thinnest cell-walls, or use the least wax in comb building, and what use the most? 2. Would you recommend a strain that built heavy combs if you had to ship honey some distance to market?—G.

I think there is little difference. The blacks use the most wax in capping.—G. M. DOOLITTLE.

I do not know. Some think that black bees make rather thicker caps. Surely their combs are whiter.—A. J. COOK.

I think the claims of this or that variety of the honey-bee for making thin cell-walls is more imaginary than real. All these seeming differences depend more upon the variety and upon the amount of the honey-flow.—J. P. H. BROWN.

I believe the Syrians have the thinnest cappings over the honey, and the blacks the thickest. I would recommend the latter simply for the sake of appearance. In regard to the thickness of the cell-walls I cannot say.—W. Z. HUTCHINSON.

The yellow race of bees use the minimum amount of wax in constructing the combs and capping the honey. The black race uses no more wax in the side-walls than do the yellow bees, but they make it up by piling on the capping; this gives them the reputation for "white honey."—G. W. DEMAREE.

We think the weight of the cell-wall depends especially upon the temperature of the hive, not on the race. Those who tell you that one race builds heavier cells, are not sure of it, they only think so.—DADANT & SON.

Who can tell? Considerable guessing has been done on this subject, but the difference is so slight that it would require a microscopic test to fully determine it. Get the best honey-bees you can find, and do not stop to bother much about the slight difference that might be found in thickness of comb.—J. E. POND.

German bees make the brightest and thinnest combs. They use less wax and make straighter and smoother work. The yellow bees use more wax, make more uneven and darker combs, and while such combs may bear transportation better, they cost more, and do not sell as readily, and any combs can be transported safely if properly crated.—JAMES HEDDON.

1. The Syrians make the most delicate combs. The Carniolans and blacks also make light combs. The Italians use more wax in comb building than any other race. 2. The majority of people prefer combs made so delicate that in eating the wax is

hardly detected. I have seen grades of comb honey that could not be eaten without getting the mouth full of wax. It will no doubt pay the best in the end to produce the lightest combs even if we have to ship far to market.—G. L. TINKER.

The real difference is too slight for a choice.—THE EDITOR.

Doubling up Late Swarms.

Query, No. 390.—In doubling up late swarms or weak colonies, do you think it best to kill the queen of the last bees you put into the hive, or let the bees do it themselves? I suppose we have many queenless colonies.—H. C. G.

Kill the poorest queen.—DADANT & SON.

I never put in but one queen. I prefer to select.—A. J. COOK.

I think I would let the bees do it, unless there was a choice of queens.—C. C. MILLER.

If colonies are to be united in the fall, I should prefer that one had been queenless a few days.—W. Z. HUTCHINSON.

Not unless there is a difference in favor of the former. If such exists, kill the poorer one.—G. M. DOOLITTLE.

Always save and cage the best queen, and destroy the others.—J. P. H. BROWN.

Much depends upon the time of the year and the honey flow. When the bees were gathering rapidly I should let them do the killing.—JAS. HEDDON.

In case of weak colonies I think it best to kill all queens but one, and cage that one between the combs for 48 hours. With swarms having young queens, leave it to the "survival of the fittest." When the swarms have old queens I would cage one for 24 or 48 hours.—C. W. DAYTON.

If the colony receiving the bees has a good queen, I should take away the queen from the other.—H. D. CUTTING.

I always destroy the poorer queen, and then I know that the best one is saved; otherwise it would not be known which was left, as one would be as apt to be killed by the bees as the other, and there is no certainty that both even would not be destroyed by them.—J. E. POND.

I prefer to have all the colonies to be united but one, queenless for at least three days before the work of niting is done. It is not safe as a general rule, to unite colonies when both or all have queens. Sometimes they may be dumped together, queens and all, without serious consequences, but it is a careless way of proceeding.—G. W. DEMAREE.

It is best in all cases in doubling up colonies to kill one queen nine days before doubling up. Then cut out queen-cells and unite. Any other plan will be attended by some loss of bees by fighting, and necessitates the caging of one of the queens, the other to be killed.—G. L. TINKER.

Kill the poorest queen some time previously; and when uniting, cage the other queen.—THE EDITOR.

The Jolly Honey-Bee.

J. F. LATHAM.

Near a sunny wood-side, on a sloping spot,
By a purling streamlet, is my cozy cot;
Where content I labor, joyous, fit and free,
As will a busy, jolly honey-bee.

Sporting in the spring time on the balmy air;
Watching at the portal with a jealous care;
Storink up the pollen from the willow-tree,
As will a busy, jolly honey-bee.

Ere the welcome sunbeams usher in the day,
Or the pearly dew-drops catch the glowing ray;
Humming in the meadow, buzzing o'er the lea,
As will a busy, jolly honey-bee.

Nursing up the broodlings, cleaning out the room,
Cooking down the honey, from the maple bloom;
Dragging out the cripples with a Spartan glee,
As will a busy, jolly honey-bee.

Scouting through the bower, searching in the dell
For the sparkling nectar in the flow'rs'at hell;
Basking in the sun-bine merrily and free,
As will a busy, jolly honey-bee.

When the shades of eve lengthen on the plain,
Or the dark'ning heavens threaten coming rain,
He my journey homeward, from the storm to flee,
As will a laden, jolly honey-bee.

Rushing from the portal, circling in the air,
Pitching in the tree-top, clust'ring—anywhere;
Clinging in a murmur, floating from the sea,
As will a roving, jolly honey-bee.

Storing through the summer with a restless zeal
Treasure for my master, 'neath the pearly seal;
With unerring forethought—winter stores for me,
As a provident, jolly honey-bee.

Bearing home propolis, from the oozing cones;
Closing up the openings, driving out the drones—
Slipping from the aster, in the sunny lea,
As will a busy, jolly honey-bee.

When the frost of autumn, creeping on a main,
Blasts the Solidagos on the fading plain;
In my waxen chamber hugging close and snug,
As will a prudent, jolly honey—"hug."

Through the blasts of winter, in a long repose,
Till returning spring-sun melts away the snows;
And the crimson verdure on the maple tree,
Prompts to her duties—a thankful honey-bee.

Cumberland, Me.

For the American Bee Journal.

Winter Department of Bees.

J. W. BAYARD.

Misfortunes or accidents often develop important truths, that otherwise might remain a mystery for ages. Some 16 years ago, at night thieves carried from my apiary an extra strong and well provisioned colony of bees, which they wrecked in an open field a short distance away, about 6 days having elapsed before I discovered the theft. In the meantime, snow had fallen to a depth of 10 inches, and the temperature was 15° below zero, that being exceptionally cold for this latitude. On reaching the hive and lifting it from the snow, the bees responded with a, "roar," as unexpected as a clap of thunder would have been then. In attempting to adjust some of the broken combs, the bees darted at me and stung me severely on the hands, while others took wing outside, discharging a dark-colored feces on the snow. This was a strange ex-

perience under the circumstances, as I expected that all the bees had perished, or at least would be in a torpid condition.

I at once placed them in a well ventilated, dry cellar, where the temperature never falls below 40°, or rises above 50°. In the meantime I kept watch of their condition with some apprehension as to their outcome. For a time a slight rap with the knuckles on the hive would cause a lively response, when later on they grew fainter and fainter, and at the end of a month every bee in the hive was dead, superinduced by exposure to cold, over-eating and long confinement, resulting in diarrhea in its most odious form.

The above served as a pointer to further investigations among my 40 other colonies wintering on the summer stands. I found on visiting them day or night, with the temperature below zero, that a never-ending "roar" or song would issue from the bees within, indicating great activity and vigorous respiration within the cluster, in order to counteract the encroachments of their most deadly enemy—cold and frost. When a day arrived for a passable flight, all took wing that were able, whilst others, too sick, crawled out on the snow to die. Thus despoiled of their numbers to such a degree when spring finally came I was minus what had been 20 good colonies, with all the other 20 more or less crippled.

Fortunately this condition of things only obtains in exceptionally cold winters, with long-continued depression of temperature. In handling and caring for bees for over 30 years, I hazard nothing in saying that with the above or similar conditions, the same results will be realized in all future time. That a remedy is at hand is also true. It lies in the securing of the conditions of temperature that require of bees the least consumption of food of whatever kind, as well as the minimum amount of respiration and exertion, simply sufficient to counteract the encroachments of cold in our various localities of the North.

For in-door wintering of bees, all late experiments point to 45° as the central idea among advanced apiarists—where bees can ply their natural vocations, consume the least amount of stores, and suffer the minimum of loss. The same will apply to out-door wintering, only the difference of being unable to control the temperature in a degree, by our various methods of packing, and the confusion of ideas on the subject. So, for the present we must take it as it comes.

In close connection with this problem of successful wintering, comes the oft-mooted and much discussed question of hibernation. The very hidden and peculiar condition of a colony of bees during winter, has given rise to a multitude of theories, much speculation, and not a little guess-work. Rev. W. F. Clarke has long since settled the question affirmatively, from his stand-point; Prof. Cook demurs in his scientific and conservative way; whilst Mr. Demaree

and Dr. Tinker have advanced sufficiently to call for new light on the subject, if any shall be forthcoming. Allow me to place this declaration on record: While my investigations may all be superficial, and my deductions all wrong, I do most emphatically deny that bees do ever hibernate, at any time or under any circumstances, from the day a colony first enters a hive until the last bee makes its final exit!

The trouble with apiarists in the past in regard to this question, is that we have been resting the case on theory alone, in preference to getting down to bottom facts. No one, so far as I know, has yet been able to bring to view (in an optical sense) the exact movements or true status of the inside of a cluster of bees during the winter months; whereas the breaking up of the same for the purposes of scrutiny, would only defeat the object in view, with the risk of destroying the colony. The very quiet appearance of the bees forming the cluster or crust thereof, is entirely immaterial as furnishing any clue to the condition of things within. They are simply doing "picket duty," and are within the radius of the heat of the cluster; can change location at will, and take food to assist in keeping up the temperature of the hive at all times. The idea that bees wake up at regular intervals to eat, and then relapse again into sleep, rests not on the shadow of foundation in fact. They eat (not all at once) but promiscuously, at all times, and under all circumstances, more or less; just as nature and the surrounding conditions require them to do. The lower the temperature the more they eat; the stronger the respirations, the louder they sing—until finally the "roar" is distinctly perceptible from the entrance of the hive.

We all know about rapping with our knuckles on the hive, in order to get a response from within, as to life or death. If alive, the response comes quickly; but if no response is made, then the bees are dead, and the sooner they are brushed from the combs the better. The question then arises, can bees respond to a rap on their hive, if asleep, or rather, enjoying a "hibernal period?" If they can, then nature in their case has been very gracious, and left other hibernating insects, as well as animals, sadly in the lurch. For I feel very confident that nothing short of an earthquake could produce a kick from a beetle, or a growl from a wood-chuck. Surely, then, there is an apology due somewhere.

As the young professor, who knew that bees only massed on the outside of their hives as the more genial place to sleep in very hot weather, and to prove his theory ran his fingers among the clusters, and collected his pay as he went along, so with the advocates of hibernation. If at any time you become anxious to test your theory, just run your fingers down through a (so-called) hibernating cluster of bees, and collect the same kind of "coin," you having the choice of temperature, anywhere from 50°

above to 20° below zero. This would be entirely practical, and, I have no doubt, satisfactory.

The nearest approach to the inside of a cluster of bees, that I have been able to reach in the winter season, is through a tin tube 2 inches in diameter by 7 inches long, inserted through a 2-inch hole in the honey-board. This reaches completely the top centre of the cluster, and takes in very distinctly its fair proportions of all the intonations of song and sound from below; so by placing the ear to the upper end of the tube, one can more distinctly hear that never-ending song or voice of the bees, as they superintend affairs within the cluster. This tube can be left in all winter, by stopping the upper end to prevent draft, and serve as a means of observation at any time day or night, at any degree of temperature, ranging from 50° above to 20° below zero; thus proving conclusively that the honey-bee never abates one "jot or tittle" of its song of zee, zee, zee! during the lifetime of the colony, at any time or under any circumstances, or at any degree of temperature. Of course where a colony of bees reaches a state of torpidity, through the effects of starvation and cold, an exceptional case is formed, for they are virtually dead.

Athens, O. Ohio.

The Sale of Honey—Middle-Men, etc.

J. E. POND.

What is this "hue and cry" about the middle-men? Are they not as a rule as honest and conscientious as any other class of business men? If not, why are they tolerated for such a length of time and suffered to get rich in our large cities? Is the trouble with them, or are they at all responsible for it? Is it not rather with the producers? Honey-producers, as a class, are not proficient in the matter of conducting general business. This is no discredit to them, as it requires education and experience in a particular line of business to become at all proficient therein.

It seems to me that the trouble lies in the fact that vast quantities of honey are massed "all at once" into some large centre, and the producers of the crop (all anxious to obtain speedy returns therefor), are urging their commission man to sell. He, anxious to please, does sell, and as there are several houses in each large city, competition waxes hot, and low prices necessarily follow. The commission man is not to blame; he is as anxious as any one to obtain good prices, as his percentage is thereby increased, but the pressure on both sides—from the producer to sell, and the glutted state of the market—is so great, fearing that between "Scyllis and Charibda," he may be foundered, he sells with the crowd for the best price he can get.

What is the remedy? Various plans are offered, none of which to my mind

are at all practical. The best I have seen is the advice to "create a home market." Not 20 per cent. of the people of the United States use honey at all, and not 10 per cent. to any extent. The people must be educated up to a honey standard, and this can only be done by putting the article within their reach. There are but few things not absolute necessities that will sell themselves.

It is not over-production, and will not be so long as three-fourths of the people never see a drop of honey from Jan. 1 to Dec. 31. California produces honey at a profit at 5 cents per pound. If it is not over-production, or high cost of producing that is the trouble, can we not well assume that it is lack of education? At any rate let us not charge the middle-men with being swindlers until we find them dishonest; but let us look for the real cause, and see if we do not find it pretty near home.

Foxboro, O. Mass.

For the American Bee Journal.

Honey Market—Producers' Association

A. D. STOCKING.

As the question of the marketing of honey is attracting a great deal of attention now, I wish to give my experience in this line, and to make a few suggestions which may be of interest to some.

I was located 6 miles from Ligonier, Ind., and was the first to introduce honey in sections in the market there; whenever I went into town I always took a small case of one-pound sections and showed it to all I met. I sold what I could and took orders; I also left some at two good grocery stores on commission. I set the price at which my honey was to be sold, and told them I did not care at what price others sold—this honey was mine, and if they did not sell it they lost nothing; and that when the other was out of the way they could sell mine. I established a high reputation for the quality and style of my honey which I was very careful not to lower, and I have ever since sold my honey at a higher price than any other that was ever brought into the same market. I have never been able to supply the demand, and I never but once went over 6 miles from home with honey, and never asked any one what they would give for honey. I had a good trade amongst the farmers who had once kept bees but had lost them; they had become accustomed to a free use of honey. They came to my apiary and generally would take such as I did not think nice enough to put on the market. I have sold as high as 100 pounds to one farmer.

A great deal has been said against farmers and others keeping bees, but I have found that those who have kept a few bees and have become accustomed to the free use of honey, and then lost their bees, have proved to be the best customers; and I believe that any plan used to bring the mass of the people to become ac-

quainted with the use of honey, will greatly extend the market. But some may say that I produce but a small amount of honey, and need not be troubled for a market. I grant that I am but a small bee-keeper, yet the second season I sold over 1,600 pounds of honey, and those who have a much larger amount must make a stronger effort to increase their market; I believe a great deal can be done by going amongst the farmers.

Last season there were several bee-keepers in the vicinity of my market. I visited all that were likely to have honey to sell; I set a price for honey, and they all agreed to sell for no less, and they did not; yet there was not enough to supply the demand, and a good deal was brought in from a distance and sold at a lower price. Much might be accomplished by producers taking this course in their own vicinity.

I believe that much good might be accomplished by a honey producers' association for the bee-keepers of the country, by ascertaining the amount of honey likely to be put upon the market, the amount produced in the different parts of the country, the prospects of the demand, the prices it would be likely to bring, and the publication of the same. But to establish a uniform price for honey would be impossible, for the reason that the supply may be large in one locality, and the price low; in another part of the country the supply may be short, and the prices high; and shipping honey from one locality to the other will be accompanied with too much expense and loss.

Again it would be impossible to unite the majority of bee-keepers in such an association, and if it could be done it would be accompanied with so much expense as to make it impracticable, as it would be a heavy tax upon the honey-producers.

An effort has several times been made to obtain reports of the prospects of the supply of honey in different parts of the country, through the district and county associations; but they have always failed. The associations referred to by the different correspondents are all organized by capitalists, and none of them control but a small portion of the products of the dairy, etc.; and I apprehend there are but few capitalists among bee-keepers.

It would be much more profitable, I think, to drop the discussion of this question and devote our efforts to the home markets and the reduction of the cost of production. Much more might be accomplished by one or more prominent bee-keepers in each township, in seeing every bee keeper in his own township and uniting them all in a township organization for their own protection and benefit. Let them establish a price for their honey, and work in unison with those of adjoining townships to sustain uniform prices and work up the honey market amongst the farmers and in the towns in their vicinity, and, if necessary, buy up all honey that would be likely to injure their markets. Such associations could report

to, and work in unison with their county or district associations. What honey is sold in the towns would be left on commission with good, wide-awake grocers, the association establishing the price at which it is to be sold; being careful to establish and maintain a high reputation for the quality and purity of their honey. Much more might be accomplished in this way than by any producers' association, and thus the problem of the honey market would be solved.

Now is the time to work up such organizations and prepare for the coming season's operations; it can be done at little expense, and would result in great good to all.

Almena, 9 Mich.

For the American Bee Journal.

U. S. Honey-Producers' Association.

J. M. HANBAUGH.

To organize a controlling per cent. of the honey-producers of the United States, and thereby bring them under the controlling influence of the association, is a task not easily accomplished. Can the North, the South, the East and the West be brought together under one bond of brotherhood, so that there will be no infringing of rights, one upon the other, in the financial transactions of the entire honey traffic of the United States? Can our organization be so strong that we can successfully "bull" and "bear" against the laws of supply and demand?

We will suppose for argument's sake, that we are now organized, and have proclaimed to the world that the prices on our product shall no longer be trailed in the dust, and consumers must pay us 15 cents a pound for extracted honey, and 25 cents per pound for comb honey, or go without it; what does any one think would be the result? I believe the mass of the consumers would argue that they can obtain granulated sugar at 15 pounds for a dollar, being equivalent to less than 7 cents per pound; from this they will say they can make syrup costing less than 6 cents per pound; hence the folly of paying 15 cents per pound for honey when they can get a fair article of syrup for 6 cents per pound. Sorghum molasses can be bought from 40 to 60 cents per gallon, and the larger per cent. of the consumers will live on sorghum at those figures rather than to pay at the rate of \$1.65 per gallon for extracted honey.

Can any tell how this state of affairs can be benefited by an association of honey-producers? We might be able to raise a "corner" on our product, but at the present low rates of other sweets, it would eventually succumb, and at last be governed by the laws governing the supply and demand.

To me, there appears to be but one remedy, and one road out of the mire, and that is expressed in this short sentence: *Increase the consumption of honey!*

Do away with commission men entirely, and sell only to the retail dealer

and the consumer. Let honey seek its level along with other products of man's labor, and when we cannot produce it at the prices the times and circumstances justify, let us step out and surrender to those who can. We should endeavor to increase the demand by giving the consumer something to "tickle his taste," and by our honest, square dealings, let him know that he can rely upon our word, and feel that he gets value received for his money.

We should endeavor to maintain good prices by placing a superior article upon the market, put up in such shapes as will attract attention, and suit the convenience of the purchaser; but until the farmers, cane and sugar producers, wool-growers, etc., effect a "corner" on their products, I believe it useless for the honey-producers to organize with that end in view; on the other hand, I believe it to be detrimental to their interests. While I believe in organizations to defend our rights, elevate and increase our industry, I do not believe in "corners," monopolies, etc. Spring, 1901.

For the American Bee Journal.

The Prevention of Increase, etc.

ADEL GRESH.

I have been looking in vain over several of our prominent bee-papers to find some experienced apiarist give his method—or some practical one—whereby increase could be prevented, and yet get the full benefit of work from the bees, in producing comb honey in sections. Nearly all agree that prevention of natural swarming is not practical, but hint or say increase could be practically prevented; but I have the first to see who ventures to give explicit details of how he accomplishes the object: It begins to look to me as if their methods were considered "tricks of the trade" not to be divulged. I know that hiving back into the same hive is not practical with me. Hiving back into a hive whose colony sent off a swarm some days previously, is condemned by good authorities. Uniting swarms or parts of swarms, when swarming at the same time, is of little benefit, unless swarms are small, and, even then the object is only partly attained.

Mr. Simmins' method of preventing the desire to swarm may work in England, but I have my doubts about it succeeding in my apiary. Still I am glad that Mr. Simmins has given his method to the public, as it gives us ground to work and experiment on, and all methods should be given a fair trial, and if each would contribute his theories, or better still, his practice in this direction, together with results, I believe the problem would eventually be effectually solved, for "in the multitude of counselors there is wisdom." Let those who have had any experience on this line report it in the BEE JOURNAL, giving full method, for the benefit of the fraternity in general.

As to legislation, I doubt if any good could be accomplished by it; but I think much might be done to promote sales of honey, and hold prices at a reasonable figure by united effort.

Weedville, 8 Pa.

Comb Foundation—Foul Brood.

CHAS. H. VAN VECHTEN.

I could not do without foundation at any price. I use it in full sheets in the brood-frames and in the sections. By its use a pound of bees can be built up into a good colony when the bee-keeper has no empty combs; and by putting it into sections in full sheets, it is wonderful to see how the bees build it out, and the amount of honey they store from Alsike clover. My bees averaged 160 pounds of clover honey per colony. I use a chaff hive something like the "Falcon," only the ends have hooks to keep the doors in, a catch to the bottom, and the cover is on hinges with a wooden staple and stick on one corner. When the cover is open the stick holds the cover level, where tools and crates can be piled on. The back is double-walled, and a false bottom is under the hive, both of which are to be packed. The hive takes 8 frames, 10x16½ inches. I wire the frames and use a steel wire for a brace instead of a tin post. The hive has an 8-inch entrance and a 1-inch hole 6 inches above the entrance for free circulation. By putting 2 bushels of chaff on the hive, the bees will winter as well as calves or horses.

In answer to the question whether extracting causes foul brood, I would say that there are quite a number of bee-men in this locality, and some of us have kept bees for 30 years. We work for comb honey in sections, and I never heard of a single case of foul brood here. I should think that revolving the brood in all stages, with such force in extracting, would kill some of it in its first stages; but I notice that Mr. E. France, of Wisconsin, extracts from all the combs, and his bees never had the foul brood. I also read of a farmer who had a lot of bees in box-hives, and they were rotten with foul brood. It seems to be hard to decide.

Victor, 10 N. Y.

For the American Bee Journal.

Best Method of Marketing Honey.

THOS. TRACY.

There seems to be a question as to the best method of market honey. In many of the large cities the wholesale houses have ceased buying honey, going to the commission house to fill their orders, and the retailer only buys from day to day, throwing the carrying all on the producer or market man.

Honey shipped by promiscuous freight to commission men, for them

to pay freight, etc., and sell without dictation, is what spoils the market. Have control of the car; load it yourself; ship to yourself; pay your own freight; unload it yourself; deliver it to four or six of the best houses in the city in good condition; set your own price, and hold it as long as you please. The retailer that buys honey for 12 or 13 cents per pound, and sells it for 25 cents per pound is the worst man connected with the business, keeping half or more of the people from buying any, and the rest from using half they want.

Sell your honey to somebody, or buy somebody else's. All should not go to market; ten men with one ton of honey will break down the market more than one man with ten tons. Commission men are a part of the community, and probably about an average; somebody must handle the honey between the producer and the consumer or retailer. I produce a few tons of nice comb honey every year, and will sell it as it comes from the hive for one-half what I should ask for it in a distant city, with curing, crating, shipping, freight, drying, commission, carrying, risk, etc.

Let every man sell as much honey as he can at home, and as many as desire to do so, let them peddle it, and there will yet be hundreds of tons to be marketed. Let us hear no more about the commission men—they are a necessity, and are what we make them.

Feeding to Stimulate Brood-Rearing.

C. THIELMANN.

A great deal has been written in the bee-periodicals about stimulating bees, but so far as my experience has taught me, stimulative feeding of bees in early spring does more harm than good, and therefore, of late years, I have fed my bees in the fall instead of in the spring, provided they had not plenty of stores to winter on and for the spring. I intend that they shall have enough food the middle part of October to last them until May. I let them do their own feeding in the spring, and they will "make their nest" just as it suits them best; also put their stores where it is most convenient for them to use it.

By so doing the cluster is not broken up, no excitement is created by which many of the most vigorous bees are lost in going too far from the hive, getting chilled, and never return; no heat (which is so much needed) is lost, and the colony, if let alone, is progressing faster than we imagine.

I fully agree with Mr. Heddon's idea, given as follows: "The best way to build up weak colonies in the spring (supposing they have plenty of honey and pollen in the hive) is to keep them as warm as possible!"

It is an unquestionable fact that warmth for a weak colony, or any colony, is indispensable for good progress

in the spring; the more warmth the better, especially at night, after they are on their summer stands. All stimulative feeding will be in vain, or even is harmful, if the colony is not kept warm, and every unnecessary disturbance or excitement is damaging at any time of the year, but mostly so in the spring; and we cannot feed bees in the spring without creating more or less excitement and disturbance.

Thielmanton, O. Minn.

For the American Bee Journal.

Marshall Co., Iowa, Convention.

The Marshall County Bee-Keepers' Association met at Marshalltown, Iowa, on Saturday, Jan. 15, 1887. The morning session was spent in a social way, and no doubt the time was well employed.

At 1 p. m., the President and Vice-President being absent, Mr. A. Pinkerton was called to the chair. The usual order of business being disposed of, Mr. Pinkerton made a few remarks on the subject of surplus arrangements.

He uses the one and two pound sections, preferring the open-top sections so as to tier them up, by placing empty ones under those just being filled or finished. For his retail trade he prefers the five-pound box, for he finds it about as easy to sell a five-pound box to many of his customers as to sell one and two pound sections. For producing extracted honey he uses the two-story Langstroth hive.

Mr. L. Koeper opened the discussion on spring management of bees. He winters his bees in the cellar, puts them out as soon as the weather permits in the spring, which is generally not until some time in April. This is done in the afternoon. He closes the hive-entrance to suit the colony. In two or three days he examines all, and unites weak colonies, if any are found. He does not keep queens over three years, for a young queen lays the best. By close attention he makes his queens lay to their greatest capacity, so as to have all colonies strong by the time the white clover crop comes. To simulate breeding he feeds liquid honey, which he warms and places in troughs two or three rods from the bee-yard. He puts cut-straw on the honey to prevent their drowning. The feed is put out in the afternoon, and he has never had any trouble with robbing by placing feed out in this way. He also uses rye flour for pollen, and thinks that a little feeding of this kind for two or three weeks, or until the bees begin to store from the fields, is a great help. He feeds inside the hive if the weather does not permit the outside feeding. He examines the hives often, and assists the bees by placing empty combs in the centre of the brood-nest as needed; and as more room is required he enlarges the size of the brood-chamber. If the pollen becomes spoilt he cuts it out, and does not leave the combs in after they become a little old. He said that it is

best to have new combs occasionally, for they are more healthy, and the bees will be larger in size.

Mr. Diller said that he does not feed his bees, but when he puts them out he keeps them as warm as possible by covering the hives with cloths or quilts; that is all the spring care he wants his bees to have. He does not manipulate them much, as he believes the disturbance injures them.

A. Pinkerton said that his bees worked while he was disturbing them, and did not care for it. Others present took the same view, that the disturbing or manipulating was no detriment, but an advantage when properly done.

Mr. Koeper stated that he had an extra large colony build up in the way described by his spring management; that he did not allow it to swarm, but worked it for honey, and during our good honey harvest of 1886, he took 500 pounds of surplus from it. It was mostly extracted. He has a large-sized hive, so that he extracts from the body of the hive. He extracted every third day. He also had a case of sections on top of the hive. Mr. Koeper is a native of Germany, where he received a good training in apiculture and horticulture. He made the same report to me once before, giving the exact number of pounds, which was a little over 500.

The subjects for discussion at the next meeting are: "Summer management of bees," W. P. Cover; "Honey-plants," L. Koeper; "Surplus arrangements," A. Pinkerton.

The society then adjourned to meet on Saturday, April 16, 1887, at 10:30 a. m., in the Court House at Marshalltown, Iowa. J. W. SANDERS, Sec.

Open Cider-Mills and Bees.

J. R. ROEBUCK.

I am glad that Mr. J. Lee Anderson has noticed my article on page 9, and partly replied to it on page 42. His opposition to my views proves that the subject is not one-sided so far as we are concerned. The reader will please notice that in my first article I referred to "open cider-mills," and not to "cider-mills" only, as Mr. A. has it. I attempted to show some of the injuries bees sustained by having access to open cider-mills; these he has not denied. Then I asked, what shall be the remedy?

The remedy impliedly proposed by Mr. A. is for an apiarist to "keep his bees on his own premises," and then says that he is "not interested in any cider-mill," but in nearly 100 colonies of bees, but that that does not prevent him from using "reason and common sense." Whom he is quoting as using reason and common-sense I do not know. What is the difference, or who cares who is interested in cider-mills?

This, with me, is not a question as to which we will have, or which shall go to the wall, but how to legislate so as to have the benefit of both cider-

mills and apiaries, the former to use up the fruit of the orchard for the benefit of humanity, and the apiary or bees to carry the pollen and fertilize the blossoms of the orchard and fields, and to gather honey from every open flower which would otherwise be wasted. Both can prosper, and should be had side by side. Since Mr. A. has named the familiar characters of "Jones and Smith," and made out a case for comparison, let me use the same for a case that came under my personal observation last September. It is as follows:

Jones owns a home, has nearly 100 colonies of bees, has kept his bees for over 15 years, and of late years made a specialty of giving his undivided time to them during the working season of bees, making a comfortable living from them. Last September his neighbor Smith erected a cider-mill not over 200 yards from Jones' apiary; the mill is of the most improved pattern, having a capacity of 150 to 200 barrels of cider per day. Jones went to Smith saying, "You will ruin my bees." Smith replied, "I do not want to do that; I will run the mill and see." The result was that on the first day a few bees got around the mill, the second day a larger number, and the third day the scene resembled that of half a dozen or more swarms about clustering on the mill, going into the grinder, on the pomace, on the flowing cider, etc. Smith being a good sort of a man concluded that it was too bad, and stopped operating; had he continued, and had "Jones" been Mr. Anderson, the result would have been (at least I think so) that Mr. A's "nearly 100 colonies" would have been ground up, drowned, killed and diseased in a very short time. In this particular case Jones used common sense by offering to help Smith, free of charge, to board and screen up the mill, to which Smith consented, and there was no further trouble, except from the pomace. The workmen at the cider-mill, and the neighbors all agreed that Smith did right, and that if he had not allowed or helped to close his mill, Jones and the community would have had to get their honey from some other source, and that Jones' business would have been ruined. Suppose Smith had kept on (as he might have done) and told Jones to "keep his bees on his own premises," what amount of "common sense" would it have taken to keep the bees at home?

I agree with the Editor of the BEE JOURNAL, that "class legislation is undesirable except in rare cases," but I think that this is one of the "rare cases." I also believe that we ought to be interested in cider-mills, and that every man has a right to build and operate cider-mills, cheese factories, chemical works, dye-factories, powder-mills, etc., but I do not believe (and legislatures have shown by wise laws that they do not believe) that these industries should have the right to contaminate the air, and poison pure streams of water to the destruction of health, and the killing of farmers' cattle that by nature have

the right to pasture the fields through which such streams flow. Powder-mills are good in their place, but are not allowed in populous cities. All these and many other industries ought to and do exist, but are justly prescribed.

So cider-mills can and ought to interest us enough to want them, but they should be closed and prescribed from doing unnecessary damages to other industries equally as important and honorable. Bees cannot be kept from—and ought not to be kept from—occupying the place nature, or a Wise Creator has chosen for them to occupy, any more than one should waste his time in trying to reverse any other law of nature.

Burton City, 3 Ohio.

For the American Bee Journal

Disturbing Bees in Winter, etc.

B. Z. SMITH.

Why is it that so many of our best apiarists claim that noise above a beecellar will make no difference with our bees? They say, put them under the kitchen where the children romp and play; while they may winter there, I prefer a cellar separate from anything else.

My bee-cellar has two coats of plastering 4 inches apart, over-head, then one row of brick (as it is a brick cellar under ground), and then the sills of a honey-house, shop, or whatever I care to use it for. The other day, as I wanted to do some work in the shop, I thought it would be best to see if noise would molest the bees. So I quietly slipped into the cellar, after engaging my brother to strike on the floor, and found that the bees, on entering, very quiet, but alas! the very first stroke raised a loud hum, and the longer the noise continued the worse they were, until they began to fly from the hives quite often, about as we have noticed them doing in March, at a very warm time, when they are generally breeding, and very warm weather causes great uneasiness.

I am quite certain that none of the hives touch the wall, as I was very particular about this when placing them in the cellar. I am also very sure that no more noise was made than five or six boys would make when romping in a kitchen over the bees. I have some knowledge of this as I was brought up in a family of six boys. Is it not quite certain that such noise or jarring vibrates the air, walls and everything in close connection? I am led to wonder whether or not nearly all bee-keepers would not prefer a cellar where there would not be any disturbance in the least.

My cellar to-day is at 45°, with some water on the bottom, which is pure, as it comes from a sand vein and passes right out at the tile, which is 8 inches, and is also the ventilator. The entrances of the hives are all wide open, and the lids are raised about 1/4 of an inch. There are 150 colonies in a room about of 1,000 cubic

feet, and are surely in fine condition. How they will come out in the spring of course remains a query, but I can say that I have been quite successful for 6 years in wintering in this way, with the exception of the year we had so much of the so-called bark louse honey-dew, when we lost about 30 per cent. of our bees.

I believe in wintering bees on their natural stores, and plenty of it; if sugar syrup is better for them than honey, it surely is better for mankind. Then why produce honey? Of course sugar syrup will be fed to colonies that are scant of stores, when honey is not to be had.

Tuscola, Ills., Feb. 14, 1887.

For the American Bee Journal.

Tin-Rests in Surplus Cases.

N. N. BETSINGER.

I wish to show the advantages in the use of tin-rests. In a surplus arrangement space is its greatest value, and when it is occupied by wood or taken up with bulky substances to accomplish its object, it is in that proportion deficient. In my experiments in producing comb honey I have found the nearer the sections come to the brood, the sooner they were occupied by the bees; therefore tin for section-rests are infallible.

The strengthening of tin-rests is considered as yet imperfect, and, with many, an unsettled question. Where metal separators are used and so adjusted as to come in contact with the tin-rests, they can be very securely fastened by means of soldering, which makes a section support in strength second to none, and yet maintaining the same advantage found in any other more cumbersome section-rest—of admitting the sections longitudinally in a solid line.

There is also another advantage in the tin-rests that cannot be found in any other; that is, where tiering-up is desired, just bee-space can be given between the upper and lower case, and not allow the section supports of the upper case to come in contact with the top of the lower sections, which will, of course, greatly alleviate the difficulty caused by propolis on the sections, and also prevent the union of the two cases. Further, the danger of crushing bees in tiering the cases is greatly lessened, without the necessity of using an extra rim for such a purpose.

Marcellus, N. Y.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

The Western World Guide and Handbook of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides his own, with \$3.00, for one year, we will present a copy of this valuable book.

Local Convention Directory.

1887. *Time and place of Meeting.*
Apr. 12.—Stark County, at Canton, Ohio.
Mark Thomson, Sec., Canton, O.
Apr. 16.—Marshall County, at Marshalltown, Iowa.
J. W. Sanders, Sec., LeGrand, Iowa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER-BOX

Well Satisfied.—A. F. Currier, Du Plain, Mich., on March 7, 1887, says:

I put my bees into the cellar on Nov. 24, 1886, and took them out on March 2 for a flight. They were happy, and seemed to enjoy the warm sunshine; it did me good to see them. But the best of all was that all but one colony out of the 22 were in good condition. I carried them out in the morning, and back at night. I am well satisfied.

North American Bee-Keepers's Society.—Aaron Hunt, Gordon, Ohio, writes:

I would like to suggest that the next meeting of the North American Bee-Keepers' Society be held during the Fat Stock Show at Chicago next fall. Then the members can get lower rates on all the railroads; at least such was the case here last year. I would like to hear from others in regard to this matter.

Examining Bees, etc.—A. C. W., of Minnesota, ask the following:

1. When is the best time of the day for a novice to examine a colony of bees? 2. Which is preferable, 8 or 10 frame Langstroth hives for producing comb honey?

[1. At about noon.

2. If for top-storing, the 8-frame hive is better, so as to force the bees to store in the sections.—ED.]

Ethical Principles, the Rights of Property, etc.—James Heddon, Dowagiac, Mich., writes thus:

In reply to Mr. G. M. Alves, I would say that my limited study of common law (and patent law) prepare me to accept the abstract principles as laid down in his last article, on page 154. I am aware that Nature is cold and cruel; that she appreciates no difference between justice and piracy; that the great law of "the survival of the fittest," by which the hawk must survive upon the flesh and blood of smaller birds (whose agony he seems to enjoy, as with beak and claw he tears them in pieces), or perish for want of food, is shocking to the moral ethics of civilized man. I know that property right of land (which Henry George says is not right at all) origi-

nated as Mr. Alves says, but for all this it requires no delicacy on my part to refrain from burning the wood my neighbor has chopped, or the coal he has dug; nor is he unjustly or unwisely "selfish" in asking me to allow him alone to enjoy the results of his labor until I exchange with him an equal result of my labor.

Transferring Bees, Planting Trees, etc.—A. Vought, Illawara, La., writes:

I have bought some log "gums" with bees in them. I shall transfer the bees by the Heddon process. He says: "Twenty-one days later I drive the remaining bees, etc." 1. Now, I wish to make two or more colonies of one, as they are very strong; must I rear or buy queens, or will they have started queen-cells and hatched a young queen in 21 days? 2. I wish to place a row of trees around my pasture, with a view of using them as posts for a wire-fence in the future. What kind shall I plant? 3. What kind of honey-plants can I raise along ditch-banks and fences, that will not be damaged much by horses tramping upon them in turning while cultivating the crop.

1. Mr. Heddon answers: "They will have a new fertile queen at the time of the second drive. 2 and 3. One acquainted with the climate and soil could not advise you. J. W. Winder, Jackson Pass. Depot, New Orleans, La., or Paul L. Viallon, Bayou Goula, La., would, no doubt, give you the information, if you write to them for it."—ED.]

Early Spring.—T. T. Phlegar, Pearisburg, Va., on March 3, 1887, writes as follows:

I put into winter quarters 12 colonies of bees, and have lost one on account of its being too weak when winter began. The spring is nearly 20 days earlier this year than last, when the first pollen was brought in on March 20; this spring it is March 2. Last year was too cool and wet here for bees. I think the coming season will be a favorable one.

Bee-Keeping in Texas.—J. N. Colwick, Norse, Texas, on Feb. 9, 1887, writes:

I commenced bee-keeping in 1882, when I found a swarm in an oak tree, and with the help of my brother we brought it home, after having run away from the stump several times for fear of stings. These bees increased the second season to 4 colonies; one was killed by mice in the winter, and 3 came through and swarmed. I had in "box-gums" 10 colonies when fall came, besides having taken about 200 pounds of comb honey. A carpenter made 3 two-story Simplicity hives for me, to which I transferred 3 of the weakest colonies. In the spring of 1884 I transferred the

remaining 7 colonies, and increased all to 18 in 1885, besides extracting about 250 pounds of honey. In the spring of 1886 I purchased 9 colonies, sold 4, and packed 28 for winter. I had to feed them in the forepart of the summer. Bees gathered some honey last fall. I examined one colony Feb. 2, and found about 4 inches square of eggs and a few larvæ; they now have eggs in three combs. They brought pollen from elm on Feb. 2. Do bees weigh the same if starved, as they do when they gather plenty of honey? Or, will a pound of bees contain the same number in a good season as when they find no honey, and have no more in the hive than they will consume?

[The difference would be almost imperceptible, in either case.—ED.]

May Convention of Bee-Keepers.—R. F. Holtermann, Brantford, Ont., says:

In reference to the proposed convention to be held in Chicago in connection with honey markets, is May not rather late for those who have work to attend to at that time—in fact for all bee-keepers? It should be a success, and I should regret a failure, even in a measure, for any such reason.

[If a convention is to be held this spring, the time and place should be announced at once. If delayed much longer it cannot be held until the fall, and then it might save much expense to hold it the day before or after some other important convention.—ED.]

My Experience with Bees.—Thos. Ellicott, Fentonville, Mich., on Mar. 5, 1887, says:

I have had fair success keeping bees, although I have met with some losses. Last summer I secured 2,300 pounds of comb honey, and 100 pounds of extracted from 24 colonies, the most of them being very light in the spring. I now have 80 colonies, and I have paid out for the bees about \$70 in cash.

Bees Working Hard.—G. B. Cartmell, Jackson, Tenn., on March 5, 1887, writes:

My bees have wintered well. I have not lost a colony. I have 23 colonies all strong in bees. They carried in the first pollen on Feb. 10. Peach and plum trees have been in full bloom for a week, and the bees are working hard on them.

Reversible Honey-Boards.—James M. Goodrich, South Frankfort, Mich., writes:

My reversible bottom-board for the Simplicity hive is made thus: The board is 3 inches longer than the hive; there is a rim on three sides of it, $\frac{3}{4}$ of an inch wider than the bottom-boards are thick, and the same thick-

ness as the body of the hive. The boards reach across the hive, and are the same length as the hive is wide on the inside, and are halved or matched, the rim being nailed to the board, so that it projects $\frac{3}{8}$ of an inch on each side of the board nailed to the hive, which rests on the rim, and this leaves a fly-hole $\frac{3}{8}$ of an inch in front, the width of the hive, and the entrance-blocks are held as firmly as in the portico hive, and the bottom-board is the same either side up.

Abundance of Bloom.—W. S. Douglass, Lexington, ☉ Tex., March 8, 1887, writes:

My bees have wintered in splendid condition as usual, if supplied with honey; each had from 30 to 40 pounds of nice honey to winter on. On Feb. 1 they began to bring in pollen very fast from the elm, and now wild peach is yielding both honey and pollen; cotton-wood is also yielding pollen. Fruit-trees are in full bloom, so the bees are having all they can do. I have one strong colony that is clustering on the outside in the heat of the day. All of the hives are becoming crowded with bees. I noticed horse-mint springing up by the thousands. The weather is delightful here; some of the farmers have corn large enough to cultivate, while others have just planted theirs. Some people are planting cotton.

Bees and Grapes, etc.—Louis Werner, Edwardsville, ♀ Ills., on March 7, 1887, writes:

I have had a little difficulty with a neighbor about bees and grapes. He got up a petition and had all sign it who would, to get me out of the city; but I have worked hard and convinced the City Council that bees do not puncture grapes, so they declared that the bees were my support, and they threw it out, saying that it was only prejudice, and that was all. The party could not give bond for the costs of a suit, so they gave it up. Thus the case is ended so far. Bees have been working on maple and elm since Feb. 27, and they are in fine condition, having plenty of brood and young bees. Bees have wintered nicely, and the prospect for a good year in this locality are quite flattering. I will have drones flying by April 1, and I think there will be early swarming and plenty of white clover this year.

Stop the Extractor.—F. L. Merrick, Waldron, ☉ Ills., writes as follows:

I heartily agree with Mr. James Heddon, on page 155, about holding a North American Bee-Keepers' Convention next May; not for the purpose of exhibiting bee-keepers' supplies, or anything of the kind, but to discuss the best methods of producing honey—whether it is best to continue to extract honey. I agree with Mr. Heddon, that we must have a change; that we should produce "gilt-edged comb honey;" and put our ex-

tractors aside for a few years at least. So long as extracted honey shall be produced in such quantities as it has been for the past few years, we will be obliged to sell our gilt-edged comb honey for about 12 or 13 cents per pound. But by ceasing to extract honey, we have every reason to believe that we can agree on a price for comb honey that will be remunerative. We may have by all odds the most interesting meeting that ever was held on this continent.

Early Spring Indicated.—B. T. Baldwin, Marion, ☉ Ind., on March 8, 1887, writes:

I began the winter with 94 colonies packed in chaff on the summer stands; all are alive yet and in good condition, except 2 or 3 that are queenless. The maples have commenced to bloom, and the bees gathered their first pollen from that source to-day, which is 10 days earlier than last season, 42 days earlier than in 1885, and 14 days earlier than in 1884. Hence we will have an early spring if it holds out. Do not the best honey years follow late, backward springs, and poor years and failures follow early springs? Can "P. Benson," of Marengo, Ill., tell?

Prospects Favorable in Alabama.—B. B. Toney, Holly Tree, ♂ Ala., on March 7, 1887, writes:

I made next to nothing out of my bees last year; I had 70 colonies in the spring, and obtained 25 gallons of honey, all told. They increased to 111 colonies, and were without honey the last of August. I was preparing to feed the 25 gallons of honey to the bees, when I noticed that they were bringing in honey, and in 4 weeks they had from 20 to 50 pounds of honey each, which was of good quality. Till to-day I have lost but 3 colonies, leaving at present 108. The peach-trees are now in bloom, and bees are now doing well. Everything is now favorable for a good crop of honey; last year it was too wet and cool for its secretion. My average per colony was 4 pounds! Now have not I made a better report than did Dr. Miller, on page 44 of the BEE JOURNAL for 1886? I would rather have had a better one to make, but I am glad that it is no worse.

Bees Quiet in the Cellar.—D. E. Hopkins, Indian Ford, ♀ Wis., on March 8, 1887, writes:

I put 69 colonies into the cellar on Nov. 25, 1886, and they are all right. They have been very quiet all winter; the temperature has not varied over 40°. The cellar has a ground bottom, and is perfectly dark. I ventilate it with a 4-inch pipe connected with the heating stove above. Also a 4-inch pipe extends through one of the cellar windows, to let in cold air if needed; it has a damper that can be closed when it is too cold. The bee-room is 9x18 feet, and 10 feet high. I use Langstroth hives, and tier them up 4 high, after removing the caps, and leave the full entrance open.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c. Not much call for extracted, and very little for comb. **BEEWAX.**—25c. R. A. BURNETT, Feb. 21. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10@12c.; in 2-lbs., 9@10c.; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8@8½c.; in 2-lbs., 7@7½c. Extracted, California, 5@5½c.; Buckwheat, 4@4½c. Supply of comb honey is large, and demand for all kinds is improving. **BEEWAX.**—21@23c. MCCAUL & HILDRETH BROS., Jan. 21. 34 Hudson St.

DETROIT.

HONEY.—Best white comb, 10@11c. Supply large and sales are slow. **BEEWAX.**—23c. Mar. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—Extracted is firm at 4@4½c., and comb at 8@12c. per lb. **BEEWAX.**—19@21c. Feb. 9. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively. **BEEWAX.**—24 cts. per lb. Feb. 11. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 4@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way. **BEEWAX.**—Good demand, —20@22c. per lb. for good to choice yellow. Jan. 22. C.F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, 1-lb. sections, sells at 12½@13c.; second quality white, 10@11c.; white 2-lbs., 10@11c. Buckwheat, 8@9c. Extracted, 5@6c.—Market dull. **BEEWAX.**—25c. Mar. 9. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

Continuous Advertising brings much larger returns, in proportion to the outlay, than periodic or spasmodic advertising.

By Using the Blunder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1 00	..
and Gleanings in Bee-Culture	2 00	.. 1 75
Bee-Keepers' Magazine	1 25	.. 1 25
Bee-Keepers' Guide	1 50	.. 1 40
The Apiculturist	2 00	.. 1 70
Canadian Bee Journal	2 00	.. 1 75
Rays of Light	1 50	.. 1 35
The 7 above-named papers	5 25	.. 4 50
and Cook's Manual	2 25	.. 2 00
Bees and Honey (Newman)	2 00	.. 1 75
Binder for Am. Bee Journal	1 60	.. 1 50
Dzierzon's Bee-Book (cloth)	3 00	.. 2 00
Root's A B C of Bee-Culture	2 25	.. 2 10
Farmer's Account Book	4 00	.. 2 00
Guide and Hand-Book	1 50	.. 1 30
Heddon's book, "Success"	1 50	.. 1 40
A Year Among the Bees	1 75	.. 1 50

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the **BEE JOURNAL**. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the **BEE JOURNAL** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

ADVERTISEMENTS.

Extracted Honey For Sale.

We have a large quantity of **CHOICE WHITE EXTRACTED HONEY**, in kegs holding from 200 lbs. to 225 lbs. each, which we will deliver on board the cars at 7 cents per lb. Orders solicited.

HEDDON'S CATALOGUE

For 1887, (40 pages.)

NOW READY.

The New Hive.

I have many more testimonials like the following, from Leading Bee-Keepers of this country. See 1887 Catalogue, to know what Prof. Cook, W. Z. Hutchinson, F. P. Stiles, T. L. VonDorn, F. Boomhower, and Doctors Tinker, Mason, Miller and others think, after many of them have thoroughly tested the New Hive:

Your hive is novel, and I propose to try it.
E. J. COOK, (Bro. to Prof. Cook.)
Owosso, Mich., Feb. 11, 1886.

Please send me descriptive circular of your new hive: as the thing seems a novelty to me, and I am anxious to understand it.
W. S. CARSON.
Cynthiana, Ky., Jan. 22, 1886.

I have been reading your book and I regard it as most valuable acquisition to our bee literature. Your new hive is a wide departure from the old order of things, and I can see much to commend it, in the hands of a master.
J. W. PORTER.
Charlottesville, Va., July 2, 1886.

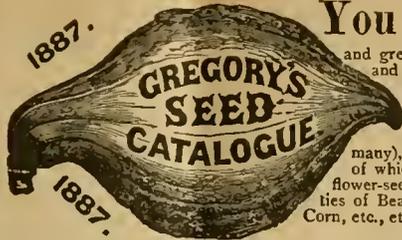

I note with pleasure your improved reversible and interchangeable hive. I consider it THE hive, though my experience in the bee-business has been limited, yet I see in this hive a great revolution in handling bees, making it a pleasure to handle them.
S. J. JACKSON.
Southern Agt. of the Southern Despatch fast ft. line.
Atlanta, Ga., Aug. 9, 1886.

I have in use 26 hives embracing your late inventions, and to say that I like them would be stating it mildly. Your principles, I think, have come to stay. I find there exists considerable prejudice against your new hive, it being so much different from the hives in general use here, and I predict that because it is so different, requiring a system of management peculiar to itself, it will not meet with such general approbation as it deserves.
D. S. HALL.
South Cabot, Vt., Oct. 4, 1886.

When I first saw your new hive, in your home apiary, a year and a half ago, its construction and system of management being so different from any other hive, I was not favorably impressed with it; but in canvassing the subject in my own mind afterward, I thought of the excellent results that had attended the use of your other inventions, and it occurred to me that possibly this might afford me equal satisfaction. The more I studied the hive, the plainer its advantages appeared to me, and I determined to give it a comprehensive trial. After the past season's use of nearly 100 of them, I am prepared to endorse more than you claim for it. In my judgment, it will revolutionize our business, and he who would produce honey at a profit, will not be slow to adopt this hive as soon as he realizes how much it lessens the cost of production. While my own financial interests would be enhanced, were its sale restricted, I am not selfish enough to desire to keep my brother bee-keepers from enjoying so good a thing. Wishing you the ample success that your labors in the cause of bee-culture justly merit, I am cordially and fraternally yours,
DWIGHT FURNESS.
Furnessville, Ind., Oct. 10, 1886.

THE "BOSS" ONE-PIECE SECTIONS.

Patented June 28, 1881.

WHILE attending the North American Bee-Keepers' Convention at Indianapolis, we learned there was a rumor afloat that the Patent on the ONE-PIECE SECTION had been set aside—circulated by unprincipled parties, to mislead bee-keepers. We would say in regard to this, that such is not the case. It is now before the U. S. Supreme Court, at Washington, and will probably be decided before a great while, when we will notify all through the Bee Journal. Until then pay no attention to rumors.

Before ordering write us for prices. We will furnish you Sections as cheap as the cheapest. Let us hear from you before you order. Address,

J. FORNCROOK & CO.,

1A1f Watertown, Wis., Nov. 1, 1886.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. March 23, 1887. No. 12.

Forward! March! And March is here, blustering some, but it is drying up the mud and letting the ice and snow melt gently under the rays of Old Sol. So far, the bees are doing finely, and everything promises for a good season for both bees and honey.

Shipping Honey to Great Britain was the subject which brought the Ontario Bee-Keepers' Association together at Toronto, on March 16. After much discussion it was decided that the shipping of honey in the future be left to individuals, or that some competent persons should purchase it in Canada and take it under their personal supervision to Europe and sell it there for themselves. The association concluded that it could not undertake the work.

B. Z. Smith, of Douglass County, Ills., has issued a circular on the advantages of Alsike clover, which he is freely distributing among the farmers in his locality, in order to increase honey production. This is very praise-worthy, and shows energy and business-like qualities, which should be practiced by apiarists all over the country. Mr. Smith requested us to get up a Leaflet some weeks ago on this subject, but we were feeling so unwell then that we could not undertake it. Now we have done so, and as it is just the time to sow the seed, let them fly all over the country.

The Outlook in Florida.—Mr. John Y. Detwiler writes thus to the *Dispatch* :

Mr. Ira D. Barber, of New York, has been here for two weeks, and expressed himself highly satisfied with the condition of the colonies. Mr. B. is a veteran bee-keeper, and is one of the few men who winter their bees successfully. He and his brother keep nearly 500 colonies. His first visit to this place was in December, 1883, and now, since the mangrove has been destroyed, he expresses the opinion that the outlook would not justify much of an expenditure for the production of either comb or extracted honey.

To be Known, a man must keep his name before the people, and let them know where he is, and what he is doing, as well as what he has for sale.

More Lies about Honey.—Mr. T. R. Whinery, of Winona, O., writes to the BEE JOURNAL as follows :

On page 611 of Johnson's New General Encyclopedia I find the following: "Honey is said to be now much adulterated with glycerine, and even imitated, as a whole, by combining the latter product with other material, and flavoring with appropriate essential oils." Now I would like to know whether it is possible to adulterate honey with glycerine.

It is "possible" to mix glycerine with extracted honey, but it is *not done*, because it is not profitable to do so—and all adulterators look out for that; and is their prime incentive. Glycerine is worth three or four times as much as extracted honey, and you may as well talk about adulterating silver by putting "pure gold" into it, as to think of adulterating honey with glycerine!

Since the Wiley lie about comb honey was published as a "scientific pleasant," every editor, author, and correspondent seems to have a "license" to add more lies about honey to the large stock already published. They will go so far as to even intimate that honey is made as a whole from glycerine and other ingredients, flavored with essential oils. The fools never stop to think that this "stuff" would cost three or four times as much as the pure, unadulterated, extracted honey could be purchased for! These fellows lie out of whole cloth when the truth would serve them far better!

Mr E. Sandford writes thus to the editor: "I think you ought to ask for some able article on the question of grocery-men not wanting to sell extracted honey, for fear that it will hurt the sale of their syrup trade. Then let bee-men have it published in their home papers."

This is a question of "business," and we hardly know what more could be said to induce grocery-men to push the sale of extracted honey when put up in nice salable packages, than has already been printed in this JOURNAL. If any "able articles" are offered on that subject they will receive our best attention and full endorsement.

A West Virginia Bee-Keeper tells how he out-witted the middle-man of his home town, as follows :

Last fall I drove into a town, a few miles distant, with a load of honey, and went to the principal dealer in honey and stated my price. Said he: "I can buy just as nice honey as that for 10 cents." "And you retail it for 20 cents, do you?" "Yes, and have no trouble to get it." "Well," said I, "you will have trouble in the future." So at the house adjoining his store I commenced selling nice comb honey at 18 cents, and extracted at 12½ cents, or 10 pounds for \$1. I visited this town once a week while my honey lasted, selling on each trip an average of 50 pounds of comb honey, and 450 pounds of extracted. It is needless to say that the sale of honey by middle-men in that town was completely ruined.

Well, this is *stale*. It was written for the BEE JOURNAL by J. A. Buehanan, and published on page 106. It is "going the rounds" of the papers without credit, when it should have been credited to this paper.

Mr. James Heddon is now an editor. He has just purchased the *Dowagiac Times*, and his first number is on our desk. It looks well and reads well, and we wish him success in this new field of labor.

Bee-Keeping in Russia, says Ben : Perley Poore in the *American Cultivator*, is carried on to a great extent—the annual product being valued at two and a quarter millions of dollars. The expenditure is chiefly made by the Greek Church, the ceremonies of which require such a large consumption of wax candles as to greatly favor this branch of rural economy in Russia, and preserve it from the decline to which it is exposed in other countries, from the increasing use of stearine, oil, gas and other fluids for illuminating purposes. The rearing of bees is now almost exclusively dependent on the manufacture of candles for religious ceremonies, and on the consumption of honey during Lent, it being then used instead of sugar by the strict observers of the fast. The government encourages this branch of rural industry, as affording to the peasant an extra source of income, and has adopted various measures for the accomplishment of this end.

Another "Find" of Wild Honey is thus mentioned by a correspondent from Utica, Pa., in the *New York Sun*. He says :

A few days ago James Cousins and S. P. McCracken were going through the woods, when they were surprised to see bees swarming about an old and very tall tree, near the top. Believing that the tree contained a great store of wild honey, the two men set about securing it. Two 25-foot ladders were spliced together and run up the tree, but they fell 25 feet short of reaching the spot. Cleats were then nailed on the trunk of the tree from the top of the last ladder to the hollow place. Standing on the top pair of cleats one of the men chopped a hole in the trunk. A hollow place 10 feet deep and 14 inches in diameter was found. It was packed full of honey. The mass was taken out entire, without breaking the immense comb, and lowered successfully with ropes to the ground. There were over 300 pounds of honey. After securing the honey the bees were lived, and will lay up their next season's store in a modern hive.

Who says that Pennsylvania is not a bee State? How about combs 10 feet long vs. Langstroth frames! Big story! Happy Cousins!

Catalogues for 1887.—Those on our desk are from

Aspinwall & Treadwell, Barrytown, N. Y.—38 pages—Bee-Keepers' Supplies.
Frank A. Eaton, Bluffton, O.—1 page—Section-Case and Skeleton Honey-Board.
E. S. Armstrong, Jerseyville, Ills.—36 pages—Reversible and Crown Bee-Hives, and Bee-Keepers' Supplies.
Mrs. J. N. Heater, Columbus, Nebr.—4 pages—Bees, and Bee-Keepers' Supplies.
F. A. Salisbury, Syracuse, N. Y.—28 pages—Apiarian Supplies.
Arthur A. Davis, Clark's Green, Pa.—12 pages—Bees, Apiarian Supplies, etc.
J. C. Wilms, Waupun, Wis.—8 pages—Bees, Poultry and Eggs.
Abbott Brothers, Southall, London, England—50 pages—Bee-Hives and Appliances.
Thos. Jackson, Portland, Me.—10 pages—Small Fruit and Nursery Stock.
E. M. Bullard, West Swanzy, N. H.—28 pages—Poultry, Seeds, Plants, etc.

A. L. Swinson, Goldsboro, N. C.—2 pages—Queen.

Frank Leslie's Sunday Magazine for April is redolent with the breath of spring, which will soon break all over the land. Here we have picture and poem, song and story, carrying with them the graceful recognition of re-awakening Nature. There are several very beautiful full page engravings, and this number will certainly be generally recognized as an excellent one.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Contracting the Brood-Nest.

Query, No. 391.—I use a hive holding 9 frames about the Langstroth capacity. After swarming I wish to reduce the number to 7 frames. Would I secure as much honey by using two dummies, one on each side of the brood-nest with a bee-space all around the dummies, or would it be better to use a close-fitting board, and shut the bees out from passing around them?—Subscriber.

I do not think that it would make any difference.—A. J. COOK.

I prefer a close-fitting board.—H. D. CUTTING.

Use close-fitting boards.—C. W. DAYTON.

Either will do, with very little difference in favor of either.—G. M. DOOLITTLE.

The latter method is not so convenient, and possesses no advantages over the former.—W. Z. HUTCHINSON.

I see no objection to the dummies with a bee-space. I have successfully used them.—J. P. H. BROWN.

I think it is better to fasten the bees out from the space occupied by dummies.—G. L. TINKER.

In hot weather the dummies will probably do as well, but for cold weather the close-fitting board is better.—C. C. MILLER.

In the summer months I prefer to let the bees pass under and around the "fillers" at the sides of the combs. I prefer common, loose division-boards hung bee-space apart, to any solid dummy.—G. W. DEMAREE.

We do not believe in close-fitting division-boards. We want a bee-space at the bottom, at least. But we would never advise reducing the hive after swarming.—DADANT & SON.

I do not think it would make much difference which method is adopted. As a matter of convenience, relative to winter packing, I should prefer the tight-fitting boards, as they could be used as a double wall.—J. E. POND.

There would be no difference, only the "dummies" with space all around them are much easier to handle. If you contract at all, why not contract to five Langstroth frames? I am sure that better results will thus be realized. I have practiced contraction on an extensive scale for 5 or 6 years.—JAMES HEDDON.

There is but little choice between these methods.—THE EDITOR.

Characteristics of Best Bees.

Query, No. 392.—Have we what may be called gentle strains of bees that are the equal, as producers of comb honey, of some of the more ill-tempered varieties? In other words, does ill-temper and extra-working quality exist in bees as inseparable factors?—L.

2. Yes, sometimes.—C. W. DAYTON.
1. Yes, certainly so. 2. Not necessarily.—G. M. DOOLITTLE.

Ill-temper and extra-working qualities are *not* inseparable qualities.—W. Z. HUTCHINSON.

To the first question, I answer yes; to the second, no not in all cases.—H. D. CUTTING.

1. Yes. 2. No, but some very cross bees are also very good workers; for instance, the Cyprians.—DADANT & SON.

Yes, most assuredly. Ill-temper and business are not necessary companions.—A. J. COOK.

I am afraid there is too often some connection between the two; still it is possible that a colony of the best workers may also be very gentle.—C. C. MILLER.

I really think so. What we call well-bred Italians are classed with the gentle varieties of bees, and although I have tried nearly all the races and varieties of bees, I know of none superior, as a rule, to the Italians for comb honey, and for all the purposes that bees can be put to as a source of profit.—G. W. DEMAREE.

Ill-temper and extra-working quality *need not* exist in bees as inseparable factors; but a very great degree of gentleness in bees is usually attended with a want of energy. A little "snap" in bees is quite as necessary as it is in human beings.—J. P. H. BROWN.

Yes; most undoubtedly. The best honey-gatherers I ever had were the progeny of a gentle queen; these workers were beautiful in color, and so gentle that smoke was seldom required in manipulating them. I have a number of colonies of very gentle bees that were fine workers, so I can say in answer to the second part of the query—not by any means.—J. E. POND.

I think we have, but I have seen no very valuable bees that were exceedingly gentle. A little crossness seems desirable, but not so cross that they cannot be handled without smoke when storing honey. The Syrio-Albino bees are fairly gentle, and there are no better workers as comb-builders. My conclusion is that extra-working quality in bees is somewhat like the go-ahead and resolute working traits of some men—it is always accompanied by a combative and fiery spirit.—G. L. TINKER.

Yes, we have them in judicious crosses of the best strains of German and Italian bees. This answers your last question in the negative.—JAMES HEDDON.

Bees from fine, "gentle" queens are in many cases superior to any cross, ill-tempered or irascible bees in the world.—THE EDITOR.

Transferring Bees Early.

Query, No. 393.—Having 6 colonies of bees, 4 of which are in box-hives, and all in the cellar (here we put them out in the latter part of April), and wishing to stimulate them for rapid increase, will it be wise or prudent to transfer them when first put out of the cellar, as I do not want them in box-hives?—A. G., Vt.

Do not transfer them until the weather is warm, and honey being gathered.—W. Z. HUTCHINSON.

Transfer in fruit-bloom time. Do not transfer until they begin to get honey from some source.—C. W. DAYTON.

I should prefer to wait until fruit bloom.—G. M. DOOLITTLE.

I would not advise transferring so soon; wait until the first fruit bloom.—H. D. CUTTING.

You can transfer them when put out, if you will perform the operation in a close, warm room; use precaution against robbing; and feed regularly, so that they may not want for sufficient stores.—J. P. H. BROWN.

Transfer them during fruit bloom. You may transfer them earlier, if you feed them and keep them warm, but we would not do it, for there is more danger of robbing.—DADANT & SON.

In my locality I would not transfer bees before fruit-bloom, and I suppose it is the same in your locality.—C. C. MILLER.

I would do it at the time of fruit bloom, or in time of fruit bloom, if by the old method; or at the time of swarming, just before they swarm, if by the better "Heddon method."—A. J. COOK.

There are both advantages and disadvantages connected with so early transferring, and which you will receive the most of depends upon the season, and your skill and management.—JAMES HEDDON.

If they have plenty of stores I would not transfer them until they begin to work on the fruit-bloom. Bees that have plenty of stores do not need stimulating. When bees are transferred when working in the fields, they right things up in better style than if transferred in the fall or too early in the spring. The weather should be warm enough for the bees to spread themselves all over the combs, or they are apt to patch up clubbed-shaped combs.—G. W. DEMAREE.

I would either transfer them when first put out of the cellar, or wait until after swarming, and then pursue the Heddon plan of transferring. I regard it a mistake to transfer bees from box-hives during fruit bloom. It gives them a great back-set from which they do not recover for weeks after. Transfer before they have any brood to speak of, or else wait until you get a full stock of bees, is my advice.—G. L. TINKER.

No, wait until fruit-bloom. Then the weather will be warm enough so that you can "do the job" safely, and the incoming honey will cause the colonies to build up and repair rapidly, and also prevent any tendency

to robbing that would be sure to follow the attempt to transfer earlier.—**J. E. POND.**

Transfer them during fruit-bloom.—**THE EDITOR.**

Catching Swarms.

Query, No. 394.—Is there any successful method of catching swarms as they issue from a hive?—**Monticello, N. Y.**

Why, certainly; consult the books.—**A. J. COOK.**

None that I should care to practice.—**G. L. TINKER.**

Some use a bee-tent with reported success.—**G. M. DOOLITTLE.**

I have never used a swarm-catcher; but, in my opinion, a swarm-catcher is a possibility, but not a practicality.—**W. Z. HUTCHINSON.**

Yes. If you see the swarm in time you can catch the queen as she comes out. We have done it often.—**DADANT & SON.**

They can be caught with a net placed before the entrance. I have often caught them in that way when several swarms were issuing and were liable to cluster together.—**C. W. DAYTON.**

I have failed to find a good, practical method. A few low trees in the vicinity is good enough for all practical purposes. If they attempt to leave, catch them with a shot-gun.—**H. D. CUTTING.**

They can be caught by means of a long box partly covered with wire cloth. The box must be placed over the entrance of the hive just when the swarm starts out. I tried this plan during our great swarming year, 1883, but I do not think it "successful" or practicable.—**G. W. DEMAREE.**

I know of no certain method. One plan is: On the eve of swarming or before, place the empty hive beside the old one, and adjust a yard to the entrances of both hives. This yard, by swarming doors, will admit the queen into it from the hive, but as she cannot get out nor back into the old hive she has to pass into the empty hive followed by the swarm. This plan worked well with fully developed queens, but not with virgin queens.—**J. P. H. BROWN.**

That depends upon the style of the hive, how arranged in the apiary, and how closely that apiary is watched. Possibly, yes.—**JAMES HEDDON.**

My queens' wings are clipped, so that if desired the swarm can be caught as it returns. Others have caught swarms at issuing by allowing them to run into an arrangement prepared for the purpose.—**C. C. MILLER.**

Quite a number of plans have been given during past years; none of them, however, have seemed to me to be practical. I know of nothing better for the purpose than a queen and drone trap; that will catch the queen, and then of course you can manage the swarm.—**J. E. POND.**

Use a swarm-catcher, or a drone-and-queen-trap.—**THE EDITOR.**

Queen-Excluding Sections.

Query, No. 395.—Would it be advisable to make the slots in the sections, so that when two are placed together they will be queen-excluding, and thus save the expense of queen-excluding honey-boards? If not, what would be the objection to this plan?—**KY.**

While the plan might be feasible, I have never tried it.—**J. P. H. BROWN.**

I do not think you can get sections made exact enough to work.—**C. C. MILLER.**

This plan will do if you must exclude the queen at the expense of ventilation and convenience.—**DADANT & SON.**

No. Such an arrangement could not be made perfect enough to accomplish the object.—**G. M. DOOLITTLE.**

No. We need to see between the sections. I prefer $\frac{3}{8}$ of an inch space. We need the honey-board anyway, to keep the sections neat.—**A. J. COOK.**

In this locality, with the great amount of propolis, they will fill up too many of the spaces. I have had trouble in this line.—**H. D. CUTTING.**

A queen-excluding honey-board is not always needed, and the openings cannot be made sufficiently exact in the manner mentioned.—**W. Z. HUTCHINSON.**

I believe that plan would work to advantage, in getting the bees into the sections, but it might be objectionable by reason of brace-combs. It certainly would save the expense of a honey-board.—**C. W. DAYTON.**

No; the objection would be that the ordinary sections could not be made accurate enough, and if they could be, bees are disposed to stop up the narrow passages made of wood. The use of perforated zinc as a queen-excluder is not open to this objection.—**G. L. TINKER.**

I have never tested the matter, but fear the workers would not occupy them readily if the slots were so narrow as stated. It is difficult at times to get bees into sections, even when a much larger space than would allow a queen to pass through is given.—**J. E. POND.**

The objection to the plan is, sufficient accuracy of the width of the slots cannot be obtained in that way. Besides, every section would have to be perfect, and this would add to the cost of making the sections. The shrinking and swelling of wood makes that material unreliable as a queen-excluder.—**G. W. DEMAREE.**

That will not work; I have tried it. Sections are never made perfect enough; they never will be. Wood in any shape will never prove a success for forming queen-excluding work-passages for bees.—**JAMES HEDDON.**

The "slots" could not be sufficiently accurate to be depended upon.—**THE EDITOR.**

The annual meeting of the Stark County Bee-Keepers' Society will occur on Apr. 12, 1887, in Orange Hall (over Farmer's Bank), Canton, O. Officers for the ensuing year will be elected. All bee-keepers are urged to be present, and those having hives or fixtures are requested to bring the same for exhibition. **MARK THOMSON, Sec.**

For the American Bee Journal.

Proposed Honey-Producers' Association

G. M. DOOLITTLE.

I have carefully read and re-read the article on this subject, found on page 774 of the BEE JOURNAL for 1886, and I must confess that I am that thick-headed that I cannot see anything of benefit in the course advised for the world as a whole; not but what I would be the last one to cry prices of our production down to the helping to enrich another beyond a fair compensation for his labor, for this would be unjust to myself. The question that comes to me (and ought to come to every one, it seems to me), is, have I a right, by any combination of persons or monopoly of any kind, to extort money from any or all, that I may receive and reap a benefit to to myself? I claim that I have no such right, and any effort on my part so to do is contrary to the teachings of Holy Writ, and shows me to be selfish, not loving my "neighbor as myself."

Again, I object to such a wholesale slaughter of our commission wholesale-dealers. These are charged with being responsible for the low prices of honey, but for the life of me I cannot see how or where. Honest, sober thought, it seems to me, will convince any person who loves his "neighbor as himself," that our present prices of honey have come from a production so great that the "thousandaire" cannot purchase it all, while the wages of the day-laborer have been so reduced that he cannot afford it as a luxury as they could 12 to 16 years ago, when they were getting 300 per cent. better pay than they are now. The persons who have their thousands are not the majority class who consume honey; if they were there would be no oppression in advancing prices to a certain extent.

Who are the consumers of honey? The majority of them are the laboring class who now get from 75 cents with board to \$1.50 and board themselves, for a day's labor. Will Mr. Baldrige change his occupation as an apiarist at the present prices of honey with any of these, thinking to make money at it? I would not. I could not do the labor of any of these men for a single month, and yet I manage my apiary and have double the money as pay for the same at the end of a year that they do; this from the sales from the apiary even at our "ruinous" prices.

Again, the commission men are charged as having "chief interest"

Regulating the Price of Honey.

GEO. F. ROBBINS.

in their commission, cutting prices to "get ahead of their rival commission neighbor." With my knowledge of commission men, this is "slanderous." I have on my books the names of a score or more commission men of whom I would not listen to reports regarding their bad practices, any sooner than I would to such a report regarding my pastor, a brother churchman, or my nearest neighbor. In fact, I know that they do not cut prices for the sake of making sales.

Two or three years ago I had honey in the hands of several of these, and to meet what I was very desirous of meeting, I wrote each to cut prices so that my honey might be sold inside of two weeks, so as to give me the cash I needed. What was the result? With a single exception they all replied by advancing me a liberal amount on my consignment, and saying that they could not cut prices for me, as it would injure the market and cause much loss to others who had placed honey in their hands. To be sure I have found one or two commission men whom I have had to drop from my list; so I have of neighbors and even bee-keepers, but I wish it understood that I believe commission men as upright as the average of mankind.

Then we are told that "every important business, almost, has an organization." Has the wheat-grower such an organization? the fruit-grower, the butter-maker, or the wool grower? These are all parallel cases. If they have, why is it that our farmers are selling wheat for less than the cost of production? Why was it that hundreds of bushels of small fruit was sold the past summer so low as not to pay the cost of freight and handling, say nothing of producing? Are we not getting crazy in thinking that we must organize or do something to prevent our being cheated and beaten by those outside the bee-fraternity?

Once more Mr. B. puts the retail price of honey at from 15 to 25 cents per pound, according to quality, and says that we should supply our home markets first. Does he not know that such prices would exclude our honey from nearly every such market in the land?

A year ago I thought I would try the plan of giving a good, round commission to our store-keepers, and see if I could not enlarge the sale of honey in our town. From the quotations given in the bee-papers I figured what I thought my honey would net me shipped to commission men, and to this I added 20 per cent., as that was the commission I had decided upon as being great enough to induce the local stores to try to push the honey sales.

I then selected what I thought would be sold at home (taking only the *very choicest*, so as to be sure and have all count in the right direction), and shipped the balance, as I had formerly done. The price placed on the home-sold honey was 16 cents, instead of Mr. B's 25 cents, but the result gave only two cases of honey sold. What was the trouble? The store-

keeper was not to blame, for he used all his persuasive power. A little conversation that I overheard will explain all. It was this: A customer said, "What is the price of honey?" The store-keeper replied, "Sixteen cents. It is nice; let me sell you some."

"What is the price of your best C sugar?" "Six cents."

"Put me up 10 pounds of the sugar, for with it and some water I will make 13 pounds of syrup which will do me just as well as honey; for the prices of labor will not warrant me in any such extravagance as purchasing honey." So said the customer.

When I got returns for my honey shipped to commission men, most of them had sold it for from 1 to 2 cents above quotations, so that I had lost one cent at least per pound on what had been sold at home, and made a failure besides.

Again, it is the bee-keepers of the West that are grumbling as to prices this time, while the year before it was we of the East. Why is this? Simply because last year there was a large crop in the West, while the year before the large crop was in the East. Does this not show us that supply and demand is the great regulator of all this, and not organization? The Bee-Keepers' Union cannot fix the price of honey for the United States, even at the risk of losing that \$1.25 offered to it by Mr. Fayette Lee, if it will do so. My honey brought 1½ cents per pound more in 1886 than in 1885, and does any one suppose that I would have the Union fix the 1885 price on the honey of 1886? No. I hope that bee-keepers will see the folly of such nonsense.

As to the columns of the bee-papers being used as an advertising medium for commission men, I did not so understand it. I supposed that was a part of what belonged to me as a subscriber. No, Mr. Editor, I object to leaving these reports out, and I am not ashamed to have it known that I do so object! After the organization, that Mr. Baldrige wishes is perfected, will he rent a store in some of the many smaller cities of the West, handle and sell all the honey that is sent to him, become responsible for all losses, worry and bother, and pay for the privilege of quoting the prices of honey in the different papers—all for 5 per cent. commission? I trow not. Yet this is all a large proportion of the wholesale commission men ask.

I wish to emphasize Mr. Heddon's statement, that "if we as bee-keepers desire to bring ourselves into bad repute... we could not do it faster than by perfecting this proposed organization," or causing to be enacted legislative laws, both of which, as I understand them, are looking toward that which is not for the good of all concerned, but rather toward selfishness.

Borodino, © N. Y.

The Union Bee-Keepers' Association of Western Iowa will hold their next annual meeting at Dexter, Iowa, on Saturday, Apr. 9, 1887, in the Council Room, at 10 a.m. All interested in bees or honey are requested to be present.
J. E. PRYOR Sec.

When Mr. Baldrige said that the commission merchants are largely responsible for the low prices of honey, I think he made a statement that he cannot sustain. It may be so, but I more than doubt it. From what I can learn, I judge that the dealers have good reason to lower prices. It is certainly reasonable to suppose that considerably more honey could be sold at from 11 to 12 cents per pound than at 14 to 16 cents. I am not insensible to the effects of competition in lowering prices; but even commission merchants will generally get the best prices they can; and I should say that a man in that business is far better qualified than are producers, to judge how near or at what prices the demand will take in the supply. I do not believe that the supply could be disposed of at prices 3 cents higher than those now obtained.

But there is yet a soberer phase to this whole matter. The question occurs, are combinations right? for that is what the idea of a honey-producers' association means. I hate combinations. They are the very bulwarks of monopoly, and who does not hate monopolies, except the few who profit directly by them? To be sure, monopolies generally work to the benefit of the few and to the detriment of the many. It is much easier for 100 brewers or fruit-jar manufacturers to combine, than for 100,000 farmers or 10,000 bee-keepers. The last two appear to me impossible, it is true. But we are now assuming, for the sake of argument, that such consolidation of interests and effort are possible. Would such be any the less monopoly, because engineered in the interest of a greater number? Whatever may be the legitimate benefit of association of interests, they always beget clannishness, and clans are characteristically narrow and selfish. There is a great deal of human nature in them, as Mrs. Chaddock would say.

The producer thinks that the middle man makes all the money; the middle man says the producer gets it all. The capitalist tells you that his employes are the only ones who make anything; the employes do not think so, by a long ways. The purchaser thinks a certain price for honey is "awful high," the apiarist calls it "awful low." So it goes. Now, to be fair with one another, each should place himself, so to speak, in the condition of the other, then adjudicate his warring claims. Hence we honey producers may well pause and inquire if our combinations and arbitrary prices are right.

Mr. B. thinks that 20 to 25 cents per pound for nice honey is only a fair price, and 16 to 18 cents is fair for inferior grades. If he were a wage-earner at \$2 per day—or less—he would not think so. The laborer with a good appetite, who cannot spread the sumptuous table that his employer

can, will be one of our best patrons, if he can reach our prices. But he cannot reach 20 cents per pound, and it is a wrong to keep it beyond his reach if we can otherwise make a living at the business. This I am confident we can do; and, I repeat, *must* do, if we continue to produce honey in such quantity as we do now.

During the last four years I have fought the downward tendency of prices as stubbornly as any man, but recognizing, as I must, both the necessity and the righteousness of the decline, I can best yield and "make the best of it."

There are two reasons for the downward movement in the prices of honey. One is the general change in the standard of values. Property is increasing much more rapidly than the circulating medium, and the one must adjust itself to the other. The second reason is the rapid growth of the industry itself. There is so much more honey thrown on the market than there was five years ago. That honey has declined out of proportion to other commodities, I agree is true; but it will not always be so. We must, and will, reach a more permanent footing soon. As water will find its level, so our industry will find an equilibrium as nearly as any occupation ever does.

But, chiming with others I would say, there are two things we must do: First, lower the cost of production; second, develop our home markets.

As to the market reports, that column is one of the first I look for, and I would be sorry to miss it.

Mechanicsburg, © Ills.

For the American Bee Journal

Feeding Syrup to Bees.

J. L. HUBBARD.

I desire to thank those who responded to my query (No. 374) on the above subject, and will now give my experience.

Some 18 or 20 years ago I was selling my surplus bees, and frequently had occasion to feed them, buying sugar at times by the barrel. Thinking the hives did not gain as fast as desirable, I occasionally weighed one before and after feeding, and came to the conclusion that I got an average increase of about 6 pounds for 10 pounds of sugar dissolved to make 16 pounds of syrup. I used to let the syrup boil, but if less than 6 pounds of water was used it would skim over when cool and granulate in the cells. After getting an extractor I added a portion of honey to the mixture and had no more trouble with granulating in the cells, and could use less water.

My object was to show the expense of feeding sugar in comparison with honey. It is an easy matter to have plenty of honey stored in combs for this purpose, saving the labor of extracting and the expense and trouble of re-feeding, for there is a great loss in re-feeding extracted honey as well as feeding sugar syrup.

An experiment in this line I find recorded in another paper. The cor-

respondent says: "To 20 colonies was fed 3,500 pounds of extracted honey, or an average of 175 pounds per colony in 35 days. The total amount of comb honey received from the 3,500 pounds was only 1,250 pounds, or 62½ pounds per colony, all in one-pound sections. The total amount for the 20 brood departments was 800 pounds, or 600 pounds of the 3,500 pounds of extracted honey stored in the 20 hives."

Here we see 1,650 pounds was used for brood rearing and other purposes, while 1,850 pounds was stored, an average of less than 5½ pounds for each 10 pounds fed. In this case a large increase of bees is reported, which was of some value.

Section-Case for Surplus Honey

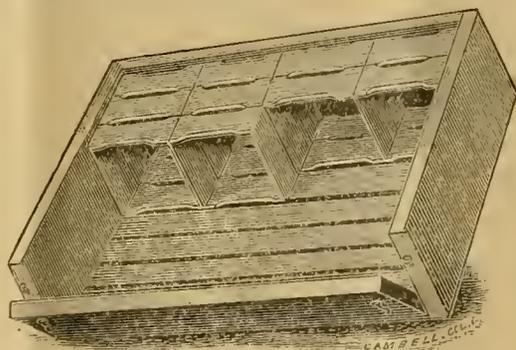

FRANK A. EATON.

I use an 8-frame Langstroth hive for comb honey, and make a section-case of the same material, and of the

one bee-space between each tier. The sections are protected from brace-combs on the bottom, by the slats, the same as in a wide frame without the use of a skeleton honey-board, with a bee-space above and below it, which takes up a valuable space, besides separating the sections too widely from the brood-chamber. The movable or hinged side loosens the sections all at once, making it easy to remove them, and also allows the removal of sections if desired on the hive.

There are important points of construction that would not show in an illustration. The case embraces all the advantages of single-tier, wide frames, and a regular open-case combined, as it allows the use of separators or not, as desired. With wide frames an outer case is necessary to hold them. All I have is the outer case and the bottom-bar of the wide frames combined, doing away with the top and end bars, thereby admitting of taking hold of the top of the section instead of working the sections out of a wide frame, as it is usually done.

Bluffton, © Ohio.

Section-Case for Surplus Honey.

size of the hive. The crates are painted, and when set on the hive they form part of it. If separators are desired, they may be used in this case by slipping a ½-inch strip of tin between the two end rows of sections, so as to prevent the separators from going down between the slats; then, as you put in a row of sections place a separator in. However, I have no need of separators; by using sections 7 to the foot, without separators, they hold as near a pound as it is possible to obtain, and nearly every section can be crated. This statement is not made at random, but from actual experience, in obtaining comb honey without separators from 100 to 150 colonies for the past four years. Many of the cases in use have to be used inside the hive cover to protect them from the weather, and more than one or two cases cannot be used at a time, and have them so protected.

The cover raises with this case, as fast as tiered up, setting on the case the same as on the main hive, it being made of the same material as the hive, thereby protecting the sections the same as the brood-chamber.

It admits of tiering up to the best possible advantage, there being but

For the American Bee Journal

Temperature and Ventilation.

C. W. DAYTON.

As I believed too much upward hive-ventilation had been given in previous winters when the colonies were in the cellar, when the bees were carried in last fall each hive received two or more thicknesses of burlap that was pretty well covered with propolis. This would greatly retard upward circulation, but still allow some draft. The temperature (as in other winters) has been very steady, never going below 41° or above 43°. On raising these burlap coverings I find the bees motionless, and the underside of the burlap covered with many very large drops of water. Sometimes where the bees cluster close to the covering, the drops of water will be on the outside of the covering, and again where the bees cluster low on the combs the moisture will be attached to the upper part of the combs. Giving the hive a slight jar, a drop will become detached, and in proceeding downward unites with another and another, until quite a

quantity of water plunges into the cluster and greatly aggravates the bees.

For the first 50 days no moisture appeared, but from that time on until 90 days after putting them in, the water has appeared. The tendency for the accumulation of moisture (considering the temperature and humidity of the cellar), was so slight that it required nearly 90 days to become visible. Had the temperature of the cellar been lower, it would have taken less time, and *vice versa*. If the temperature of the cellar was low, the warm circulation of the cluster would not proceed upward so far before meeting air whose temperature would condense its moisture. If the temperature is steady the condensation will continue.

It may be supposed that a low temperature causes the bees to generate a greater amount of heat. This is not the case—they only cluster closer together or more compact, and while the temperature is increased at the centre of the cluster, it is less at the outside. I hardly think bees ever resort to activity to become warm.

When the temperature is low a large share of the bees on the outside of the cluster become more or less torpid, so that the cluster may be broken and shaken from the combs, and there will be but few bees in the centre of the cluster that are able to take wing immediately. This may be so in the case of a large colony. Then if the colony was small all of the bees might become torpid or chilled, and a little more cold prove fatal.

I have never noticed indications that the bees on the outside of the cluster changed places with those on the inside when they were in winter quarters, or when they were not rearing brood. When the temperature is such that many of the bees on the outside of the cluster become inactive, they are not wintering well, and though they may remain quiet for a time, indigestion will eventually disorder them. In the case of a large colony there might be comparatively few diseased, so as to manifest symptoms of disease during the remainder of their confinement, but enough healthy bees may still remain to build up the colony to gather honey. If the colony was small, the sick ones would be likely to include all, so that it would soon dwindle away if they should not abscond as soon as removed from the cellar.

When the temperature is low, say at 30°, it causes the bees to cluster compactly, and a large part of the cluster becomes chilled and inactive. If the temperature is high, they remain active and ready to leave the cluster at any occasion. The place to fix the temperature is where the bees on the outside of the cluster will remain clustered because of the cold and for safety. But few if any of them should become stiffened by the cold. Then when there is no disturbance on change of temperature, the bees will remain clustered and motionless all winter, but may be immediately roused to action. When this condition is maintained 90 out of

100 strong colonies will come out strong and healthy in the spring. If the colonies are suspended in "mid-air" the temperature must be 44°. A lower degree of temperature will require coverings of cloth or cushions. The temperature at the center of the cluster averages about 70°, and 56° at the outside, when the bees are quietly clustered.

Case for One-Pound Sections.

DR. C. C. MILLER.

In the following letter Mr. Funk refers to a case he has already mentioned on page 121:

"BLOOMINGTON, Ills., March 7, 1887. —I have spent considerable time calculating on a surplus arrangement for comb honey this winter, as I will have to rig up from 50 to 75 more colonies for comb honey this year than before.

On page 121 the reader may see the result of some of my speculations. I think I can make it work. Possibly a strip of wood laid across the honey-board cross-wise, and strips between the cases might be an advantage to support the sections. What does Dr. Miller think of the case as described on page 121?

The objections I have to the T supported case, are the spaces between the sections, and in open-side sections these would be still worse; but I think the case preferable to the Heddon, although my experience is very limited.

The object of this letter is to get Dr. Miller's opinion on some other style of one-pound sections than the 4¼x4¼. With his T case, and the case I intend to use, 4 sections will not be long enough for the Langstroth hive; that is, the case that takes 4 sections (4¼) lengthwise will not be as long as the outside of a Langstroth hive, and of course we do not want another rim or cap over the case.

What would Dr. Miller think of a section 5 inches high by 3 11-16 inches wide? Five of these would fill a case that was 20 inches long, and allow ¾-inch for each end-piece, and give 1-16 of an inch space to allow the section to slide in. His T tins would want some room, but they would make the case stronger, and the ends could then be a little thinner. What length of case does he use now? Also what sections? The advantages of this section would be several—first, and the main one, the case would be as long as a Langstroth hive. Second, this section would look just a little better proportioned than the 4¼—more like the 6¼x5¼, and all know they appear nicer than the 4¼x4¼. The main objection would be an odd size section—but perhaps they would take well. I know they would if they were given favorable mention.

My 240 colonies are doing nicely; I think they will winter well.—H. W. FUNK."

Mr. Funk being a practical beekeeper of good common-sense, and

withal, I think, a good friend of mine, I do not need to try hard to make a very smooth reply.

And now what under the sun does he want to get up a new section for? If every man is his own manufacturer it does not make so much difference, but the fewer kinds there are, the easier, and to a certain extent the cheaper we can get them from the makers or dealers. Is it true that an oblong section presents any more attractive appearance than a square one? I doubt it much, and I do not think that Mr. Funk would care much for anything of the kind only as a kind of a necessity. The necessity arises from the fact that a super long enough for four 4¼x4¼ sections is not as long as a Langstroth hive. Allow me to say that in actual practice that presents no great difficulty. My hives are 20½ inches in length, and my T supers 19½, a difference, you see, of 1½ inches. At the back end there is a space, which, following in the footsteps of Adam Grimm, I consider desirable for ventilation; but if at any time I want the space closed, I simply lay a little pine strip over it, and it is just as well, I think, as if super and hive were the same length. The regular Langstroth, which is better, has frames ⅝-inch shorter than mine, so there would be less space to shut.

The open-side sections have been tried, perhaps, more than Mr. F. supposes. I gave them a pretty fair trial. The claim that separators are not needed with them did not prove true in my case, and I do not know of any advantage they possess, although theoretically I thought I saw advantages. I do not believe they will do anything to prevent swarming.

Mr. Funk objects to the space between sections in T supers. Put T tins on the top as well as on the bottom (they only cost \$1 per 100), and no bee can touch the side of the section.

If Mr. Funk should make such an arrangement as he has mentioned, I think 1-16 space for the sections to slide in, will be rather close work.

I never tried it, but I think I should like the ⅝-inch board used as a follower. But that could be used in the T super, and I believe Mr. F. might like the T super.

For the American Bee Journal.

The Cappings over Honey.

C. P. DADANT.

The reason which Mr. Hutchinson gives, on page 152, for the non-candyng of the honey referred to, is not satisfactory to me. If the protection which the cappings afford is sufficient to prevent candyng, it must also be sufficient to prevent the absorption of moisture. It is a fact worthy of notice that the same grade of honey which when extracted swells the barrel in which it is contained (air-tight), bursts the cells, and oozes out when left in the comb. I have seen the statement by different parties, that

honey which is left a long time on the hive, will ripen, even if sealed. To my mind the explanation of this is found in Mr. Dibbern's article on page 150. When any honey begins to work or ferment, the bees find it out and attend to it themselves.

There might, however, be one point which would divide the decision of the question, between Mr. Hutchinson and myself. It might be that during the hurry and bustle of a big crop, the bees do not seal the cells as carefully as they would afterwards, and perhaps the leaving of the honey in the hive until long after the crop is ended, permits them to attend to what they had before neglected. This would explain why honey-comb, which has been a long time on the hive, is tougher than that which is removed as soon as sealed. But the fact remains to me most positive, that the "bees aim at compact coverings for their honey, while the caps of the brood-cells are porous!"

I would suggest to Mr. Dibbern, that the honey in old combs ferments more readily, only when this old comb has contained unsealed honey which has fermented in the cells. If all the honey put by the bees into old comb fermented, there would not be an ounce of sound honey in the brood-chamber of an old colony. Like the juice of all fruits, honey will ferment in sealed vessels if it contains the minute germs, or spores, that are the seed of fermentation. The fermentation is more or less prompt, more or less active, according to the different degrees of temperature and the greater or less amount of watery particles, which furnish the oxygen indispensable to such transformation.

Chaff Hives for Winter.

C. G. BEITEL.

In Mr. J. H. Andre's letter, on page 154, he advances an idea that I have had for some time. I winter all my bees on the summer stands in chaff hives, but I could never see the benefit of chaff on the sides, for although an absorbent of moisture, none can reach it there, surrounded and enclosed with boards as it is, and I had decided to try a hive which contains air-tight chambers, lined with paper, but this as well as the chaff hive can only retain the warmth but a short time beyond a single-walled hive, and prevents the rays of the sun from warming it as quickly as a single-walled hive. I have never had much loss from the chaff hives, but my objection to them is their weight and cost over single-walled hives.

Now my convictions are, that bees never die from cold if properly prepared; give them plenty of good food, have them strong, and they will survive the most protracted cold spells, because in these spells they do what Mr. Clarke calls "hibernating," and they eat little or nothing. Diarrhea is not caused by pollen, but by

bad ventilation, so that they are compelled to absorb or inhale their own moisture, sweat, breath, or whatever it is called (which in the case of humanity we all know is a deadly poison), to obviate which an absorbent, such as a cushion on top, is necessary. I have therefore come to the conclusion that a single-walled hive, with a half-story on top containing a cushion, with plenty of good food, will see any strong colony through the coldest winter.

Protection of Apicultural Inventions.

J. E. POND.

The principle upon which our patent laws are based is as nearly correct as it is possible to make it. The best minds in the world have given the subject careful attention and study, with the result that our system of patent-right protection is the model one of the world. The basis of these laws is the generally recognized idea, by all men of all countries, that the inventive genius of man in any direction that will prove of value, should as much be protected as any other property he may possess, and for the reason that the results of brain-labor are property in any sense in which the word can be used; and to take advantage of these results without the consent of the inventor is theft, and theft of a meaner kind than that of purloining his horses, cattle or money. All honest men admit this, and admitting it, they ought in common decency to respect such property rights as much as they do the contents of a man's pocket-book.

Unfortunately all men are not thus honest, and many that would not steal a penny seem to think that it is all right to rob an inventor by using his invention without his consent, and if possible without his knowledge. The patent law steps in here, and guarantees to the honest inventor such protection as it can afford. What is this protection? It is the granting to the inventor the right for a certain length of time to own and control his invention, and to pursue the infringer and make him pay such money damages as he can show that he has suffered.

Now it may not be known to all that law in patent cases can only be purchased at very expensive figures, and right here is where the trouble lies in protecting patent bee-hives and apicultural appliances. The inventor and patentee of a valuable machine that costs largely to produce, or that is used largely in expensive manufactures, can well afford to pay the high cost of litigation, as the damages that will be gained are large also. Now let us apply this idea to the inventor of a bee-hive, section or any other article of use in the apiary. In the first place the demand for such articles is limited, to a certain extent, and the profit necessarily very small; the infringer, as a rule, is not a manufacturer (supplying a large trade,

but an individual in an apiary of not very considerable size. The cost of pursuing into the courts an infringer in a small way, is the same, or nearly so, as the large one, but the damages received in the way of cash, or its equivalent, is small, and in nearly every case would not be sufficient to pay the fee charged, and earned too, by the attorney conducting the suit.

In cases like the above, protection does not protect, for while the law is ample, the inventor is ruined in applying it for purposes of self-protection.

For the above reasons, and for many others that might be given, would they not make this article too long, I deem the patenting of any appliance of our apiaries as an expensive luxury, and one that will not serve the intended purpose. Not that I do not believe in patents, for I do most thoroughly and completely; but the experience of Father Langstroth is ever before me, and I know of no reason why any other would succeed better than he did. The remedy for this state of things may be made the subject of a future article; a complete one will be found, however, in the application of the "golden rule," by allowing to every honest inventor all his legal and moral rights in his invention, and respecting his property produced by brain labor, as though it was his actual chattels or money.

If this state of things should obtain, there would be far less bickering and disputes over hives, etc., and I guarantee that no larger prices would be demanded for them than we are now paying. Is there a bee-keeper in the country who does not recognize the obligations of the moral law? Why not then apply the same to their dealings with their fellow-men?

Foxboro, Mass.

For the American Bee Journal.

Phenol and Foul Brood.

S. J. YOUNGMAN.

The first known case of foul brood in this county (Montcalm) was discovered by Mr. A. F. Moon (a veteran bee-master, but now deceased) while transferring a colony from a box-hive to the Harbison hive, over 20 years ago. Mr. Moon was assisted by a Mr. Hiram Rossman; although the malady had never before been seen by Mr. Rossman, it was not new to Mr. Moon, who had met with it repeatedly in transferring.

In the fall of 1885, Mr. Rossman and myself visited an apiary near Greenville, Mich., where foul brood was said to exist. Mr. R. was able at once to detect the presence of the disease, principally by the peculiar odor arising from the hive when opened, and later on by the depleted condition of the hive, and other unmistakable characteristics of the disease. This one case seemed to be all, although it was quite an extensive apiary, and the bee-keeper had been careless. We advised him to destroy the affected colony, which he did, and he recently

told me that he has had no recurrence of the trouble.

I have since seen many cases of foul brood, the result of importing some bees from the South, and find that in the first stages it may be easily eradicated by the use of absolute phenol, fed with diluted honey. First extract all the honey that the affected colony may have, and pour the medicated feed directly into the cells of brood, as well as empty cells, and upon the bees, if they should be in the way. Phenol is carbolic acid in a more concentrated form, and is one of the greatest disinfectants known. All having any trouble with foul brood among their bees should try this remedy; they will find that this much-dreaded disease will soon yield to this treatment.

Cato, Mich.

Read at the N. E. Michigan Convention.

Items in Bee-Keeping.

R. L. TAYLOR.

In bee-keeping the spirit of the adage, "Take care of the pence, and the pounds will take care of themselves," is as applicable as in financial matters, so I will recount some of the "little things" which I have learned in my experience in the apiary.

HOW TO CUT FOUNDATION.

The most convenient way I have discovered to cut foundation into pieces of the right size for sections, is to take a board a foot wide or more, and somewhat longer than the sheets of foundation, to one end of which nail a head-board against which to lay the sheets of foundation to keep them even. This head-board should extend above the main board about 2 inches. Now on each edge of the main board, beginning from the head, at intervals corresponding to the size of the pieces into which it is desired to cut the foundation, securely nail blocks so placed as to extend sufficiently above the board as to slightly overtop the largest pile of foundation it is desired to cut at one operation. These blocks are to guide the rule, and are much better for that purpose than nails.

Now fill the board with foundation, putting in as many piles as the width of the board will accommodate, taking care to keep them of an equal height, and with a good knife, a good lubricator, and a straight edge, begin at the foot of the pile of foundation, and it will be found but the work of a moment to cut from 100 to 500 pieces of just the size required.

For cutting the wax there is nothing so good as a case-knife of good material, with about one-half of the length of the blade removed in such a manner as to leave the remaining part of the blade with a slant from the point of the edge back. Of course the knife should be pretty thin.

For lubricating the knife for cutting wax, nothing is better than a solution of Babbitt's concentrated lye. This lye cannot be well kept exposed to the air, and it seems to lose

its virtue when kept any great length of time in solution; but I have found that it can be kept conveniently in a dry state in a common Mason fruit-jar, if the cover of the jar be kept screwed down.

MATERIAL FOR BEE-FEEDERS.

If wooden feeders are used, no doubt many have had trouble as I have with their checking, so as to cause leakage. By using basswood for feeders I have entirely rid myself of that trouble.

HOW TO CARRY BEES.

For carrying bees into the cellar and taking them out, where two persons are at command, I have found very convenient a horse made by fastening two pieces of light scantling about 18 inches apart, side by side, and supplying the platform thus made with 4 legs of convenient height. The scantling may be fastened together by simply nailing four or five pieces of narrow board across, leaving a space clear for a pair of handles like those of a wheel-barrow at each end; that is, the ends of the scantlings are to serve for handles. The legs should be well braced. Upon this two persons may carry 2 or 3 colonies easily, rapidly, and with little disturbance to the bees. This horse will also be found very convenient for carrying empty hives, cases with sections, etc.

DARKENING CELLAR WINDOWS.

The easiest and most effective way to exclude the light from windows in a bee-cellar, is to tack over the sash of each a piece of tar-paper, such as is used in the walls of buildings. If it is desired to use the window for ventilation, and at the same time to exclude the light, make a light box about 6 inches deep without top or bottom, of such size that when set on its side it will just slip into the window-frame; fill this box with hay or straw, kept in place by narrow slats nailed across both top and bottom, then slip it on its side into the window-frame in such a way as to leave the sash free to open and shut, and there will be ventilation day or night without danger of admitting light.

HOW TO SHEET WAX.

Some may be interested in knowing the proper method of dipping wax for foundation-making. It is a very simple process, but it cost me a good deal of time to learn one or two very simple things. I cannot enter into details, but will say that there cannot be much trouble if the dipping-boards are kept sharp; that is, keep every corner of every edge (side and end) as pronounced and perfect as sharp tools can make them on straight-grained wood, and see that the boards are thoroughly water-soaked, and then have the wax barely warm enough to prevent its hardening on the surface. In other words, the temperature of melting wax is the best temperature, though it will answer to have it a few degrees warmer. It should be remembered that it requires considerable time to reduce the temperature of boiling wax.

A GOOD WAX-EXTRACTOR.

Having a large number of combs to render into wax, I found it a slow operation to effect this with the Swiss wax-extractor, so having a can about 2 feet in diameter, and 20 inches deep, I had a basket made of perforated tin, such as is used in the Swiss wax-extractor, about 5 inches deep, and of a diameter just such as to allow it to slip feely inside the can. The basket is strengthened with heavy wires across the bottom, and has legs of folded tin about 4 inches long, and wire rings for handles.

To operate it, I put the can on the top of the cook-stove in my honey-house, with 2 or 3 inches of water in it; put in the basket and fill up with combs, frames and all, and cover closely. With a fire under it, the water being shallow, it boils quickly, the steam melts the combs in a few minutes, when the frames can be removed and the can refilled—a process which may be repeated several times before removing the refuse; before doing which, opportunity must be given for all the wax to run through the basket. Of course care must be taken to keep the can always supplied with water. The melted wax may be drawn off through a faucet in the can.

Lapeer, Mich.

For the American Bee Journal.

How to Market Honey.

A. D. STOCKING.

Mr. Joshua Bull, on page 133, has exactly given my experience in marketing honey, in a much better manner than I am capable of doing. I have long argued this manner of selling honey, and I believe that if this plan was more generally carried out, it would soon solve the problem of the honey market. His plan of small cases for family use I have used for several years, and I am satisfied that I have sold more honey than I could have done without them. I made them to hold from 6 to 18 one-pound sections of several different sizes.

Like Mr. B., I had nice show-cases standing in a prominent place on the counters of the grocers; I also would leave some of these small cases with them, and many a time I have sold a small case where but one or two sections would have been sold but for them. I gather up the cases in the spring, and mine are good yet. Those who have not tried this plan would be surprised at the results. I also have found an excellent market amongst the farmers. I have had the market prices of Chicago quoted to me, but I have placed my honey by the side of imported honey, and have always sold it at a higher price; and then the contrast between my nice, clean honey, beside the other, would be so great as to advertise mine.

Almena, Mich.

There is no Mistake in insisting that—as in all other things, so in advertising—the best is the cheapest, no matter what its first cost may be.

Local Convention Directory.

1887. *Time and place of Meeting.*
 Apr. 9.—Union, at Dexter, Iowa.
 J. E. Fryor, Sec., Dexter, Iowa.
 Apr. 12.—Stark County, at Canton, Ohio.
 Mark Thomson, Sec., Canton, O.
 Apr. 16.—Marshall County, at Marshalltown, Iowa.
 J. W. Sanders, Sec., LeGrand, Iowa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Bees all Right.—F. W. Schafer, Deesville, ♀ Iowa, on March 14, 1887, says:

Bees have wintered nicely so far; out of 22 colonies wintered on the summer stands only one died, and that dwindled on account of diarrhea, I think. Thirty-six colonies in the cellar have come through all right so far. I put them out-doors on the morning of March 12, and some were at work in the afternoon. My father, who has about the same number of colonies, lost two.

Using Foul Broody Combs.—One of our Canadian subscribers writes as follows:

Suppose that foul brood makes its appearance in an apiary that has been run for extracted honey; the combs have been exchanged from one hive to another during the honey-flow, and a good many of them have been taken from diseased colonies, and are at the present time mixed up with combs from healthy colonies. What is best to do with them? Would you melt them all up, or will they be safe to use again?

[By all means melt up the combs—it will not be safe to use them as they are.—ED.]

Bees in Fine Condition.—A. J. & E. Hatfield, South Bend, ♂ Ind., on March 15, 1887, write:

Our 230 colonies of bees are still in the cellar, and to all appearances they are in the finest possible condition.

Peach-Trees in Full Bloom.—J. W. Howell, Kenton, ♂ Tenn., on March 10, 1887, writes:

My bees gathered their first natural pollen on Jan. 25. The weather has been fine ever since, and the bees have been working lively. Peach-trees are in full bloom, and bees are getting the nectar from them. My colonies are strong and healthy. I lost only 3 out of 125 colonies, in wintering, and all wintered on the summer stands in Langstroth hives. I ship no honey to market. I have built up a home market, and sell all I can produce. I get 12½ cents for sections of 1-lb. each.

Bees in Good Condition.—Otto Kleinow, Detroit, ♂ Mich., on March 11, 1887, writes:

Bees are in very good condition; I expect to have early swarms, as most of my colonies are very strong. I have about 110 colonies of Italian bees; some have Albino queens mated with Italian drones. I also have a few pure Albinos. I think the bees of the queens that are crossed with Albinos, or with Italian drones, are very good honey gatherers—a little better than light-colored Italians.

Alsike Clover for Fodder.—Mr. Wm. M. Carr, Bradford, ♀ N. H., on Feb. 26, 1887, writes thus:

Have you published a leaflet showing the advantages of Alsike clover for fodder? If not, I should think a circular for distribution among farmers would find ready sale among bee-keepers who wish to increase the cultivation of Alsike among their neighbors.

[We have been requested several times to publish a Leaflet on this subject, and will do so at once, as suggested. Its title will be "Alsike Clover for Hay and Pasturage." It will be ready for delivery as soon as this JOURNAL is in the hands of its readers. The prices will be 50 cents per hundred; 500 copies for \$2.25, post-paid. Order at once and scatter them far and wide.—ED.]

Bees in the Cellar.—Jas. W. Mills, Melleray, ♂ Iowa, on March 15, 1887, writes:

My bees are in the cellar yet. I have lost one colony so far, and some more of them have the diarrhea. I would put some of them out for a cleansing flight, but my cellar is so small, and the hives are crowded in so that I would disturb all the rest of them. One man who had 5 colonies in the cellar, lost all of them. I think that extracting last fall was the cause. Another man had 27 colonies and lost 7. I believe they were on the summer stands.

Condition of Bees in Missouri.—John Blodget, Empire, ♂ Mo., on March 12, 1887, writes:

My bees wintered well, and are bringing in pollen from the maples. I wintered them on the summer stands packed in oat-chaff. Some of my neighbors have lost very heavily, even 70 per cent. of their bees. Clover is all alive, and in all probability we will have a good year for honey. Last year the forepart of the season was good, and then it became so dry that I had to feed some nuclei to keep the queens laying until heart's-ease bloomed; but to the surprise of all there was no honey from that worth speaking of, so feeding was again the order of the day, or lose the weak nuclei, and they have wintered finely.

Legislative Protection.—Reuben Havens, Onarga, ♂ Ills., writes:

As a bee-keeper I ask no special legislative protection; I expect success only by *hard work*, strictly honest dealing, and striving to meet the wants of my customers in quality, style, and price of product. I find that pleasant words, kind acts, and the free use of honey will do more in controlling a "waspy" disposition than law. When these fail, and "forbearance ceases to be a virtue," and your pockets are large and full of money, go to law; not before. I fully endorse the action of the officers of the National Bee-Keepers' Union, and think if 3,000 instead of 300 would give their support to the Union it would prove grandly successful in protecting the rights of bee-keepers, and securing better prices for honey.

Wages in an Apiary.—C. W. B., of New York, asks the following:

What wages should an experienced man have for taking care of 130 colonies of bees, spring count, from the time they are taken out of the cellar until they are put back in the fall? The apiary is to be worked for comb and extracted honey, and about 50 queens to be reared for the apiary.

[Very much depends upon the locality, how well the 130 colonies are worked, etc. In general terms, I think a modern practical apiarist who is well up with the times, should command one-half more wages, to say the least, than a common laborer. I consider bee-keeping, in its true sense, partly a profession.—JAMES HEDDON.]

Wintering in a Damp Cellar, etc.—Esau Russell, Tiffin, ♂ Iowa, on Mar. 14, 1887, writes:

Last fall I moved my apiary of 70 colonies over three miles, and put them into a cellar of a house where nobody lived last summer, the beginning of December. After they were in 2 or 3 weeks water began to come from the entrances of some of the hives. I gave them more ventilation, and it soon stopped, but the cellar did not prove to be a good one, for the hives became moldy, so I put them all out, and the bees had a good flight on March 1 and 2; it was none too soon, as a great many of them had the diarrhea. I lost 7 colonies out of 70. One colony is a puzzle to me. A little while after I put them out I noticed drones coming out of the hive. A neighbor bee-keeper here said the colony was queenless. I told him that I did not think so, as it was a strong colony of pure Syrians. I examined them and found the queen and capped brood. The drones are fine ones; there are about 70 of them, I should think.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c. Not much call for extracted, and very little for comb.
BEEWAX.—25c. R. A. BURNETT,
 Feb. 21. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10@12c.; in 2-lbs., 9@10c.; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8@8½c.; in 2-lbs., 7@7½c. Extracted, California, 5@5½c.; buckwheat, 4@4½c. Supply of comb honey is large, and demand for all kinds is improving.
BEEWAX.—21@23c.
 MCCAUL & HILDRETH BROS.,
 Jan. 21. [34 Hudson St.

DETROIT.

HONEY.—Best white comb, 10@11c. Supply large and sales are slow.
BEEWAX.—23c.
 Mar. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—Extracted is firm at 4@4½c., and comb at 8@12c. per lb.
BEEWAX.—19@21c.
 Feb. 9. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively.
BEEWAX.—24 cts. per lb.
 Mar. 11. BLAKE & RIPLEY, 57 Chatbam Street.

CINCINNATI.

HONEY.—We quote for extracted, 4@7c. per lb. Nice comb brings 12@15c. per lb. in a jobbing way.
BEEWAX.—Good demand, —20@22c. per lb. for good to choice yellow.
 Jan. 22. C. F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, 1-lb. sections, sells at 12½@13c.; second quality white, 10@11c.; white 2-lbs., 10@11c. Buckwheat, 8@9c. Extracted, 5@6c.—Market dull.
BEEWAX.—25c.
 Mar. 3. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 11@12c.; 2-lbs., 10@11c. No call for dark. Whites extracted, in barrels and kegs, 10@6½c.; in small packages, 7@8c.; dark, in barrels and kegs, 3@5c. Demand fair and supply ample.
BEEWAX.—25c.
 Mar. 5. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8½@11. Extracted, white, 4½@4¾c.; amber and candied, 3¾@4c. Trade is quiet.
 Jan. 10. O. B. SMITH & CO., 453 Front St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lbs., 8@10c.; white clover 2-lbs., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 6c.; dark, 4@5c.; white sage, 5@5½c.; amber, 4½@5.
BEEWAX.—20@23c.
 Jan. 13. CLEMONS, CLOON & CO., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 8½@4½c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4½@5c.; in cans, 5@6c. Market dull.
BEEWAX.—Firm at 21c. for prime.
 Feb. 3. D. G. TUTT & CO., Commercial St.

Continuous Advertising brings much larger returns, in proportion to the outlay, than periodic or spasmodic advertising.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

OUR CLUBBING LIST.

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club

One yearly subscription for the AMERICAN BEE JOURNAL must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

ADVERTISEMENTS.

20 COLONIES of BEES for Sale, in 8-frame Langstroth hives, wired combs, strong in Bees and every way desirable—at \$6.00 per colony. **F. D. NAGLE,** 11A3t SOUTH HAVEN, MICH.

THOS. G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL.

The NEW Heddon Hive.

WE have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cover, bottom-board, and top and bottom of each sectional case has one-half of a regular bee-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bured for wires.

A **SAMPLE HIVE** includes the bottom-board and stand; a slatted honey-board, and cover; two 6-inch brood-chambers, each containing 8 frames; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separators, and the other without separators. This latter chamber can be interchanged with the other surplus, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

It is absolutely essential to order one nailed hive as a pattern for putting those in the flat together correctly.

Hives, nailed and painted, \$4.00 each.

HIVES READY TO NAIL.—In filling orders for these hives, in the flat, we make 6 different combinations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers:

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 18 frames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—in interchangeable, but not reversible. Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus stories as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-chambers. Price, \$2.30 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deductions from the above prices: Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at 1/2 cent each, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives, 5 per cent. discount; for 25 or more hives 7 1/2 per cent.; for 50 or more, 10 per cent.

THOMAS G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL.

Extraordinary Exchange!

HAVING disposed of my Bee-Supply business, at Des Moines, Iowa, to Joseph Nyaewander, I hope my friends and customers will be as generous with him in orders and good-will as they have with me. I am no longer in the supply trade here after March 1, 1887. **J. M. SHUCK.** 12A2t

WANTED, an active, reliable man in every city and town, desirous to work up local fraternal benefit societies. Cash pay. Address **THOMAS G. NEWMAN,** 925 West Madison St., CHICAGO, ILLS.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$6.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable slides in the Comb Baskets. The \$3.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$3 00
For 2 Langstroth " " 10x18 " ".....	8 00
For 3 " " " " 10x18 " ".....	10 00
For 4 " " " " 10x18 " ".....	14 00
For 2 frames of any size, 13x20 " ".....	12 00
For 3 " " " " 13x20 " ".....	12 00
For 4 " " " " 13x20 " ".....	18 00

HOW TO WINTER BEES,

ELEVEN Essays by eleven prominent bee-keepers, sent to all who apply. Address, **HENRY ALLEY,** Wenham, Mass.

DON'T GET LEFT!—Nothing extends reputation equal to the brilliant Chromo Bee-Card. See page 77, or address, **J. H. MARTIN,** HARTFORD, N. Y. 6W(3tm)40t

100 COLONIES of Italian BEES for Sale. **DANIEL WHITMER,** 9A9t South Bend, Ind.

100 COLONIES of BEES For sale cheap. Reason, too many. **H. NEUHAUS,** Burlington, Racine Co., Wis. 7A8t.

BEE JOURNAL

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. March 30, 1887. No. 13.

After the Shower, the tranquil sun ;
After the snow, the emerald leaves ;
Silver stars when the day is done ;
After the harvest, golden sheaves.

To Make Alsike Bloom Later, the first growth may be cut when about 6 inches high, thus delaying the blooming time until about the close of the white clover honey yield. It will pay to do this, for unless it is done, the white and Alsike will bloom at the same time.

A. O. Crawford has sent us a sample of his "Carton," or folding box for inclosing sections of comb honey. On the front and back of the box are nice printed labels giving the name and address of the apiarist, etc. The "Carton" makes a neat and attractive package, as well as keeping the honey from the dust while on the grocer's shelves.

The Production of Comb Honey as practiced and advised by W. Z. Hutchinson. This is the title of a new pamphlet of 45 pages, just from the press. It is very entertaining and practical, and any one interested in the production of honey in the comb will be benefited by its perusal. The subjects presented are: Securing Workers for the Harvest—Supers—Separators—Sections—Tiering-up—Hiving Swarms on Empty Combs, on Comb Foundation, or on Empty Frames—Building Drone Comb—What Shall be Used in the Sections—Wax, etc. It can be obtained at this office for 25 cents.

Leaflet No. 2, entitled "Alsike Clover for Pasturage and Hay," is now ready for delivery. It should be scattered at once into every neighborhood, in order to induce farmers to plant Alsike, that the bees may have the advantage of it for pasturage. We send them by mail 50 copies for 30 cents; 100 for 50 cents; 500 for \$2.25—all post-paid. It will pay bee-keepers to scatter these Leaflets, even if 9 out of 10 avail nothing. If ten farmers out of a hundred plant Alsike in any neighborhood, the bees will reap a very substantial reward.

Shipments of California Honey.—In their "Annual Market Review," Messrs. Sebacht & Lemcke estimate the California honey crop for 1886 at 2,000 tons of extracted and 500 tons in the comb. As to what became of this honey, they remark thus:

Exports to foreign localities have been very small compared with former years, and are as follows: To England during 1886, were shipped 3,475 cases (of these 1,500 cases were shipped before July 1, and belong to the crop of 1885). To France, 588 cases were shipped, and to Australia, China, Honolulu, British Columbia, etc., about 1,200 cases. Besides these exports by sea, some shipments have been made via New York and New Orleans to England, France and Germany, but in all they aggregate hardly over 2,000 cases of honey.

In 1885 the shipments to Europe were much larger, and besides large shipments via New Orleans from the Southern Counties, some 10,000 cases of honey were shipped only to England from here and Wellington by sailing vessel, and 11,000 cases in 1884 during the twelve months.

The small shipments to Europe in 1886 were caused by the low prices ruling there in consequence of too heavy shipments in the preceding years, and by no means by a decreasing demand abroad, because California honey finds more and more favor everywhere.

If the shipments to Europe during the past year must be called small, they have been unusually large to the Atlantic, Western and Southern States of this country. In 1886 2,643,440 pounds of honey were shipped by rail overland from here and Southern Stations against 1,270,000 pounds in 1885. These large shipments were made practicable in consequence of the low overland freights, and in consequence of a small crop in the Atlantic and Western States, and it is to be hoped that the freights will never be as high as before for honey, so that also in the future a large business can be done in this country with our honey.

The supplies on hand have been considerably reduced by these shipments overland, and in this city they are, at the present time, smaller than in 1886. We estimate stocks on hand in this city to be 1,000 cases of extracted honey and 700 cases of comb honey, and in the interior hardly over 4,000 cases of extracted honey and 2,000 cases of comb honey will be found.

The flooding of the Eastern and Southern States with California honey during the past year, has been ruinous to prices, and a very great detriment to all the honey-producers outside of the Pacific Slope. The Review states that the prices received by California apiarists were only "from 3 to 4½ cents per pound, according to quality." These prices are ruinously low! and, as a result, the prices all over the United States have been lower than ever before!

But now the "prospect" is brighter!! California will have only half-a-crop this year, and prices in San Francisco have already advanced 25 per cent., with a "rising" tendency! In Europe, the large stocks of last year have been greatly reduced, and there will be a lively demand in that quarter—this will also enhance prices! The quantities of extracted honey now held in all great Marts of Trade should not be sacrificed—for now the prospect of an advance in price is better than it has been for a year. Those who have honey in the hands of commission men should hold it "firm" at fair figures, and thus sustain and "bull" the market!!

The "gloom" on the honey market is passing away, and the "fog" is being lifted by the bright sun of "rising values," which even now begins to arise on the East horizon! Very soon will it bring joy and gladness to the apiarists all over the country!!

Good Advice to beginners is given by F. L. Dougherty in the *Indiana Farmer*, in the following lines:

In beginning bee-culture do not spend too much money—he contented with small things—supply yourself freely with bee-books and literature—do not be economical on this point; then get a few colonies of black bees to be Italianized afterward; read, observe, and make good use of your observations.

Hon. C. F. Greening, of Grand Meadow, Minn., has great confidence in Italian bees. He says he knows them to be good, and that they will gather honey and multiply when black bees will starve. He has demonstrated that they are earlier and later at work, are stronger, and moth-proof.

Swarming is at its height here about the last of June and the first of July. During this time it is essential for the bee-keeper to be constantly on the watch for issuing swarms, unless he practices dividing, and knows their condition from constant association.

Room for storing honey must be abundantly furnished at a time when it is being gathered. If not supplied, idleness will be encouraged, and perhaps loss from swarming incurred.

Another lying newspaper item about comb honey has already appeared in the *Milwaukee Sentinel* and other papers, which reads thus:

The artificial honey now made in New York, is so close to the genuine that only the experts can detect the difference. It is in "racks" the same as the natural product, and then the wings and legs of a few dead bees are to be found to further the deception. It can be sold at a profit for 10 cents per pound, and the honey-bee may go.

That "racket" must have "racked" the brain of the writer—for the "natural product" of comb honey is put up in "sections," not racks! and it does not contain the "wings and legs" of dead bees! There is not a truthful sentence in the whole paragraph!

Catalogues for 1887.—Those on our desk are from

George Neighbour & Sons, London England—70 pages—Bee-Appliances.

Martin & Macy, North Manchester, Ind.—24 pages—Bees, Queens, and Bee-Keepers' Supplies.

J. B. Mason & Sons, Mechanic Falls, Maine—24 pages—Bee-Keepers' Supplies.

Geo. H. Knickerbocker, Pine Plains, N. Y. (Silas M. Locke, Manager of Bee-Farm)—4 pages—Bees, Queens and Smokers.

Chequasset Kennels, Lancaster, Mass.—6 pages—Dogs.

Levering Brothers, Wlota, Iowa—8 pages—Bee-Keepers' Supplies.

S. H. Blosser, Dayton, Va.—8 pages—Queens and Supplies.

A. O. Crawford, South Weymouth, Mass.—8 pages—Bee-Keeping Specialties, Cartons, etc.

Rev. R. H. Fisher, Oshkosh, Wis.—14 pages—Silk-Worms and Silk-Culture.

C. D. Duvall, Spencerville, Md.—16 pages—Queens, Bees and Poultry.

For a Public Man, who has served the country in the Cabinet and the Diplomatic service as Minister at the greatest European courts, and as her ablest and most philosophic historian, George Bancroft is little known to the majority of readers, so far as his personality is concerned. The opening article in *Frank Leslie's Popular Monthly* for April, presents him to us as he is, and the sketch by Asburn Towser is extremely clever. The Voyage Down the Red Sea is cleverly told by Col. C. Chaille Long, whose knowledge of Egyptian matters is so wide, and who shows great personal observation and skill in describing. The stories, of which there are several, are extremely good reading.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—Ed.]

Size of Apiary for One Man.

Query, No. 396.—In running an apiary for comb honey, desiring no increase, and using the latest improved hives and supers, how many colonies can one man, having a good knowledge of the business, handle so as to bring the best returns for the money invested and the time spent?—J. C. MILLS.

From 100 to 200 colonies.—J. P. H. BROWN.

I should say about 100 colonies.—G. M. DOOLITTLE.

Those words, "desiring no increase," make it difficult to answer; perhaps 100 colonies.—W. Z. HUTCHINSON.

It varies according to the methods and fixtures employed, from 50 to 400 or 500 colonies.—C. W. DAYTON.

It all depends upon the man, season, locality, and circumstances.—H. D. CUTTING.

Much depends upon the man and the management; perhaps 100 colonies.—C. C. MILLER.

I think about 150 colonies; though I do not claim to be authority in this matter.—A. J. COOK.

One hundred and fifty to 200 colonies can be managed by one man in light, easily-manipulated hives, except in the height of swarming time.—G. L. TINKER.

If I had everything ready, cases, sections, foundation in frames and in sections, etc., so as to have no work to do except to adjust and manipulate things in the apiary, I could manage 100 colonies easily enough.—G. W. DEMAREE.

Very much depends upon the education and natural ability of the apiarist; also upon the kind of bees (Germans are the best), and much depends upon how the apiary is located; also the buildings for convenience; also how much work has been done during the winter preceding. In any case do you not plainly see that that number of colonies which will keep one man busy during the rest of the season, will require this man and an assistant during a few weeks of the time?—JAMES HEDDON.

An answer to this question will be largely guess-work. Different localities will give different results; different seasons, too, will do the same. Ordinarily I should guess that about 65 colonies would be all that one man could well care for, and even with that number there would be times

when a little help would prove desirable.—J. E. POND.

Probably from 100 to 200 colonies.—THE EDITOR.

Moving Bees to Buckwheat Pasturage.

Query, No. 397.—1. Would it be advisable to move 30 or 40 colonies of bees 14 miles the latter part of July, on a spring-wagon, in order to get them in a locality where they would work on buckwheat, there being no buckwheat in this locality, 2. What would be the best way to ventilate each hive while moving them?—Pennsylvania.

1. It has been done with good results. 2. Cover the frames with wire-screens; place a frame about 2 inches deep under the hive with entrance ventilation.—H. D. CUTTING.

1. Yes. 2. Open the hive-entrance to its full capacity, and cover with wire-cloth; also remove the cap or cover to the hive and tack over wire-cloth or coarse gunny-bagging. Keep the hives shaded during removal.—J. P. H. BROWN.

I would hesitate to try it. In this climate the weather is very hot in July, but to cover the bottom and top of the brood-chamber with wire-cloth, and move the bees in the night, or on a cloudy day, they would not suffer severely.—G. W. DEMAREE.

It would be advisable if you have the time to attend to it. Use wire-cloth over the brood-chambers to ventilate them, and move after night.—G. L. TINKER.

1. No. 2. I ventilate the hives by covering with wire-cloth; that is tacked to a rim whose size allows it to drop over the brood-chamber, the regular covering having been removed. This is quick of adjustment.—C. W. DAYTON.

It probably would ventilate the hive at both top and bottom; also leave a space of 3 or 4 inches both above and below the combs.—W. Z. HUTCHINSON.

1. Yes, if the buckwheat field and yield is good, and no flowers are yielding where they now are. 2. By using plenty of wire-cloth. How it should be applied depends upon the hive.—C. C. MILLER.

1. Yes. Extract nearly all their honey first. 2. Remove the upper stories and put wire-cloth over the top of the brood-nest. Move them at night. We have moved bees at all seasons, but have abandoned summer moving, although it pays well sometimes.—DADANT & SON.

Buckwheat is an uncertain plant for a honey-yield. If it should yield honey well, the experiment would result favorably. I should give about 2 inches of room over the frames, confining the bees with wire-cloth over the whole top of the hive; this with a large entrance and a shaded wagon, would give sufficient ventilation for the distance stated.—J. E. POND.

It might pay well and it might utterly fail of success. Buckwheat does not always secrete nectar. Ventilation should be given above and at the side of the hive, especially at the side. If hot, it is better to move in the night or early in the morning.

Great heat and strong colonies are bad companions.—A. J. COOK.

That depends upon the season and your surrounding circumstances. To ventilate the hives, place a 2-inch rim the full square of the hive, covered with wire-cloth over each brood-chamber. Give the bees water often.—JAMES HEDDON.

Yes; it probably would. The honey should be extracted before starting, and wire-cloth nailed over the brood-chamber.—THE EDITOR.

Unpainted vs. Painted Hives.

Query, No. 398.—Is not an unpainted hive both warmer and drier than a painted one, if not permitted to become wet?—H.

No, sir.—J. P. H. BROWN.

Practically, no.—A. J. COOK.

I believe it is.—G. L. TINKER.

Yes, so my experience says.—G. M. DOOLITTLE.

It is drier, but not warmer.—C. W. DAYTON.

Theoretically, yes; but I prefer them painted, by all means.—H. D. CUTTING.

It is warmer, we think, but it absorbs and evaporates moisture more readily. On the whole, we prefer painted hives.—DADANT & SON.

I once thought that an unpainted hive had some advantages over the painted ones, in the way you mention, but after trying the matter practically I have decided that I was mistaken. I now prefer to paint them.—G. W. DEMAREE.

In practice I can see no difference, only that paint preserves the wood, and best of all, prevents it from becoming darker colored than any beehive should ever be.—JAMES HEDDON.

Probably very little, if any, difference in warmth; and why should it be drier? If I understand the question, neither hive is to become wet. An unpainted hive, in theory, will ventilate itself through the pores of the wood, but in practice no perceptible difference will be found, in my opinion. The painted hive will last far the longer.—J. E. POND.

If "not permitted to become wet," how could it be drier? We cannot see how it could be either drier or warmer under the circumstances mentioned.—THE EDITOR.

Carniolan-Italian Bees.

Query, No. 399.—Is a cross between Carniolans and Italian a profitable bee?—H. W.

We do not believe in Carniolans at all.—DADANT & SON.

Not as good as the pure Italians.—J. P. H. BROWN.

I can see no reason why it should not be.—H. D. CUTTING.

They are about as good as a cross between the Italians and our best black bees.—G. W. DEMAREE.

I should prefer crossing 2 strains of unrelated Italians.—G. M. DOOLITTLE.

I do not believe the Carniolan bee is equal to the German for such crossing.—JAMES HEDDON.

A cross between the Carniolan and black bees might be, but the cross named would in my estimation be highly undesirable.—G. L. TINKER.

I think so; it remains to be seen. I have a cross between Syrians and Carniolans, and I like it; though I shall know more about them with longer experience. I am not yet prepared to speak of these.—A. J. COOK.

Who knows? As yet the Carniolan bee has not been here long enough to be given a thorough test, and of course crosses with it stand the same. I myself do not believe that any crossing with the Italian will be any improvement upon that race, or produce as profitable a bee for any purpose.—J. E. POND.

We much prefer pure Italians.—THE EDITOR.

Harvesting the Honey.

LOUISE S. HARRIS.

The long, bright summer-days were o'er,
The bees poetic hum
Was hushed, till near meridian height,
Plodded the morning sun.

Sweet summer—our poetic dream
Of nectar and of flowers;
Of hazy halo o'er the lawn,
And sylvan woodland bow'rs;

Arcadian haunts, that poet's love—
The mystic, the sublime,
Brought down to earth to rear aloft
An apiarian shrine.

But now the woods like huge bouquet
Of crimson, russet gold,
Tinted by skill that's infinite,
The death of summer told.

The nipping frosts their work had done,
The flowers along the waste
No longer flirted with the bee,
That sought their sweets to taste.

All Nature spoke of hoding storms,
With black-flag soon unfurled;
To waken from poetic dreams,
And face a stern, cold world!

And so I donned by hat and veil,
And pupils, (I had three)
Who saw beyond them golden sheaves
Garnered by fancy free;

We marched along, a phalanx strong,
For foraged sweets so free—
"Good heavens!" and blue-eyes hid away,
"It stung me on the knee!"

"Ah! ah! oh! oh!" her comrade sighed,
"My! honey ought to sell
Five times as high"—but off she flew—
"A bee's got in my veil!"

But Sam was left, a freckled youth
With yellow, sun-burnt hair,
Who "wa'n't at all afraid of bees!"
And vowed he'd "stay right there!"

And so we tolled for weary hours,
And plied the crates on blgh,
While myriad stings and aching backs
Caused many a stifled sigh.

The poetry our souls had filled,
Oozed out at every pore—
The melody of humming bee
Was now vindictive war.

Sam moved his veil to "squirt the juice,"
("Twas trickling down his chin.)
"By jingo!" and he stamped and yelled—
"The bees are rushing in!"

And still they came with fresh recruit,
Till overcome with pain,
He beat a most uncouth retreat,
And ne'er returned again.

And so I harvested alone
My golden treasures tall—
But now a sign is up—"For Sale—
Bees, Poetry and All."

Correspondence.

Prevention of Swarming—That Chip.

S. SIMMINS.

My thanks are due to W. Z. Hutchinson for his kindly notice of my pamphlet in the valuable AMERICAN BEE JOURNAL. Now I notice that he intends to give us some collective evidence in regard to wax production. Whatever he brings forward in his interesting style will be eagerly read by all; but I am afraid there is much yet to be done before anything definite can be arrived at. The resources and temperature of one's locality, the best bee for the purpose, will all have an important bearing upon the settlement of this question for individual bee-keepers.

My own position at this time is that foundation is used in many cases at a loss—not in all; and every intelligent bee-keeper will soon find out which way he is going, when his attention is once directed to this matter.

I presume Dr. Miller works his apiary for comb honey, or he could not have much difficulty in preventing the issuing of swarms if working for extracted honey. Now I wish the Doctor could be here during the summer, and I would show him those powerful colonies working right along all the time without attempting to swarm, having no attention whatever except a proper manipulation of the supers. In fact, the bee-keeper's skill is shown, not by constantly cutting out the combs between the brood-nest and entrance, but by so regulating the surplus arrangements that the bees are so busy in the sections as to be quite unable to finish off the combs next to the entrance. This is fully explained on page 10 of my non-swarming pamphlet.

The foregoing refers to hives placed one above the other, called by us "storifying;" but here we have many long hives in use, and the frames with starters being on the same level and parallel with the brood-combs, it will be found necessary to cut out the new combs occasionally as they are built out more rapidly in that position; but with 10-frame hives tiered up, and the lower body having only starters in every frame, as before stated the strongest colonies do not swarm, or fill out the brood-chamber.

I do not claim to prevent swarming with any but colonies in normal condition. In case of superseding a queen, of course there is the liability of several young ones hatching out and a swarm going off. Then, again, there are those miniature swarms

from queen-rearing nuclei complained of in some quarters, though that is a thing almost unknown to myself.

Perhaps I need hardly say that if wax is to be produced at a profit, it will be done while working for extracted—will it become again "strained" honey? At present prices it will be a question whether "less labor and more wax in connection with a smaller average of honey with many more colonies," will pay better than "more labor with fewer colonies, a higher average, less wax, and a large stock of combs needing careful attention all the time they are not occupied." I venture to state that "Time" will decide in favor of the former where many colonies are kept. By placing several empty chambers under the brood-chamber before the swarming season arrives, with the entrance only in the bottom box, the owner of many hundred colonies may find something else to do during what has hitherto been considered the busiest and most expensive time in the extracting apiary. There is no crowding; the brood-nest is regulated according to the incoming stores, as the combs are carried forward in proportion, and thus there is no undue waste in feeding an excess of brood, as often is the case where the queen has an unlimited number of empty cells at hand.

Though hitherto it does not appear to have been observed, the latter statement shows wherein lies the success of the plan of hiving new swarms upon starters only. It is the non-production of many more consumers just at the height of the "flow" which gives the advantage.

Now, though I have told the Doctor that swarming has been prevented, while rousing colonies working in sections can be carried right along, I will not touch that "chip," but leave it for Mr. Hutchinson to strike off next season, though if Dr. Miller will do as I have shown, Mr. H. will not find it there, as the other will himself remove it.

One thing more and I have done: Many bee-keepers think they have no need to prevent swarming; but rather than submit to the least uncertainty when working for comb honey in particular, will it not prove a very much wiser plan to prevent natural swarming, and make increase by division at the most suitable time?

Rottingdean, England.

For the American Bee Journal.

Fertilization of Queens, etc.

W. T. HOHENSHELL.

For some time I have been giving considerable thought to the subject of fertilizing queens in confinement; and during the season of 1886 I was determined to try my plan, which was to build a tent out of bleached muslin about 10 feet square, and have the walls spotless white, which was easily done by shading so the sun would not shine on the tent at all, but have plenty of light.

My way of preparing the bees for this object was as follows: I took some combs out of hives where there were young queens that had not begun to lay, and where there was brood hatching, and put them into an empty hive, closed it up, and kept it in a warm place until the drones hatched, then I put the new colony in the tent and inserted a selected queen-cell. My idea was that as the bees were all young, they would know nothing of the outside world, and therefore work as if in the open air, which they did to a great extent. But the worst trouble seemed to be that there was not room for them to fly backward and forward enough to locate, before they would strike the canvas, and therefore some of them would not return to the hive; but I almost overcame this trouble by leaving the top of the hive open, which did no harm, for it never rained in their little world.

They worked nicely on honey which I kept in the tent all the time. As I was very busy I experimented with only two queens, both of which proved successful. I expected to try it in a larger tent the coming summer, had my health not failed so that I am obliged to dispose of my apiary and go west. I will give any one the privilege to experiment on my plans, and I feel sure success will be attained if patience be used.

I have always been very successful with bees, and my honey was never equaled by the honey of any one in this locality. It has invariably taken the first premium wherever exhibited. I sold in my own vicinity during the season of 1886, over 5,000 pounds of comb honey, at 12½ cents per pound.

To find sale for honey it is necessary to produce it in the best possible shape, and create a market for a good article. I tried shipping to commission men, but it did not prove satisfactory. I shipped a car-load to Chicago during 1883, and I had part of it shipped back, which I sold for 16 cents per pound, while it was worth only 8 or 10 cents in Chicago.

Munster, 8 Ills.

Read at the Vermont Convention.

Marketing our Crop of Honey.

MISS M. A. DOUGLAS.

At the close of our annual honey season, or doubtless before, to the intelligent, enterprising bee-keeper the ever-recurring question, "Shall we sell our honey or give it away?" presents itself in all its different phases, for his careful consideration.

If the fruits of the apiary are to yield profitably it depends very largely upon the sale of our honey, and we are glad that so many well-developed minds are at work seeking to solve this intricate problem. I am told that in Orwell, Vt., they have what is known as the Fruit-Growers' Association, for the purpose of disposing of their products. Would it be advisable or possible for the "many men of many minds" belonging to the

bee-keeping fraternity to accomplish anything by this method?

In the editorial of a recent copy of the *American Apiculturist*, I find the following significant suggestions: "The unequal distribution is evident to the observing man, and if the producer would sell his honey in country villages and to his neighbors at the price the commission man pays him, there would be but little left to ship to the city markets, and we think there would not be honey enough to go around." I should like to give special emphasis to the fact that unfortunately the producer is too many steps from the consumer.

Last fall one of my neighbors sent a shipment of honey to a leading commission house in Boston, where just the commission was 10 per cent.—\$10 for every \$100 sale—besides freight and cartage. He expressed the opinion that that rate was too high, and as the old man said, "Them's just my sentiments too;" and they would certainly be endorsed by the commission man himself, if he only realized the amount of expense and labor represented by every crate of honey, to say nothing of the stings and arrows of those outrageous bees—"the heartache and the thousand natural shocks that flesh is heir to"—a consummation not devoutly to be wished!

The editor above referred to also remarks that "there is not a country market where honey is kept on sale all the year round. If honey were kept prominently before the people as certain lines of pickles or chow-chow, there would be much more sold. The bee-keeping pursuit is away behind everything else in its method of advertising; even our county fairs—the place above all others for calling people's attention to our product—are in a great measure neglected. If it pays to advertise every other thing under the sun, it pays to advertise honey. It pays to circulate leaflets. If those already printed by different publishers do not suit the locality, print one that does; distribute fancy cards with your business, and you will sell honey directly under the nose of the bee-keeper who does not advertise.

"There is at present a great complaint about low prices, but 5 cents per pound for extracted, and 10 cents for comb honey ought not to scare the enterprising producer. (I fear it may be conducive to blues!) It will cause it to be put into the hands of thousands who never tasted honey before. It will furthermore have a tendency to make it a staple article." But to bring this about I am firmly convinced that one more thing is needful—people must be more thoroughly enlightened upon the subject!

During last fall a business man called upon me to purchase some honey. In our conversation I mentioned some extracted honey which I had for sale, and to my great astonishment, he did not know what it was—had never seen any—so of course I had the pleasure of exhibiting some. It is my custom, as far as possible, to avoid speaking of liquid honey as "strained," because that expression is so suggestive of filth.

If the consumers were better posted as regards the medicinal properties of honey, it certainly would be used freely, habitually and universally, and quack-doctors would have turned to them a cold shoulder. Speaking from personal experience, I believe it is second to no other medicine for a cold, and its use is reported to have cured lung trouble and warded off diphtheria. Then our dyspeptic friends will be glad to know that it aids digestion, and debilitated persons rejoice because it feeds and strengthens the muscles.

Next let us consider it briefly from an economic point of view. Suppose a pound of honey costs 10 cents, and a pound of butter 20 cents; since these foods are unlike, they can only be compared by market value; hence we have two pounds of honey equal to one pound of butter.

Again, in speaking of the low rates of honey, almost all other lines of goods are proportionally low, and it is not entirely discouraging to the apiarist, unless he be one of those unfortunate, constitutionally tired creatures who is satisfied to rest on the down-hill side of his occupation without even a struggle to so much as get a glimpse of the summit from afar; distress and starvation stare him in the face, and as a final result he will be left behind, and eventually "frozen out." On the other hand, the enthusiastic honey-man will resort to the "intensive system," and learn to produce more pounds of honey at a cost less than ever before.

It is asserted that almost every thing is adulterated now-a-days, and this state of affairs should be favorable to the apiarist, for when once reputation for furnishing pure honey is established, success is almost inevitable! Buyers that are accustomed to first-class honey, put up in attractive packages, are not satisfied with any second grades, but we have occasional accounts which give greater stress to the point that the taste of consumers should by some means be cultivated to demand only the A No. 1 article. Mrs. Mahala Chaddock, of Illinois, evidently believes in suiting the article to the customer, judging from the following extract from an experience recently given by her under the head of "Honey in too much style:"

"Two or three weeks ago I sold a man a box of honey. I drove up to his grocery and gave him the box and told him I would come back and attend to it after I had tied the team. I did not get back quite as soon as I expected, and when I did I heard the conversation in the next room. The man said: 'May be she won't want you to cut it out.' 'I don't care what she wants,' said the woman, 'we buy the honey and pay for it. We can't eat the boards, and we are not going to pay for them. If we have got to eat boards for a living, we can go to the lumber-yard and get some cheaper than these.'

"Here I went in, hoping to stop the desecration if possible; but it was too late. I had been very careful to get that nice honey all into good shape,

rejecting, as I prepared it for market, all the sections that were not entirely sealed over, and leaving out all in which a single cell was broken; and after all to have it cut out, broken out, and punched out with great big thumbs and fingers, and dumped into a big bucket to settle down and all run into each other, just to save paying for the sections, was a little too much.

"I sustained myself as well as I could by repeating over to myself, 'Cast not your pearls before swine,' and 'He that is filthy, let him be filthy still,' and other scriptural injunctions, but all would not do—I was mad—not altogether from the money that the sections would bring, but the wooden-headedness of it all. But I only said I'd know what kind of honey to bring them in the future, and I'd cut it out at home and bring it in a bucket, and not have the honey dripping all over town."

But how shall we market our honey? Shall we labor on unceasingly? Shall we produce the very best article possible? Shall we obtain special customers and create a home market? Shall we organize? Shall we permit circumstances to rule, or by faithful, persistent effort over-rule circumstances? remembering that the resolute, the indomitable will of man can achieve much, and that

"Heaven is not reached at a single bound,
But we build the ladder by which we rise,
From the lowly earth to the vaulted skies,
And we mount to its summit round by round."
Shoreham, Vt.

For the American Bee Journal.

Putting Four-Piece Sections Together.

REUBEN HAVENS.

The main point in making ready sales, and getting the highest price for honey, is to have it neat and attractive. The eye as well as the palate must be pleased. To secure this we must have sections of uniform size, neat, and nicely put together. To accomplish this, I have been troubled in these two ways: First, in getting the bee-space between the brood-frames and supers, so that brace-combs would not be built, I find it hard to regulate. A little sagging of the frames when the spaces are made exactly right, causes trouble. In raising supers, and tiering up, the sections become daubed with honey and comb.

The other difficulty has been in getting sections put together snug, solid and smooth. Sections are not always of exact length and thickness, and in putting them together the ends of the dovetail often project so that it is impossible to fit them snugly in the supers and shipping-cases. They are out of square, and in packing the combs are cracked, causing leakage, making it very disagreeable to handle the honey, and it is impossible to sell it for anything but a second-class article.

For some time I have been experimenting with a device for putting

four-piece dovetailed sections together. It consists of an iron plate $4\frac{1}{2} \times 12$ inches, slightly concave the long way, with two beveled jaws attached, one solid, the other movable, and adjustable to any size of section. To use it, place it on a bench, or if you desire to sit, take it on the lap, drop one side of the section between the jaws, place another piece in position with the left hand, and with a light blow with a hammer drive it together; in the same manner place the third piece, then remove and place the fourth piece in the jaws and drive together.

I have just completed one with which I can put dovetailed sections together very firmly, and have them of exact size, with no projecting ends. If the pieces are a little long, it only makes the sections more firm. It is impossible to have the sections larger than the size for which the machine is set. I can put together one-half more sections in a given length of time than by any other plan that I have ever tried. The device is very simple, and if rightly made it cannot get out of repair. It is durable and not expensive. I expect to have my honey in nicer shape the coming season than I have ever had it, by the use of this device.

Legislation for Bee-Keepers.

DR. C. C. MILLER.

When I saw on page 57 an article on this topic, with the well-known name of "J. E. Pond" attached, my interest was at once aroused. But the very first thing comes up "priority of location." Now will Mr. Pond tell us of a single person who has ever advised, requested or desired any legislation on "priority?" And if he has reference to the question as to legislation given to a committee by the North American Bee-Keepers' Society, there certainly was no "priority" in that. Why it is that everybody tacks on "priority," I cannot imagine.

Although it may seem presumptuous in one who knows so little of law as I do, to talk to a lawyer, I think that Mr. Pond will bear with me, if I say how things look to me. He objects to special legislation. Is that the same thing as class legislation? I suppose it is, as several have made vigorous protests in both prose and poetry against class legislation. He says special legislation "is simply making laws for the protection of a certain class against all others." This does not materially differ from a definition of class legislation lately given—"legislation in favor of one class as against one or more other classes"—so I suppose they are one and the same.

In the case under consideration, what is the class in favor of which, or for the protection of which, legislation is asked? I suppose Mr. P. will say, the class of bee-keepers. Now

will he tell, *against* what class? Is it against blacksmiths or lawyers? Neither of these classes care a blue button who keeps bees, or where they are kept, any more than Mr. P. and I care who has the oyster beds, only so we can have plenty at low prices. Is it against milliners or merchants? They are just like the blacksmiths and lawyers; and just the same indifference will be found among all other classes until we come to farmers, gardeners, fruit-growers, and all those who have to do directly with the products of the soil. Is the proposed legislation against these classes? They are interested in having plenty of bees to secure perfect fertilization of flowers, and so any legislation desired by bee-keepers will surely not be opposed by farmers. Does not the objection then that the desired legislation is *against* other classes, fall to the ground?

Mr. Pond takes the ground that "bee-keeping, like every other occupation, should be governed by the same general laws, competition alone being allowed to control." We are together there, and if the desired legislation were obtained there would be exactly the same competition among bee-keepers that there is today among farmers. He then insists that "the 'survival of the fittest' is the only law that can be made that will prove just and equitable." And there we are decidedly not together, if by that he means that bee-territory shall forever remain open with no boundary lines. If it is just and equitable for bee-keepers, why not for farmers? Neither do I think it cowardly to ask for bee-keepers just what farmers have.

I confess to thorough surprise that there should be such general opposition to a measure that looks to me so fair for all, and which I believe would be for the general good, and I can only understand it by the general agreement to unite the priority idea with this.

Allow me to impress the fact that so far as I know, no one has ever advocated obtaining legislation in favor of "priority of location." The investigation set on foot arose from the present condition of affairs in the business. It is the opinion of many, and is in accord with the general tendency in all other callings, that a business can be carried on more profitably if those engaged in it confine themselves mainly, if not exclusively, to that one business; that is, it is more profitable to have 1,000 colonies of bees cared for by 10 men than by 100, as the 10 can afford to be thoroughly posted in the business, can better afford to invest in the proper implements and fixtures so as to secure the crop with the least expenditure of time and money. But there is this difficulty in the way: If a man invests money and time for preparation in the business, he wants to feel that the investment is a safe one, and under the present state of things it is not entirely so, for after he has made a fair start, there is nothing to hinder one or a dozen from starting bees close by and all around him.

The question arises, is there any way to obviate this difficulty? for at the bottom should lie the desire to gather for the general public the most honey for the least money. There may be difficulties in the way that I have not seen, but it appears to me that some way might be devised whereby each bee-keeper should own his territory, just as a man owns the territory on which he farms, the territory for nectar being considered an entirely separate affair from the farming territory.

Instead of going into any additional reasons why this course would be wise, I may as well say right here that I think it is not best to take up any more space with the subject. If bee-keepers do not want anything of the kind, that ends it. And, Mr. Editor, if you will kindly print this article, I will promise never again to send to you anything in the same line so long as I stand entirely alone in my views. I thought those views were right, and in the line of the greatest good to the greatest number. I still think so. I venture the prophecy that if ever the time comes when all the nectar of the country is gathered, and honey becomes a regular article of diet upon every table, it will be when such provision is made that a man may feel secure in his own field against intrusion—secure that no one else may gather the nectar from fields of artificial pasturage of his own planting, and that no one may sit down beside him with bees that have the foul brood, or a strain of bees that will spoil his.

With thanks to all, for the kindly spirit shown, even when opposing me, I have done.

Marengo, 5 Ills.

For the American Bee Journal.

Saying their Catechism.

WM. F. CLARKE.

The following burlesque of page 52, is meant as a harmless bit of pleasantry, and I hope will be received in the same merry mood in which it is written. I have never admired the catechismal method of teaching apiculture, and though invited to do so, have never joined in it. Catechisms were the horror of my childhood. We had a series in vogue then called "Pinnock's Catechisms," and geography, history, grammar—even religion—were taught in this way. I conceived a dislike for catechisms which I shall never get over. I do not consider them a good method of instruction. It is like taking a drink of water by tea-spoonsful, each teaspoon held by a different hand. I prefer to take a draught of water in copious mouthfuls and abundant swallows, and to hold the cup myself. I saw a tempting chance for a shot at folly as it flies," so I loaded and fired off my little poetic pop-gun. I hope the discharge will hurt nobody.

TEACHER.

First class in bee-keeping will rise. And listen, while I catechise.

In tiering-up with section-cases, Between them should we leave bee-spaces?

A. J. COOK.

Yes, certainly, dear teacher, I'm Quite sure we ought to, every time.

DR. MILLER.

No special reason I assign, But I leave spaces between mine.

H. D. CUTTING.

In my bee-practice, I endeavor, To bring the sections close together.

C. W. DAYTON.

And so do I, I think it best That sections on each other rest.

W. Z. HUTCHINSON.

We always ought to leave bee-spaces Between the tiers of section-cases.

DR. TINKER.

For them I see no earthly need, Save to manipulate with speed.

G. M. DOOLITTLE.

To my mind, needless is such space, Though some great stress upon it place.

DADANT & SON.

We most respectfully suggest That sections on each other rest.

DR. J. P. H. BROWN.

Sections are easier to keep clean When there is no bee-space between, But I allow a quarter inch, So bees can pass without a pinch.

J. E. POND.

"This question is a mooted one," And must be argued just for fun; I'm for continuous passage-ways, And don't approve of a bee-space.

G. W. DEMAREE.

"According to my practice, yes," And I am always right, I guess. I smash my bees, if there's a crowd, Unless bee-spaces are allowed.

JAMES HEDDON.

Bee-spaces "every time," and when The dawn of bee-light comes to men, No one will ever think of placing Sections together without spacing.

TEACHER.

You all are right, my scholars wise, And each, whichever mode he tries, Will be successful, less or more, In getting all his bees may store. Guelph, Ont.

For the American Bee Journal.

Sections Filled with Comb.

W. Z. HUTCHINSON.

It is with much interest that I have read the articles that have lately appeared in the BEE JOURNAL on this subject. Mr. Heddon has several times told me that he preferred sections filled with foundation, early in the season, to those containing combs of the previous season. He said the bees would begin work sooner upon the foundation, seal it over more quickly, and smoother. Mr. R. L.

Taylor expressed similar views at the late convention at Bay City, Mich. Mr. Dibbern goes still further, and says that honey stored in these half-finished combs of the previous season was imperfectly ripened, and hence it kept very poorly.

I believe all of the above bee-keepers to be truthful, but I am at a loss to understand why their experience with empty combs in sections should be so diametrically opposite to that of Mr. Doolittle and myself. Perhaps this assertion will bear a little qualification. I can think of one reason why honey stored in drawn comb *might* remain longer unsealed than that stored in foundation that was drawn but slightly in advance of the filling, *i. e.*, the drawing out and filling were both in progress at the same time. The opportunity for ripening is greater when the honey is not very deep in the cells; aside from this, I am unable to account for so widely different results.

My experience is very nearly like that of Mr. Doolittle. When the flow of honey is bountiful, and the body of the hives well filled with bees, brood and honey, and the brood-nest is shallow, but little coaxing is needed to induce bees to make a start in the supers, let them be filled with foundation or drawn combs; but, sometimes, the honey-flow starts out very slow, and the bees, especially if Italians and in a deep brood-nest, hesitate to make a start in the supers. Honey is stored in the brood-nest until there is not room for another drop, then brace-combs are built and filled with honey, and, as a last resort, the sections are entered and work begun. In my experience, a case of sections containing half-finished combs of the previous season, is worth nearly as much early in the season as a case of finished sections of honey.

In my apiary, these empty combs just over the brood-nest are very attractive to the bees. Almost as soon as put upon the hives the bees will begin crawling over them, and as soon as there is a drop of honey to spare it is placed in these combs. The bees really seem anxious to fill them with honey, and in doing this the brood-nest is relieved of all pressure, *i. e.*, it is not crowded with honey, and, as a consequence, there is more room for brood.

Another thing, this empty comb above the brood-nest acts as a sort of stimulus to the bees—it puts them in a mood for storing honey. While a colony with foundation only in the sections is hesitating about making a start, one with empty combs in the sections will have commenced storing surplus; by the time the one with foundation has begun work in the supers, the one with empty combs will be ready for another case of sections; and by the time the one with foundation is ready for a second case, the one that had empty combs in the first case will also need another case, while the first case will be ready to come off!

I will admit that there is not always so great a difference in favor of empty combs in the sections; but

with my locality and methods, a case of sections filled with combs is worth nearly as much in the spring as a case of finished sections of honey; and the honey stored in these half-finished combs has always been sealed over as quickly as any other, and of as good quality and fine appearance.

Rogersville, 6 Mich.

For the American Bee Journal.

Using Sections with Old Comb.

C. THEILMANN.

I have read Mr. Dibbern's article on page 150, and would like to say a few words in justice to myself and other prominent bee-keepers whose experience does not agree with Mr. D's; also to bring out more fully the unquestionable benefit and use of partly-filled or unfinished sections after the honey harvest is over.

I was much surprised after reading Mr. D's article, as my experience of late years with partly-finished sections is the reverse of his, though some years ago I had the same trouble as he has had. He says: "I found after these sections of honey built from old comb had been on the racks a month or two, they would show a sweaty appearance with indications of souring, such as bulging the caps, and the honey running out."

It appears that Mr. D. is not making the best use of nice comb built in sections, by melting the comb and burning the sections, else he would value such combs in sections very highly, and secure No. 1 honey with them every time, and which would not sour on that account. I used to get such honey from old sections, but I have overcome all the difficulties he refers to, and now I get as good and as nice appearing comb honey, by using the sections and combs left over, as can be produced; at least it sells for the highest market price, and has also the best reputation at home.

For the benefit of those who do not know how to make the best use of old sections filled with nice comb, I will describe my method, which is as follows:

After the honey harvest is over, I hasten to take from the hives all the surplus arrangements (I have only one kind of them, which hold 24 one-pound sections each), and sort out all the sections which are not marketable or finished; as a rule these are the latest put on, and contain fall or dark honey. When all are sorted out I extract them as clean and as soon as possible. While taking them out of the extractor, I shave off all the bulged or uneven combs, if there are any, also the outer edges of such combs as are nearly full size (this latter operation takes off the thick rim on the end of the cells, and the comb will be finished and capped with new wax, which makes a nicer appearance). At this extracting the combs can be shaved with the honey-knife to any size without breaking or crumbling. After they are fixed up, I place the empty sections in the sur-

plus arrangements, and in the evening I place them (sometimes three or four of them tiered up) on some strong colonies, and let the bees clean up everything nicely over night. The next morning I take them off and store them in the honey-house, when they are ready for another harvest.

I presume Mr. Dibbern would call this "puttering," but I can assure him that I can do this more quickly, and with more benefit financially, than he can cut out and melt the combs and burn the sections; not forgetting the time it takes for putting foundation into new sections. I alone extracted and fixed up over 1,000 sections, as above described, in two days last fall. To burn old sections is nonsense for an experienced bee-keeper; mine never get old in appearance as long as I have control of them, and I am aware that there are many more bee-keepers whose old sections are kept as clean as mine, but it appears that the "progress" of some bee-keepers has not as yet reached that point.

When I am ready to market my honey, hardly any one, as a rule, can tell which are old or new sections, and by letting the bees clean out every particle of honey, after the sections are extracted, the combs will keep sweet and nice, and the new honey put into them will keep as good as if new combs had been built. I can secure much more honey when the combs are already built; many times the bees will fill a case before they would enter one with only foundation in the sections. Even comparatively small colonies enter and fill the sections with combs, that would not touch them with only foundation; neither will the queens be apt to deposit eggs in such sections sooner than they will otherwise. I use no excluding honey-board, and out of over 10,000 sections filled with honey last season there were only *nine* with some brood in them, and five of which had foundation only.

To show that my bees will still do like Mr. D's bees did, and like mine have done years ago (by my manipulation; and that locality or climate has nothing to do with it, when they finish up old combs with some honey left in them from the previous year, which will look bad, will sour and burst open, I will give the following experience:

A year ago last fall, by an oversight, a case of unfinished sections which were partly capped over, and ready for the extractor, got in under some surplus arrangements in my honey-house. I did not discover it until last spring. I then took the opportunity to experiment with 12 sections in the case that were finished the most. I put them on a hive in a surplus arrangement, with 12 new sections with foundation; the bees filled and capped them all with clover and linden honey, but the difference between the new and the old sections was like white and black—the white was the same as all my clover and linden honey of late years, but on the old combs the bees (or rather I) had played the same "trick" as years ago;

the honey was unsalable, and in every way as Mr. Dibbern describes his honey in old combs.

The reader can see by the above that the nature of bees does not change, and that they cannot make spoiled honey good; and in order for the bee-keeper to secure nice comb honey in old combs, he must extract the honey from them and let the bees clean out every bit before it gets old and sour. By doing this we can get just as good honey, in every respect, in old combs as in new ones.

Theilmanton, O. Minn.

For the American Bee Journal.

Have Bees the Sense of Hearing?

ELIAS FOX.

In reference to Mr. Brimmer's article on this subject on page 121, I would like to make a few suggestions.

We are all well aware that the sound of bees' wings vary, and also that their odor varies, which is equally as well demonstrated when they are angry. The same difference that there is in the vibration of the bees' wings is as plainly noticeable in the sound of the cylinder of a threshing machine, which, as the speed is increased, emits a sharper sound; it is also the same of the wind—there is a vast difference between the sound of the gentle breeze, and the raging cyclone.

If a few bees lead a colony to a tree a mile or more away, it is on the same principle that where one or two sheep of a flock go, there also will the rest go; or the same as a covey of prairie chickens—if one flies, the whole flock follows, which is nothing but natural, and is caused wholly by sight. I would like to know how Mr. Brimmer knows that the tree a mile away was previously selected. In making a noise to stop absconding swarms, if they stop at all on account of it (which I very much doubt), I would rather think that it was more the movements that attracted their attention than the noise. I presume the bees would have stopped just where they did, if he had not made any noise, unless it was the movements that caused them to stop; and it is altogether likely that those colonies that were brought back two days in succession, would have remained just the same if the queen's wing had not been clipped. If such was not the case, they surely would have come out of the hive again and indicated their intention just the same.

I have had one new colony come out after being hived two days, and at a time when I was away from home; when I returned I found them clustered on a fence-post toward a forest. I returned them to the same hive without clipping the queen's wing, and they remained contentedly. If I had been at home and pounded the bottom out of a tin-pan, I might have thought that the noise saved my bees. Thus it goes; we should not jump at conclusions, "but prove them as we go."

We have all, doubtless, heard young queens piping in the hives, but under all circumstances I would much rather think that it was vibration that causes the answering. Mr. B. asks, how is the presence of a queen communicated through the swarm, if they cannot hear? I will say that it is either by the odor or vibration, or both. I would like to ask him why it is after a queen is in one's fingers, that the bees will cluster on the fingers, if they do not scent the queen.

I had a colony leave the hive last summer, and I caught the queen and caged her (her wing being clipped), and as far as she touched the ground I could see bees hunting for her like a hound on the track of a fox. They even found an old dried up queen that had been thrown out a week or two before, and clustered on her. Now if there is no evidence that bees are not led by the sense of hearing, why, I am no judge.

Hillsborough, Wis.

For the American Bee Journal.

My Experience in Bee-Keeping.

DAVID BROWN.

Being provided with the best bee-books that I could obtain, some 20 years ago I commenced bee-keeping, and with considerable success. But removing to this State my bees were left in the old home in the East, and many years passed before I again returned to bee-keeping. The study of the nature of bees and their habits has always been a pleasure to me, aside from the profits derived from them.

In the spring of 1885 I secured 2 colonies of bees, choosing colonies that were not only strong in numbers, but the most active and persistent workers in the apiaries from which I secured them, thereby getting a strain of good workers. During the summer of 1885 my 2 colonies increased to 8, and supplied me with over 350 pounds of comb honey in one-pound sections, and were, I thought, in fine condition for wintering, with abundance of stores. I wintered them in an outside root house 10x24 feet, and 8 feet high, covered with about 10 inches of earth. When the earth was frozen so as to give a low temperature, I covered it with a coarse litter to retain the frost and give uniformity of temperature. By this means I secured a temperature of 34°, and retained it at that temperature up to March 25.

They were put in their winter quarters the last week of November, and were there for 4 months. We hear of the theory of "hibernation," but this was the nearest thing to it that I ever expect to attain to; there was only the slightest sound to be heard—quiet and still for four months, and the amount of honey consumed was scarcely noticeable. And in what fine condition they were when put out! I could not conceive of them being any better—lively and ready for business, which they commenced in good earnest.

I omitted stating how I prepared them for putting into the cellar. I placed 6 dry corn-cobs crosswise of the frames at regular distances, and over them laid a piece of burlap cut one inch larger than the top of the hive; placed the cover on long enough to give the burlap a set to place, and all was ready. The cover was removed when taken to the cellar, and free ventilation allowed through the burlap. The cobs allowed the bees to pass over the frames at any time if they felt so disposed.

I thus had 8 colonies to start with last spring, and all in fine condition. On May 6 I had the first swarm, which was a very large one, and I had 7 first swarms by May 11. I removed queen-cells to prevent second-swarms. Most of the first swarms had their comb completed in the one-story Simplicity hives in six days after being put in, and were well supplied with brood. (I use full sheets of foundation.) During the latter part of June and the first of July, all (both old and new colonies) repeated the swarming process, and queen-cells were again removed, only allowing first swarms; while a few cast swarms in August. It will be noticed that I aim to allow only first swarms, thereby securing only strong swarms ready to go to work.

In the fall I had 37 strong colonies, all the increase by natural swarming, and a surplus of 2,000 pounds of comb honey in one-pound sections, and 400 pounds of extracted honey.

I placed my bees in the same cellar, and up to January they were wintering finely, though at a temperature of 41°. The temperature is very uniform, though not so low as I had it last winter. I have not shipped any honey to a distance, but am pushing a home market, and am having increasing demand. My honey is in beautiful shape, boxes well filled, and cappings white and inviting. My aim is, that none shall surpass me in placing before the people honey in more marketable form or of better quality; and so far I have succeeded. Maple Creek, Nebr.

Convention Notices.

☞ The Wabash County Bee-Keepers' Association will meet at North Manchester, Ind., on April 20, 1887, at 10 a.m. AARON SINGER, Sec.

☞ The semi-annual meeting of the Southern Illinois Bee-Keepers' Association will be held in the Court House at Benton, Ills., on Wednesday, April 20, 1887, at 10 a.m. All are invited to attend. F. H. KENNEDY, Sec.

☞ The Union Bee-Keepers' Association of Western Iowa will hold their next annual meeting at Dexter, Iowa, on Saturday, Apr. 9, 1887, in the Council Room, at 10 a.m. All interested in bees or honey are requested to be present. J. E. PRYOR Sec.

☞ The annual meeting of the Stark County Bee-Keepers' Society will occur on Apr. 12, 1887, in Grange Hall (over Farmer's Bank), Canton, O. Officers for the ensuing year will be elected. All bee-keepers are urged to be present, and those having hives or fixtures are requested to bring the same for exhibition. MARK THOMSON, Sec.

☞ The Des Moines County Bee-Keepers' Association will meet on April 26, 1887, at the Court House at Burlington, Iowa, at 10 a.m. All interested in bee-keeping are invited to attend. Articles sent for exhibition, to the Secretary, at Middletown, Iowa, will be exhibited and returned or sold, as directed. JOHN NAU, Sec.

SELECTIONS FROM OUR LETTER BOX

Good Prospects for 1887.—F. J. Sawin, Monmouth, Ills., March 21, 1887, writes:

My average yield of comb honey last year was 93 pounds per colony; of extracted honey, 162 pounds per colony. From just one colony I took 293 pounds of extracted honey. My bees have come through the winter in splendid condition, and the prospect is good for a crop of honey. Clover is alive and looks fine. I like to compare reports on wintering.

A New Use for Sweet Clover.—C. H. Dibbern, Milan, Ills., writes:

It has usually been supposed that the sweet or melilot clover was of no use, except for the honey produced. I find, however, that the stalks contain an excellent fiber that may prove very useful for various purposes, especially in the manufacture of twines. Enclosed please find a sample. Is this not like Abe Lincoln's rat hole, "worth looking into?"

[Yes; and we have looked into it. We have interviewed several hand manufacturers of twine, but they cannot use it; so we sent the sample to a firm who make, by machinery, hemp rope, and they say that it will probably answer the purpose, and want to obtain a bale of it, so as to give it a thorough trial and determine its cash value for such purposes.—ED.]

Scarcity of Honey in Virginia.—T. T. Phlegar, of Giles County, Va., on March 19, 1887, says:

How funny it sounds to hear the bee-men of the North say that they cannot find ready sale for their honey, when with us here, 125 miles from any thing like a city, we can hardly get enough honey to sweeten a little sage-tea for the baby's sore mouth. A few cans this way would be quite a treat.

Sundry Questions.—F. S. C., of Wabash Co., Ind., propounds the following questions:

1. Are bees that have been wintered in the cellar more liable to chill when put out, than those wintered out-doors? 2. If on a nice day in mid-winter a colony is put out for a flight, and the bees spot nothing; and on mashing a bee it is found almost as empty as a shell, would a flight do such bees any good? 3. Will bees store as freely when excluded from the queen, as when with her?

[1. Yes. 2. No. 3. Yes.—Ed.]

The Work in the Apiary.—A. A. Fradenburg, Port Washington, O., asks the following questions:

Having 50 colonies of bees in the spring, all in good condition, how much of one man's time should it take to care for them properly for one year? All are to be worked for comb honey in one-pound sections, no allowance being made for making new supplies, or the care and marketing of the honey after it is once put in the honey-house. In other words, how much time per colony, per year, is required to do the necessary work in the apiary?

[This question is practically answered on page 196.—Ed.]

Good Results.—Mr. T. W. Colbert, (20), Smith's Valley, Ind., on March 21, 1887, says:

I commenced the season of 1886 with 9 colonies; increased them to 20, by dividing, and took 700 pounds of comb honey in one and two pound sections, which I sold at home at 20 cents a pound. My bees have wintered finely. I packed them in clover chaff, which, I think, is better than anything I have ever yet tried for packing.

Bees Wintered in a Cave.—R. C. Aikin, Shambaugh, Iowa, on March 18, 1887, writes:

Bees have wintered well in this locality. I put mine in a cave in a dry hillside, and so far I have lost only 3 colonies out of 52. The ones lost were no better than nuclei last fall; two of them starved, and one was queenless. I think I left them out too long. They were put in on Dec. 24, and taken out on Feb. 28. I would have left them in longer, but they were beginning to soil the hives, so I put them out; after a flight I put 3 back, and they are quiet yet. The temperature was from 30° to 40°. I think they would have done better if put in earlier and kept warmer. We had a month of winter before I put them in the cave. I had 28 colonies in the same cave the winter before, and lost none. I increased the 28 to 52, and produced 2,000 pounds of honey, mostly extracted. That was less than one-half the previous season's average. The dry weather accounted for the difference.

Young Bees Out, etc.—D. D. Danisher, Madison, Wis., on March 20, 1887, says:

My bees are all right so far—24 colonies in the cellar and 6 out-doors. Six colonies with Cyprian queens have plenty of young bees out on the combs already. There is a fair prospect for a good honey harvest. I sold half of my honey at 10 and 11 cents per pound. Extracted honey is sold here for 5 cents per pound. Every store has plenty on hand. Some Chicago comb honey is selling here for 12 cents per pound. I sell all of my honey at home. I kept all my bees 5 miles in the country last summer, and they did finely. I expect to keep them there this summer. There was 10 acres of Alsike clover close to my bees last year, and they did a "land-office business" on it. I had only one natural swarm.

Fastening Foundation—Feeding Bees.—E. W. H., of Indiana, asks the following:

1. I see that the top of the sections I have purchased have a cut for putting the foundation in. How is the foundation to be fastened in? 2. Is there any danger in putting out feed for bees where there are no other bees near, if the feed is a rod or two from the hives? Will it set the colonies to robbing each other?

[1. Use a foundation fastener; or if you do it by hand, run melted wax in the "guide-groove," and the foundation will be held firmly by it when it cools.

2. It is safe to feed at the entrance by using a feeder, or to place honey in combs over the frames; but there is always danger when honey is exposed near the apiary. The further it is removed, however, the less the danger.—Ed.]

Wintered Well—Honey Thieves in Prison.—Wm. H. Graves, Duncan, Ills., on March 21, 1887, writes:

I began the winter with 100 colonies of bees, 55 on the summer stands, and 45 in the cellar. So far all have come through in good condition, except 2 of those out-doors. I have put out part of those that were in the cellar. They gathered the first natural pollen on March 12, the day I put them out of the cellar. The next six weeks is when I usually lose the most bees; the weather at that time being so variable, they will "spring dwindle" in spite of any precaution on my part. They fly out during bright spells of sunshine, and are overtaken by cold waves and clouded sky, preventing their return to the hive. Two of the parties who stole my honey last fall are now serving two years' sentence in the State's Prison of Ohio; they had broken out of jail and came here, and were taken back again about Dec. 1, 1886.

White Clover all Right.—R. R. Murphy, Garden Plains, Ills., on March 21, 1887, writes:

Bees have wintered well. I lost one colony out of 102 put into a bee-house, and that was queenless last fall. One colony had the diarrhea pretty badly from some cause, but it is a fair colony yet; it will probably die, though. The white clover has not been winter-killed, so if the season is favorable, we will have a good honey year.

Not Lost a Colony.—Jno. B. Sample, Elizaville, Ind., on March 21, 1887, says:

My bees are doing well. I have not lost a colony. They were gathering pollen on March 12. There are not many bees in this neighborhood.

The Weather in New York.—G. M. Doolittle, Borodino, N. Y., on March 21, 1887, writes:

This winter (it is winter here yet, although the month of March is called a spring month) has been a severe one on the bees that are on the summer stands in this locality. There has been but one day during which the mercury has gone as high as 44° in the shade since Nov. 3, or for nearly five months. As it needs 45° in the shade for bees to fly, with snow on the ground, it will be seen that the bees have been confined all of this time. The result is that many colonies are uneasy, and a few are soiling their combs and hives badly. Many will die if an opportunity does not come soon for them to get out. Those in the cellars are in fine condition.

Novel Way of Selling Honey.—M. L. Barney & Bro., Hartford, Wis., on March 24, 1887, write:

This is the way we sold our honey last year: We accidentally met a traveling-man who was selling gloves, mittens, etc.; we gave him a sample of extracted honey in a ½-pint flask, put \$10 in his hand, and said, "sell." In a few days we were over-run with orders at 8 cents per pound, delivered on the cars here. In 3 weeks our entire stock of honey was sold to country stores in northern Wisconsin, on 30 days' time, and all good sales. Over 3 tons was sold. Honey in pails we sold for 10 cents per pound.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS.
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, post-paid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10¼@12c.; choice, 12¼@13c. Not much call for extracted, and very little for comb.
BEESWAX.—25c. R. A. BURNETT,
 Feb. 21. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10¼@12c.; in 2-lbs., 9¼@10c.; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8¼@8½c.; in 2-lbs., 7¼@7½c. Extracted, California, 5¼@5½c.; buckwheat, 4¼@4½c. Supply of comb honey in large, and demand for all kinds is improving.
BEESWAX.—21@23c.
MCCAUL & HILDRETH BROS.,
 Jan. 21. 34 Hudson St.

DETROIT. ||

HONEY.—Best white comb, 10@11c. Supply large and sales are slow.
BEESWAX.—23c.
 Mar. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4¼@4½c. amber, 3¾@4¼c. Comb, white, 10¼@13c.; amber, 7¼@8c. Market firm.
BEESWAX.—Firm at 20@23.
 Mar. 21. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively.
BEESWAX.—24 cts. per lb.
 Mar. 23. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 4@7c. per lb. Nice comb brings 13@15c. per lb. in a jobbing way.
BEESWAX.—Good demand, —20@22c. per lb. for good to choice yellow.
 Jan. 22. C.F. MUTH & SON, Freeman & Central Av

CLEVELAND.

HONEY.—Choice white, 1-lb. sections, sells at 12½@13c.; second quality white, 10@11c.; white 2-lbs., 10@11c. Buckwheat, 8@9c. Extracted, 5@6c.—Market dull.
BEESWAX.—25c.
 Mar. 9. A. C. KENDEL, 115 Ontario Street

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 11@12c.; 2-lbs., 10@11c. No call for dark. White extracted, in barrels and kegs, 3@6½c.; in small packages, 7@8c.; dark, in barrels and kegs, 3@5c. Demand fair and supply ample.
BEESWAX.—25c.
 Mar. 5. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8¼@11. Extracted, white, 4¼@4½c.; amber and candied, 3¾@4c. Trade is quiet.
 Jan. 10. O. B. SMITH & CO., 453 Front St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lbs., 8¼@10c.; white clover 2-lbs., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 6c.; dark, 4½@5c.; white ssgs, 5@5½c.; amber, 4¼@5.
BEESWAX.—20@23c.
 Jan. 13. CLEMONS, CLOON & Co., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price is for choice white clover. Strained, in barrels, 3¾@4¼c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4¼@5c.; in cans, 5@6c. Market dull.
BEESWAX.—Firm at 21c. for prime.
 Feb. 3. D. G. TUTT & CO., Commercial St.

Continuous Advertising brings much larger returns, in proportion to the outlay, than periodic or spasmodic advertising.

By Using the Binder made expressly for this **BEE JOURNAL**, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the **BEE JOURNAL**. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the **BEE JOURNAL** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are reduced, as follows:

- For 50 colonies (120 pages).....\$1 00
- " 100 colonies (220 pages)..... 1 25
- " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

ADVERTISEMENTS.

BEES wanted for Plano, Organ, Watch, Opera Glasses, Mulberry-trees or Silk-worms.—Address, Silk-culturist Fisher, 235-8th St., Oshkosh, Wis. 13A1t

WANTED.—A Situation in some California Apiary. I have had 10 years' experience with 80 to 100 colonies. I am troubled with catarrh, and my physician advises me to go west. I have for sale 50 COLONIES of Bees. Will sell Hybrids for \$5; Pure Italians, well marked, \$6; or Selected Italians, such as I would breed from, for \$7 each.

Also a 12-inch Dunham Foundation Machine for \$20. Or will sell the whole outfit, with sections, 40 empty frames, &c., for \$300. Must be sold before May 1st. Correspondence solicited.

W. T. HOHENSHELL,
MUNSTER, LaSalle Co., ILL.

P. Rock & B. Leshorn eggs for hatching; by good stock. Will exchange for Italian Bees by lb., Queens, Sections or Foundation.
13A1t L. W. LIGHTY, Mulberry, York Co., Pa.

W. Z. HUTCHINSON,

Rogersville, Genesee Co., Mich.,

HAS written, published, and now offers for sale, a little book upon

"THE PRODUCTION OF COMB HONEY."

Its prominent feature is the exhaustive manner in which it treats of the non-use of full sheets of Comb Foundation in the brood-nest when hiving swarms; but it touches briefly upon some of the most important points connected with the profitable production of Comb Honey.

Price of the book, postpaid, 25 cts.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable slides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

- For 2 American frames, 13x13 inches.....\$8 00
- For 2 Langstroth " 10x18 " 8 00
- For 3 " " 10x18 " 10 00
- For 4 " " 10x18 " 14 00
- For 2 frames of any size, 13x20 " 12 00
- For 3 " " 13x20 " 12 00
- For 4 " " 13x20 " 18 00

The NEW Heddon Hive.

We have made arrangements with the Inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nailed and also in the flat.

The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cover, bottom-board, and top and bottom of each sectional case has one-half of a regular bee-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

A SAMPLE HIVE includes the bottom-board and stand; a slatted honey-board, and cover; two 6-inch brood-chambers, each containing 8 frames; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separators, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

It is absolutely essential to order one nailed hive as a pattern for putting those in the flat together correctly.

Hives, nailed and painted, \$4.00 each.

HIVES READY TO NAIL.—In filling orders for these hives, in the flat, we make 6 different combinations, so that our customers may make a selection from the sample nailed hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers:

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 16 frames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—it is interchangeable, but not reversible.—Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus stories as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-chambers. Price, \$2.30 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nailed hive. Price, \$2.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deductions from the above prices: Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at 1/2 cent each, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives 5 per cent. discount; for 25 or more hives 7 1/2 per cent.; for 50 or more, 10 per cent.

THOMAS G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

Extraordinary Exchange!

HAVING disposed of my Bee-Supply business, at Des Moines, Iowa, to Joseph Nysewander, I hope my friends and customers will be as generous with him in orders and good-will as they have with me. I am no longer in the supply trade here after March 1, 1887.

12A2t J. M. SHUCK.

BEES for Sale Cheap.—Black and Hybrid bees in ten-frame Langstroth hives, strong in bees, and on straight worker comba. Put on cars for \$4.00 per colony. Will ship in hive or in light shipping-cases. No disease. 13A4t **H. L. Pangborn,** Maquoketa, Iowa.

20 COLONIES of BEES for Sale, in 8-frame Langstroth hives, wired combs, strong in Bees and every way desirable—at \$6.00 per colony. **F. D. NAGLE,** 11A4t SOUTH HAVEN, MICH.

CLOVER SEEDS.

We are now selling Alsike Clover Seed at the following prices: \$8.00 per bushel, \$2.25 per peck, and 25 cents per pound. Also, Melilot or Sweet Clover Seed: \$6.00 per bushel, \$1.75 per peck, and 20 cents per pound, by express or freight. All orders promptly filled upon arrival.

THOS. G. NEWMAN & SON,
923 & 925 West Madison Street, CHICAGO, ILL.

ARMSTRONG'S New Reversible Hive.

The cheapest, simplest and most practical Hive ever offered to the public.

H. D. Cutting, of Clinton, Mich., says:—"Let me congratulate you on having such a good hive; your 'reversible' section-case is perfection itself."

Sample Hive, complete and painted, \$2.50.

Send your name and post-office address, plainly written on a postal card, and receive our 32-page Illustrated Catalogue, free.

Address, **E. S. ARMSTRONG,**
9A4t JERSEYVILLE, ILLS.

Wooden Pails for Honey!

We can furnish regular Wooden Water-Pails—well painted on the outside, and with 3 iron hoops and a tight-fitting wood cover, at \$2.25 per dozen. They will hold 25 lbs. of honey, and when empty, can be utilized for use as an ordinary household pail.

THOS. G. NEWMAN & SON,
923 & 925 West Madison Street, CHICAGO ILL.

HOW TO WINTER BEES,

ELEVEN Essays by eleven prominent bee-keepers, sent to all who apply. Address, **HENRY ALLEY,** 11A4t Wenham, Mass.

100 COLONIES of Italian BEES for Sale. **DANIEL WHITMER,** 9A9t South Bend, Ind.

100 COLONIES of BEES

For sale cheap. Reason, too many. **H. NEUHAUS,** 7A8t Burlington, Racine Co., Wis.

A Year among the Bees,

BEING

A Talk about some of the Implements, Plans and Practices of a Bee-keeper of 25 years' Experience, who has for 8 years made the Production of Honey his Exclusive Business.

BY DR. C. C. MILLER.

Price, 75 cents, by mail. This is a new work of about 114 pages, well-printed and nicely bound in cloth. Address,

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

A SAMPLE COPY

Of the AMERICAN APICULTURIST will be sent free to all who apply.

Address, **HENRY ALLEY,** Wenham, Mass. 10A4t

A NEW HONEY-EXTRACTOR.

THE SIMPLEST and cheapest in the market. No special constructed can or vessel required. Any common molasses or whisky barrel or other suitable vessel at hand will do. It extracts as clean and fast as any other two-frame extractor. It is suitable for American or Langstroth frames up to 13x20. It weighs only 8 lbs., ready for shipment. Price in the flat, \$2.50; set up, \$2.75. State right to make, use and sell, \$1.00. Date of patent Feb. 9, 1876. Send for circulars to the inventor and manufacturer. **J. C. MELCHER,** 10A6t O'QUINN, Fayette Co., TEXAS.

Vandervort Foundation Mill.

6 Inch, Price, \$20.00.

It makes the finest extra thin Foundation for comb honey. For Sale by

THOS. G. NEWMAN & SON,
923 & 925 West Madison Street, CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. April, 6, 1887. No. 14.

The Best Honey Weather is when it is warm and moist, when the air is full of electricity and a storm approaching.

The Apiary of Wm. Couze, in Ontario, was destroyed by fire on March 15. It consisted of 120 colonies of bees, with the necessary implements for the apiary.

An Apiarist in France claims that he has made experiments which prove that only from 6 to 8 pounds of honey are used by the bees to produce a pound of comb.

George E. Hilton, President of the Michigan State Bee-Keepers' Association, has been nominated for Supervisor of Dayton Township, Newaygo County, Mich.

It is Poor Economy to use old and dirty sections for comb honey. It will pay better to commit all such to the flame, and buy new and clean sections for new and delicious honey.

During the year 1886, 11,000 pounds of beeswax were shipped from California by sea to Europe; 41,000 pounds overland by rail, mostly to New York, and 3,000 pounds via Panama to New York.

While there has been great pains taken in breeding queens, it is plain that too little attention has been given to the propagation of good drones to make bee-keeping more profitable.—*Indiana Farmer*.

Two Little Boys were discussing the strength of a bee. "He can pull more'n a fly," said one of them. "Well," said the other, "I dunno how much he calls pull; but when he backs up to you and pushes, I guess you'll fall back every time."

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

Honey-Candy.—It is praise-worthy to place good, wholesome, and health-giving "candy" within reach of the children, instead of the poisonous stuff that now tempts their appetite to the expense of their health. This would make another outlet for the consumption of the large crops of honey now being produced. We know of some persons who would gladly manufacture it for the market, but are not "posted" as to how to do so.

Now, we invite every person who knows how to make candy, jumbles, or anything of a similar nature from honey, to write out the recipe and send it to us for publication at once. Please do not lay this copy of the BEE JOURNAL away and forget it, but sit down now and send it, so as to be in time for next week's JOURNAL. It is in the general interest of bee-keeping to do so.

Alsike Clover is but sparingly grown in the Northwest at present, but it is a "prime favorite" with those who know its good qualities. In order to answer many queries that are being received, we quote the following from the *Farm, Stock and Home*:

When once seeded it is always seeded. While the crop does not interfere with cultivated crops, is in no sense a pest, yet when cultivation ceases a good crop of Alsike will soon follow. It makes an excellent fall feed, good until snow covers the ground, and as soon as snow is off in the early spring cattle will leave hay and other fodder to eat Alsike, if they can have access to it. A case of hoven has never been known to follow the freest indulgence in Alsike by very buogry animals.

The stalk is finer than red clover, so that while it makes an excellent pasture, it is no less superior for hay. For low lands it is the best of all clovers, while on uplands it has proven to be second to none. During last summer's drouth, while all other pastures were dried up, the Alsike was fresh, luxuriant, and keeping stock in splendid condition.

Seed with grain, wheat preferred, and sow in connection with timothy, eight quarts of the latter to two of Alsike.

Lizzie Cotton.—Mrs. L. Harrison, in the *Prairie Farmer*, remarks thus about this "queen of humbugs":

In an Ohio paper she says: "I have invented a hive and new system of bee-management, which render the business pleasant and profitable. I have received one hundred dollars from a sale of box-honey from one hive of bees in one year." It is strange that people will be taken in by such advertisements.

A pleasant, old white-haired grandfather was here last week. He said: "I had been reading this woman's advertisement for several years, and I sent to her for a hive; I paid \$12 in Maine for it, and \$2 expressage; she wanted me to pay her \$14 more for a pencil drawing of the hive, but I did not do it. I have had some hives made like hers, and they cost me \$1.25 apiece."

Several of her late circulars have been sent to this office by apiarists to whom she had sent them, but had been warned in advance, and did not send her any money. Our advice is: Do not send money to any one unless you know they are reliable, and are doing business on the "square."

Dandelions, willows, and skunk cabbage are the first to yield honey to the bees in the spring. Then comes the blossoms of fruit, hard maple, white clover, small fruits, basswood, sumach, winding up with goldenrod, aster, Spanish-needle and smart-weed.

Opinions Differ.—How very silly it is to condemn another because of an honest difference of opinion. We cannot all see alike, and it is well that we cannot, else there would be no advance made in the pursuit. We are forcibly reminded of these differences by some remarks made by Mr. C. H. Dibbern, in the *Plowman*. He says:

Bee-keeping has made great progress during the last twenty years; but I am inclined to think that even greater progress will be made during the next decade or two. Singularly enough, some good bee-keepers see no advantages in some of our best improvements. Doolittle does not believe in comb foundation, but would not do without separators. Heddon likes foundation, but condemns the separators. Dadant makes very nice foundation, but prefers to extract all his honey. Hutchinson and Clarke, and others are enthusiastic over invertible hives, while Pond and Demaree say they are no good. Now were we to discard all the things that even good bee-keepers condemn, I fear we would have but little left besides the old "gums" of former days. I find nearly all the great improvements that are generally recognized a good thing. The extractor, comb foundation, honey sections, cases for hives, shipping-cases, separators, and many other things are grand improvements. I have made some valuable experiments with invertible hives this season, and firmly believe they are the hive of the future.

Counteracting Fermentation.—That the "sting" and poison apparatus of bees have another object than that of a weapon of defense, is shown by the following from a German source:

At a meeting of the Physiological Society of Berlin, it was stated that when the bee has filled the cell either with pure honey or a mixture of pollen-dough and honey, and has completed the lid, a drop of formic acid obtained from the poison bag connected with the sting is added to the honey by perforating the lid with the sting. Numerous experiments have shown that this formic acid preserves honey and every other solution from fermentation.

The Globe, of Flint, Mich., thus mentions Mr. Hutchinson's new book on "The Production of Comb Honey":

The cover of the book is particularly attractive, being of board exactly the color of fine beeswax, and crumpled to imitate comb foundation. The *Globe* Printing House issued the work, and feels no backwardness in fathering the job, as it is the finest piece of typographical execution ever turned out of the office.

The printing is a credit to the craft, and we congratulate the *Globe* upon the job of work.

New Catalogues and Price-Lists are on our desk. Those desiring to obtain any of them should send to the addresses given—not to us. The following have arrived during the past week:

Earle Clickenger, Columbus, O.—1 page—Bee-Keepers' Supplies.

W. W. Biles, Duarte, Calif.—14 pages—Bee-Keepers' Supplies.

S. Valentine & Sons, Hagerstown, Md.—36 pages—Albino and Italian Queens and Bees, and Apiarian Supplies.

Jos. W. Newlove, Columbus, O.—12 pages—Apiarian Supplies, Small Fruit, Plants, etc.

Simon P. Roddy, Mechanicsville, Md.—2 pages—Bees and Queens.

M. W. Shepherd, Rochester, O.—6 pages—Bees, Ferrets, etc.

Charles Stewart, Sammonsville, N. Y.—1 page—Apiarian Supplies. This is on the back of one of Martin's "Chromo" cards.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Bee-Space above the Sections.

Query, No. 400.—1. Will bees work in the sections as well with a bee-space above as with a close cover? 2. Would a bee-space prevent the use of so much propolis above the sections?—W. J., Tenn.

1. Nearly if not quite as well. 2. It will help greatly in my locality.—C. C. MILLER.

1. I think so. 2. The bee-space does protect against propolization.—A. J. COOK.

1. Yes, they will work better. 2. Certainly, it prevents so much propolizing.—JAMES HEDDON.

1. No. 2. The difference is small in either case.—C. W. DAYTON.

1. I prefer the close cover. 2. It does with me.—G. M. DOOLITTLE.

Quite as well, but it would not lessen the amount of propolis.—J. P. H. BROWN.

I prefer no bee-space above the sections, and I get no propolis on the tops of them.—H. D. CUTTING.

Yes, bees will work just as well with a bee-space between the sections and the cover, and the space will prevent propolis being placed upon the top-bars of the sections.—W. Z. HUTCHINSON.

I hardly think that it has anything to do with the working of the bees in the sections, but I could not be induced to have the bees crawling all over the bottoms of my hive covers when I lift them off. I shut the bees down at the tops of the cases with cotton or enameled cloth. This keeps the tops of the sections clean, and enables me during oppressively hot weather to wedge up the covers and admit air between the cloth and the cover, thus cooling the bees without permitting them to leave the apartments of the hive.—G. W. DEMAREE.

1. This is a question on which there is much dispute. I prefer continuous passage-ways; others do not, so every one must test for himself. In answering this question, I assume that it does not mean just what it says; for so far as I know, space above is only used when tiering. 2. I do not think any difference will be found.—J. E. POND.

1. Yes. 2. No; if you desire to keep the sections quite free from propolis you should use wide frames to hold 4 sections. With a suitable case

they are the easiest to manipulate, and the most satisfactory in all respects. The first cost is a little more, but the saving of labor in the apiary by their use will soon over-balance their extra cost ten to one. It is my belief that we shall look in vain for a better system to handle sections.—G. L. TINKER.

There is probably but little difference, but that little is in favor of a bee-space.—THE EDITOR.

Amount of Honey Used by Bees.

Query, No. 401.—Do bees consume more honey when they have an occasional flight, than they do in continued cold weather—on the summer stands?—Arnold.

Yes, decidedly.—C. W. DAYTON.

They do not in this locality.—G. M. DOOLITTLE.

They consume the most in cold weather, unless occasional flights induce them to breed.—DADANT & SON.

Theoretically, no; for if it is warm enough to fly they do not consume as much to keep up animal heat.—H. D. CUTTING.

My experience is that they do consume more honey when they have frequent flights during an open, mild winter.—J. P. H. BROWN.

It depends upon how cold the weather may be, and also how much protection the bees may have. Well protected bees consume far less honey in confinement.—G. L. TINKER.

I have found that it is brood-rearing that requires large consumption of honey. My bees always come through in the best condition if they can fly out often, and I have never discovered that their stores are affected by frequent flights.—G. W. DEMAREE.

It depends something upon how cold. In steady weather, just cold enough to keep them from flying, they will consume less, probably, than in weather warm enough for them to fly, or than in very cold weather.—C. C. MILLER.

It depends. If the temperature is mild, but just so as to keep the bees quiet, yes. If subject to great extremes then it might be otherwise. I find when I keep my cellar at just about 45° Fahr., the bees eat the least.—A. J. COOK.

With me, bees have consumed the most honey in a long, cold winter. If there should be frequent flights, as the result of continued warm weather, there perhaps would be less stores consumed; but if it should be extremely cold between the flights, it might be otherwise.—W. Z. HUTCHINSON.

Repeated experiments in my own apiary (where I always winter the bees on the summer stands) prove that the warmer the winter the more stores there are consumed. The reason is obvious. Increased activity caused by heat, when great enough to induce flight, will of course cause a greater consumption of stores, than

when quietude caused by cold prevails.—J. E. POND.

No, sir, if none is consumed in breeding, and these flights are not too frequent and extended. When bees exercise they live largely on bread. Bees consume less honey in moderate winters of even temperature. Very low temperature arouses the bees to activity and increased consumption of honey, and later bread, and then bee-diarrhea follows.—JAMES HEDDON.

No; unless they are breeding, when it is warm enough for the "occasional flights."—THE EDITOR.

Building up Colonies in the Spring.

Query, No. 402.—What is the best and most feasible method for "building up" colonies in the spring, in time for the white clover honey harvest?—E. B., Ills.

By wintering them perfectly.—JAMES HEDDON.

By using warm packing.—C. W. DAYTON.

Feed enough to keep up breeding and keep the hive warm. Reduce or expand the brood-nest to suit the needs of the colony.—DADANT & SON.

Pack them up snugly so as to retain the warmth; see that there is food in abundance; "only this and nothing more."—W. Z. HUTCHINSON.

This is too large a matter for this place, but I think it has been fully treated in back numbers by G. M. Doolittle and others; also in the various books.—C. C. MILLER.

Slight stimulative feeding, Heddon notwithstanding, or to please Bro. Clarke, "in my opinion." Then equalize and get all colonies strong.—A. J. COOK.

If any bees go into winter with hives full of honey, so as to have plenty of stores in the spring, they will build themselves up if they are packed warm at the top of the brood-nest.—G. W. DEMAREE.

By systematic feeding, and giving frames of clean worker comb as fast as the number of bees will justify.—J. P. H. BROWN.

By the reversing of the brood-nest and spreading of the brood, as I have often given in the BEE JOURNAL. Experience is needed, however, in this matter to be successful.—G. M. DOOLITTLE.

It will require more data than is given, to tell. It will depend upon the size of the colony to start with. Some could not be built up so soon. My own plan is to draw frames of brood from strong colonies and give to the weak, as fast as they can be spared and cared for, being careful to see that all have plenty of stores both for consumption and for brood. I do not know of any better building-up process for any state of affairs.—J. E. POND.

See that they have sufficient food and are kept warm.—THE EDITOR.

The Building of Drone-Comb.

G. M. DOOLITTLE.

I have read with interest the various discussions of Mr. Hutchinson and others on the drone-comb question, and it seems to me that many do not fully understand the conditions under which it is built. The idea of no drone-comb does not lie in a small brood-chamber with a surplus arrangement above it, by any means, as many of the given reports show. My own experience also convinced me of this fact, years ago, when I among the first, if not the first, advocated a very small brood-chamber with the surplus arrangement put directly above it, to secure all worker-comb. When the conditions are right, worker-comb is just as apt to be built where no surplus arrangement is used as otherwise, and the only reason for using the surplus arrangement is in making the conditions more generally right than they are likely to be without it.

What are the right conditions for the building of worker-comb? Simply this: The right force of bees so that the queen can follow them in comb-building with her eggs, so that as soon as the cells of any comb are deep enough to receive an egg, a worker egg is laid therein. As long as these conditions exist only worker-comb is built, I care not how old or unprolific the queen is, or how prolific.

From the above it will be easily seen why a large colony with an unprolific queen builds mostly drone or store comb, and a small colony with a young prolific queen builds all worker comb.

That all may understand how to easily get worker-comb built, I will give the reader some of the experiments I have tried, and the grounds gone over, so that little by little I arrived at the truth regarding the above.

Among my first recollections of comb-building I found that, with a good queen and a large colony of bees placed in a 12-frame Gallup hive (giving 2,100 cubic inches of comb-space), the 9 central combs would be generally all worker-comb except the lower corners or parts of three or four of the outer ones, while the three outside ones and the parts noticed would generally be drone-comb. The outside sheets would generally be filled with honey, showing that these combs were built especially as store comb, while the corners mentioned would have drones in them, showing that only a small portion of this drone-

comb was really built for the rearing of drones. Now while this large amount of drone-comb was of little harm the first year, yet during June of the next year the surplus honey in these combs was converted into drones to fill the combs, which drones, after being hatched, consumed quite a share of the honey gathered by the colony; thus making a serious thing of what was built for store comb. If the queen with the colony was an old or unprolific one, matters were still worse, as in this case one-half or more of all the comb in the hive would be of the drone size.

The above and the amount of honey stored in these outside combs caused me to cut my hive down to 9 frames, so as to obviate both difficulties; but I soon found that I had only remedied the latter, as I did not put on the boxes until the hive was two-thirds full of comb, for at that time all considered it an "unpardonable sin" to put boxes on when a swarm was hived, unless it was where two or more swarms were hived together, in which case the putting on of boxes would not influence the comb-building any, for there would still be a force of bees large enough to keep the comb far in advance of the queen.

I was almost ready to give up in despair (no comb foundation being in use at that time), when one day quite a small swarm came out with a queen only a year old. I was about to put them back, when I decided to hive them for increase, considering that the colony in the fall would be worth more than the honey they would obtain if returned; and in the hiving of this swarm I got my first real light on the drone-comb subject. I did not look at this colony for three weeks from the time it was hived, except to see that the combs were being built true in the frames; therefore imagine my joy to find the frames filled with comb (except a few inches at the bottom of the two outside combs), and every bit of it was worker comb, and filled with brood, except a few pounds of honey along the top-bar.

In a week or so I opened the hive again, expecting to find that the two outside frames had been finished down with worker-comb, but was disappointed, for it was drone-comb. I asked myself why, and soon reasoned out what I thought was correct, in believing that as soon as the young bees began to hatch—which they were doing when I first opened the hive—the queen had all the egg-laying she desired to do in the vacated cells, so no longer kept "hand in hand, as it were" with the bees, they built the rest for store comb.

The next year, to thoroughly prove my position, I hived a part of a large swarm which came out with an unprolific queen, in a hive containing but three frames. I took enough bees to just fill these three frames in three weeks, according to my best judgment, but got a few too many, as they had the three combs built in 17 days, the queen having a worker egg in every cell except a few at the top for pollen and honey. I now moved along the division-board and placed an

empty frame between two of the others, and during the next four days this was filled a little over half full of worker-comb, which the queen occupied with eggs; but as soon as the young bees began to hatch, she only went over the vacated cells, which caused the rest of the frame to be filled with drone-comb. From this I took the cue which has controlled me in all my after work, and which is the father of what is known as the Hutchinson plan of getting worker-combs built in the brood-chamber while working for comb honey.

Without going over all the ground of my failures, and how I was led step by step along to perfect success, I will simply say that success is only obtained by getting such an amount of empty surplus room above, with the right size of brood-chamber below, that the bees build comb below only as fast as the queen occupies it with eggs, while there is room above for all their extra resource of wax and comb-building propensities. The reason why Mr. Hutchinson has been so eminently successful where others have failed, is because his observations have led him to more nearly comply with the above than have the less successful ones.

Before closing this article I must notice an item bearing directly upon this subject. I see it advised in a recent paper, by a would-be writer on the subject of apiculture, that an empty comb should be given a swarm at the time of hiving. In my younger years I tried this, and as a result I could get only drone-comb built in a colony so treated, and the same holds true in giving a comb of brood to a swarm to keep them from absconding, as advised by so many, especially if any of the brood in the comb is hatching so as to give the queen room to lay her eggs in this comb. Where much brood is hatching in a hive, or there is empty comb in the same, the only remedy for drone-comb is full sheets of foundation or frames of worker-comb.

Borodino, ⊙ N. Y.

Securing Good Prices for Honey.

WM. H. GRAVES,

I feel greatly interested in the discussion of the subject of "obtaining remunerative prices for our honey." To me it is of more importance than anything else connected with the business. The wintering problem has never burdened my mind to any extent, as my losses have always been light; but it is a subject of some concern to me to convert a nice lot of 4,000 or 5,000 pounds of honey into money, without selling it at a price below cost of production, thereby ruining future prices for other beekeepers, and myself also. As any one who has been in "the business" any length of time knows, it is no easy matter to raise the price after having been reduced.

I have ever refrained from sending any honey to our large commercial centres; I have never shipped a pound

of honey to a commission house. Not that I have any ill-feeling toward them, but because I thought I could do better to build up a trade nearer home. I may be mistaken, but my deductions from the present discussion in the BEE JOURNAL leads me to think that one of the principal factors in solving the problem is this: Ship less honey to the large cities; canvass your own neighborhood, keep your country towns well supplied at all times in honey put up in an attractive shape. In my experience in selling extracted honey in the country or country towns in small packages, I find that a package that can be utilized after the honey is used is far better than anything else for this purpose. I prefer quart and pint fruit-jars; also glass jelly-moulds.

Duncan, © Ills.

For the American Bee Journal.

Honey-Jumbles—Bee-Legislation.

DR. C. C. MILLER.

In part reply to Mr. J. W. Parks' questions on page 139, I would say that I have never seen but one kind of honey-jumbles, and the one from whom I got them, I understand, has not been able to obtain from the manufacturers the recipe by which they are made. I think they cost about 11 cents per pound at wholesale, making about \$5 per barrel. The first sample I had last summer. After lying for weeks in the open air, where ordinary jumbles or cookies would be dried and stale, these honey-jumbles were as fresh as ever. Not only were they nearly as good, but I could see no possible difference whatever.

During the past winter I have had some that were frozen. Whether the freezing made any difference I cannot say, but when kept in the kitchen cupboard, these have dried somewhat, in which condition they are not so good. Kept open, in a cool pantry, they become more moist, and if left in this condition long enough, they become too wet for pleasant eating. Kept in a covered tin-pail in either place, they undergo no change, or at least the change must be very gradual. After they have dried in the kitchen cupboard, if placed in the cool pantry, they become moist and as fresh as ever again. Whether too moist or too dry they never appear to have an old taste. There is certainly something remarkable about their keeping qualities, and grocers acquainted with them will keep them in preference to other things of the kind, just because they will not grow old on their hands.

As to their eating qualities, as in everything else, tastes differ. I think, however, that most persons would consider them a very nice article to put on the table for even a company tea. I am very fond of them. If warmed in the oven just before being placed on the table, I think no one could tell that they were not fresh baked. If honey is used to any extent in their manufacture, I think it

would be to the interest of bee-keepers to encourage their use.

LEGISLATION FOR BEE-KEEPERS.

In my article on page 199, I have given my promise to argue no further the desirability of legislation. Since that article was written, two writers have argued the matter on the opposite side in this paper. As I have promised to keep my mouth shut, it is the proper thing for me to shake my fist at them and boastfully tell them how I would have chewed them all up into little bits, if I hadn't promised to let them alone. Seriously, I do not think it would be difficult to controvert their views, but I am not very sorry I made the promise, for there is enough of the coward in me to make me glad to get out of a fight, and you know,

"He that fights and runs away
Will live to fight another day;
But he that is in battle slain,
Will never live to fight again."

My thanks are due Mr. Heddon for the manly way in which he has surrendered. It is no discredit to him as a disputant, for the simple reason that I had the easiest side to work on.

At Indianapolis, Mr. N. N. Betsinger made a—I am not sure whether it was a threat or a promise, in either case it was good natured—that he would give in print the hardest blows he knew how to give, against the desirability of legislation. I was surprised that he should keep silent so long, but was still more surprised when he did speak, to find that he—the only one who said he would fight me—should be the only one to come out and strike some sturdy blows on my side.

Scraper for Cleaning Hives, etc.

I. W. ROLLINS.

The accompanying illustration represents a "scraper" for cleaning hives, frames, bottom-boards and sec-

tions. A blacksmith made the one I use, with my directions. The following description shows how it is made:

Take a piece of steel as thick as a heavy butcher-knife, $3\frac{1}{2}$ inches long, $1\frac{1}{4}$ or $1\frac{1}{2}$ inches wide; punch or drill holes $\frac{1}{2}$ inch from each end, and $\frac{1}{2}$ inch from one edge. These holes should be about $\frac{3}{8}$ inch, or a little less. The handle should be about 6 inches long, direct measure, $3\frac{1}{2}$ inches at the end solid, and the part next to the blade split and brought around in a bow, entering the holes in the blade and riveted solid. The handle should be set so as to give the blade a little

pitch, something like a hoe. Now sharpen the wide edge and each end. In use, the fore-finger can be inserted in the bow of the handle.

Pan-Handle Bee-Keepers' Convention.

The Pan-Handle Bee-Keepers' Association held its second meeting on March 3 and 4, 1887, in Wheeling, W. Va. The officers of the association are as follows:

President, Henry Leweday, of Wheeling; Vice-Presidents, John A. Buchanan, Phil Tisher, H. J. Shriver, and L. C. Seabright; Secretary, W. L. Kinsey, Blaine, O.; and Treasurer, August Geotze, Wheeling.

President Leweday delivered his address, after which the Secretary read a constitution and by-laws, which was adopted.

The first question discussed was,

ESSENTIALS TO SUCCESS.

J. A. Buchanan said he believed that to become a successful bee-keeper it was necessary that certain qualifications must be inherent in the would-be apiarist; he must have a great fondness for the pursuit; such love and appreciation of the beauties of nature as will lead him to become interested in the mysteries connected with a colony of bees; he must be naturally patient, persevering and energetic. Order and system go hand in hand in this pursuit. Sloven or laggard persons need not attempt bee-keeping. Promptness to do the right thing at the right time is the key-note to success in bee-keeping.

W. S. Taggart, of Barton, said in regard to the essential qualities of a bee-keeper, that any person of good common-sense could obtain the knowledge of bee-keeping mechanically, the same as some learn music, a trade, or any other business. Bee-keeping can be imitated the same as any other business; all it requires to be a bee-keeper is to read, think, and then add practical work to thought.

BEST LOCATION FOR AN APIARY.

John A. Buchanan said: From my experience I would prefer a location well upon the sunny side of a hill, as the higher altitudes give a more even temperature. Cold air, being heavier than warm air, sinks to the valleys where there is apt to be a greater degree of dampness. I have an apiary in a valley, and one on a hill; in the spring of the year when bees are weak and need the most favorable condition to enable them to keep the greatest possible amount of brood warm, it is then that I find my hill apiary rapidly out-stripping the bees in the valley. If bee-keeping alone was the only object in view in selecting a sight, I would only locate in such places as would show by the flora of the surrounding fields to be specially adapted to the producing of honey. It might be well to look a little after the markets of the place. I should want to have my honey produced within easy marketable dis-

tance of a number of towns and villages, with not too much opposition.

C. E. Ketter remarked that in his region (Monroe Co., Ohio), about half way up the hills, is the best locality, on account of its being above the fog in the morning, and that the bees have down hill to carry honey instead of carrying all the honey uphill, where the apiary is located on top of a hill. By locating the apiary half-way up a hill the bees are more sheltered from storms.

On the second day the convention discussed the subject of "Prevention of Swarming."

C. E. Ketter—I have never had any success in repressing swarming.

P. Tisher—Bees will not swarm so long as they have unfinished combs between the brood-nest and the entrance.

A committee was appointed to wait upon the State Fair Association of West Virginia, to make arrangements in regard to premiums for apicultural exhibits at the next Fair. The committee consisted of Henry Leweday, L. C. Seabright, and W. L. Kinsey.

An essay was read by L. C. Seabright on "Spring treatment of bees."

The convention then adjourned to meet at Wheeling, W. Va., on Oct. 26 and 27, 1887. W. L. KINSEY, Sec.

Regulating the Price of honey.

JAMES HEDDON.

It is amusing to notice the "tanglement" and confusion many are in regarding the "survival of the fittest," "priority of location," "special legislation for bee-keepers," and the "proposed honey-producers' association." Some one attempts to combat Dr. Miller and misses his propositions and hits some one else. Another strikes a supposed death-blow at Mr. Baldrige, and only hits Dr. Miller a faint "tick;" and so it goes.

On page 181 Mr. Doolittle brings in a new feature to the problem, viz: charity. Well, I admire this turn, for I see no other way out, and, besides, every good man really should and does feel happy to think that if lose he must, some poor person is gaining as much.

While I consider it no argument, and entirely out of place here as an argument, I had many times thought that I would resume my old practice of retailing at home at wholesale prices, undergoing the extra labor involved by so doing, for the benefit of neighbors and the relief of the city markets.

My object in beginning this article was to correct the idea that we who desired a meeting, expected or desired to "corner" the honey market, and starve the consumer. We do not expect to destroy the natural channels of trade, but simply to regulate them and endeavor to keep others from turning them out of their natural and proper course. I am not going to bind myself to let some appointed person sell my product, or tell me

what I shall take for it—no, nothing of the sort. I want to meet bee-keepers to discuss the best ways and means of disposing of our crop; just the same as we meet to discuss the "how" of production.

I believe that such a meeting and its report will create a world-wide sentiment, based upon truth, and one which will be of lasting benefit to both producers and consumers. Let us meet and discuss all the questions relating to whether it is better to produce more or less comb honey; what styles of packages are best; how we should grade it; how to work up the home market, and how to dispose of it in city markets; whether or not it pays to have all the honey "gilt-edge;" how to equalize prices over the whole country when the same grades are offered; what is the best style of shipping-crate, and—why, about how much it costs to produce honey the country over; and all these things that will help the producer to more correctly "make up his slate" in advance.

Let us see that the children of the poor have their honey at as low a price in one location as in another, allowing for transportation. It does not aid these children to have the prices raised by passing our honey through the hands of too many middle-men. Any subject that is so vital to our interests as this—one that can find so much room in such a bee-paper—must surely be worthy of *one* special convention! Do you not think so, reader?

Some Proofs that Bees do Hear.

J. W. BAYARD.

The question as to whether bees have the sense of hearing, being one of secondary importance to bee-keepers, has attracted very little attention or discussion through the bee-papers. Some years ago the BEE JOURNAL published some tests, made by Sir John Lubbock, an English scientist, which had the merit of ingenuity and simplicity combined, but otherwise were extremely superficial and unsatisfactory.

About the year 1870, the late Mr. Adam Grimm, of Wisconsin, was one of the largest queen-breeders in America, importing his original stock from the Alps of Italy, claiming for them great superiority over queens obtained from the low country in the South, and as being more vigorous and hardy. I then gave him a trial order for 15 queens, and as a matter of convenience to us both, he sent them in installments of 3 or 4 at a time. One morning in the month of August I received by express a package containing 3 queen-cages, replete with queens and bees. (Cages in use then were six times as large as our modern cages that are sent by mail.) I opened the package carefully, placing the cages some 8 or 10 inches apart on a table. I turned to look after

something in another part of the room, when to my utter astonishment I heard the loud piping of queens from all three of the cages, and hastening to the spot, I found a regular colloquy in progress, not all speaking at once, but calling and answering, back and forth, with much regularity and great vigor as a challenge to mortal combat. Soon after the queens concluded their part of the programme, the bees in all the cages set up their ever familiar zee, zee, zee! as a *finale* to the performance.

I will venture the opinion that the most obtuse apiarist in all the land has recognized a well defined and expressive language among bees, such as rage, joy, defiance and contentment, as well as a call for help or an appeal for mercy. No longer ago than last June, I released a queen from her cage to a hybrid colony about dark; early the next morning I made an examination and found her "balled" by a small knot of bees. Upon releasing her from their grip, she darted over the combs, and when attacked by other bees she fairly screamed for mercy or help. On taking her from the hive I found her wings and one foot badly mutilated. In all my experience I find where queens are balled for destruction, they make these pathetic appeals to their captors, but they are seldom, if ever, heeded.

Not so with worker bees when they get into limbo; when squeezed by the manipulator in handling their combs, and call for help, the response comes quickly, and very often with a vengeance, as I have many objective lessons long to be remembered. That bees manifest no symptoms of alarm or fear at any outside noise or racket, is only proof of their indomitable pluck and courage to defend all that comprises their home and perpetuates their existence. They live in a noise all through their lives, created and perpetuated by themselves, hence they pay little attention to the uproarious clatter from day to day, whether artificial or natural, that is going on around them.

The Production of Comb Honey.

OEO. E. HILTON.

As I have made the production of comb honey a success for the past eight years, a review of what I consider the best methods may be of value the coming season. I trust it may present to some new ideas whereby they can increase their profits in this our chosen pursuit.

The first and the most important factor is a full hive of bees at the commencement of the honey-flow. And here an essay of interest could be written on spring management. This question is often asked: "When is the proper time to put on the surplus cases?" The majority of the bee-books say, as soon as little bits of new comb are seen being built along

the top-bars of the brood-frames. My answer is, as soon as the surplus season opens; in this latitude it is at the opening of the blackberry and raspberry blossoms, followed closely by the white clover, which is our main source. Previous to this the crates should all be prepared with sections filled with full sheets of thin foundation. The bee-keeper should also be provided with a zinc queen-excluding honey-board. I like these the size of the surplus-crate. This avoids all propolizing and snapping and cracking of crates in taking off, and all brace-combs from being built from the under side of the sections to the top of the brood-frames.

With me, there is no time looked forward to with more interest than the putting on of the surplus-crates; neither is there a time when the apiarist should exercise better judgment. Approaching a hive, I examine it closely, and if up to the standard, namely, well filled with brood and working bees, I remove all bits of comb from the top-bars, lay on the zinc queen-excluding honey-board, and put on one crate containing 28, $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{4}$ sections. All things considered, I think this size the best.

Perhaps the next colony I approach, I have not been able to build up to the standard. This I leave until I find another not up to the standard. I remove the best combs of brood and young bees (being careful not to take the queen), remove the four combs containing the least brood from No. 1, and change places with them, using judgment in making up the brood-nest, keeping the brood in the centre of the weak colony, and the combs containing the least brood in the centre of the now strong colony. I proceed as before, and put on the surplus arrangement, and out of the 2 weak colonies I have one ready for the honey-flow; and my experience is that more honey is received, and of a better quality from this one than would be received from the 2, if left to build up during the honey-flow; besides, the trouble of going over the apiary so many times as required in the bit of comb plan, is saved.

I will now consider the apiary supplied with surplus arrangements, and that the bees are well at work in the sections, and the busy season is on hand. The sections must now be watched closely, and as fast as the crates are about two-thirds full of honey, raise them up and put an empty one, arranged as the first, under it; this leaves a space to be filled with combs and honey between the brood-nest and the partially-filled crate on top. This is just as the bees do not want it, and, as a rule, just as they are coming to a point where the swarming-fever is liable to overtake them, they find this great hole in their midst, and it is surprising how they will double their energies to fill this cavity; at the same time they will be finishing the upper crate.

It is my custom at this stage of the proceedings to go over the apiary every week. My crates are so arranged that I can draw out all the finished sections, replacing with empty

ones, keeping the crate containing the least honey at the bottom, and the one nearest completion, at the top. This prevents the bees running over the finished sections, and removing it as fast as finished, gives it its virgin whiteness.

This system largely does away with the swarming-impulse just at the height of the honey-flow; but occasionally a swarm will issue in spite of everything. In this case what shall be done to prevent the cessation of honey-storing in the surplus department? My plan is as follows:

As soon as the swarm has left the parent hive, take off the surplus arrangements, lift out all but one comb and carry them to a new stand. Put in from 4 to 6 empty frames, according to the size of the swarm, filling the rest of the brood-chamber with a division-board, put on the zinc honey-board and surplus cases just removed, and close the hive. I proceed with a basket and shake the swarm from their alighting place into it, and dump them in front of the hive whence they came. I watch them closely until I am sure I have the queen, and the work is done. The remaining bees at the alighting-place, as soon as they discover the absence of the queen, will return to the old stand; so will the field bees remaining on the 7 combs that have been carried to the new stand, and all the bees in the fields returning home gives the same working-force as before. The desire for swarming is satisfied, and the work in the sections goes on as though nothing had happened. The 7 combs have plenty of nurse-bees to care for the larvæ in them, and at the same time they are so depleted in old bees that they very seldom send out a second swarm.

I want to say just a little in regard to the handling and disposing of comb honey. I have bought considerable honey at different times to sell again, and invariably I have been obliged to go over the whole lot and clean up the sections. I am sorry to say that honey is a luxury and not a staple at the present time. In times of taking off honey, have the good wife or sister, or some good, careful girl, at the honey-house with a knife or piece of glass, and have her carefully remove all the propolis and bad stains that may appear on the sections; put them away—the best on one shelf, and the second grade on another, with a sheet of paper between every two tiers to catch any drippings that may occur, as the honey stains the wood, and the nearer "gilt-edge" we keep our product the more we shall realize for the same.

In packing for shipment, I find no crate giving as general satisfaction as one holding 14 or 16 of these sections. Glassed at each end, they range in weight from 12 to 15 pounds; they stand shipment well, either by freight or express, and the retailer frequently sells a whole crate to a single customer.

I cannot urge too strongly the use of the zinc queen-excluding honey-board. I consider it one of the grandest inventions of the age—no brood in

the sections, no fastening the sections, crate and all to the brood-frames, thus tearing off the bottom of the sections, or lifting the brood-frames out by their adhering to the crate; in fact, with the experience I have had with them, I would as soon think of putting on sections without foundation starters as to think of putting on a crate without a queen-excluding honey-board.

For the American Bee Journal.

Management while Extracting.

J. J. WALLER.

My experience in bee-keeping extends almost as far back as my recollection, but it has been only a few years since I first began to keep bees on improved principles. The first extracting of honey that I ever witnessed, was by a neighbor who used what I now consider a very imperfect machine. Instead of having a revolving comb basket, the whole can turned, and the honey ran out as it was extracted. Previous to this I had read "Langstroth on the Honey-Bee," and perhaps two or three other works on bee-keeping, but my first practical lessons were taken from this neighbor.

I do not know that I have learned and adopted the best ways, but upon the subject of which I now write, I am pretty sure that for me my plan is the best; and yet with all the subjects discussed in the bee-papers, I do not now remember to have seen this more than mentioned. I do not doubt but that my plan is an old one to most bee-keepers, and it may be that it will provoke a smile from experts in our calling. I believe, however, that in giving my experience I may do good in leading others to a better way.

The practice of most bee-keepers, so far as I have seen and read, is to go to the hives as they stand in the apiary, and remove the combs to be extracted from, taking them into the honey-house or some other place for working them. I find several objections to this arrangement, and the principal one is, that at nearly all times robber bees are troublesome. We all know how it enrages bees to have robbers with their peculiar noise, prying into a hive from the top, it matters not how careful we are to subdue the bees of the hive opened. I know that some will say that we ought not to extract when robber bees are troublesome, but I find they are very bad most of the time, and somewhat so all the time. At the beginning of extracting last summer, I examined two of my best Italian colonies, and from each I got six stings in the face!

In a late number of the BEE JOURNAL, Mr. McNeill explains how he makes and uses his bee-tent, or screen-house, and intimates objections to Mr. Heddon's make of the same, one of which is that on account of its weight the hives have to be carried to it for manipulation. Now, to me

this is no objection, but there are other objections to any screen-house which render them impracticable to many bee-keepers.

In lieu of bee-tents and screen-houses, I have built a room for extracting purposes which I find to be very convenient on other occasions also. By the side of my meat-house, which is very tall, I built a shed room 8x10 feet. I have a bench made of a dressed 12-inch board extending the full length of the room to the left as it is entered, and just right to work on without stooping. In one end is a window, and in the other the door.

I find this room to be comfortable, and as there is no floor except the ground, there is no trouble climbing steps. When extracting I simply carry a hive (after smoking the bees a little) into this room, and close the door and window, and place at the old stand an empty hive, except that it has a frame of empty comb. The bees returning from work will collect on this comb, and after returning the hive with bees it is but little trouble to shake them off and let them return to their proper home. All the bees that take wing while working a hive, will collect on the window, and there remain until released, unless the window is arranged to let them pass out; but as I would rather they were in the window than in the decoy hive, I let them remain until their own hive is returned to its stand.

One great advantage in this over out-door manipulation, is that one is not compelled to be forever stooping, as the hive can be raised to any height without extra trouble. Another great advantage is, there are no robber bees to bother, and if a few bees do get angry and take wing, they very soon take to the window and are trapped.

I suppose many would object to the above plan because of the labor necessary in carrying the hives to and from the place of work; but if the house is built in a convenient place, close to the bees, I do not think the labor as great as if they are worked at their stands in the apiary.

I would be glad to see this subject discussed (either *pro* or *con*) by some of our experienced bee-keepers, such, for instance, as those whose names appear in the Query Department of the BEE JOURNAL.

Shaking Queen-Cages in Transit.

GUST. NURHARD.

I wish to draw the attention of bee-keepers who feel interested therein, to the abuse committed by inquisitive clerks in the post-office and express-office on the queen-cages with queen-bees while in transit. There is hardly a queen-bee shipped to Oregon which has not to stand hard shaking of inquisitive clerks to satisfy their curiosity whether the bees are alive or dead; and as bees that have traveled

a long distance, and have become used to shaking so that they will not answer the shaking call by buzzing, if they are alive or dead, they are shaken so much more violently, and if they then refuse to respond, the clerks' curiosity will even go so far as to use their pocket-knives to break open one corner of the larger cages, before they will desist.

I have noticed that every queen's fertility through this shaking curiosity is more or less injured in transit; but that the queens in smaller cages suffer the most, is reasonable. Would it not be well, if it can be done with any prospect to discontinue this injurious nuisance of inquisitive clerks, to apply to headquarters of the Post-office Department, and of the express companies' officers, to forbid clerks shaking any queen-cages with queen-bees while in transit?

Often are bees thus injured, and if upon their arrival they do not prove what was represented, the shippers are unjustly charged with dishonesty. Nearly every queen that I received personally out of the post-office or express-office, I found the clerks shaking the cage at the time of my arrival there; and if not they would surely commence shaking violently as they handed the cage to me. It is not as well bad intention as inquisitive ignorance, which commits the harm. If those clerks could be shown the harm that their inquisitive ignorance does, perhaps this nuisance might be abated without trouble or ill-feeling.

Portland, & Oreg.

Farm, Stock and Home.

April Work in the Apiary.

E. W. POWELL & SON.

As it is nearing the time to take bees out of the cellar, a short article perhaps will not come amiss on that subject. We do not take our bees out until April 10 or 15, if we can help it (I mean if we can keep them quiet). If we lose control of the temperature of the cellar, or if from any other cause the bees become diseased, we are compelled to take them out as soon as the snow is gone; but even then, I am not sure but the best way would be to let them have a good flight and then return them to the cellar until settled warm weather has come.

Before commencing to take the bees from the cellar, we provide ourselves with a litter, by fastening two small poles together with two cross-pieces, having the poles long enough to receive four hives at a time. We commence taking the bees out about four o'clock in the afternoon, two men taking four hives at a time. In this way the bees are carried steady and without a jar. We carry out as many in one evening as our backs will allow, and often get up early and take out some more before it is light the next morning. We take them out in this way to prevent the bees from swarming and mixing up, which they

will do sometimes if taken out in the morning of a bright day.

As soon as the bees are out of their winter quarters, they must be examined, their hives cleaned out, etc. We have a long box which we put on a spring wheelbarrow, in which to carry empty combs, scraps of comb, and our tools, which consist of a smoker, a knife to prune the combs with, a chisel to loosen the frames, and sometimes the bee-veil, though usually we have this last article over the face when we start.

We now commence at one end of the first row of hives, examining each one in succession, cleaning out the dead bees, if there are any, and supply honey to any that are in need, from those that can spare it. We give each colony just what combs they need for immediate use, using a division-board to close up the space to just the room they can use during the cold nights of spring. The empty combs we place outside of the division-board; those containing a little honey are carried to the honey-room until they are needed. We make a careful record of the condition of each colony, the number of frames they occupy, the amount of brood and honey contained, etc.; then, after packing snug and warm, the bees are not disturbed again for two or three weeks, or until they have filled all their combs with brood, when more room is given.

Mankato, & Minn.

For the American Bee Journal.

The Guelph, Ontario, Convention.

WM. F. CLARKE.

On March 23, 1887, the Guelph Bee-keepers' Association met in the Council Chamber at Guelph, Ont., at 1 p.m., the President, Rev. W. F. Clarke, in the chair. The Secretary read the minutes of the last meeting, which, on motion, were confirmed. Then followed the

PRESIDENT'S ADDRESS.

Fellow Bee-keepers:—We meet near the close of a winter, which, though a long one, has not been altogether unfavorable for bees, and it is to be hoped that a few days will bring the welcome disclosure that our losses have been slight. Last season was an unpropitious one in this locality for honey-production, and, as we are not apt to have two bad years in succession, we may look forward to the coming summer as one in which nectar will abound, and our industrious little workers gather plentifully both for themselves and us.

At the present time, there are several matters of interest and importance pressing on the attention of bee-keepers. One is the low price of honey. Honey is cheap and likely to remain so. It has been proposed to form honey producers' associations to regulate the market price of honey. I do not think this course would have the desired effect. No wheat growers' association could fix the price of

wheat. No cheese or butter association could fix the price of dairy products. The law of supply and demand will ultimately control these matters, in spite of all our devices. All we can do is to cheapen the production of honey by adopting the best labor-saving devices in our apiaries; offer only a first-class article for sale, and so get the best price going; spread information concerning the value of honey as food and medicine; set ourselves to develop a local market, by exciting a home demand; and, above all, avail ourselves of that British mart, which, through the enterprise of the Ontario Government, and the labors of our commissioners has been proved to be readily accessible to us.

Another matter of special interest to us is the rights of bee-keepers as involved in the recent suit of McIntosh vs. Harrison. This case went against the bee-keeper. His bees were declared a nuisance, and the court granted an injunction against their being kept in close proximity to the blacksmith shop of his neighbor. This lawsuit undeniably grew out of a quarrel between neighbors. The bees had been kept near the blacksmith shop for years, and would have been kept there still, without objection, but for an unhappy dispute about a pigeon. It would have paid Harrison to have cleaned out the pig-pen himself, and sprinkled plenty of deodorizing matter around it, rather than go to law. An expense of about \$1,000 has been incurred by the litigants—\$300 for the plaintiff, and \$700 for the defendant. The plaintiff has got what he wanted at a high cost, and is probably as sorry as the defendant that the matter ever went into court. This case decides nothing as to bee-keeping in general. Bees may be a nuisance kept close to a blacksmith shop, where sweaty horses are apt to get a sting now and then, but this does not prove that they are a nuisance everywhere within corporation limits.

It is thought by some that we must have special legislation to define the rights of bee-keepers. If so, the sooner it is attended to the better. But, perhaps it might be as well to "let sleeping dogs lie." The common-sense and good-feeling of the general public may be counted on to put up with a little temporary annoyance, rather than injure one of the rising industries of our country—that to which we are indebted for the most luscious condiment that can tickle a human palate. People, in general, are forbearing. Witness the extent to which the dog nuisance is tolerated, though "dogs delight to bark and bite," kill a great many valuable sheep, and occasionally cause the death of human beings by that terrible disease, hydrophobia. My voice is not for war over the Harrison suit. It would never have been instituted, but as the result of ill-feeling, which ought not to have come into existence.

Priority of location is another matter which is attracting much attention among bee-keepers. It is proposed by some to pass a law securing to the first comer as a bee-keeper into

a neighborhood, the exclusive ownership of the bee-forage within certain limits. As well might you give the first village store-keeper exclusive right of trade until the population reaches a certain number, and so on with the first blacksmith, the first shoemaker, and the first preacher. One man may want the whole loaf to himself, and another feel that half a loaf is better than no bread. They must "catch as catch can," and settle the matter as best they may. We now have too much legislation, and consequently too much litigation. It is good for the lawyers, but bad for the common people. We do want more legislation of a higher kind. The golden rule and the law of love have only to be carried out to end all the faction fights between capital and labor, and this is amply sufficient to regulate the relations and locations of bee-keepers; otherwise we must bow to that inexorable law of nature which provides for the "survival of the fittest."

A long and interesting discussion followed, mainly in regard to the best means of securing the British market for our surplus honey product. The following resolutions were then passed:

Resolved, That this association is of the opinion that in order to render permanent the good results of last year's honey-exhibit in England, it is desirable that Canadian bee-keepers co-operate in making as large a consignment as possible the coming year; and that the Ontario Bee-keepers' Association be requested to appoint a commissioner to go ahead of the consignment and make sales, it being understood that the Government grant be a guarantee fund for the one commissioner as it was for the four last year, and that after deducting such expenses as the grant does not cover, there be a dividend, share and share alike among the consignors; also, in case this is done, the members of this association engage, season permitting, to supply at least 10,000 pounds of honey, all such honey to be duly inspected before acceptance for shipment.

Resolved, That we consider the directors of the Ontario Bee-keepers' Association are in duty bound to lay before the bee-keepers of this country a financial statement relative to the Canadian honey-exhibit in England last year.

Resolved, That the Secretary be directed to send a copy of the foregoing resolutions to the President of the Ontario Bee-keepers' Association, and that the President of this association and Mr. R. F. Holtermann represent this association at the meeting of directors, that may be called to consider this matter.

Resolved, That agricultural societies be respectfully requested to appoint no parties as judges of honey and apiarian supplies except those who have had experience as bee-keepers.

Mr. R. F. Holtermann then read a brief essay on "Manipulation and Mutilation," pointing out the evils of a too frequent disturbance of the

brood-nest. The essay was discussed at some length.

The thanks of the convention were, on motion, voted to the Mayor and corporation for the use of the Council Chamber; also to the President for his address, and to Mr. R. F. Holtermann for his essay.

The convention then adjourned to meet on Thursday, Sept. 1, 1887, in Guelph, at 10 a.m.

Guelph, Ont.

Local Convention Directory.

1887. *Time and place of Meeting.*
- Apr. 9.—Union, at Dexter, Iowa.
J. E. Pryor, Sec., Dexter, Iowa.
- Apr. 12.—Stark County, at Canton, Ohio.
Mark Thomson, Sec., Canton, O.
- Apr. 14.—Eastern Indiana, at Richmond, Ind.
M. G. Reynolds, Sec., Williamsburg, Ind.
- Apr. 16.—Marshall County, at Marshalltown, Iowa.
J. W. Sanders, Sec., LeGrand, Iowa.

F. H. Kennedy, Sec., DuQuoin, Ills.
- Apr. 26.—Central Michigan, at Lansing, Mich.
J. Ashworth, Pres., Lansing, Mich.
- Apr. 26.—Des Moines Co., at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.
- May 5.—Sheboygan County, at Hingham, Wis.
Mattie B. Thomas, Sec., Sheboygan Falls, Wis.
- May 24.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
D. A. Fuller, Sec., Cherry Valley, Ills.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Disastrous Weather for Bees.—E. F. Smith, Smyrna, N. Y., on March 24, 1887, says:

My bees are in bad condition, and have had no flights since the first week in November—142 days. March has been colder than February. We had a regular blizzard from the northwest on March 22, and there is a great depth of snow. Unless we have a change soon, there will be very few bees left in this region; some have already lost all, and others one-half or more.

Two Colonies in a Hive.—W. Mason, Fillmore, Ind., on March 28, 1887, writes:

On page 59 I promised to report my experience in wintering two or more colonies in one hive. Now that winter is past I can say that I see no benefit in the plan for wintering. I do not think they will make as good a showing as single colonies; yet my test was not a fair one. The last of January we had a few warm days with the temperature up to 60° above zero in the bee-house; the bees became excited, leaving the hives and getting down on the floor, thus leaving several colonies weak. I was away from home at the time, but returned the day it became cooler; see-

ing the situation, and finding the temperature still at 62°, I resorted to putting in ice until the bees became quiet, but too late to save my bees from loss, which may be at the cost of several colonies. So the test is not a fair one. But I learned that bees will not remain quiet in as high a temperature for me as some have claimed. They are the most quiet for me at from 35° to 40°, and fairly quiet up to 50°; but above that they get restless. Our winter since Jan. 20 has been mild; there has been quite a loss among colonies that were hived late last fall, but the strong colonies have come through all right.

Samson's First Colony of Bees.—N. W. Aflerbaugh, Cameron, ☉ Nebr., sends this "old, old story" of 3,000 years ago:

Samson went down to Timnath and saw a woman in Timnath of the daughters of the Philistines, and when he came back he told his father and mother, and said: I have seen a woman in Timnath that I love; and Samson said unto his father and mother, get her for me, for she pleaseth me well; then went Samson down, and his father and mother to Timnath, and came to the vineyards of Timnath, and behold a young lion roared against him, and Samson killed him, and he went and talked with the woman, and she pleased Samson well. After a time he returned to take her for his wife; on his way he stopped to behold the carcass of the lion, and in it he found a colony of bees and honey; and he took thereof in his hand, and began to eat, and coming to his father and mother, gave some to them to eat. Samson had a marriage feast, with honey for supper 1141 years before the Christian era—over three thousand years ago.

No Loss for Four Winters.—Abner Brown, Lansing, ♀ Mich., on March 25, 1887, says:

Last fall I prepared 5 colonies of bees for winter, and have now taken them out, and find all in excellent condition—no signs of disease, and with plenty of stores. This is the fourth winter that I have saved all the bees that I put up the previous fall.

Sweet-Clover Fiber for Cordage.—C. H. Dibbern, Milan, ☉ Ills., writes:

I am pleased to notice, Mr. Editor, that yourself and the cordage company seem to be interested in the matter of utilizing the sweet clover fibers mentioned on page 203. My attention was first attracted by passing my piece of about two acres of the dry stalks of sweet clover, and seeing the fiber wave in the wind. I broke off a few stalks and secured the sample I sent you. I should judge that the stalks contain about as much of the fiber as the ordinary hemp, and very much like it. I would gladly send on a bale of several hundred pounds, as requested, but to secure that amount by hand is a job I do not

covet. It is quite likely that the fiber is now somewhat injured by exposure through the winter. The object I had in view was to call attention to the possible value of sweet clover as a fiber-producing plant, and hope that those having a knowledge of the proper treatment of hemp, and machinery for handling it, will take it up.

Building a Bee-Cellar.—J. H. Stanford, Cherokee, ☉ Iowa, asks the following questions:

I want to build a bee-cellar the coming summer. 1. How large should the room be to hold 75 colonies? 2. Would you ventilate it with tile? If so, how deep would you lay it? How long? and what size? 3. How high should the walls of the cellar be? 4. How many windows? 5. Is a cement floor the best? 6. Is it best to run water through the cellar? 7. Would you build an outside stairway? 8. Is it best to lath and plaster the joists overhead or ceil it with pine flooring? Bees have wintered well so far. I put out 3 colonies, but it was too cold for them to fly.

[1. Two hundred square feet or more, somewhat depending upon the size of the hives.

2. I would ventilate the cellar with tile, and I am trying hard to find out just how. At present I should say 6 to 10 inch tile, not less than 5 feet to the bottom of the drain, and *not less* than 150 feet long. Probably this would ventilate a larger cellar.

3. Seven feet is a good height.

4. One is probably enough.

5. I have used a cement floor in one cellar, and I doubt if it is of any advantage.

6. I have had no experience. If you can easily try it, do so, and report the result both with and without.

7. By all means, if possible.

8. Lath and plaster, I think.—C. C. MILLER.]

Fearing Chilled Brood.—W. H. Martin, Falls City, ☉ Nebr., on March 29, 1887, says:

It has been cold here for more than a week, and I fear that chilled brood will be the result. A swarm of bees was found on March 1 clustered on a hedge-fence near this place. One young man said he could tell the reason why; they were in a rented hive, and had to move out!

The Prospects in Kentucky.—J. J. Waller, Pleasure Ridge Park, ♀ Ky., on March 25, 1887, writes:

I reported last summer that my bees were gathering "honey-dew" from the black walnut leaves, and promised to report further concerning the outcome. That "honey-flow" did not last long, as we had a very hard wind and rain storm which destroyed

the most of the little insects, which Prof. Cook said (and I do not doubt its truth) produced the sweet substance. My bees, however, gathered it so freely while it lasted, that about one-half of their winter stores consisted of it; and I had fears as to its healthfulness for winter use, but I am glad to say that so far as I can see, it had no injurious effect whatever. I have lost but 2 colonies of bees out of 65, and I think that they were overcome by cold, on account of the way they clustered on their combs. We certainly had an easy winter on bees in Kentucky. I think the mercury only on two occasions was below zero, and then only a few degrees; yet I do not remember to have ever seen as thick *pure* ice. My opinion is that bees have generally wintered well in this part of the country, and now if we knew how to successfully control swarming, I think we could look forward with bright hopes to a large honey crop.

Cheap Production of Honey.—E. Sandford, Nokomis, ☉ Ills., on March 24, 1887, writes:

I do not see why there is so much complaining about the price of comb honey when compared to other things. I think that if some bee-keepers would supply their families from the market instead of from their own apiaries, they would find that the same money would go much further in buying something that would answer about the same purpose. I think their undivided attention should be turned to cheap production.

Results of the Winter, etc.—J. A. Reeds, Hinesboro, ☉ Ills., on March 30, 1887, writes:

My bees have wintered apparently all right. I did not lose a single colony out of 130 in the cellar; but they are dwindling away during this cold weather; some colonies are getting very weak. I helped a neighbor put his bees out of the cellar; he had 70 colonies, and all were alive. I hear of many bees dying that were left out unprotected during the winter. I had 100 colonies last year, which I worked for honey, and they stored 6,300 pounds of comb and extracted honey. The clover seems to be frozen out pretty badly here. I do not expect as good a flow of honey this year as we had last.

Plant Alsike Clover.

Leaflet No. 2, entitled "Alsike Clover for Pasturage and Hay," is now ready for delivery. It should be scattered at once into every neighborhood, in order to induce farmers to plant Alsike, that the bees may have the advantage of it for pasturage. We send them by mail 50 copies for 30 cents; 100 for 50 cents; 500 for \$2.25—all post-paid. It will pay bee-keepers to scatter these Leaflets, even if 9 out of 10 avail nothing. If ten farmers out of a hundred plant Alsike in any neighborhood, the bees will reap a very substantial reward.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c.—Sales have been larger this month than at any time since November, and prices average a little lower for comb than the above.
BEE SWAX.—25c. R. A. BURNETT,
 Mar. 28. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 10@12c.; in 2-lbs., 9@10c.; off grades, 1 to 2 cts. per lb. less. Buckwheat, in 1-lb. sections, 8@8½c.; in 2-lbs., 7@7½c. Extracted, California, 5@5½c.; buckwheat, 4@4½c. Supply of comb honey is large, and demand for all kinds is improving.
BEE SWAX.—21@23c.
 MCCAUL & HILDRETH BROS.,
 Jan. 21. 34 Hudson St.

DETROIT.

HONEY.—Best white comb, 10@11c. Supply large and sales are slow.
BEE SWAX.—23c.
 Mar. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4¼@4½c.; amber, 3¼@4¼c. Comb, white, 10@13c.; amber, 7@9c. Market firm.
BEE SWAX.—Firm at 20@23c.
 Mar. 21. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively.
BEE SWAX.—24 cts. per lb.
 Mar. 23. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 3@7c. per lb. Nice comb brings 11@14c. per lb. Demand fair.
BEE SWAX.—Good demand,—20@23c. per lb. for good to choice yellow.
 Mar. 29. C.F. MUTE & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, 1-lb. sections, sells at 12½@13c.; second quality white, 10@11c.; white 2-lbs., 10@11c. Buckwheat, 8@9c. Extracted, 5@5c.—Market dull.
BEE SWAX.—25c.
 Mar. 9. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 11@12c.; 2-lbs., 10@11c. No call for dark. White extracted, in barrels and kegs, 8@8½c.; in small packages, 8½@7c.; dark, in barrels and kegs, 4@5c.—Demand good.
BEE SWAX.—25c.
 Mar. 28. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: Comb, extra white, 12@13 cts.; amber to white, 8½@11. Extracted, white, 4¼@4½c.; amber and candled, 3¼@4c. Trade is quiet.
 Jan. 10. O. B. SMITH & CO., 453 Front St.

KANSAS CITY.

HONEY.—We quote white clover 1-pounds at 12c.; dark 1-lb., 8@10c.; white clover 2-lbs., 10@11 cts.; dark 2-lbs., 7@9c. Extracted, white clover, 5c.; dark, 4@5c.; white esge, 5@5½c.; amber, 4½@5. **BEE SWAX.**—20@23c.
 Jan. 13. CLEMONS, CLOON & CO., cor. 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 10@12c.; latter price for choice white clover. Strained, in barrels, 3¼@4¼c. Extra fancy of bright color and in No. 1 packages, ¼ advance on above prices. Extracted in barrels, 4½@5c.; in cans, 5@6c. Market dull.
BEE SWAX.—Firm at 21c. for prime.
 Feb. 3. D. G. TUTT & CO., Commercial St.

Continuous Advertising brings much larger returns, in proportion to the outlay, than periodic or spasmodic advertising.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

OUR CLUBBING LIST.

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club

One yearly subscription for the AMERICAN BEE JOURNAL must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

More Premiums.—Mr. L. J. Diehl, of Butler, Ind., offers a colony of Italian bees as a present to the person sending to this office the largest club of subscribers for 1887. The subscriptions may be sent in at any time before the first of May at our regular club rates, and additions made as desired, but it must be stated that you are working for that premium, so that we can keep account of the subscriptions.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

Convention Notices.

The Wabash County Bee-Keepers' Association will meet at North Manchester, Ind., on April 20, 1887, at 10 a.m. **AARON SINGER, Sec.**

The May meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held at Rockton, Ills., on Tuesday, May 24, 1887. **D. A. FULLER, Sec.**

The semi-annual meeting of the Southern Illinois Bee-Keepers' Association will be held in the Court House at Benton, Ills., on Wednesday, April 20, 1887, at 10 a.m. All are invited to attend. **F. H. KENNEDY, Sec.**

The Union Bee-Keepers' Association of Western Iowa will hold their next annual meeting at Dexter, Iowa, on Saturday, Apr. 9, 1887, in the Council Room, at 10 a.m. All interested in bees or honey are requested to be present. **J. E. PRYOR Sec.**

The annual meeting of the Stark County Bee-Keepers' Society will occur on Apr. 12, 1887, in Grange Hall (over Farmer's Bank), Canton, O. Officers for the ensuing year will be elected. All bee-keepers are urged to be present, and those having hives or fixtures are requested to bring the same for exhibition. **MARK THOMSON, Sec.**

The Des Moines County Bee-Keepers' Association will meet on April 26, 1887, at the Court House at Burlington, Iowa, at 10 a.m. All interested in bee-keeping are invited to attend. Articles sent for exhibition to the Secretary, at Middletown, Iowa, will be exhibited and returned or sold, as directed. **JOHN NAU, Sec.**

The Central Michigan Bee-Keepers' Association will hold the spring meeting in Pioneer Hall, Capitol Building, at Lansing, Mich., on April 26, 1887, at 10 a.m. A cordial invitation is extended to all bee-keepers. If any have troublesome questions, bring them with you, or send them to the President, at Lansing, Mich. **J. ASHWORTH, Pres.**

System and Success.

All who intend to be systematic in their work in the apary, should get a copy of the **Apary Register** and commence to use it. The prices are reduced, as follows:

- For 50 colonies (120 pages).....\$1 00
- " 100 colonies (320 pages)..... 1 25
- " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

THOSE who expect to buy an Incubator will consult their interest by addressing, **RELIABLE INCUBATOR CO., 14A3t Decatur, Macon Co., Ills.**

THE WESTERN WORLD GUIDE and HAND-BOOK OF USEFUL INFORMATION.

For HOME SEEKERS or Tourists, Capitalists or Laborers. A vast amount of information not to be found elsewhere at any price.

A cloth-bound book, 4x7 inches, 288 pages. Price, 50 Cents.

The following is only a part of the Contents: Colored Maps of all the States and Territories, including Alaska and District of Columbia. Diagrams showing area, population, products, Government, State, School and Indian Lands of the several States. Histories of each of the States from the Earliest Times. How to Acquire Lands of any kind belonging to the Government by any forms of entry, who may acquire them, and the different laws applicable to the different sections. Postal, Pension and Patent Laws of the United States. Coats-of-Arms of the States and Views of Celebrated Places, and of life in different regions. Rules for measuring Lumber, Logs, Grain, Liquids, Tables of Weights and Measures of all kinds, Interest Rules and Tables, Lumber Tables. Systems of Land Measures in various parts of the United States.

Contains also a Million Useful Facts. The Weekly Bee Journal, for one year, and the Guide, postpaid, for \$1.30.

THOMAS G. NEWMAN & SON, 923 & 925 West Madison St., CHICAGO, ILL

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the American Bee Journal.

It contains 220 profusely illustrated pages is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. Bound in cloth, \$1.00, postpaid.

A Liberal Discount to Dealers, by the Dozen or Hundred.

THOS. G. NEWMAN & SON,

923 & 925 West Madison St., CHICAGO, ILL.

The AMERICAN BEE JOURNAL for a year and the book, "Bees and Honey," will be sent for \$1.75.

BEES! 300 COLONIES ITALIANS

READY for spring delivery at 60 cts. to \$1.00 per pound, according to time. Choice Queens and Brood cheaper in proportion. Also ADJUSTABLE HONEY-CASE and other Supplies. Circular free. **OLIVER FOSTER,** Mt. Vernon, Linn Co., Iowa.

THE BRITISH BEE JOURNAL

AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published every Week, at Ten Shillings and 10d. per annum, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited by T. W. Cowan, Esq.

The British Bee Journal and the AMERICAN BEE JOURNAL, one year, for \$3.00.

Jones' Frame Pliers.

FOR taking frames out of hives, or moving them in any way desired. It is made of jappanned iron, and can be utilized in many ways. It has a long claw for loosening frames, and a book which may be used for carrying other frames besides the one held by the Pliers. Price, 40 cts., by mail.

THOS. G. NEWMAN & SON,

923 & 925 West Madison St., CHICAGO, ILLS.

700 POUNDS OF BEES.

DURING first 1/2 of May I will sell the above at \$1.25 per pound. Also Untested Italian Queens bred from Imported Mothers, to go with the Bees, for \$1.25 each. Cash must accompany orders, and be sent before April 20. Reference 1st Nat'l Bank here. **E. BURKE,** Vincennes, Indiana.

THE HORSE,

By B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents—in English or German.

THOS. G. NEWMAN & SON,

923 & 925 West Madison Street, Chicago, Ill.

BEAUTIFUL.

ALL-IN-ONE-PIECE Sections, smooth inside and out. Comb Foundation, Alsike Clover Seed, and everything needed in the apiary.

Send for free price list, and samples of Sections and Foundation.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. April 13, 1887. No. 15.

Oh! Happy the lily
That is kissed by the bee;
While quitting tranquilly,
Oh! quite happy is she.
Also, happy are both,
As when lovers confide,
The gallant chieftain doth
Embrace his lovely bride.

M. M. Baldrige has gone to Mississippi, where he will remain for several months, having some bee-interests there which require his presence and personal attention.

"Bees," says the *Scientific American*, "can remember a man." We didn't know that, but we have frequently had reason to believe they could dismember him.

"Who Imported the first Italian bees, and when was it?" asks a correspondent. We reply that Mr. Samuel B. Parsons is credited with that achievement. His first queens were received in March, 1860.

Made a Slate.—The Bee-Keepers' Magazine for April announces a slate for officers for the projected Honey Producers' Convention for May. It is this:

President, James Heddon; Vice-President, A. J. Cook; Secretary, W. Z. Hutchinson; Treasurer, Thos. G. Newman; Historian, Rev. W. F. Clarke.

No, sir; we shall *smash that slate* in advance. We announced last November (page 723) that we could not accept any official position, if the organization was effected, and gave good and sufficient reasons for our decision. We then added:

The editor of the BEE JOURNAL already has more "public duties" than he can well perform, and bears more of the "honors" which such bring than he cares to carry.

If the convention is to be held in May, it is quite time for arrangements to be announced. Would it not be better to defer it until the meeting of the North American Society, to be held next fall?

Another Fraud.—Mr. Willis M. Barnum, of Angelica, N. Y., has sent us a marked copy of a circular sent out by a "concern" in South Bend, Ind., which calls particular attention to a "Recipe" which it has for sale called "Golden Crystal Honey." Agents are advised that it puts "a paying business within the reach of all," with "profits immense!"

Our readers will laugh at the immense profits when they read this:

Profits as a result from the manufacture of the Golden Honey. One hundred pounds can be made in less than one hour at a cost of less than 7 cents a pound, and sells readily at an advance of bee-honey for 25 and 30 cents a pound, many people preferring it to bee-honey.

Any one should know that pure extracted honey can be purchased for the price which this "vile compound" can be made, and which agents are expected to sell at 25 to 30 cents per pound! But "the Agents' Friend" does not tell them *where* they are to find "auckers" to buy the "vile trash" at such an extravagant price, unless they may find it in the paragraph which reads thus:

The Golden Honey is an article of unsurpassed excellence, and it is fast working its way into the homes of private families and public hotels. With unstinted perseverance our efforts have been crowned in securing a secret to manufacture the Golden Honey, and we defy the best judges to tell it from the purest bee-honey, and many experts pronounce it superior, as not like the bee-honey, it will never ferment or become rancid, but will keep any length of time in any climate. There are nine ingredients used in the composition of the Golden Honey, any one of which if absent it would be impossible to create the bee principle, consistency and flavor of our Golden Honey.

Hotel keepers usually know too much to be taken in by such villainous trash, and certainly know more of the cost of food products than to pay three times the price for it that would buy pure honey!

The "fool-killer" ought to make a trip to South Bend and "rid the earth" of the deceitful rascal who wrote the above paragraph. While he *defies* "the best judges to tell it from the purest bee-honey," yet these same "experts pronounce it superior" because, forsooth, it will not "become rancid."

We have heard of rancid oil, rancid butter, rancid bacon, but never thought any one would be such a fool as to think honey would become rancid! The composition of the "nine ingredients" called "Golden Crystal Honey" may become rancid, but could never become as rank as the brains of that bombastic writer!

The "Agents' Friend" tells its dupes that they can make a profit of \$150 on 1,000 pounds of its vile compound, and adds: "You will always find ready sale for the Golden Honey," the recipe for which "costs only two dollars, with the exclusive right to manufacture and sell in a town of not over 20,000 inhabitants." They are assured that there is "big money in the business" by the writer, who adds:

GROCERYMEN ARE GLAD TO GET IT, as very many of their customers will buy it in preference, and pay more for it than for the bee-honey. Any ordinary kitchen utensils are only necessary for the making of the honey, and the increasing demand will soon double any amount of capital that may be invested in the business.

This caps the climax! First it was *just as good as* bee-honey; then it was *superior* to it; now customers will pay more for it than

for bee-honey, and therefore "grocerymen are glad to get it!"

This is unbounded cheek, or else the ravings of a lunatic. The fact is that there has been so much of a hue-and-cry about adulteration, that it is quite difficult to convince consumers that even pure honey is the genuine article, when offered to them; but this crank would have us believe that consumers prefer this "composition" to pure honey, and are willing to pay for it three or four times the price of the pure honey!

"What fools these mortals be!"

Bees Dislike the Odor of the stable; and horses when in a state of perspiration are very liable to be stung, if in the neighborhood of an apiary. The San Diego, Calif., *Union* contains the following from a correspondent, who had a valuable horse stung so badly, so that in his agony he rolled upon the ground:

A smudge was made with damp straw, and the bees thus driven away from the horse, then the animal was given a good dose of laudanum—several tea-spoonfuls altogether—and in this manner the pain was considerably relieved. He soon recovered sufficiently to be taken to the stable, and was then thoroughly sponged with a strong solution of common baking soda and water. This was repeated, and the result was the animal entirely recovered; if this treatment had not been adopted he would unquestionably have died.

While the soda is an excellent remedy, perhaps a better thing to have used would be a solution of ammonia. It is well known that a little of this will quickly relieve the pain when a person is stung, and it would doubtless act much quicker on the horse than would the soda solution. However, either is good, but the application of laudanum to quiet the suffering animal seems to be a novelty in veterinary practice.

Sections Filled with Comb.—Some one has sent us an article of 10 sheets on the above subject, but as it bears no name, post-office, county, or State, we know not from whom it came. Will the author please supply this deficiency in order to save it from the waste basket, as we publish no anonymous communications.

It is said that the sting of a bumble-bee contains only one-fiftieth part of a drop of poison, but it sends it home with as much enthusiasm as if it were a gallon.—*Burlington Free Press*.

New Catalogues and Price-Lists are on our desk. Those desiring to obtain any of them should send to the addresses given—not to us. The following have arrived during the past week:

J. C. Bownan & Co., North Lima, O.—18 pages—Bees, Queens, Apiarian Supplies and Poultry.

E. T. Flanagan, Belleville, Ills.—8 pages—Bees and Apiarian Supplies.

F. J. Crowley, Batavia, N. Y.—6 pages—Bees, Queens, and Bee-Keepers' Supplies.

Charles Hill, Mount Healthy, O.—1 page—Queens.

L. L. Esenhower & Co., Reading, Pa.—10 pages—Grape Vines.

H. H. Brown, Light Street, Pa.—20 pages—Bees, Queens, and Apiarian Supplies.

C. D. Black, Brandon, Iowa—6 pages—Bees, Queens, and Honey.

C. L. Eakin, Wadestown, W. Va.—1 page—Bees, Queens, etc.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

When to Put on Section-Cases.

Query 403.—1. Ought the super or case of sections be put on the hive of a swarm at the time of hiving? If not, when? 2. Ought they to be put on the hives of old colonies before the brood-chamber is filled with brood and honey?—E. & W. M., Va.

I answer yes to both questions.—W. Z. HUTCHINSON.

1. At the time, or very shortly after. 2. Not as a general rule.—C. C. MILLER.

1. Yes. 2. Yes, as soon as harvest opens. Read Mr. Hutchinson's new book.—A. J. COOK.

1. It depends upon the method of management. 2. They should be put on when the hives are filled with brood, and before there is any honey gathered.—C. W. DAYTON.

If metal queen-excluders are not used, it will not do to put on the cases until the brood-nest is fairly started below. I put on the cases in the spring as soon as warm weather has fully set in, and the bees are gathering some surplus. A glance at the top-bars of the frames will usually show white bits of wax, if the bees are ready for the surplus cases.—G. W. DEMAREE.

1. I prefer to wait a day or two until the bees get well started below, before putting on the sections; though when pressed for time, I have placed them on at the time of hiving, with good results. 2. No. Bees will not work in supers as long as they can find room below.—J. P. H. BROWN.

Yes; and usually the super should be one taken from the old colony that swarmed. Whether or not the old colony is ready for surplus receptacles is not positively determined by the amount of honey or brood, or both, which the hive contains.—JAMES HEDDON.

1. If the swarm has left a hive with a case of sections on, take that case and put it on the hive in which the swarm is put. 2. When you see new comb along the top-bars of the frames, and new brace-combs, then it is a good time to put on sections.—H. D. CUTTING.

1. In using what is known as the Hutchinson plan, yes. If a full hive or brood-chamber of 2,000 cubic inches is used, it is just as well to wait a week. I prefer the former. 2. Not before the hive is filled with brood.

It is poor policy to allow much honey in the brood-chamber during the height of brood-rearing.—G. M. DOOLITTLE.

If the bees are hived on frames filled with comb or foundation, and a queen-excluder used over the tops of the frames, the sections may well be put on when the swarm is hived, as time will thereby be saved. Otherwise wait two or three days or so, until the queen begins laying below.—G. L. TINKER.

1. Yes, with the hives I use it is best to put on one or two cases of sections before hiving. But if you use a large brood-chamber like the 10-frame Langstroth, it is only an exceptionally good honey-flow that it is worth while to put on any sections. 2. When the colony gets to be strong in bees, is the time to put on sections. It is better to put them on then, even if some time before a honey-flow.—G. L. TINKER.

It depends upon the method adopted. In answer to both questions we would say, give them the supers either at the time mentioned or soon after.—THE EDITOR.

Getting Bees out of the Sections.

Query 404.—I am troubled about getting bees out of the sections when the latter are filled with honey. I use two-pound, close-top sections. I have to take the sections out of the case and brush the bees off. Can you inform me of any better way?—Wisconsin.

Use open-top sections, and smoke them out.—C. W. DAYTON.

Turn over the case and apply a little smoke, and then carry them into a dark room with a small opening emitting a little light, and the bees will pass out. Do not use close-top sections.—J. P. H. BROWN.

Use open-top sections, when by the use of smoke the bees can be driven off the honey down below before the sections are taken from the hive.—G. M. DOOLITTLE.

One way is to put the bees in a tent of wire-cloth or mosquito netting, having a hole in the top of the tent, and the bees will come out themselves. See page 55 of "A Year Among the Bees."—C. C. MILLER.

With your close-top sections you cannot practice tiering up. With two sets of sections on, if you leave off the hive-cover at night, you will have but few bees in the top case of sections early in the morning, and they can be taken off with ease, placed in a well-lighted room, and all bees will go to the windows.—H. D. CUTTING.

It is no easy task to get bees out of a section case in which close-top sections are used. I have a little closet standing in close proximity to the apiary, which has a door so as to take in the cases. The closet will hold quite a number of cases at one and the same time, and when the door is shut the place is perfectly dark. The shutter of the door has a bee-escape in its centre. The bee-escape permits the bees to leave the closet, but they cannot return. With my open-top

sections I smoke the bees down, then lift the case and carry it to the "bee-escape," and leave them there until the bees return home. I could not describe how the "escape" is made, here, for want of space.—G. W. DEMAREE.

Every bee-man has his "pet-method" for taking the bees out. A good way is to place the crate on a board not far from the hive, covering it with a sheet. The bees will crawl up under the sheet, and will promptly leave, unless they have the queen with them. Care must be taken not to give ingress to robber bees.—DADANT & SON.

Use open-top sections. Pour a perfect deluge of smoke down upon the bees, when most of the bees will run down. Take off the case and tremulously shake it in front of the hive, which will dislodge most of the bees. The case should then be carried to a room having windows so arranged as to allow the bees to escape, but let none in.—W. Z. HUTCHINSON.

In the first place I would not use close-top sections. I prefer wide frames to hold 4 sections, and make the separators movable, so the bees can be shaken from 4 sections at once. They do not brush off readily. The only perfect and wholly satisfactory method of taking comb honey is by the use of wide frames to be removed one at a time as above. It is the only method by which the honey can be taken without more or less injury to the capping. It is easy to take 60 pounds of honey free from bees inside of 10 minutes by this plan.—G. L. TINKER.

Probably the method you mention is the speediest. If a number of cases of sections are placed in a barrel or box, and a piece of cloth thrown over the open top, the bees will soon crawl or fly to the cloth, and can there be shaken off. Put the section-cases into a close room, and the bees will soon go to the windows, when they can be released.—J. E. POND.

Put crates of sections in a bee-tent or bee-house. The bees will leave and may be liberated from the tent or house at the apiarist's pleasure. I have placed section-crates in a large dry-goods house, over which I spread a blanket, leaving only a small hole. The bees would leave the sections. When the bees are not gathering, this last method may endanger from robbing.—A. J. COOK.

Yes. It is better to use open-top sections (one-pound sections preferred), and place the case on end (so the light will shine through it), smoke one side, then pick up and shake off and out nearly all the bees, then place it on end in a screen-house or darkened room until the rest desert. There will be no queen nor possibly brood in the surplus-case if you use the queen-excluding honey-board. This is the way I have done for years, and now in running the new hive for extracted honey, I do it with my extracting supers, and in both cases so quickly that robber bees cannot get in their work, even if they should be

on the war-path at the time.—JAMES HEDDON.

The "better way" is to use open-top sections, and drive the bees out by the judicious use of the "smoker."
—THE EDITOR.

Destroying Inverted Queen-Cells.

Query 405.—What is your actual experience in regard to bees tearing down queen-cells when the cells are inverted?—Missouri.

have none.—G. M. DOOLITTLE.

have had no experience.—C. C. MILLER.

I have never watched to see if cells were torn down after inversion.—W. Z. HUTCHINSON.

As I do not *invert* queen-cells, I have no experience in regard to bees tearing them down.—J. P. H. BROWN.

My experience has been that they will, and that they will not. I could give numerous experiments causing me to believe that inverting will not settle the swarming question.—JAMES HEDDON.

They do not tear them down if they are well under way of completion; but if inversion is employed in season, they will abandon the work and begin anew, t'other side up.—C. W. DAYTON.

My experience is with only 3 colonies. I inverted the brood-nest each week, and had no swarming, but got a fine lot of surplus comb honey.—A. J. COOK.

I have given the matter only some attention to gratify my curiosity, and I am satisfied that while such unnatural manipulation will cause the bees to destroy some of the cells, the plan will not work as a rule. I prophesied some years ago in the columns of the AMERICAN BEE JOURNAL that reversing hives, etc., would "play out" when put to practical test, and the prophecy is coming to pass sooner than the "prophet" himself had any idea of.—G. W. DEMAREE.

Both. I have found them torn down at once, and also allowed to remain. As yet an inverted queen-cell has never produced a queen for me. My experiments in this direction, however, have been few, as the idea proved itself to me to be unnatural and impracticable, after a brief trial.—J. E. POND.

Plant Alsike Clover.

Leaflet No. 2, entitled "Alsike Clover for Pasturage and Hay," is now ready for delivery. This should be scattered into every neighborhood, in order to induce farmers to plant Alsike, that the bees may have the advantage of it for pasturage. We send them by mail 50 copies for 30 cents; 100 for 50 cents; 500 for \$2.25—all postpaid. It will pay bee-keepers to scatter these Leaflets, even if 9 out of 10 avail nothing. If ten farmers out of a hundred plant Alsike in any neighborhood, the bees will reap a very substantial reward.

Correspondence.

This mark \odot indicates that the apiarist is located near the center of the State named; \circ north of the center; \ominus south; \oplus east; $\omin�$ west; and this \odot northeast; $\omin�$ northwest; \oplus southeast; and $\omin�$ southwest of the center of the State mentioned.

For the American Bee Journal.

"The Production of Comb Honey."

WM. F. CLARKE.

Long ago, one remarked, "Of making many books, there is no end," and it will probably be so to the end of time. It is remarkable how soon some books become obsolete. They are left behind in the march of progress, and remain, like mile-stones, having only one function, that of marking the headway that has been made. Looking over my library the other day, I was struck with the number of books valued in their day, that are now nothing but beads on a wire, mere counters and markers, keeping record of how the game of thought has gone on.

Mr. Hutchinson's modest little book certainly marks an epoch, but I scarcely think will be ephemeral, because it brings out some of those great apicultural principles which we are slowly discovering, but which when once they have arrived within our field of vision, are there to stay. One of these is the necessity of using means to multiply workers in time for the honey harvest. Of course this is not new with Mr. Hutchinson, but he has emphasized one of those means, viz: *warmth*, in a more forcible way than common. He proposes to pack bees after their removal out of the cellar, in order to protect them from the cold snaps of early spring. This packing he would retain until the time has arrived for putting on supers.

Mr. Hutchinson anticipates this objection: why not practice out-door wintering, then winter protection will answer for spring? His reply is that the saving of stores by cellar wintering will pay for the expense of spring packing four times over; also, that it is only by cellar wintering that the thing can be reduced to a system; the system being one of uniform food and uniform temperature. Uniform food means sugar, which many of the best bee-keepers eschew; and uniform temperature is a delusive idea, though clung to with much pertinacity by Mr. H. and others. Let me endorse most emphatically *spring protection*, no matter how you get it, and at this point risk a prophecy to the effect that we shall yet find a clue to the mastery of this difficulty in some style of all-the-year-round protection, protection against both cold and heat, and I rather think we shall discover it in the house-apiary. Personally, I would give considerable if Messrs. Vandervort and Oliver Foster would tell us all they know on this subject.

I am sure that in these days of cheap honey, we must find a cheaper and less laborious way of bee-management than to feed sugar in the fall, remove hives to the cellar, put them out in the spring, provide outer cases, pack our bees, unpack them, and store away cases.

I think that Mr. Hutchinson exaggerates the difference between the stores required in the cellar and outdoors, when he says it will pay the extra cost of spring packing *four times over*. Let Cyula Linswik, A. G. Hill, A. J. Root and other successful out-door winterers give us their figures, and I do not think they will sustain this strong assertion. But, I say again, let us have the spring protection, anyhow, and at whatever cost. I am inclined to think we shall yet find a way of adding to spring protection artificial heat as a help to early brood-rearing. Market gardeners are ahead of us with their hot-bed methods of forcing spring vegetables. We must discover a method of forcing young bees. We have found out that we cannot do it by stimulative feeding. What we want is a hive in which heat can be maintained in early spring at the brood-rearing temperature. Something more is required in the line of hive invention. I can plainly discern the *desideratum* the exigency calls for, but alas! I have no inventive faculty. If I had, I should have made my fortune long ago, not as a hive inventor, but as a novel writer. I have the faculty of composition, but not that of invention.

The main object of Mr. Hutchinson's book is to give prominence to the principle of comb-building in its relation to honey storing. He believes there is a "balance of power" to be maintained between these two, and I think he is right. He is of the opinion that we have deranged this balance by a too large use of empty combs, and of comb foundation. He does not give us theory, but the result of careful experiment. I will not attempt to condense his system in this review. It is clearly and forcibly stated in his book. Let me advise all bee-keepers to get the book, study it, and practice along the lines it so plainly marks out. Mr. Hutchinson's candor and modesty are conspicuous in his closing sentence: "I desire and request the freest of criticisms; and let those who, for the first time, adopt the methods herein advised, do so upon no larger scale than that on which they can afford to meet failure; and if failure comes let them report it, together with the accompanying circumstances, and all will find me ever ready to explain and defend my views; or, if necessary, acknowledge my errors." Nothing can be fairer than this, or more likely to elicit the truth.

Mr. Hutchinson's book is a step in advance not on the new Heddon hive, but along with it, and this fact will doubtless expose him to the criticisms of those who think they have discovered in it "the sum of all villainies." He may expect to be ridiculed as a copyist, to have every old, obsolete bee-book ransacked for some-

thing that can be tortured and twisted into a germ of his new idea, and possibly he will be accused of trying to deprive comb foundation men of their legitimate profits, or even of their livelihood. But the great mass of intelligent bee-keepers will recognize in this *brochure* a modest, honest, earnest attempt to help those who, as the dedication says, "are getting their bread and butter by producing honey to spread on the bread and butter of others." It will help them too, because whether they adopt the author's methods or not, it will make them more observant of results, more studious of nature's laws, and more intelligent in their management of the "little, busy bee."

I am particularly pleased with the chapter on "The secretion and utilization of wax." Short though it is, it lays down principles that are not only of great importance to the matter specially in hand, but to bee-keeping generally. There has been, in my opinion, far too much done in the way of trying to revolutionize the bee. The bee is peculiar, and its value largely depends upon its peculiarities. We must utilize these, not fight them. I heard Sam Jones the other day. Among other things, he said, "I am objected to because of my peculiarities. These are what make me Sam Jones. Take these away, and I should not be myself at all, but somebody else, and probably somebody of no account." We have tried to make the bee breed in public by an everlasting opening out of the brood-nest, when like all other creatures, its instinct teaches it to breed in seclusion; we have tried to prevent it from swarming; we have turned its house and home upside down; and we have tried to make it cease wax-making and comb-building, and devote itself as exclusively as possible to honey gathering. If we could have made comb walls as well as foundation, we should have done it. "Every fool will be meddling," and there is some fool about the wisest of mankind. Now let us stop trying to re-make or re-model the bee, and take it as it came from the Creator's hand. The bee is a wax-maker and comb-builder, as well as a honey-gatherer and storer.

Who knows but there is a waxy element in the honey that needs to be abstracted before it goes into the cells? At any rate, while we appreciate and admire the assiduity of the bee in the honey line, let us not forget that there is, no doubt, a sphere for the exercise of the other function that will cause mankind, down to the end of time to nank,

"How skillfully she builds her cell,
How neat she spreads her wax."

With these fraternal words, I cordially welcome Mr. Hutchinson to the noble army of authors!

A Lady's Experience with Bees.

MRS. H. HILLS.

DEAR EDITOR:—I have had a general clearing up of letters, catalogues, etc., which have accumulated since I began bee-keeping, three years ago; and thus all the courteous and kindly replies which you have so generously given to the seemingly unimportant questions of a novice, have been brought again to mind. I can no longer delay the attempt to express my thanks. In no single instance have you failed to give close attention to every question, and you have unstintedly given your time and results of your experience to a beginner, and always in such a manner that the receipt of a postal or letter from you has been a pleasant incident in bee-keeping life.

Thus far I have written no report of my apiary to the AMERICAN BEE JOURNAL, preferring to wait until definite ground might be reached. Three years of close attention to bees and bee-literature ought to bring the novice to such point.

During the winter of 1883-84, long-continued ill-health and an indefinable longing for some out-of-doors pursuit, led to a general search for some path into such vocations. Silk-culture was at first decided upon, and correspondence opened in that direction. It was decided finally that in planting the mulberry trees, it would be safer and better to raise them from the seed. A quantity of this, both Chinese and Russian, was obtained; and I may add, that I have now several hundred of these trees set for a hedge around the apiary.

Meanwhile another member of the household became interested in bees, and on April 10, 1884, brought home 2 colonies in box-hives; also borrowed Quinby's book, and begun to study bee-keeping, ordering me also to do the same. How mysterious are the secrets of bee-keeping to the novice! I shall never forget how impossible it then seemed, to gain a clear knowledge of the many "ways that are dark" connected with the pursuit.

But soon the weather admitted of frequent visits to those box-hives, with glass under the doors, at the back. Hour after hour was spent in watching the movements—apparently tending "no whither"—of the busy little elves; and when one day after long waiting, so much patience was rewarded by seeing a veritable drone, it was recorded in the note-book as a great event.

It did not take many weeks to convince me that bee-keeping was the desirable avocation, provided that it could possibly be carried out by a woman. Correspondence was opened with two successful lady apiarists, who at once responded with the necessary encouragement and advice. If Mrs. Harrison and Mrs. Gould should notice this report, they will doubtless call to mind the ludicrously anxious missives which they at that time received from a stranger. Their kind-

ness carried the novice through the initiation ceremonies of the never-to-be forgotten day—May 30—when both colonies cast immense swarms within two hours of each other; and I became the happy possessor of 4 fine colonies of bees.

Since that day I have had what certainly might be called uninterrupted success. On Sept. 1, 1886, the apiary numbered 41 fine colonies, all from those 2 colonies in box-hives. I have never lost a colony from any cause whatever, and the surplus honey during the three years, as nearly as I can calculate, was 82 pounds per colony, spring count, after deducting the cost of wintering all colonies.

Analyzing and Ripening Honey.

SAMUEL CUSHMAN.

A close reader of our bee-periodicals for the past two years might have gathered together from the various articles the following ideas: The nectar of flowers is not honey until changed or ripened by the bees. It is natural sugar, water, a small quantity of albumen, gum and essential oil or flavoring. Bees are able to abstract much of this water, absorb and discharge it before the nectar is deposited in the hive. Formic acid, the active principle of bee-poison, is frequently added to this nectar, a large amount being required by new honey, and but little to preserve ripened honey. This acid is a preservative, also chemically changes the natural sugar to its inverted form—a change that the chemists are familiar with. This change gives honey that smooth, mellow taste for which honey from the old box-hives is celebrated. The heat of the bees causes the excess of water to evaporate, and favors or is necessary for this chemical change. Bees treat capped honey with this acid, which is absorbed by the porous capping. The cappings of honey are porous until varnished or gummed over by the bees.

The legitimate purpose of the sting is to insert this acid into uncapped honey, and to pierce the cappings of sealed honey; stinging is but a side issue. This view seems to be supported by the fact that when bees are not gathering honey, a sting causes much more effect, supposed to be caused by the accumulated poison; and that stingless bees from South America store little honey, as they are unable to preserve it. Hybrids, which are the worst stingers when there is no honey to be gathered, are the best honey-gatherers.

Some think that the "crop," or honey-bag of the bee is where this acid is secreted and added to the honey. It is said that a normal colony with plenty of this secretion may prevent and cure foul brood. Formic acid is similar in its nature to phenol (carbolic acid) and salicylic acid—agents used by bee-keepers to cure foul brood. They are all preserva-

tives, and cause death to fungus or germs. This acid can be noticed in new honey by its irritating effect, but old honey, where its strength is neutralized or expended, is smooth and mild.

Raw nectar, or ripe honey that is heated and the acid expelled, does not keep so well. New honey, if extracted, may be thickened by evaporation, but this causes loss of flavor, and such honey is imperfectly changed from a lack of the constant addition of this acid. Generally, honey is ripe as soon as capped; however, much is ripe that is not capped, and much is capped that is not ripe.

The longer the honey is cared for by the bees, the more completely it is ripened. The Dadants and many others work on this principle, leaving the extracting supers on the hive until the end of the season. Such honey can be bottled as soon as extracted, and there is no loss of flavor.

Probably some of the above is simply theory. How and when formic acid is added, cannot be easily known, and will require careful experiments to determine. Rev. W. F. Clarke says that he has experimented in a way to cause him to think that the sting of the bee is used as a trowel in comb-building, and that stinging is not its legitimate use. Will he kindly describe these experiments? I think that honey lacking formic acid or the required heat, would be more liable to the coarse granulation often complained of. Fall honey is soon taken from the hive, and this is more liable to granulate in the comb even in capped cells.

The ripening of honey seems to me an important matter. This is an age of progress, and while the best and most successful producers—many of them—do not accept these views, this is not sufficient to discard them.

The above ideas may throw some light upon the unsatisfactory results of the analysis of samples of honey in comb by the Government chemist. Many prominent apiarists furnished samples, the purity of which they could swear to. Some of these samples were pronounced apparently adulterated, and others apparently genuine. At the Detroit meeting of the North American Bee-Keepers' Society, this matter was referred to by some of the members who had furnished samples, and the sense of the meeting was that such a report was unjust, and caused unmerited injury to the industry, and that Prof. Wiley should only have published a report on that which he was sure of, instead of classing the honey as "adulterated," "apparently adulterated," and "apparently genuine." This report, "Honey and its Adulterations," may be found in the United States Agricultural Report for 1885, pages 109 to 117, or the *American Apiculturist*, Vol. III, page 265. Prof. Wiley is the one who started the sensational story that comb honey was made by machinery filled with glucose, and capped over by machinery, and who afterward admitted it to be "a scientific pleasantry." This was from a government employe.

According to these results of the analysis of honey it may not be safe for an honest producer to offer as many do, \$100 reward to any one who will prove by analysis that his honey is not strictly pure.

According to the principles referred to, the samples taken off the hive as soon as gathered, would be nearly pure nectar somewhat evaporated, and would have a large proportion of natural sugar, styled by chemists, cane sugar or sucrose. That more ripened would have less cane-sugar and more inverted sugar; and that thoroughly ripened would have little or no natural (cane) sugar, and more natural glucose or grape-sugar and inverted sugar. If the best ripened honey is to be taken as a standard, then all not as thoroughly ripened will be pronounced "apparently" adulterated. This matter of judging the purity of honey by analysis is an important and a serious one to honey-producers, and is worthy the attention of our ablest men. We hope Profs. Cook and McLain, of the United States, S. Corneil, of Canada, Frank Cheshire, of England, and others may be able to experiment in a way to throw more light upon this subject.

Mr. McLain, with the help of the chemist of the Agricultural Department, should be able to do a service worth more to our pursuit than several years' expense of the Experimental Station. If the chemist should be furnished with honey thin and just gathered, that just capped and that capped and on the hive until the end of the season, the result of the analysis of such honey showing the proportions in each of the natural, inverted and grape sugar, would be of great value. One lot might be analyzed when it was taken from the hive, and another lot stored in the usual honey-room until the time it is usually sold. It all should be from the same source and from the same colony which should be kept of uniform strength the entire season.

Pawtucket, 3 R. I.

For the American Bee Journal.

Preventing or Controlling Increase.

A. A. FRADENBURG.

In my 10 or 12 years' experience, I have been trying to learn how to control swarming, and I have concluded that it is best to let a colony swarm once, then prevent all after-swarms, so far as possible; but by getting one prime swarm from each colony it does not necessarily follow that we are obliged to have an increase of 100 per cent. from all that do swarm.

For the benefit of Mr. Abel Gresh (whose article appeared on page 167) and others, I will give the plan I tried last summer, and the results; but I am not the originator of it, for I read it in some paper last year. It is as follows:

As soon as a swarm is out, and has begun to cluster, or after it has clustered, put an empty hive in a new

location; then put off all the surplus receptacles of the parent hive, take the frames out of the brood-chamber and destroy every vestige of queen-cells, and put these same frames in the empty hive. But leave 1, 2 or 3 of the frames, as you may desire, with brood, honey and adhering bees in the parent hive, leaving them only one queen-cell. Then fill the balance of the brood-chamber in the new hive with empty combs or foundation, or empty frames.

Now put the surplus receptacle that was taken from the parent hive and put it on the new one; shake the swarm, that has clustered nicely by this time, in front of the new hive. Now they have swarmed according to nature, have a new home, and are satisfied on that score. In a short time the queen will be attending to her own business amongst the brood, and the workers will be working hard storing honey in the sections, as they have no other place to put it, and the bee-keeper need not wait a week or more to see any increase of honey stored.

I tried the above plan on 7 swarms last summer, and it was a success in every case, except one that swarmed again after 3 or 4 weeks; but I was satisfied it was caused by a desire to supersede their queen, and they allowed too many queens to hatch.

Now about the parent colony, or what was left of it: I generally left 2 frames of hatching brood and one queen-cell, then filled up the hive with empty combs, and with what straggling bees returned it made a pretty good colony with plenty of stores by fall, and the whole 7 are all right at this time. If I wanted but little or no increase, I should leave but one frame and but little brood—just enough to retain the returning bees, then put several such together; or else have the next swarm where the last one left.

The Cause of Low Prices for Honey.

R. C. AIRKIN.

Much is being said about markets, monopolies and associations. We can theorize and talk, but practice and experience is what opens our eyes. I have never known what it is to lack a market for my honey. Experience has taught me that the most of our troubles are our own making. I consider that the credit business, coupled with pride and mismanagement lies at the bottom of the whole trouble. For example: I wish to buy more bees. My neighbor will sell me 10 colonies and wait until January for the pay. I jump at the chance, thinking that I can sell honey to pay for them. The crop fails; I have done business on capital that was not my own; I have done business on the prospects of good health and prosperity.

My neighbor sees my condition. I cannot pay legal proceedings; waste

one-half of the stock of bees to collect the pay and interest on the other half. But to be a little more lenient, say the time of payment is extended until another January. The season this time proves fair, but interest runs up the bill. I have been putting in my time on dead property (by dead, I mean unprofitable). It has cost me something to keep these bees, and putting all together, I find myself "hard run." Now what do I do but sell at a sacrifice, not because I want to injure a neighbor who is in the same business, nor do I want to lower the prices one particle. Common-sense would teach me the folly of such actions, but I sell at a low price because I must have money and cannot wait until the people are ready to buy, so I give them a "bait" by "offering cheap." Had I used a little common-sense at first and not taken risks that I was not able to carry, I might have saved myself the loss. Experience has taught me that it is better to have a surplus on hand than to sell all we have at once, and be out the balance of the year.

Here is a case just to the point: Last fall a certain man had a nice lot of honey. He was in debt, and his creditors had the "upper hand." He placed his honey on sale, part of it in a grocery with instructions to sell at 12½ cents per pound. It did not go very fast at first. The creditor said it was too high; that certain others were selling for less. (This, however, was not true, at least for the same grade of honey.) The final result was that the best comb was sold at 10 cents per pound, and by mid-winter that man had no honey left.

Another experience: I have been for 12 years a limited producer of honey. I sold only in my home market, and have never had sufficient honey to supply the demand any season. I gave a young man a few lessons in bee-keeping. He undertook to enter the business for himself. He had about 15 colonies, put his crop on my market and sold at 16½ cents per pound. I had been, and was at the same time, selling at 15 cents. Now because I would not advance to his price, he became angry and ordered his sold at 12½ cents or less, if I should follow him down. I just held my honey at 15, and if it would not sell at that, I held it until the other was gone. The result was that I had mine a short time, and the other sold out and retired disgusted, and has not bothered me since.

Organization of producers will not and cannot regulate the market. But if we would only "make haste slowly" we would be better off. It would be better to "legislate" to make it a finable offense to go in debt when we have not the capital to enable us to get through without damaging others. Let every man live within his means, and keep a few dollars in his pocket, and when prices are below first cost, do not sell. The man that is "well fixed" financially, is not the man that lowers prices; and the poor man who has gotten himself "into the box" will not have crop enough to supply a market for a whole season. If the

unfortunate man is spoiling your market, buy him out and help him and yourself too.

The man, association, or corporation that takes advantage of those who may be subject to their power, damage themselves as well as others. The real rogues are very few compared with the mass of the people, and we will have but little trouble with dishonesty if we would but be honest with each other in every respect. We ought all to give as well as receive good prices.

Shambaugh, ♀ Iowa.

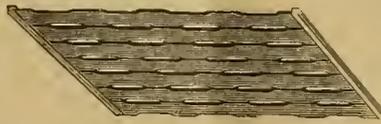

For the American Bee Journal

A Section-Case for Comb Honey.

J. W. POWELL & SON.

Having noticed a section-case described on page 183, we would like to say a little on the subject, especially as that case is something like the one we use. We began where Mr. Eaton has, but we think we have taken a step or two in advance, as will be noticed by editorial comments on our section-case on page 147. As we have received quite a number of letters asking for more definite description, we will endeavor to give it.

Our honey-board is like the engraving. The bottom of our case is made in the same way, except that the slats are nailed fast on the bottom of the case in a rabbet $\frac{3}{8}$ of an inch deeper

than the thickness of the slats, which gives a bee-space below the case. The rabbet is cut just the same on top as on the bottom, which gives room for the honey-board.

The case is made reversible, by fastening some small sheet-iron buttons on the sides, which holds the honey-board in place, thus keeping the sections secure in any position. The centre of the slats are kept from sagging by strips of wood $\frac{3}{8}$ of an inch square, tacked crosswise, or tin strips may be used and folded like this ; or if separators must be used, why not fasten those T tins inside of the case like this ; or use the $\frac{1}{2}$ -inch strips of tin that Mr. Eaton speaks of? We do not use separators, and so we will let those who use them, arrange that to suit themselves.

In conclusion we will say that although this case is entirely original with us, still we do not intend to patent it. All are at liberty to use it, and if it should be found to possess superior merit (and we think it will), we do not fear but that all honorable and fair-minded bee-keepers will give us full credit for the invention.

Mankato, ♀ Minn.

The semi-annual meeting of the Southern Illinois Bee-keepers' Association will be held in the Court House at Benton, Ills., on Wednesday, April 20, 1887, at 10 a.m. All are invited to attend.
E. H. KENNEDY, Sec.

For the American Bee Journal.

The Cappings over Honey.

W. Z. HUTCHINSON.

At the convention in Detroit, Mr. Jones said: "We sometimes have honey so thickened that it does not fill the cell more than half full. If the capping was air-tight, how could this evaporation take place?" Mr. Doolittle said that he had seen honey so thickened by sections of it standing upon a mantel-piece, that it did not occupy more than one-half of the space in the cellar. If the cappings were impervious, this could not occur.

When Messrs. Dadant, Poppleton and myself were discussing this in the hotel at Indianapolis, Mr. Poppleton said that two lots of honey taken from the same case and hive, and stored by the same bees—in fact, exactly the same, the one kept in a dry atmosphere, and the other in a moist one, would show conclusively that the cappings were not impervious, as the honey in the dry atmosphere would become thicker, occupying less space, while that in the moist atmosphere would absorb moisture until it oozed from the cells or "sweat."

I do not know that fermentation increases the bulk of liquids—it certainly generates gas, and it is *this* that blows out "bung" and "raises the mischief." When honey "sweats" we do not find the cells partly filled with gas, but running over full of diluted honey!

The only moral I can draw from this discussion is, keep your honey warm and in a *dry* atmosphere.

Rogersville, ♀ Mich.

For the American Bee Journal.

Hives for Preventing Swarming.

F. A. SNELL.

I have read with much interest the articles which have appeared in the various bee-papers in relation to Simmins' method of preventing or controlling swarming, with a hope of finding something new and practical; but as I understand it, it is not new. The idea of such a hive was first advanced by D. L. Adair, of Kentucky, I think, and he invented a hive known as the "New Idea" hive, which attracted much attention for a time. Its merits were fully described in the BEE JOURNAL by Mr. Adair, E. Gallup and others in 1871 or 1872.

Many bee-keepers tried the hive, as it had quite a reputation for a few years. I made and tested the hive, and will say that swarming could be well, or quite well controlled by extracting, yet the hive did not prove practical. Briefly stated, the hive was arranged as follows:

The frames were used one tier only, and run crosswise of the entrance. From the front to the rear the hive was 2½ to 3 feet, to suit the taste of the bee-keeper. In use, the frames near the entrance were to be only part full of comb, or, if full combs were

there placed, the honey from such was to be frequently extracted. I tested the hive for extracted honey three seasons. I then arranged it for comb honey. I contracted the brood department and gave a passage for bees out and in. I placed a set of honey-boxes in front of the brood-nest, and one in the rear, and one and two tiers on top.

But for comb honey I could not run the hive so as to control swarming, and the hive was laid aside. It did not suit me for extracted or comb honey. I have taken the AMERICAN BEE JOURNAL for 20 years, and it is a real treat to look over the old numbers. In those days I could readily get 25 cents per pound for all the comb honey I could produce, and 15 to 18 cents for extracted honey.

Milledgeville, Ills.

For the American Bee Journal.

The Prevention of Increase.

E. C. L. LARCH, M. D.

This is a subject of vast importance to bee-keepers generally. When working for extracted honey there is but little difficulty, hence I shall confine myself to the production of comb honey, having 15 years' experience in the management of bees; three years of the time was devoted to the task of learning the instincts, nature and habits of the "busy bee," and I have in a measure succeeded. I usually keep about 120 colonies, have no losses to report during that time, and my bees have a habit of doing just what I expect them to do.

The first thing to do, is to have no old or decrepit queens; the queen should be one year old, just in her prime. Second, get the bees to working in the boxes as early as possible, keep the hive shaded and sufficiently ventilated to get the bees to work in the boxes. Give them some foundation in the brood-chamber, and when the larvæ is two or three days old, cut this out and fasten a suitable amount in the boxes, and the bees will always commence work above, if strong enough; but should they resolve on swarming, let them have their way, and as soon as they are clustered, open the hive and brush the bees off of the combs into an empty hive, and give them one comb of brood having the oldest queen-cells. Return the combs to the hive from whence they were taken (first cutting out queen-cells), and supply the place of the comb that was taken out, with an empty comb or foundation, or, what is better still, move the frames together so as to contract the brood-chamber, and place a division-board on the outside of the combs.

Return the honey-boxes or sections, and give the swarm and put it in a new location. Thus you have the swarming impulse effectually destroyed, and the comb in the new hive must remain on the old stand for a nucleus for queen-rearing; give them empty combs or frames of foundation when needed, or, if preferred, unite

these nuclei whenever there are enough for a strong colony, and enough bees to work in the sections above; also give them a good young queen and they will, if rightly managed, soon go to storing honey the same as an old colony.

By this plan the increase is limited to 10 per cent, should they all swarm, which they will never do, and, besides, it is the most satisfactory plan that can be adopted for securing comb honey, and getting a moderate increase, which may be always utilized by doubling up weak colonies whenever the apiarist desires no increase of colonies. But success depends upon the knowledge and skill of the apiarist, as well as upon his energy, perseverance and industry.

Ashland, Mo.

For the American Bee Journal.

Legislation for Bee-Keepers.

J. E. POND.

I had intended to drop the discussion of this question entirely with my last article, but Dr. Miller says on page 199, "will Mr. Pond tell us of a single person?" etc. This question related to the matter of priority. In reply I will say that no one, so far as I have any knowledge, has ever "requested or desired legislation on 'priority,'" but it impresses me quite forcibly as a logical proposition, that in order to legislate that some one man shall be the man to keep all the bees in a given locality, a decision as to whom that man should be, must be made, and it would work manifest injustice to say that the first one who started the business, should give way to a follower. For this reason I cannot see how the question of legislation as desired by Dr. Miller can be divided from that of priority.

Now I will ask Dr. Miller a question; not a legal one, but a common-sense one, viz: Why should some one man's bees have the sole right to gather the free offerings of nature, even if in the form of nectar from all the surface in a given locality, any more than this same man should have the sole right to sell the honey his bees gather in the same neighborhood? or again, why, if A and B have adjoining estates, each owning large tracts of land, should A have legislated to him the right to gather honey from B's land, and B be debarred?

Individually I do not care a snap about the question, but as a man who strongly opposes monopolies, and believes in equal rights to all before the law, I must insist that under the constitution of the United States no legislation can take from me the right to enter upon and engage in any business or occupation that I may choose, provided I conduct a legal business in a legal manner. Legislation is restrictive and necessarily so; the very first thing that is implied in law is restraint; the advocates of bee-legislation, and I fear Dr. Miller with the others, have the idea, judging from their words, that the legislature can

make or unmake, can allow or suppress. This is not so. In order to suppress any business, etc., it must be declared a nuisance, and if not so declared no law can be constitutional that prevents each and every man that may choose from engaging in it.

Political economy is the science that all legislatures strive to employ. Supply and demand will invariably regulate matters, and this same law will regulate the business of bee-keeping as well as any other.

One thing more I will ask of Dr. Miller, and then I will drop the discussion. Will he give us an idea of the form of legislation that would suit him, and then if the form is in anywise restrictive of the rights of any other person, will he show us how he would harmonize such legislation without "bill of rights?"

Foxboro, Mass.

For the American Bee Journal.

Mr. Hutchinson's New Book.

PROF. A. J. COOK.

One of the first things that Mr. A. I. Root said to me the other day, as we met at my farm in Owosso, Mich., was this: "I have read Mr. Hutchinson's new book on comb honey, as I came here. It is so good that I have only one criticism: It is too short." I have, since that, read the brochure myself, and I agree with Mr. Root, except in the criticism.

I like what an English scientist recently said in "Nature," to-wit: "Now in these days, and in the interest of readers, if there is one thing against which more than anything else a resolute stand ought to be made, it is unnecessary printing. The day is yet far distant when every page of printed matter shall contain something that is new, and nothing not new; but this is the impossible ideal which all writers should keep prominently in view." How well Mr. Hutchinson has done this.

I need not say to the readers of the AMERICAN BEE JOURNAL that Mr. H. is second to no American writer on apiculture, in practical common-sense, and in directness and precision. This book shows him at his best. Honey—especially extracted honey—is now down to bed-rock prices. How opportune, then, the direction which shall lead to the maximum yield of that—and that is comb honey—which shall bring the maximum price. Just this is Mr. H.'s aim; and I doubt if any bee-keeper among us could do it better. Mr. H. has boiled this recipe right down, and made all so clear that most, if not all, can at once profit by the advice.

The mechanical part of the work is good; especially to be commended is the beautiful cover—yellow paper stamped by the comb foundation mill. It is surely a good foundation for the excellent matter within. It is as exquisite as it is unique.

I am the more happy to praise this book, as I have personally proved the

value of most of its suggestions, and can recommend them to all. The bee-keeper who does not invest 25 cents for this work, makes a mistake.
Agricultural College, ♀ Mich.

Local Convention Directory.

1887.	Time and place of Meeting.
Apr. 14.	—Eastern Indiana, at Richmond, Ind. M. G. Reynolds, Sec., Williamsburg, Ind.
Apr. 16.	—Marshall County, at Marshalltown, Iowa. J. W. Sanders, Sec., LeGrand, Iowa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Welcome Change of Weather.—Geo. E. Hilton, Fremont, ♂ Mich., on April 3, 1887, says :

Last Monday morning the ground was covered with snow to a depth of 8 inches, and at daylight the mercury was just at zero. To-day at 3 p.m. it is 70° above zero, and the bees are bringing in pollen, although there is plenty of snow in places. My bees never wintered better—in fact it sounds more like June than April, in the apiary to-day.

Rough on Bees.—Jacob Oswald, Maximo, ♂ on March 30, 1887, says :

The month of March came in like a lamb, but went out like a lion. On March 29, we had a regular blizzard from the northwest, with 2 or 3 inches of snow. The temperature was down to zero, and everything seemed to be freezing after 6 weeks of pleasant weather. Bees on the summer stands suffered severely.

Wintering Bees in the Cellar.—M. O. Tuttle, Osage, ♂ Iowa, on April 1, 1887, writes :

I put 80 colonies of bees into the cellar last fall. A stove was kept in the cellar, the chimney being built from the bottom of it. The temperature has been kept at from 38° to 45° until March 15, since which time it has been kept at 48° to 50°, and sometimes even 55°. My bees are quiet, and they seem as happy as they do on an eve in June. I do not expect any

loss of any account. Some of my neighbors put their bees out on March 8 and March 9, and we have had some very cold weather since. I visited one apiary to-day where 40 colonies were out, and they seemed as lively as on a warm day in June. But the bee-keeper said that they are much lighter now than when he put them out. A few of us bee-keepers here are putting our bees into the cellar in a different manner or arrangement of the hives, than I have yet seen described. Our bees wintered nicely one year ago, and if we all succeed usually well this year, I shall be tempted to give the plan in the BEE JOURNAL. I have handled bees more or less for 10 years, and I have always made them profitable when I attended to them. The winter here has been good for clover, and if our bees continue strong until May 1, we shall be prepared for a grand honey season—our first.

Early Black Drones.—Mr. Gideon Crews, Gray's Summit, ♂ Mo., on April 3, 1887, writes :

On April 1 I noticed drones flying from a colony of black bees. Is this not rather early for them in this latitude? Would it not be best to cut out the drone-comb in this colony at once, as I do not want any black drones?

[Yes; destroy the drone-comb at once, if black drones are not desired.—Ed.]

Bees in Good Condition.—S. H. Mallory, Decatur, ♀ Mich., on April 6, 1887, writes :

Bees seem to be in good condition here in southern Michigan, this spring. We have had several warm days since March 1, and the bees have had a good flight, which was badly needed, as they had been confined since November, although packed on the summer stands. That is the way I winter my bees, and I think it the safest way in this latitude, if properly packed, as they can remain in the packing until settled warm weather.

Very Quiet Bees.—J. A. Reeds, Hinesboro, ♂ Ills., on March 30, 1887, writes :

Yesterday morning I was smoking and overhauling my bees, and to my surprise I found a case where one had passed into the state of hibernation, as I supposed; for they were very quiet, and on raising the lid I called them dead. I took out the combs where they were clustered, took some of the bees in my hand, and still they seemed to be dead; I then threw them on the ground. There were many bees that had crawled into the combs. I took all the combs to the room where I keep them, and in an hour or two I passed the hive; the sun was shining on the bees, and to my surprise I could see them move. I had

looked out the queen at first, and supposed she was as dead as the rest. So I thought I would experiment a little. I took the hive into the house, put it on the cook-stove, and put a slow fire in it. I could see that they soon moved more and more, and then began a hum. I have about two-thirds of them now alive in the kitchen. I will put them back on the stand as it gets warm. I believe I could have saved all of them had I not scattered them around everywhere. They were out of honey, and had destroyed all their brood. Will this colony do any good? I never heard of such a case, except when Dr. Miller found the ground squirrel.

[Several of such cases have been reported. If taken care of and fed they will be all right.—Ed.]

Feeding Maple Syrup.—Willis M. Barnum, Angelica, ♀ N. Y., on April 1, 1887, writes :

So far bees seem to be wintering well; yesterday the air was full of them. I am feeding maple syrup, occasionally, to stimulate brood-rearing. All bee keepers are happy!

Wintered without Loss.—M. H. Freeman, Olustee Creek, ♂ Ala., on April 1, 1887, writes :

My 100 colonies of bees have wintered finely without any loss, and on the approach of spring they began gathering pollen and rearing brood. The earliest pollen gathered that I observed was on Jan. 26, from the arbor-vita, an ornamental tree or shrub that decks many Southern yards. Since then fruit bloom and many wild flowers, with whose names I am not familiar, have furnished the bees with honey and pollen. On March 24 I hived a large swarm which issued from a hybrid colony in a single story Langstroth hive. This is quite early, I think, as the usual time for swarming is in April.

Do Bees Talk and Hear?—R. M. Osborn, Kane, ♂ Ills., writes :

If bees do not have a language, and cannot hear, then I do not see how they manage to keep so well organized as to appoint guards at the hive-entrance, comb-builders, workers, etc., and committees to clean cells for the queen to lay eggs in, and to attend to her wants; to attend and see after the young larvæ; to cap brood and to clean cells for storing honey; to forage for nectar and pollen; to cap the honey and bring in water for necessary uses for the colonies; to examine and determine on the time necessary to supersede the old queen; to build the required queen-cell to rear a queen that may be the cause of the death of the old queen, unless she escapes by flight, and, after the cell is capped, a special committee of braves is appointed to guard the cell and keep the old queen from destroying it; for she is guarded by her loyal braves, and a committee of her loyal braves is sent

out to look for a new location, and the loyal braves inform her that the virgin daughter is singing in her prison cell, and the guards are breaking the seals to release her from her 16 days' imprisonment. The old queen's loyal braves are a committee of thousands, and then she is informed that they will lead or conduct her to the selected location, and all civil business inside is suspended for a few minutes, the guards are relieved at the entrance, and join the old loyalists in their flight to their "new home," and the young virgin queen, in about 5 days, takes a wedding flight with a crowd of fat, lazy drones, and returns the same day, if not molested by pirates; the colony is re-organized, and the drones are ordered exterminated.

Drones Flying.—Dr. H. R. Dorr, Worden, ♀ Ills., on April 2, 1887, says:

My bees are doing splendidly this spring. I have one fine colony of Italians that have drones flying today. Who can beat that for this latitude? Bees in this neighborhood were carrying in pollen on March 1. My bees were left to winter on the summer stands in chaff hives. I have not lost a colony for three winters in succession. I await a rich harvest for the bees this year.

View of an Apiary.—Mrs. J. N. Heater, Columbus, ♂ Nebr., writes:

I send you by this mail a view of my bees in their winter quarters, to be placed in your "bee-keeper's album." I have always used the chaff hives for wintering, and with uniform success.

[It is a very pretty scene. The ice-covered hives and trees, in the sunshine, makes it attractive. It is placed in our bee-keeper's album, as requested.—ED.]

Loss by Spring Dwindling.—Chas. F. Uhl, Millersburg, ♂ O., on March 30, 1887, says:

I hear of a great many bees throughout this locality that were dying during the last two months. A great many of them were lost by spring dwindling. So far I have wintered mine all right; they all had a nice flight three days ago. But the coming two weeks will try them the hardest. I am generally successful in wintering my bees on the summer stands. I also use the Langstroth frame, and mostly the single-story chaff hive, and some two-story chaff and portico hives. My bees are pure Italians.

Our Various Climate.—W. J. Davis, Youngsville, ♂ Pa., on March 30, 1887, writes:

The BEE JOURNAL gives us Northern people some strange reading. For instance, in January and February to read of bees carrying in pollen and honey, drones flying and swarms is-

uing, while we in northwestern Pennsylvania are ice-bound, and not a bee dare leave the cluster. Yesterday the piercing wind and driving snow made out-door existence anything but comfortable, and this morning the mercury was just at zero. Possibly some of our Southern brethren, sweating in the shade of leafy trees, may gather some comfort by the reflection that up here we have "cool breezes." Truly, a broad land is ours. Before the ice leaves our Northern lakes, we may feast on the strawberries of the South; and before we dare commit a melon seed to the ground, the luscious melons of the South are in our market.

Fastening Foundation in Sections.

—L. N. Tongue, Wonewoc, ♂ Wis., writes:

Mr. E. W. H., of Indiana, on page 203, asks how foundation is to be fastened in sections where a groove is cut. The best, easiest and fastest way is to melt of wax two parts, and of rosin one part, by putting in a shallow dish over a lamp wick turned down so as to keep the wax just melted; not let it get hot enough to melt the foundation when dipped into it. Take the section in one hand, the foundation in the other, and dip it into the melted wax and place it in the cut in the section. You must have but little wax in the dish at a time. One can fasten in this way as fast as he can pick up a section, and it will stay, too.

Cold and Stormy March.—Arthur Todd, Philadelphia, ♂ Pa., on March 30, 1887, writes:

The month of March has been very cold and stormy, with a bright sun, often a freezing wind affording bees no chance to fly without danger. Since putting my bees into winter quarters I have not disturbed them. We had one mild day some three weeks ago, and every colony was flying, so I hope for a slight loss. Yesterday and today we have had a blizzard; the temperature was 20° Fahr., and high wind and snows prevailed.

Rain Needed Badly.—B. F. Carroll, Dresden, ♂ Tex., on April 4, 1887, says:

Rain is badly needed in this State now. There has been none in places since last October. Bees are doing well here.

The Alsike Clover Leaflet.—James Heddon, Dowagiac, ♀ Mich., writes:

The new Leaflet on the of planting Alsike clover is a move in the right direction. I say "right direction" because its propagation is not only of interest and profit to bee-keepers, but it is a most profitable plant for the farmer. Mr. Baldrige is one of those bee-keepers whose clear comprehension and long experience makes him authority on subjects connected with our chosen pursuit. Our wisest bee-keepers will

distribute these leaflets by the thousands. I have copied it into my weekly paper, and a thousand subscribers will thus be given the benefit of it. As there are many persons in the world who live and suffer in the canker of envy and jealousy, there may be many bee-keepers who had better get some farmer neighbors to distribute the leaflets than to do it themselves.

Bees in Fine Condition.—J. C. Armstrong, Bromley, ♂ Iowa, on April 6, 1887, says:

I took my bees out of the cellar on April 1, and I have never had them winter in better condition. I used to be anxious to give them a flight in mid-winter, but I have gotten over that. They had been confined 135 days, and had commenced breeding. They began gathering pollen the next day after their liberation. If the weather had required it, I believe I could have kept them confined a month longer.

Honey Yield from One Colony.—J. H. Higgins, Victoria, ♂ Tenn., writes:

I desire to know what has been the largest amount of comb honey any one has obtained from one colony, as an average for the past 10 years. Will some one please answer through the AMERICAN BEE JOURNAL?

The numbers of the AMERICAN BEE JOURNAL for the first 3 months of this year have been very valuable to every one interested in bee-keeping—every number has been worth the cost of a year's subscription. The question department is a grand help to me.

Bees Working Hard.—T. S. Hall, Corinth, ♂ Miss., on April 4, 1887, says:

Bees are in fine condition; they are swarming, having wintered finely. Thousands of yellow drones are flying from the Italian colonies that are bringing in the honey fast. It is a beautiful sight to see the yellow Italian bees from 100 hives all at work, and all in a rush.

Lost None in Winter.—Abe Hoke, Union City, ♂ Ind., on April 7, 1887, writes:

I reported 33 colonies in winter quarters on the summer stands—32 in straw hives, and one in a three-frame observatory hive in wood and glass. The one in the observatory hive is all right so far, and so are the 32 in straw hives. One was queenless, and was being robbed, so I united it with another; it had plenty of honey. Two or 3 colonies are light in bees, but have plenty of honey; 5 or 6 are not crowded with honey, and I have fed 8 of the lightest ones. I will have to feed if the weather does not change soon. I have not lost an entire colony in the three past winters. Maple bloom is entirely destroyed on account of severe weather.

AMERICAN BEE JOURNAL
 Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for 1887, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked comb, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12½@13c.—Sales have been larger this month than at any time since November, and prices average a little lower for comb than the above.
BEE SWAX.—25c. R. A. BURNETT,
 Mar. 28. 161 South Water St.

DETROIT.

HONEY.—Best white comb, 10@11c. Supply is large and sales are slow.
BEE SWAX.—23c.
 Mar. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4@4½ cts. Comb, white, 7@13c. Market firm.
BEE SWAX.—Scarce at 19@22c.
 Apr. 4. SCHACHT & LEMCKE, 122-124 Davis St.

SAN FRANCISCO.

HONEY.—We quote: Old comb, extra white, 12½@14c.; dark, 8@11c. Extracted, amber and candied, 3½@4c.; extra white, 4½@5c. Outlook is gloomy, as rain is needed badly.
BEE SWAX.—Scarce at 22@23c.
 Apr. 5. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively.
BEE SWAX.—24 cts. per lb.
 Mar. 23. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 3@7c. per lb. Nice comb brings 11@14c. per lb. Demand fair.
BEE SWAX.—Good demand, 20@23c. per lb. for good to choice yellow.
 Mar. 29. C. F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, 1-lb. sections, sells at 12½@13c.; second quality white, 10@11c.; white 2-lbs., 10@11c. Buckwheat, 8@9c. Extracted, 5@6c.—Market dull.
BEE SWAX.—25c.
 Mar. 9. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 11@12c.; 2-lbs., 10@11c. No call for dark. White extracted, in barrels and kegs, 8@6½c.; in small packages, 6½@7c.; dark, in barrels and kegs, 4@5c.—Demand good.
BEE SWAX.—25c.
 Mar. 28. A. V. BISHOP, 142 W. Water St.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal1 00..	
and Gleanings in Bee-Culture2 00..	1 75

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the **BEE JOURNAL**. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the **BEE JOURNAL** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

By Using the Binder made expressly for this **BEE JOURNAL**, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Dr. Miller's Book, "A Year Among the Bees," and the **BEE JOURNAL** for one year, we will club for \$1.50.

Convention Notices.

The Wabash County Bee-Keepers' Association will meet at North Manchester, Ind., on April 20, 1887, at 10 a.m.
AARON SINGER, Sec.

The May meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held at Rockton, Ills., on Tuesday, May 24, 1887.
D. A. FULLER, Sec.

The Des Moines County Bee-Keepers' Association will meet on April 23, 1887, at the Court House at Burlington, Iowa, at 10 a.m. All interested in bee-keeping are invited to attend. Articles sent for exhibition, to the Secretary, at Middletown, Iowa, will be exhibited and returned or sold, as directed.
JOHN NAU, Sec.

The ninth annual meeting of the Texas State Bee-Keepers' Association will be held at McKinney, Collin Co., Tex., on May 4 and 5, 1887. All bee-keepers will find a hearty welcome. No hotel bills to pay. An interesting programme is ready. Come one, come all.
B. F. CARROLL, Sec.

The Central Michigan Bee-Keepers' Association will hold the spring meeting in Pioneer Hall, Capitol Building, at Lansing, Mich., on April 26, 1887, at 10 a.m. A cordial invitation is extended to all bee-keepers. If any have troublesome questions, bring them with you, or send them to the President, at Lansing, Mich.
J. ASHWORTH, Pres.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are reduced, as follows:

- For 50 colonies (120 pages).....\$1 00
- " 100 colonies (220 pages) 1 25
- " 200 colonies (420 pages) 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

The Production of Comb Honey, as practiced and advised by W. Z. Hutchinson, can be obtained at this office, for 25 cts.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

As there is Another firm in Chicago by the name of "Newman and Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

There is no Mistake in insisting that—as in all other things, so in advertising—the best is the cheapest, no matter what its first cost may be.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

Advertisements.

PRACTICAL Bee-Keeper wanted for four months. Correspondence solicited.
15A1t E. D. KEENEY, Arcade, N. Y.

BEEES AND QUEENS a Specialty.—Unteated **QUEENS** in May, \$1.00. After June 1st, 75 cts. Price-List of Full Colonies, two and 3 frame Nuclei, Hive, Foundation, &c., Free.
15A7t JOHN NEBEL & SON, High Hill, Mo.

100 Colonies of Italian Bees, Strong, first-class in every respect, For Sale at reduced prices.
15A1t E. C. L. LARCH, Ashland, Mo.

Extra Thin FOUNDATION
In 25-Pound Boxes.

WE CAN now furnish **VAN DEUSEN'S'** Extra-Thin Flat-Bottom Foundation put up in 25-lb. Boxes, in sheets 16½x28 inches, at \$12.50 per box.

All orders for any other quantity than exactly 25 lbs. (or its multiple) will be filled at the regular price—60 cents per lb.

This Foundation runs 12 feet to the lb.—The above is a special offer, and is a Bargain to all who can use that quantity.

DR. FOOTE'S
HAND-BOOK OF HEALTH,

HINTS AND READY RECIPES.

Is the title of a very valuable book that gives a great amount of information, of the utmost importance to Everybody, concerning their daily habits of Eating, Drinking, Dressing, Sleeping, Bathing, Working, etc.

IT TELLS ABOUT

- | | |
|--|---|
| What to Eat,
How to Eat it,
Things to Do,
Things to Avoid,
Perils of Summer,
How to Breathe,
Overheating Houses,
Ventilation,
Influence of Plants,
Occupation for Invalids,
Superfluous Hair,
Restoring the Drowned,
Preventing Near-Sight-
edness. | Parasites of the Skin,
Bathing—Best way,
Lungs & Lung Diseases,
How to Avoid them,
Clothing—what to Wear,
How much to Wear,
Contagious Diseases,
How to Avoid them,
Exercise,
Care of Teeth,
After-Dinner Naps,
Headache, cause & cure,
Malarial Affections,
Croup—to Prevent. |
|--|---|

IT TELLS HOW TO CURE

- Black Eyes, Bolls, Burns, Chillsbills, Cold Feet, Corns, Coughs, Cholera, Diarrhoea, Diphtheria, Dysentery, Dandruff, Dyspepsia, Ear Ache, Felons, Fetid Feet, Freckles, Headache, Hiccough, Hives, Hoarseness, Itching, Inflamed Breasts, Ivy Poisoning, Moles, Pimples, Piles, Rheumatism, Ringworm, Snoring, Stammering, Sore Eyes, Sore Mouth, Sore Nipples, Sore Throat, Sun-stroke, Stings and Insect Bites, Sweating Feet, Toothache, Ulcers, Warts, Whooping Cough, Worms in Children.

Price only 25 Cents. Sent by Mail, post-paid.

THE WESTERN WORLD

GUIDE and HAND-BOOK

OF USEFUL INFORMATION.

For **HOME SEEKERS** or **Tourists**, **Capitalists** or **Laborers**. A vast amount of information not to be found elsewhere at any price.

A cloth-bound book, 4x7 inches, 288 pages
Price, 50 Cents.

The following is only a part of the Contents:

- Colored Maps of all the States and Territories, including Alaska and District of Columbia.
- Diagrams showing area, population, products, Government, State, School and Indian Lands of the several States.
- Histories of each of the States from the Earliest Times.
- How to Acquire Lands of any kind belonging to the Government by any forms of entry, who may acquire them, and the different laws; applicable to the different sections.
- Postal, Pension and Patent Laws of the United States.
- Coats-of-Arms of the States and Views of Celebrated Places, and of life in different regions.
- Rates for measuring Lumber, Logs, Grain, Liquids, Tables of Weights and Measures of all kinds, Interest Rules and Tables, Lumber Tables.
- Systems of Land Measures in various parts of the United States.

Contains also a Million Useful Facts.

The Weekly Bee Journal, for one year, and the Guide, postpaid, for \$1.30.

The NEW Heddon Hive.

We have made arrangements with the inventor by which we shall make and sell the Heddon Reversible Hive, both at wholesale and retail; nalled and also in the flat.

The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cover, bottom-board, and top and bottom of each sectional case has one-half of a regular Bee-space, so that the surplus cases with the sections, may be placed between the two brood-chambers, or the latter may be transposed or inverted—in fact, all parts of this hive are perfectly interchangeable. The brood-frames will ALL be bored for wires.

A SAMPLE HIVE includes the bottom-board and stand; a slatted honey-board, and cover; two 6-inch brood-chambers, each containing 8 frames; two surplus arrangements, each containing 28 one-pound sections, one with wide frames and separators, and the other without separators. This latter chamber can be interchanged with the other stories, but cannot be reversed. It is NAILED AND PAINTED, and ready for immediate use. Price, \$4.00, complete.

It is absolutely essential to order one nalled hive as a pattern for putting those in the flat together correctly.

Hives, nalled and painted, \$4.00 each.

HIVES READY TO NAIL.—In filling orders for these hives, in the flat, we make 6 different combinations, so that our customers may make a selection from the sample nalled hive, without waiting for us to quote prices, and the different kinds will be known by the following numbers:

No. 1 consists of the stand, bottom-board, cover, two 6-inch brood-chambers, 18 frames, and the slatted honey-board. Price, \$1.55 each.

No. 2 is the same as No. 1, with the addition of one surplus story containing 28 sections without separators—interchangeable, but not reversible.—Price, \$2.00 each.

No. 3 is the same as No. 2, with two surplus stories as therein described. Price, \$2.50 each.

No. 4 is the same as No. 1, with the addition of one surplus story containing 28 sections in wide frames with separators, which can be reversed, inverted, and interchanged, the same as the brood-chambers. Price, \$2.30 each.

No. 5 is the same as No. 4, with two surplus arrangements as therein described. Price, \$3.00.

No. 6 contains all the parts as described in the sample nalled hive. Price, \$2.75 each.

Those desiring the hives without the stand, honey-board or sections, may make the following deductions from the above prices: Stand, 14 cents; honey-board, 8 cents; and the 28 or 56 sections, as the case may be, at 1/2 cent each, respectively.

We will also make the following deductions on quantities ordered all at one time: For 10 or more hives, 5 per cent. discount; for 25 or more hives 7 1-2 per cent.; for 50 or more, 10 per cent.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. April 20, 1887. No. 16.

True Worth is in being, not seeming,
In doing each day that goes by
Some little good, not in the dreaming
Of great things to do by and by.
For whatever men say in their blindness,
And in spite of the fancies of youth,
There is nothing so kindly as kindness,
And nothing so royal as truth.

It is Announced that an apiarian exhibition will be held in Vienna, Austria, this month, at the Botanical Gardens.

We Acknowledge the receipt of Nos. 1 and 2 of the British "Gulde-Book" Pamphlets. They are written by Mr. T. W. Cowan, editor of the *British Bee Journal*, and published by Mr. J. Huckle, Kings Langley, Herts. They describe the making of appliances for bee-keepers, in a very lucid manner, and are nicely illustrated.

"The Open Court," a new Fortnightly Journal devoted to the work of establishing Ethics and Religion upon a scientific basis. This is the title of a new periodical just started at 175 La Salle Street, Chicago, Ills., under the able management of B. F. Underwood, at \$3 a year. It is beautifully printed on good paper, and its articles are highly entertaining, representing all phases of religious thought.

Geo. Neighbour & Sons, of London, England, state that through the *AMERICAN BEE JOURNAL* and *Gleanings* Mr. Heddon and his "new hive" are "well known in England." In a recent letter, they say that as they wish to make some hives containing "some of the features" of Mr. Heddon's, and desire to "do honor" and "not be considered pirates," they send ten dollars as a "token of respect and appreciation." As the hive named is not patented in England, this shows that Messrs. Neighbour & Sons are most scrupulously honorable and just in their business relations. With pleasure, therefore, do we put this news item on record, as a pattern for bee-keepers everywhere.

Bees vs. Grapes.—Dr. B. F. Dunkley, of Missouri, writes thus to the *Rural World* :

Ten years ago a neighbor transferred some bees from a common box-hive into a movable-frame hive. He made holes in the sides of the frame and pushed in hard hickory pins to hold the combs in the new frames, and to make the combs safe he wrapped the frame round with spool cotton thread. The first thing the bees did was to stick the combs fast with wax, then they cut away all the threads, mended all the combs, and then ate out all the *hickory pins* where they came into a comb.

What a prodigious yarn. When bees will eat hickory pins and iron nails they ought to be chained up like tigers, and not allowed to roam at will !!

Dr. D. makes a further statement in corroboration of the above. He says :

Many years ago I put a can of honey in my cellar, covered with two pieces of sack-ling, and over that a piece of oil-cloth; the first thing we knew the cellar was full of starving Italian bees (it was a very dry time), so full we could not go into it. They had cut their way through the covers and left half a six gallon jar of dead bees smothered in the jar, but no honey.

Now the bees are charged with cutting their way through oil-cloth, as well as eating hickory pins ! Next it will be said that they cut through a brick wall, or an iron door !

Big Bee-State.—Mr. John H. Rupert, of Woodcock, Pa., states his complaint in these words :

About that "land of wild honey" in this State (page 179), the editor says: "Who says that Pennsylvania is not a bee-State?" No one says so that I know of !

As another proof that Pennsylvania is a big bee-State, I will add that, last fall, while out hunting with D. A. Harman, we saw bees in the top of a large chestnut tree; we cut the tree down and found one pint of bees and about a tea spoonful of honey.

I would like to ask Messrs. Cousins and McCracken how they let that honey down with a rope ?

The word "big" was omitted by the printer. We wrote it thus: "Who says that Pennsylvania is not a big bee-State?" The experience of Mr. Rupert presents the exact opposite to that of "Cousins and McCracken"—but then it is an enormous State, big enough for all kinds of "experience" !! If they did not "let the honey down with a rope," they said they "roped it in" all the same. The whole story is very "ropy."

"Where to Keep Honey?" is the title of Leaflet No. 3, uniform in size with Nos. 1 and 2, and published at the same prices. This is in accordance with the recommendation of Mr. G. M. Doolittle, on page 245 of this number of the *BEE JOURNAL*. Its judicious use will undoubtedly increase consumption. Heretofore we have printed the first line thus: "American Bee Journal Leaflet No. 2." We shall hereafter omit the words "American Bee Journal," and simply call them "Leaflet No. 2." or any other number, as the case may be.

Onions inhaled cause sleep, rest, and refreshment. The soldier on his march, and the exhausted worker gets great strength from eating the onion. Tie a fresh onion around the neck and bruise it to make its odor thorough, and you secure sound sleep from its nightly inhalation, so says Daniel R. Clymer.

J. R. Lindley, of Georgetown, Ills., died on March 6, after an illness of one week. He leaves a wife and three little children to mourn his loss. Mr. Lindley was at the Indianapolis convention, and we little thought then that it would be the last time he would attend such a meeting. We offer our condolence to the stricken family of the brother departed. May Heaven protect and bless the little ones. We hope he carried some life insurance. We do not believe any one has a right to bring children into the world, and then not provide for them in case of death.

We Wish to Add our testimony in favor of Alsike clover, says E. W. Powell in *Farm, Stock and Home*. We raise it for the honey it contains, but consider it a splendid grass, either for hay or pasture. Our practice is to sow timothy with it for hay, as it will fall down and mat if sown by itself. Of course we only speak from our limited experience, in our own soil, which is a sandy loam from which the timber has been cleared. Alsike can be cut but once each season for hay, but will make a fine fall pasture. It also bears seed the first crop, if there are any honey-bees in the neighborhood to fertilize the flower.

Bee-Keeping in Japan.—From *L'Apicoltore*, of Milan, Italy, we glean the following item of interest :

Chevalier L. Sartori, of Milan, was, a few days ago, favored with the visit of two Japanese delegates, viz., Messrs. G. R. Hida and H. Danke, Councillors of the Japanese Ministry of Agriculture and Commerce. The distinguished visitors had not been long in Mr. Sartori's well-known apiary before it became evident that they were not novices in matters connected with bee-keeping, as their numerous and pertinent inquiries plainly testified. Nothing, it appears, escaped their observation, and much interest was exhibited when examining the new large plates recently published by Mr. Sartori, with explanations in four languages. In fact, before bringing their visit to a close, they left an order for 400 sets of these illustrations for the Government of Japan, upon which notes will be inserted in the Japanese language. Of course, the natural beauty of the Italian bee was, of itself, an object of no small interest, and a few colonies were ordered for shipment to their country. They were, however, not a little surprised when Mr. Sartori placed before them two large plates illustrating Japanese bee-keeping. Before leaving, they expressed themselves highly pleased with what they saw in Mr. Sartori's noted establishment.

New Catalogues and Price-Lists are on our desk. Those desiring to obtain any of them should send to the addresses given—**not to us**. The following have arrived during the past week :

Thomas S. Wallace, Clayton, Ills.—4 pages—Queens.
E. A. Sheldon, Independence, Iowa—1 page—Apiarian Supplies.
Cheney & Comstock, Sac City, Iowa—2 pages—Bees and Supplies.

Eucalyptus Honey for Medicine.—M. Gullmith, the French traveler, while on a journey in Australia, discovered some beehives in a gigantic eucalyptus tree, of 120 metres in height. The honey was strongly scented with the perfume of the flowers of the tree. Prof. Thomas Karraman has examined it, and believes it to have beneficial medicinal properties.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Bees Leaving Hives in January.

Query 406.—Can you give any reason why bees should swarm in January, leaving honey and brood in their hives, also queen-cells and a few bees? The day they swarmed it was very pleasant, and the sun was shining.—Louisiana.

Discontentment; something was wrong in the hive.—H. D. CUTTING.

We have known lack of pollen to cause them to leave, but there may be other causes, that we cannot know.—DADANT & SON.

They may have swarmed for the same reason that they usually do, only they were "rushing the season" a little.—W. Z. HUTCHINSON.

Such abnormal swarming is usually confined to weak colonies and to nuclei. They become discouraged and swarm out. Pleasant days after a stress of bad weather is the time they usually depart.—J. P. H. BROWN.

No. Being entirely unacquainted with the details of the case, and the actions of the bees in your latitude, I do not know whether it was satisfaction or dissatisfaction which caused them to swarm.—JAMES HEDDON.

This has long been a puzzle. It seems probable that the hive was in some way distasteful to the bees; but this is only a guess.—A. J. COOK.

I should say that it was what we call here at the North "swarming out." Dissatisfaction of some kind is thought to be the cause where bees so swarm here in April and May.—G. M. DOOLITTLE.

I suppose it is something as they might do at the North, in April or May. Sometimes it seems a mere whim, and sometimes a result, perhaps, of spring dwindling, not enough bees being left to take care of the brood before leaving.—C. C. MILLER.

Bees, sometimes in my early experience, left the hive most unaccountably. I now think the reason of their so doing was, the hive was too large for possible use. Probably in the case of the querist, too much room was given.—J. E. POND.

I can give reasons which are satisfactory to myself, but they may not be to others. I believe that bees never "swarm out" at a time when there is a quantity of young bees in the hive, unless they are absolutely starving. Three causes may contribute to the "swarming out" mania: First, starvation and discouragement;

second, a desire to supersede the queen, and third, when there are a few young bees in the hive, and the bees take a general flight—nearly all the bees take wing—there being no young bees to stay in the hive with the queen, she becomes excited and takes wing with the frolicking bees, and when out with the queen they may or may not return to their home without the interference of the apiarist.—G. W. DEMAREE.

I cannot give any reason from the data given. I have had fair colonies swarm out one or more times each day for a week, just after putting them out of the cellar. Sometimes they tried to enter other hives, which would demoralize matters. Such colonies, after they have had one flight, I shut in the hive and feed warm syrup until they learn to stay at home. If the day was warm and the bees appeared uneasy, I might release them toward evening. In this way I have saved many colonies from ruin.—C. W. DAYTON.

Abnormal swarming generally results from dissatisfaction with the hive, surroundings, weakness of numbers, or something else distasteful to the bees.—THE EDITOR.

Bees Sipping Blood.

Query 407.—Recently I was skinning a steer that had choked to death, when I saw several bees eagerly sip the blood as it flowed from the several veins. 1. Did any one ever notice bees do this before, and at what season of the year? 2. Can you suggest any reason for their gathering blood, as plenty of water was near them?—Mo.

It is not strange.—C. W. DAYTON.

I never saw anything of the kind, and I could not guess the reason.—G. M. DOOLITTLE.

Similar instances have been reported. There is probably something about blood that pleases the taste of bees.—W. Z. HUTCHINSON.

1. I never saw it. 2. Possibly they were after the salts in the blood.—C. C. MILLER.

Such statements have been made before. That bees are partial to such vital liquids is a fact, whether we always admire their taste or not.—A. J. COOK.

I never had any "blood suckers" among my bees; but I have noticed that bees sometimes resort in the spring of the year to stale water, particularly if it is alkaline. 2. I can assign no reason for their depraved appetite, unless it is a desire for salt.—J. P. H. BROWN.

2. The bees may have been without bee-bread and in need of nitrogenous food. Such bees may have been benefited by feeding them eggs or milk with syrup or honey; but in the experiment I once made in feeding eggs, I could not see that it was an advantage.—G. L. TINKER.

1. I never saw a case of this kind that I remember. 2. For the same reason that they gather many other substances, the reason for which we do not know.—H. D. CUTTING.

I have noticed that bees will work on the offal of slaughtered animals, and will visit the vaults of privies; and I have seen them sipping at the refuse of the soap kettle. I think that they are attracted by the salts nearly always present in such refuse matter.—G. W. DEMAREE.

I never heard of such a case before. Probably the bees found something in the blood that was needed. It may be the salt in the solution was the thing gathered. They probably went for the blood for much the same reason that they visit muck and manure heaps at times. *Why* is a mere matter of guessing.—J. E. POND.

Quite probably the bees needed the alkali found in the blood. Under certain circumstances they will take stale and salt water. They have been experimentally fed with eggs, meat and whisky by many at different times with doubtful effect.—THE EDITOR.

Eight-Frame vs. Ten-Frame Hives.

Query 408.—I use an 8-frame Langstroth hive; if I change to one having 10 frames, will I get fewer and larger swarms? Will I get more comb honey?—Y., Maryland.

Other conditions being the same, you would.—J. P. H. BROWN.

Yes, to both questions.—DADANT & SON.

No, not if rightly managed. To the second part I would say no, keep your old hives.—A. J. COOK.

You will get fewer and larger swarms. From foregoing reports in your latitude, you ought to get more honey.—C. W. DAYTON.

My experience says no to both questions; certainly no to the last, for this locality.—G. M. DOOLITTLE.

With 10 frames I think you will get larger colonies. As for the honey, it will depend upon the location.—H. D. CUTTING.

Likely you will get fewer swarms, and possibly less comb honey. I do not think there will be any material difference in the size of the swarms.—C. C. MILLER.

No, neither, but you will get wider lumber for covers and bottoms, and more ranges of comb in which your bees might starve to death in winter. You will both gain and lose some valuable functions. On the whole, I think you will lose more than you will gain.—JAMES HEDDON.

With proper management you would get no more swarms from the former than the latter, nor would the swarms be larger with but few exceptions. You would fail to get as much comb honey unless you practiced a system of contraction of the brood-chamber at the proper time.—G. L. TINKER.

I do not think any appreciable difference will be found. I prefer a 10-frame hive, as I can diminish or increase it to suit any contingencies that may arise. A large hive is better than a small one for that reason.—J. E. POND.

It would depend upon your management, as to whether you will get any more honey. With a good colony I have found that a section-case the right size for a 10-frame Langstroth hive will be filled as quick as a smaller one the proper size for an 8 frame hive, and the tiering-up will go on all the same. Of course the wider cases give a larger yield, because they hold more sections than do the narrow ones. The swarms are not always larger because they come from a larger hive. It is a well known fact that small hives encourage swarming. The 10-frame hive is best for this climate, as bees suffer less in the heated season, and we can contract them to suit the size of the colony at other times.—G. W. DEMAREE.

You will probably get larger swarms in many instances; in others not. You will also get more honey per colony in many instances; in others not. With a large brood-nest there is a liability of having considerable honey stored in the brood-nest, that might more profitably have been stored in the supers. Successful bee-keeping does not necessarily depend upon large yields.—W. Z. HUTCHINSON.

The difference is so slight that it would not pay to change. You might have the new hives to hold 10 frames, if so desired.—THE EDITOR.

For the American Bee Journal.

A Poetical Critique.

WM. F. CLARKE.

Dear sister Lou, that poetry [page 197]
Which tells you tale of woe,
Contains some words that seem to me
To read malapropos.

You want a better rhyme for "hum"—
"Sun" is not just the thing;
A word like "plum," or "drum," or "mum,"
The proper sound would bring.

"Mum" is the word, so please to write:
"The bees' melodious hum,
Was hushed, 'till near the noon-tide's height,
They kept no longer mum."

"Sbllime" is not well matched by "shrine,"
"Time" is a better rhyme.
They must harmonious notes combine
Who would Parnassus climb.

"Arcadio haunts that poets love,
Their mystic charms combine,
To form a beauntious arch above
An apiarian shrine."

As "sell" and "vell" don't harmonize,
You want a mate for vell.
Therefore, suppose the rhymester tries
"Rall," "pall," "fall," "tale," or "salle."

Then read, "oh! oh! her comrade said,
My honey should bring sse
Four times as high—then sudden fled,
A bee's got in my vell!"

If you your poetry would "sell,"
Like honey, it must be
Neatly sealed over, finished well,
And "fixed up to a T."

Guelph, Ont.

Leaflet No. 2, entitled "Alsike Clover for Pasturage and Hay," is now ready for delivery. This should be scattered into every neighborhood, in order to induce farmers to plant Alsike, that the bees may have the advantage of it for pasturage. We send them by mail 50 copies for 30 cents; 100 for 50 cents; 500 for \$2.25—all postpaid. It will pay bee-keepers to scatter these Leaflets, even if 9 out of 10 avail nothing. If ten farmers out of a hundred plant Alsike in any neighborhood, the bees will reap a very substantial reward.

House for Keeping Comb Honey.

G. M. DOOLITTLE.

I have been requested to give the readers of the AMERICAN BEE JOURNAL an article on "how to build, and the management of, a honey-house; i. e., a building in which to store surplus comb honey as fast as taken from the hives, in order to keep it in good condition, etc." This is a question of great importance to every producer of comb honey, and one that I feel incompetent to answer; but having had a little experience along that line, I will touch on that experience, and with it tell how I should build such a house for myself.

That honey often so deteriorates after being taken from the hive, that it is almost worthless, no matter how nice it is when harvested, shows the importance of this question, and if we can by any means provide a sure way, which is simple enough to be successful in the hands of the average bee-keeper, so as to keep our honey gaining in richness of flavor and greater density of body, as it does when left on the hive, less the travel stain of the bees, we shall have taken long strides toward the solving of how to create a demand for our production.

Still further, if we could simplify and reduce the plan so as to meet the wants of every consumer of honey, that they, too, could have every ounce of honey in their possession growing better with each week and month which passed away, instead of retrograding, we would hear less of low prices and over-production.

Put the question to the consumer of honey: What shall we do with honey to preserve its present condition, or make it a little better if possible? Nine out of ten will tell you that they keep it in the cellar, a greater mistake than which could not well be made. If Mr. Newman would get up a little pamphlet on "Where to keep honey," to go with his other excellent and instructive little books, to be distributed among the public, and for bee-keepers to hand to every one to whom they sold a pound of honey, I have no doubt but that it would increase the consumption of honey one-fourth at least, providing they (the consumers) will *believingly* read it. It matters not how much pains the apiarist may take to get his honey in nice shape for the consumer, if the consumer places it in a damp, cool cellar for two weeks before it is eaten. During that time the nice, good-flavored, well-ripened honey has changed to thin,

unripe honey, taking the flavor of the cellar or damp room, so as to be unsatisfactory to the taste, and by the end of a month it has so deteriorated as to be nearly unpalatable. All should know, whether apiarist or consumer, that a dry, airy, warm room is the only proper place to keep honey. But I have digressed.

When I first began to have honey I kept it in a pantry on shelves, the pantry being near the kitchen stove. Here it always kept well, for the piles were not dense enough to exclude the warm, dry air from permeating the whole. Later, as larger crops were obtained, I kept it in a room on the north side of the house. Here the centre and back part of the pile "sweat" or deteriorated badly, and I began looking about for the cause. I soon found it in looking back over the old pantry, and visiting Mr. Bet-singer, who at that time kept his honey in a little outside house about 6 feet square, which was painted dark, and had on it a rusty tin roof, so as to "draw the heat," as it is termed. In putting the two together I built my present honey-room in my shop which I have often described in the bee-papers.

I had thought myself perfectly suited with this, until the past fall when we had many damp, foggy, rainy days in succession, during which the sun did not shine to warm up the room in the least, nor could the windows be raised to allow a circulation of air, only to make matters worse. Seeing that something must be done, as the honey was beginning to show signs of "sweating," I brought into use an oil-stove, and with it I soon had the room warmed to 90°, which made it all right again, except a few sections of honey near the bottom and sides of the room where there was a poor circulation of air.

There are some points greatly in favor of a honey room in a shop like mine, such as having all under the same roof, so that the work of storing, crating and preparing for market can all be conducted with little labor; but, on the whole, I think there are more points, considering the question in its fullest extent, in favor of the honey-house being a separate building, but only a few feet away from the shop or general work room; so that were I to build again, I would not have the honey-house connected with the shop on account of its lack of exposure to the rays of the sun, imperfect ventilation, etc. My ideas now of such a house for 100 colonies of bees, are as follows:

Within 4 feet of the shop or work-room, at the south side, and even with the west end, I would build a house 8x10 feet square, and 8 feet high. This I would cover with cove ceiling to be painted black or dark red. For a roof I would use ¾-inch lumber covered with sheet-iron, and painted at the joints to prevent leaking, but not painted elsewhere, for sheet-iron will get hot in the rays of the sun beyond paint of any color. Near the bottom and on the east, south and west sides I would have

small windows for ventilation, which should be kept open at all times when the mercury would rise above 90° inside. These are to be secured and made so as to be opened (by sliding) from the outside. On the south side and near the top, I would have an ordinary window for light, the upper part of which should revolve to let bees out, which may come in on the honey. The door should be on the north side to correspond with one in the south side of the work-room, and both floors of the two buildings should be on a level, with a plank walk connecting the two.

For the inside of the honey-house I would have two platforms, raised a foot or 18 inches from the floor, one on the west and one on the east side of the room, to pile the honey on and leave a passage-way from the door to the window, between them, for convenience in storing and manipulation. The platforms should be made of slats set up edgewise, about 2 or 3 inches apart, so as to admit air freely, and the tubes of burning sulphur, if such is required. Such slats should also form the support for the sides and ends to the piles of sections, the slats being set off 6 inches from the inside of the building, so as to allow a free circulation of air in every direction.

A honey-house fixed as above, together with an oil-stove, will give apiarists complete control of the matter of preserving and ripening honey to their satisfaction. The oil-stove I prefer is the "Adams & Westlake." Borodino, © N. Y.

For the American Bee Journal.

Will Patents Protect Poor Inventors?

R. V. MEIGS.

On page 185, I find an article from Mr. J. E. Pond, of Massachusetts, which is full of splendid sentiment, yet which carries a false and somewhat dangerous idea, as I understand our American patent system—a branch of law which I have made a special study for years.

I refer to the idea that an inventor, if poor, and his device of ready manufacture, cannot protect his rights, but must become a victim to every one who would infringe his inventions. Such is not the case, and I very much regret that any such idea should have been put forth. We ask nothing better than a case in patent causes, in which a valid patent has been infringed, and that too from an inventor without one cent. It is true that the getting of the first decision in the United States courts is sometimes quite expensive, but after a patent has been thus sustained, all further prosecution and collection for infringements is, as a rule, quite easy and of little expense to the owner of the patent. The expenses fall much heavier upon the infringer, and his defeat is sure, and even the few rogues that are inclined to violate the just principles so well laid down by Mr. Pond, will soon, to their peril, learn better.

I will not take up valuable space with this somewhat out-of-place subject, so much as to go into any explanation, for I am sure that all who give the matter their best thoughts, on general principles will at once recognize that our Government has not left our honest inventors without protection because they may be poor, or their inventions relating to manufactures which are used in a small way by many persons.

The American patent system is among the cheapest in the world, as well as the best to protect, and the many very valuable inventions of poor but ingenious Americans, who have become rich through patenting them, and at the same time doubly enriched the world, attest the truth of the position taken in this article.

Detroit, Mich.

[As there has been one article on each side of this question, let it end here. We do not wish to give space to further argue the matter.—ED.]

Bees as Pest Carriers.

A correspondent in California has sent us an article from the *Riverside Press and Horticulturist*, asking that it be inserted in the AMERICAN BEE JOURNAL with comments. Here is the article:

I am ready to prove that the setting of fruit is not in the least dependent upon bees. I am a pioneer, and was engaged in buying and selling fruit in 1851. The orchards and vineyards about the Missions were as fruitful then as now, or have been since; yet no bee was seen in California until four or five years later. The first bees imported into California were brought by a Mr. Sheldon, who placed them in charge of B. F. Kennedy, of Santa Clara, and on returning across the bay, met his death on the ill-fated "Jenny Lind." These 2 colonies were soon under my charge. I transferred them into Langstroth hives, and sent them on their mission of usefulness.

Up to that time the orchards and vineyards never failed in their abundance of fruit. While the injury done by bees to raisins in the Santa Ana Valley has been great the past year, the injury to oranges has been greater. The bees carry the red scale from tree to tree. This scale is the most destructive and the most difficult to destroy of any that has visited the Santa Ana Valley. The young of this pest are almost too small to be visible to the naked eye. The wingless females are carried from tree to tree by the bees. Simple declarations without the evidence on which they are founded, are valueless. I will therefore give the facts which establish my proposition.

First, the manner and habit of the bee in gathering pollen makes it practicable to collect these microscopic mites with pollen and carry them from one tree to another. That

they do this, is evident from the fact that the lemon tree, which is always in bloom and covered with bees, is the first to be infected with the red scale.

Second, I planted a small orange orchard two years ago. They were taken from a nursery remote from any red scale, and appeared to be entirely free from that pest. Soon after they began to bloom, the scale appeared, while those trees that did not bloom at all were free from the pest. Hence, it is evident that the bees visiting the blossoms brought the scale. There has been a remarkable increase of this pest during the past season. Many orange groves have been dug up and burned solely on account of the damage of the red scale.

There is plenty of room in California, as yet, for both industries, but they cannot flourish together. Our valley was once a good sheep-pasture, but when it became evident that it was more valuable for fruit than for wool and mutton, the sheep had to leave. When it becomes evident that our soil and acreage are more valuable for another industry, horticulture will modestly and silently retire.—*Hiram Hamilton, of Pomona.*

Our California correspondent desired us to send it to Prof. Cook, of Agricultural College, Mich., and ask him to reply to it. We did so, and here is his reply:

I am not prepared or disposed to contradict or call in question any of the statements of Mr. Hamilton, except the first one. In that he unquestionably makes a great error, and this one mistake invalidates all the rest. He says: "I am ready to prove that the setting of fruit is not in the least dependent upon bees." This statement is a serious error, although Mr. H. is not very blamable for making it. He says that previous to 1851, California had no bees, but the crops of fruit were as good as those secured since that time. This is very likely true; but does it warrant the other statement?

There is no truth of science better established, than that bees are of great service in the fruiting of most of our plants, including our varieties of fruit trees. Often the bees are indispensable to a partial, not to say a full, crop. Let us see how Mr. H. erred in his conclusions:

It must be remembered that wild bees and other insects may and do fertilize the flowers just as well as bees if they visit the flowers. There are many such insects, especially in California where there is no rigorous winter to kill off the unprotected insects. Here in the North and East we must have bees for our plants that blossom early, as there are too few wild insects to accomplish the work. I have lived in California, and remember distinctly the swarms of insects—not bees—that I used to collect on the fruit-bloom. We see then that fruitage was possible in California before bees were introduced. But now there are acres of orchard where

there were rods or even feet then. So it does not follow that the bees are not necessary now. It may be that the wild insects would be entirely inadequate to the task, and that the bees are very necessary.

That bees may and do carry and spread the newly hatched bark or scale lice is certainly true. Yet this should not condemn the bees in the mind of the sensible man. If bees do not work on the bloom and fertilize the flowers, other insects must and will spread the pests. It is only whether it shall be bees or other insects. Again, these scale lice will be spread even though there are no bees, or even any insects at all aside from the wee lice themselves.

The apple-tree scale louse is a serious pest here; and spreads just as the orange scale lice, etc., do in California. But the small, active lice here hatch not till the bloom is all gone. Hence it must be wind and birds that scatter these pests of our orchards; and they would do the same in California. The wind in California blows so fiercely that it carries sand with so much force as to wear through window glass. Who shall say that it will not carry these minute lice even to a considerable distance?

Our California friends need the bees to insure full crops, and they must spray their trees with the kerosene and soap mixture, or some other efficient insecticide, or the scale lice will bring their orchards to naught.—A. J. COOK.

For the American Bee Journal.

Selling Dark Honey, etc.

H. O. KRUSCHKE.

I started in the spring with 30 colonies in good condition. The honey-flow was not as abundant as it would have been had we not had such unprecedented drouth and heat. What honey my bees did gather was dark, not one section of it being light honey. Basswood yielded nothing. I took off 1,000 one-pound sections, and 400 pounds of extracted honey, and increased my apiary to 72 colonies.

I began to sell the honey about the middle of August. I took some to the stores in Necedah, and received 12½ cents per section; they sold it out for 15 cents. That suited me better than trying to peddle it myself. I considered the price all it was worth, and more than I could expect to realize by shipping it to distant markets. But a "damper" was soon put on this price. Some of my neighbor bee-keepers in another town came some 15 miles through sand knee-deep, and then sold their honey on the streets at 10 cents per pound section; yes, even down to 3 for 25 cents. Their honey was fine and light-colored. Of course that stopped my sales, and I did not try to sell then.

The most of the customers preferred my dark honey to that nice white, remarking that mine was the best honey that they had seen that year;

thick, and a rich flavor, and that it tasted *like honey!* etc. So do not say that dark honey is not fit to put into the sections, or that it must be sold for wagon grease. No, it is just as nice as the whitest—you have only to find the customers who like honey; and do not run it down as regards quality, as so many bee-keepers do. I always say it is as good as any, and who will say that it is not?

My extracted honey I sold to families at 10 cents per pound, or 12 pounds for \$1. No one thought that the honey was not nice, or seemed to care about its being dark. Long before Christmas my honey was sold in a small town of not over 1,200 inhabitants. I could have sold as much more up to this time if I had had it.

I am satisfied with the result, and do not care to be instrumental in raising the price of honey. It can be done however, but of course not by "can't." "Can't" never has accomplished anything. If I owned all the honey in the county I could get what I asked for it, but perhaps I could not sell it all at a high price, but at better prices than are ruling now. But the question of having a right to do so must be left out altogether. I have a right to get all I can for anything which I produce, and have a right to combine with co-producers.

I do not want 25 cents per pound for honey. I can make a good living at 10 to 12 cents per pound, and let others live also. Those who cannot produce honey at these prices must look for something better. Bee-keeping is not a business to get rich at—at least not in a hurry. If riches are what you are after, seek elsewhere. But if your object is to enjoy life and health, and wish others to enjoy theirs, you can reach that goal at bee-keeping.

For the American Bee Journal.

Bees have the Sense of Hearing.

CEYLON NILES.

In reference to Mr. Fox's article on this subject, on page 201, I would like to give my experience. We should not jump at conclusions. "but prove them as we go." I have had 37 years' experience among bees, but I find that I can learn something new each year.

In June, 1869, I had a colony swarm and cluster on an apple tree. I hived it and placed the hive on the stand. In about 20 or 30 minutes I went to the hive and there was not a bee to be seen or heard. I rapped on the hive and found that the bees were there. I thought something was wrong, so I sat down in front of the hive and watched. In about 15 or 20 minutes a bee came and made a circuit of about 8 feet above the hive, and made a humming noise something like a drone. The bees inside the hive heard the sound and answered it. The bee kept coming nearer and nearer as it circled around the hive, till it rested on the alighting-board, then two or three bees came and met

it. The bee went into the hive, and was in there just a moment when all the bees came out of the hive and went to the woods.

In July, 1873, I had another colony quiet down in the same manner after I had hived it. I stopped the entrance so that no bees could go in or out, but left it so that they could have plenty of air. I watched it, but there was not a sound to be heard inside the hive. In about half an hour a bee came and made a circuit around the hive, making a humming sound, and the bees answered it. When the bee reached the alighting-board, I killed it. In a short time the bees quieted down. In about 15 minutes there came another bee and made the same sound, and the bee answered it. I killed this bee also. After awhile the bees quieted down as before, when in about half an hour back came three bees, and I killed them as I did the others. I watched them the remainder of the afternoon, and no more bees came back. About 6 o'clock I opened the entrance of the hive, when the bees came and clustered on the outside of the hive, but quieted after awhile. The next day the bees went to work all right.

The same week I had another colony act in nearly the same manner. I stopped the entrance and watched as before; eight bees came and I killed them. About 6 o'clock I opened the entrance, and the bees clustered on the outside of the hive. The next day they went to work all right.

I have had 2 or 3 colonies act in the same way since. This convinces me that bees can hear. I would say to those that let their bees swarm, if they do not want them to go to the woods, to try this plan and report through the BEE JOURNAL, Schuyler's Lake, © N. Y.

Read at the Albany, N. V., Convention.

The Depression in the Honey Market.

LYMAN C. ROOT.

At the last meeting of this association, held at Rochester, resolutions were adopted relative to the necessity of developing our honey market, and I was appointed as a committee of one to take such action, and make such investigations as would be likely to secure progress in this direction. These resolutions were most comprehensive, and indicated very distinctly a great work which might be accomplished. There are many who would be glad to see these results reached, but they are not induced to unite in the work. No work of this importance can be accomplished without united effort.

I shall endeavor to show some of the causes of the depressed condition of our honey market, and suggest some of the remedies. I have spent much time during the year in very close observation. Had the necessary financial aid been at hand, much might have been accomplished which would have resulted very beneficially. I should have visited the different

markets of our State, and made thorough investigations, offered premiums for the best and most attractive honey-labels, and would have offered special inducements for the best and most concise leaflet for general distribution with each package of honey sold. I should have experimented thoroughly in an endeavor to evaporate honey, until the entire moisture it contained was removed, so that we might secure pure evaporated honey in drops of suitable size to be sold as confectionery.

I believe that the time of one person qualified for the work, might, by the united assistance of the bee-keepers of the State, be profitably employed during the entire year, in placing honey as an article of food and medicine, before the public as its merits may honestly demand.

It would require more time than could be well given to one essay, to trace back through the past, the various causes which have combined to produce this depression under which we are at present laboring. Until about the year 1870, honey was produced almost exclusively in boxes holding from 2 to 8 combs, and weighing from 5 to 12 pounds. These boxes were made with wood top and bottom, 4 corner posts, and 4 glass sides. When they were well filled and capped, and all made very tight by the bees sealing all openings with propolis, they were in much better shape to pass through the hands of the dealer and into the hands of the consumer, than much of the honey produced by the later methods. But here arose objections. In removing the first glass and comb, and while using the remainder of the honey, the consumer was much annoyed, and the leaky package was often a great nuisance.

To do away with these objections as well as to secure other advantages, the single-comb section came into use. Consumers seemed willing to pay for glass on each section, for the sake of the advantages gained. Unquestionably this practice has to quite a degree diminished the amount of honey consumed, particularly those of moderate means. I have been an advocate of glassing sections, from the fact that the emergency seemed to demand it, and I do not yet see how honey can be sold in single sections, properly protected, without too great an expense to the producer, unless it is glassed.

About the time the single-comb section came generally into use, bee-keepers became very enthusiastic over the process of throwing honey from the combs by centrifugal force, and many other new methods, which resulted in great effort to produce large amounts of honey. This was carried to such an extreme, that greater effort was given to the quantity to be secured than to the quality. In the great haste to secure large yields, much of it was hurried from the combs before all the cells were capped. In glassing sections, many combs were started from the side of the boxes, and in many ways it has been put up in packages that have

leaked and were very disagreeable to handle. All of these things have had a tendency to lessen the demand. The reduction in the price of extracted honey has come largely from the fact that it has been subject to adulteration. This was the case, as might have been expected, when prices ranged high; but as they are becoming reduced, adulteration is discontinued.

Unquestionably, the greatest cause of the late depression in the honey market is the general depression of the times. The masses have, from necessity, been compelled to economize; this would prevent the use of comb honey to a great degree. It is not bee-keepers alone who have been affected by these depressing times.

That honey has not been more largely used, is not to be attributed to its undesirability as an article of food, for that is established beyond dispute. The effort in the future must be to not only lessen the cost of production, but at the same time furnish it in such perfect shape as to satisfy all the demands of both the dealer and consumer. In connection with this, the point must not be lost sight of that the general public still needs a good deal of enlightenment as to the intrinsic value of honey for the many purposes for which it may be used.

The practice of sending of products so generally to the city markets, and neglecting our home markets, has resulted greatly to our disadvantage, especially as they are at present managed, our honey being handled in the large markets by those who are not versed in all of the phases of bee-keeping. It has been impossible for them to build as firm a market as could be done by practical bee-keepers themselves.

One serious lack in our convention work has arisen from the failure to induce the wholesale and retail dealers in honey to be present at one session at least, of our meetings, at which time the subject of marketing our products should be discussed. Inducements should also be offered to secure a larger attendance of those who represent the consumers, which should be of mutual advantage. Dealers and producers should also be induced to present at these meetings samples of honey in the most desirable form for the best interest of the market.

I would recommend that all associations be urged to adopt these suggestions, and strive to correct this omission. There is greater need of earnest application in this direction than in any other branch of our calling, and too much thorough work cannot be bestowed upon it.

Bee-keepers must have in mind the fact, that to overcome these prejudices, and to build up a firm honey market, every effort must be made to have all honey placed upon the market in such packages as to prevent in every way possible, the honey from escaping and soiling other packages, or to in any way make it disagreeable to handle. Liquid honey should only be placed on the grocers' shelves in sealed packages. Every precaution

should be taken to have every comb in the sections perfectly capped, and firmly secured to the sides, so that it may be handled with the least chance of injury. In producing our honey, we must have in mind all of the necessities of the producer, the dealer, and the consumer.

Stamford, 9 Conn.

For the American Bee Journal.

Alfalfa as a Honey-Plant.

A. J. FOSS.

The following article from the San Francisco *Chronicle* may be of some interest to the readers of the AMERICAN BEE JOURNAL. San Diego county does not produce alfalfa honey, as alfalfa is not raised in sufficient quantities, but I have often seen it mentioned as furnishing honey in the counties north of this. The prospect for honey in this county is very poor indeed just at the present time, but our bees are strong, and with a few good showers we will have part of a crop; in one week more we will have drones flying. Here is the article referred to:

"The bee-keepers of Colorado recently held a State convention at Denver, in which many valuable points were brought out concerning this industry. Among other things, it seems that the most successful apiarists of Colorado are women, and the convention was largely composed of them. There was a good exhibit of honey and bee-keeping appliances, and much attention was attracted by a display of comb honey made entirely from alfalfa. It was snow white and of remarkably fine flavor. It is said that since the general introduction of alfalfa in Colorado, the keeping of bees has become a very profitable business, that plant furnishing an abundance of forage for the little insects. But it has not reached the development there that it has in California, for an apiary of 150 colonies is said to be the largest in the State, while here they frequently range from 200 to 500 colonies on a single ranch.

"It is evident from the experience of the last four years, that bee-keeping in California has received a serious set-back—that is, so far as relates to the production of extracted honey. Comb honey still sells at a price which pays a very fair profit; but it is useless to disguise the fact that at the price obtained for two or three years, the producer of extracted honey has had a balance on the wrong side of his ledger at the close of each season. Owing to the fact that much has been put upon the market in an unripened condition, it is very difficult to persuade people to adopt it as an every day, staple article of food.

"The purchaser of extracted honey at retail has no protection against the wiles of the adulterator. But with comb honey it is different. Not all the arts of the sophisticator have yet been equal to the task of producing an imitation of the wonderful work of the bee in the manufacture of comb

honey. It would seem to be the part of wisdom, then, for the bee-keepers to turn their attention more to the production of comb honey, instead of extracted honey.

"In this connection, too, it may be noted that in order to get people to become habitual consumers of honey, it must be put up in small and attractive packages and sold at a price which puts it within the reach of all, so that it may be regarded as a staple rather than a luxury, as is now the case. The bee-keepers, too, must adopt some means for bringing the excellence of their product more directly to the attention of consumers. Notwithstanding the enormous product of the apiaries of this State, it is seldom that honey is seen exposed for sale in the grocery stores at retail, and when it is offered it is generally at a price about 200 per cent. or more higher than that received by the producer. Comb honey can be sold at a very moderate price, and still leave a profit to all who handle it, but some means must be taken to induce people to become larger consumers of it, if it is hoped to remedy the existing state of affairs.

"Another reason that makes the keeping of bees a precarious business, is the liability to an almost total failure of the crop nearly every other year, owing to the lack either of a sufficiency of wild bloom or a deficiency of the supply of nectar in the blossoms. The experience of the Colorado bee-keepers in this direction seems to offer a hint, and if it is true that alfalfa will produce so good a quality of comb honey, then it will be a comparatively easy matter for California apiarists to render themselves entirely independent of the caprices of the seasons, and give them a certainty of producing a good crop every year." De Luz, Calif., March 26, 1887.

For the American Bee Journal.

Have Bees the Sense of Hearing?

D. BRIMMER.

In discussing this subject I have no object only to arrive as nearly as possible at the truth, for I have been a lover of the truth always, and while I am aware how difficult it is to come at it, so as to satisfy my own mind, much less those who are skeptical.

On page 201, Mr. Fox seems to take a different view from what I did in my article on page 121. He would have us believe that bees are wholly guided by the sense of sight, and labors to prove that the different sounds emitted are wholly from the vibration of their wings. Now, I would ask, can their wings vibrate when an ugly bee gets into a person's hair, or under his coat-collar, squealing and grunting like a young pig? I think it begins to resemble the cylinder of a thresher at a high rate of speed; and then, when bees get in a pinch, how they cry for quarters. Is that vibration?

With regard to a few bees leading a swarm to a tree previously selected,

is a fact so well established that I am surprised to find a bee-keeper who doubts it. I have been aware of it from my youth up, and I find it well demonstrated in my experience. Would Mr. Fox have us believe that they go in a body to search for a tree in the forest? If they do they have good eye-sight; for more than 40 years ago I had 2 swarms come out and unite, and I hived them, but I saw they were restless, and the next day they came out and started toward a piece of woodland, up a hill, and as they were not going very fast I followed and saw them go into a large oak out of sight of my apiary, more than a mile from the place of starting. Is it to be supposed that they could all see the hole in that tree before starting? If not, then the leaders must have had flags to beckon them on, if deaf.

When we compare a swarm of bees to a drove of sheep or covey of prairie chicks, we stray from the mark, for the same law that governs the animal race does not come under that of the insect. Mr. Fox is willing to accord to sheep a leadership, but does not tell us how the leaders attract attention; it is by the bleating of the foremost.

As to stopping absconding swarms, I would say that I was as skeptical as any one once, and laughed at the idea of stopping bees with a noise to confuse them, and by letting them have their own way I have lost many good swarms that I might have saved. But give me a good bell, the size a milk-man carries, and if I can run fast enough to a little ahead of them, I can stop 9 out of every 10 swarms. I have stopped lots of them since trying the plan.

I would like to ask Mr. Fox if he never saw a young queen in the act of piping? I have more than once while holding the comb on which she was, and I know it was not caused by vibration. It is well known that old queens can be scented by the bees, but can they do it with a virgin queen? I think not. Now if there is no evidence that bees can hear, then I am no judge.

Hloosick, N. Y.

For the American Bee Journal.

Quietude of Bees in Winter.

9—JOHN C. GILLILAND, (25-23.)

Mr. G. W. Demaree denies, on page 151, that bees ever resort to exercise to raise or keep up the temperature in the hive in winter; and he thinks the theory of exercise to counteract falling temperature was invented to bolster up the "pollen theory." The theory may have been invented for that purpose, but the fact existed long before the "pollen theory" was evolved.

The statements here given I know from personal observation in this county only, never having examined bees in other places in winter. In January, 1885, the hive and cloth covers were blown off one of my colo-

nies just after dark, and remained so until the next morning about 7 o'clock, leaving the bees exposed about 12 hours, with no covering except the clouds, and the mercury was at zero when I discovered their condition. About half an inch of snow had fallen in the early night and drifted in on them. They were roaring so that I heard them several feet away from the hive, and the bees on the outside of the cluster were continually going into it and others coming out. I both saw and heard these bees exercise to keep warm. In a few days the temperature rose up to 40° at noon, when they were quiet again, and there was a just perceptible hum, on placing the ear at the entrance. I know they were exposed all night, as it ceased to snow soon after dark, and the cover and cloth were both covered with snow.

I winter my bees on the summer stands, and know nothing about cellar wintering, by experience. I have wintered colonies packed with the enameled-cloth propped down tight so there could be no upward ventilation, and others packed and with upward ventilation; also colonies unpacked in $\frac{3}{8}$ -inch single-walled hives, with and without upward ventilation. The temperature the most of the winters was as low as 20° below zero, and has been as low as 27 $\frac{1}{2}$ ° below.

I visited the apiary at different hours in the daytime, and at night when the temperature was from 32° above zero to 24° below, and instead of the "oppressive stillness" the quietness (?) could be plainly heard, the hum or roar increasing as the mercury lowers until at 20° below zero, or lower; it can be distinctly heard 10 feet from a hive. This is kept up day and night with no cessation that I have been able to discover, until the temperature is rising, decreasing as it does so until it reaches about 40°, when there is just a perceptible hum by placing the ear at the entrance and listening closely. There is a very slight, if any, difference in the roar of the differently prepared colonies.

In the winter of 1880-81 this roar continued for over two months. In October, when there is a frosty morning with the temperature 10° below freezing, they will roar lively, and quiet down in an hour or two when the sun warms things up. With me, bees are most quiet at 40°. A higher temperature causes them to leave the cluster, and fly out, and as the temperature becomes lower they cluster more compactly, and the noise grows louder the lower it gets. Of course they do not leave the cluster to exercise, as that would defeat the object they are trying to accomplish.

This hum, when bees are clustered, is made by the true voice, as shown by Mr. Frank Cheshire, and certainly requires respiration. Therefore, to increase the hum they must increase respiration, and that is exercise. Possibly they are putting in the time, when too cold for anything else, exercising their vocal organs in getting ready for a grand chorus when spring comes. The colder the air, the more

oxygen in a given space, and this added to the increased volume taken in by increased respiration, furnishes the fuel to raise the temperature. The bees do this because instinct so teaches them.

Mr. J. W. Bayard's article is very nearly correct, and certainly so for my locality, as to the colony never ceasing their hum until dead.

Mr. Demaree is less than one degree south of this place, and it seems strange that such little distance should so change the actions of bees. It may be a strange phenomenon and an amazing philosophy that bees do this, but it is a fact here, at least. It is another fact showing that location changes nearly all rules about bees, and that each one must learn to adopt the management that suits his own location.

Bloomfield, 9 Ind.

For the American Bee Journal.

Dairymen and Bee-Keepers.

JAS. E. TODD.

I prepared the following address which was read at the Farmers' and Dairymen's Association at Oneonta, N. Y., on Feb. 15, 1887, and would like to see it in the AMERICAN BEE JOURNAL. It is as follows:

It is well, perhaps, to first notice the fact that the interest of both bee-men and dairymen in many respects is identical. I will present a few observations which I have made at different times while keeping bees, not having been without them for over 30 years. We are literally living in "a land flowing with milk and honey," and inasmuch as the production of each of the best quality and in the largest quantity depends more or less upon the other, it is well that we study the underlying principles which tend most surely to advance them. The food question, then, would seem to be of the first importance.

It is pretty generally admitted that when our pastures and meadows are well covered with a heavy growth of clover, that they are in a first-rate condition regarding general fertility and milk-producing abilities. I have been experimenting for the last few years with Alsike clover, and I find it to be the very best of milk and honey producing food for cows and bees. The way bees help to increase its growth is by more perfectly fertilizing its bloom.

Alsike clover is a hybrid or cross between the small white clover and the pea-vine clover. It grows tall like the pea-vine, but unlike it, it grows a small, fine stalk, curing when cut for hay in one-half the time and sun required to dry the coarser clover. Its blossoms are the same size as the white clover, with white color except the outer edge which is pink, presenting a most beautiful appearance. Having a small blossom, its entire sweets are easily reached by the bees, and so attracts large numbers of them, thus causing its bloom to be most thoroughly fertilized by the dust

of other bloom. Along in June, about the time that this occurs in this latitude, it may be observed that the clover head and entire stalk will begin to grow and swell rapidly, and will soon load with seed, and in good soil it will yield immense crops of hay or seed. The seed being very fine, it requires about two quarts, with one quart of the other seed, and eight or ten quarts of timothy and red-top seed mixed, per acre.

The Alsike and red-top delight in a damp, rich soil. If bees are so abundant as to thoroughly fertilize the clover bloom while in this blossom-opening stage, it would be largely for the interest of the dairyman to sow a light coating of plaster over his meadow and pastures some time in May, if his soil is of a clayey or retentive nature. But if the soil is of a sandy composition, or if bees are not abundant to fertilize the bloom, perhaps the plaster would do less good. It is also for the interest of both bee-keeper and dairyman to sow and raise large fields of buckwheat, and buy less meal feed for stock.

A good yield of grain, as well as straw, is almost certain where the honey-bees are sufficiently numerous to thoroughly fertilize the bloom, if the soil has been made sufficiently strong to produce the grain. We often hear men say that the sun has blasted their buckwheat, whereas the fact is that the soil or care was too weak to produce more than a weak growth of straw, and was exhausted at the very time that the grain began to form, or honey-bees were too few to fertilize the bloom. A buckwheat crop may be made to pay simply for the flour, and the coarser part of bran, which is an excellent milk-producing food, be obtained without cost. Buckwheat straw rightly cured and cared for, with a little grain, and fed without grinding, is very good winter food for young stock. Buckwheat is also the best of egg-producing foods for fowls, and chicks will eat and do well on it while very young.

While it is a hard and laborious study to learn telegraphy or engineering, it is little less so to become an expert at bee-culture; and here also is to be found the secret of so many failures. There seems to be an impression among men that about all one wants is a few bees and the hiving of the swarms, and a little later on, the carrying in of tons of honey. The getting of a few bees is all right, but the watching, care and labor is much more than was expected. The knowing how to do, and the doing of the right thing at the right time, are the inexorable terms of success.

If the bee-keeper sees an attempt being made by a powerful colony to rob a weaker one, help to the weaker one must be immediate, or it is of no avail at all; for as soon as the weaker one is overcome its queen is killed, and the workers compelled to turn in and help carry their own honey with their victors, home to the hive of their assailants. Neither do they seem to grieve over the transfer of allegiance, for the very next day

they will go to work as cheerfully carrying in honey from the field to their victor's hive as they had been doing in their own; but they do not yield to this without a terrible struggle. Often more than half the inhabitants of the hive will fiercely give up their lives and lie dead before their hives on the field of battle in defense of their honey, their queen and young, all of which they know will perish if they fail. The robbing difficulty can be greatly reduced, if not entirely overcome, by keeping all colonies strong, and sizing the entrance to that of the colony, and by exercising proper care while putting on or taking off honey, and otherwise opening the hives and handling the bees or honey. It is also almost equally important to do all things pertaining to bee-culture with nearly as much promptness as in the case of robbing.

There is also a good part of the year that bees need little or no care at all. The first thing to be done after getting a colony of bees, is to get them into a movable-frame hive, if they are not already in one, as soon as warm weather comes in the spring, and circumstances will permit. The choosing of the hive, too, which must be left to the person expecting to use it, very much like the choosing of a mowing-machine, is to be decided. I believe a low frame hive is preferable, and I use one, which I call the honey-chest, and winters bees safely on the summer stands, bringing forth strong colonies to take hold of the first spring bloom with vigor. The best facing for the hive is to the southwest, if there is any difference, but the main thing is to have the inside of the hive and bees right, and then all will be right.

Bee-keepers should not allow their honey to go upon the market until well assorted, keeping the white and dark separate, with prices according to quality. It is as difficult for bee-keepers as dairyman, or other producers, to agree on price or any general course of action. But they clearly should all determine to produce none for sale but the very best quality, at whatever cost of quantity. This the consumers themselves will not object to, and with almost all articles produced on the farm the same rules should be observed.

About the best course of late years for bee-keepers, is to take off the surplus honey before the dark, fall honey comes in, as it is so cheap, leaving the dark for the bees to winter on, if well sealed over, but if open it should be extracted, as it will sour in the hive and kill the bees before spring. This course will leave us only the white, best honey. Then we should see, as much as possible, that the honey is sent to market through and into hands not interested in getting prices down or damaging them.

Unadilla, © N. Y.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

Local Convention Directory.

1887. *Time and place of Meeting.*

SELECTIONS FROM OUR LETTER BOX

Swarming and Gathering Honey.

—Peter Morelein, Brussels, ☉ Ills., on April 7, 1887, says :

My bees commenced swarming to-day. The honey comes in rapidly from willow and wild plum. The weather is very hot and dry at the present time, the mercury being at 86° in the shade. Bees are building up finely.

Bees Wintered Well.—Ferd. Zastrow, Millhome, ☉ Wis., on April 11, 1887, says :

Bees have wintered in the finest condition, both in the cellar and outdoors. Our bee-keepers' association has done remarkably well by spreading the knowledge of bee-keeping among its members, for the one year that it has existed; also the AMERICAN BEE JOURNAL has been an invaluable assistant to me; every bee-keeper ought to read it.

Deep Snow in Vermont.—A. P. Fletcher, Ludlow, ☉ Vt., on April 8, 1887, says :

The snow here on the level ground is still over 3 feet deep. An apiary of bees in Manum hives is only visible above the snow, and those hives stand 3 feet and 6 inches high. One can just see the tops of the hives. The banks made by shoveling the snow from the walks in some instances are now nearly 10 feet deep; they have been deeper.

Bees Wintered Poorly.—E. N. Fisher, Ludlow, ☉ Mass., on April 6, 1887, writes :

Bees have wintered poorly in this locality. I had 30 colonies last fall, and I now have but 15 left. Some were on the summer stands, but most of them were in the cellar, the temperature ranging from 35° to 40°. During

a dry spell the last season the bees gathered a substance from the pond-lily leaves, dark colored and bitter, which gave them a diarrhea, and caused the death of most of my old colonies. We have had but two days this spring during which bees could fly, and there are quite a number of colonies in the neighborhood that are still in the cellar. I do not think we shall have many early swarms this season.

Long Winter Confinement.—C. F. Smith, Cheboygan, ☉ Mich., on April 11, 1887, says :

My 15 colonies of bees have wintered under straw absorbents in a damp cellar at 38°, for 5 months and 10 days. Above the cellar 3 healthy children have played continually. The bees have been taken out, and are in apparently good condition.

Wintering Problem Solved.—A. D. Stocking, Cedar Branch, ☉ Ind., on April 9, 1887, writes :

My 16 colonies of bees are all right, and are bringing in pollen from the willows. All colonies seem to be strong. They were wintered on the summer stands, the same as I have always wintered my bees. With me the problem of wintering bees is solved, and if I can have the three conditions, viz: the hive full of bees, plenty of good stores, and keep them dry, I would not give 10 cents per colony to have them insured to winter well.

Bees Enjoying Themselves.—John K. Rich, Cato, ☉ N. Y., on April 11, 1887, writes :

I had 18 colonies of bees last fall, 11 of which I put into the cellar the first week in November, with the temperature at 35° to 42°. I put them out on April 8, with a loss of 1 colony. Of the 7 colonies wintered on the summer stands there was a loss of 2 in chaff hives. I used 10 of the Betsinger honey-cases with wire-cloth separators; there was no propolis, and they were much more easily handled than wide frames. I shall use them exclusively the coming season. The temperature now is 75°, and the bees seem to enjoy it.

Singular Winter—Bees all Right.—W. Addenbrooke, North Prairie, ☉ Wis., on April 11, 1887, writes :

I put 130 colonies into the cellar on Nov. 24, 1886, and removed them to the summer stands on March 12, 1887. All are alive and in good condition. A few are now weak, and will be united soon, if the weather keeps as warm as it is now. On March 26, at 8 p.m., it commenced to snow, and snow fell until 4 p.m. on March 27. It drifted some, and was the heaviest snow-fall of the winter. On March 28 and 29 we had zero weather, and on April 4, we had a regular blizzard

with snow all day; since then we have had good weather. Yesterday and to-day it was 75° in the shade. Bees gathered natural pollen for the first time to-day. I banked up all my colonies with snow, put good, warm quilts on top of the frames underneath the honey-boards, kept the ground bare of snow in front of the hives, and the colonies are in good condition, with plenty of brood and young bees hatching out. This winter has been rather singular for Wisconsin—so many severe changes in a few hours.

Where is it Found?—Dr. C. C. Miller, Marengo, ☉ Ills., writes :

On page 218, in the address of Rev. W. F. Clarke, occurs the following statement: "It is proposed by some to pass a law securing to the first comer as a bee-keeper into a neighborhood, the exclusive ownership of the bee-forage within certain limits." Will Mr. Clarke kindly give the names of some who have made such a proposition, and also the place, if any, where it has been mentioned in any of the bee-papers?

Yet Snow-Bound.—J. B. Mason, Mechanic Falls, ☉ Maine, on April 9, 1887, writes :

The season here is away behind. We are yet snow-bound, the snow to-day being 3 feet deep in the woods, with plenty of drifts 10 feet deep. Last season, five days later than this, the bees were bringing in pollen.

[Here in the West, the season is quite up to time, or, in fact, it is earlier than common. Bees around the suburbs of Chicago have been bringing in pollen for ten days.—ED.]

Young Carniolans Flying.—Henry P. Faucett, Dilworthtown, ☉ Pa., on April 9, 1887, says :

Bees have wintered well so far. I lost 2 out of 50; they had a good flight to-day. In one of my Carniolan colonies drones and young bees were flying out. These drones were reared this spring. Bees gathered the first pollen on March 21, from swamp-cabbage.

Good Prospects for 1887.—G. L. Rankins, Weston, ☉ Ky., on April 11, 1887, writes :

Last fall I prepared 14 colonies of bees for winter on the summer stands; I now have 13 good, strong colonies and one weak one. They are working finely now, gathering honey from the peach, cherry and plum bloom. Apple trees are beginning to bloom, and everything looks as if we will have an early spring, and plenty of white clover. If so, we will have a fine honey crop. I am going to work all my bees for comb honey, as it sells best in this part of the country. I sold all I had last year at 12 and 15 cents per pound.

BEE JOURNAL

Issued every Wednesday by

THOMAS G. NEWMAN & SON,
PROPRIETORS.

323 & 925 WEST MADISON ST., CHICAGO, ILL.
At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for a year, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 25
" 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

The Production of Comb Honey, as practiced and advised by W. Z. Hutchinson, can be obtained at this office, for 25 cts.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

OUR CLUBBING LIST.

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1.00..	
and Gleanings in Bee-Culture.....	2.00..	1.75
Bee-Keepers' Magazine.....	1.25..	1.25
Bee-Keepers' Guide.....	1.50..	1.40
The Apiculturist.....	2.00..	1.70
Canadian Bee Journal.....	2.00..	1.75

One yearly subscription for the AMERICAN BEE JOURNAL must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duhan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediana. Mailed free. 52A40t

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the BEE JOURNAL. It is now so cheap that no one can afford to do without it. We will present a **Binder** for the BEE JOURNAL to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax :

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c.—Sales have been larger this month than at any time since November, and prices average a little lower for comb than the above.

BEESWAX.—25c. R. A. BURNETT, 161 South Water St. Mar. 28.

DETROIT.

HONEY.—Best white comb, 11@12c. Market is improving.

BEESWAX.—23c. M. H. HUNT, Bell Branch, Mich. Apr. 11.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4@4½ cts. Comb, white, 7@13c. Market firm.

BEESWAX.—Scarce at 19@22c. Apr. 4. SCHACHT & LEMCKE, 122-124 Davis St.

SAN FRANCISCO.

HONEY.—We quote: Old comb, extra white, 12½@14c.; dark, 8@11c. Extracted, amber and candied, 3½@4c.; extra white, 4½@5c. Outlook is gloomy, as rain is needed badly.

BEESWAX.—Scarce at 22@23c. Apr. 5. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 14@15c.; 2-pounds at 11@12c. Extracted, 5@7c. Demand for 1-lb. sections lively.

BEESWAX.—24 cts. per lb. Mar. 23. BLAKE & HIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 3@7c. per lb. Nice comb brings 11@14c. per lb. Demand fair.

BEESWAX.—Good demand, —20@23c. per lb. for good to choice yellow. Mar. 29. C. F. MUTH & SON, Freeman & Central Av.

CLEVELAND.

HONEY.—Choice white, 1-lb. sections, sells at 12½@13c.; second quality white, 10@11c.; white 2-lbs., 10@11c. Buckwheat, 8@9c. Extracted, 5@6c.—Market dull.

BEESWAX.—25c. Mar. 9. A. C. KENDEL, 115 Ontario Street.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 11@12c.; 2-lbs., 10@11c. No call for dark. White extracted, in barrels and kegs, 6@6½c.; in small packages, 6½@7c.; dark, in barrels and kegs, 4@5c.—Demand good.

BEESWAX.—25c. Mar. 28. A. V. BISHOP, 142 W. Water St.

Convention Notices.

The next regular meeting of the Cortland Union Bee-Keepers' Association will be held in Union Hall at Cortland, N. Y., on May 10, 1887.

D. F. SHATTUCK, Sec.

The next meeting of the West Lake Shore Central Bee-Keepers' Association will be held on May 26, 1887, in Koekring Hall, at Kiel, Wis.

FRED ZASTROW, Sec.

The May meeting of the Northwestern Illinois and Snub western Wisconsin Bee-Keepers' Association will be held at Rockton, Ills., on Tuesday, May 24, 1887.

D. A. FULLER, Sec.

The Des Moines County Bee-Keepers' Association will meet on April 26, 1887, at the Court House at Burlington, Iowa, at 10 a.m. All interested in bee-keeping are invited to attend. Articles sent for exhibition, to the Secretary, at Middletown, Iowa, will be exhibited and returned or sold, as directed.

JOHN NAU, Sec.

The ninth annual meeting of the Texas State Bee-Keepers' Association will be held at McKinney, Collin Co., Tex., on May 4 and 5, 1887. All bee-keepers will find a hearty welcome. No hotel bills to pay. An interesting programme is ready. Come one, come all.

B. F. CARROLL, Sec.

The Central Michigan Bee-Keepers' Association will hold the spring meeting in Pioneer Hall, Capitol Building, at Lansing, Mich., on April 26, 1887, at 10 a.m. A cordial invitation is extended to all bee-keepers. If any have troublesome questions, bring them with you, or send them to the President, at Lansing, Mich.

J. ASHWORTH, Pres.

The Chautauquan for May has the following table of contents:—Pedagogy: A Study in Popular Education, Third Paper, by Chancellor J. H. Vincent, L.L.D.; Architecture as a Profession, by Mrs. Schuyler Van Rensselaer; A Stellar Paint Brush, by Chas. Barnard; Studies of Mountains, by Ernest Ingersoll; The Sunday Readings; Women in the Professions, by Julia Ward Howe; Common Errors in English, by Edward E. Hale; Practical Suggestions on English Composition, by Prof. T. Whiting Bancroft; Animals of the Arctic Region, by Gen. A. W. Greely; Homes Built by Women, by Mary A. Livermore; Rich Men in Politics, by S. N. Clark; Sojourner Truth, by Harriet Carter; The Fruits of California, by Byron D. Halsted, Sc.D.; The Potter's Art, by Felicia Hillel; and Slave-Holding Anta, by Henry McCook, D.D.

Eureka Recitations is a good collection, containing nearly one hundred pieces, compiled by Mrs. Anna Randall Diehl. All those interested in providing an entertainment, should have this collection. It contains 128 pages, and is published by J. S. OOLIVIE & Co., 57 Rose Street, New York. Price 12 cents.

W. Z. HUTCHINSON,

Rogersville, Genesee Co., Mich.,

HAS the permission of the writer to publish the following:

"Forest City, Iowa, March 28, 1887. W. Z. Hutchinson, Rogersville, Mich.—Dear Sir, and Friend: I am in receipt of your pamphlet—'The Production of Comb Honey.' It is the neatest little thing I have seen lately. As a work of art it is as near perfection as printers in 'country offices' usually attain to. I venture the opinion that that cover was the work of a bee-keeper, or at least originated in his (your) creative brain. Nobody but a bee-keeper would have thought of such a unique and appropriate covering. The subject is treated in a very readable and creditable manner. I have been practicing substantially the same method, except the non-use of foundation. I shall try that this season.

Respectfully Yours, EUGENE SECOR."

Reader, if you wish to enjoy the same pleasure as did Mr. Secor, send 25 cts., and a copy of the book will be sent postpaid. 16A5t

THE NEW HIVE.

I have many more testimonials like the following, from Leading Bee-Keepers of this country. See 1887 Catalogue, to know what Prof. Cook, W. Z. Hutchinson, F. P. Stiles, T. L. VonDorn, F. Boomhower, and Doctors Tinker, Mason, Miller and others think, after many of them have thoroughly tested the New Hive:

ST. CHARLES, Illa., Feb. 7, 1887. JAMES HEDDON.—Dear Sir: Your letter dated Feb. 3rd. is received. In reply I can say that I have watched closely, and with interest, the discussion pro and con in our bee-periodicals in regard to your New Hive. Although I have not as yet been prepared, as you are aware, to give your New Hive a personal test, yet I can say, in harmony with Dr. Miller's declaration, that your invention is one that requires no practical experience, on the part of any one familiar with the art, to recognize it at once as a hive of very superior merits. Having, during the past year, given your New Hive and its management very careful thought and study, I am constrained to say that I believe it to be as far in advance of all other hives as the well-known Langstroth is in advance of the old box or beehive. I say I believe this, and in keeping with that belief, it is my present purpose to adopt your New Hive just as soon as I can shape my plans to that end. In short, I feel as though I CANNOT AFFORD to use any other hive. Having used the Langstroth, with its best modifications, since the spring of 1858, it is with a feeling of considerable regret that this resolution will compel me to bid this old friend a final adieu.

It is apparent to me that the novelty of your New Hive is as wide a departure as its utility is superior to all others. Notwithstanding that I have been hives with features resembling parts of your New Hive, still I have never seen a combination, nor am I aware of any that possesses its functions. And right here is just where the invention and patentability exist, without which you certainly would never have received the many strong and well merited testimonials which I find in your Catalogue for 1887. Having for the past 25 years given the laws relating to patents more or less attention, I have no hesitation in repeating the word of Prof. Cook and G. M. Alvey, that the "rubbish" which is already "lugged forward," in futile attempts to anticipate your claims, does not "deserve a critical man's attention."

As you seem to desire the foregoing for publication, I have taken especial pains to say nothing that I might possibly regret in the future.

Fraternally yours, M. M. BALDRIDGE.

FOR WINTER.

HARTFORD, N. Y., April 9, 1887. We have had sleighing 134 days, and we are on runners yet. This is the first general high in my bees have had, and had to dig the hives out of deep drifts in order that the bees might have fair sailing. Eighty-five wintered in my old chaff hives came through with a loss of half, and many more weak. Nine in your hives packed in 6 inches of chaff, and setting 2 inches from bottom-board, not having a general flight in over 130 days, are all in good order. Four wintered on a single case in best shape, with sealed brood. Stores the same in all the hives. Bees in the cellar are dying.

J. H. MARTIN.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. April 27, 1887. No. 17.

A Word of good counsel we ne'er should forget;
And to keep out of danger is to keep out debt!
If peace and contentment and joy you would know,
Don't live upon credit, but pay as you go!

"Practical Turkey Raising" is the title of a new pamphlet just received. It is written by Fanny Field, the most experienced breeder of turkeys in America, and published by R. B. Mitchell, of Chicago, Ills. It is written expressly for those who are interested in profitable breeding of turkeys for the market. Price 25 cents. It can be obtained at this office.

Mrs. M. Crumrine, of Bryan, O., one of Mrs. Lizzie Cotton's pupils, reports the reception of a pencil drawing of her hive (costing \$3) and states that she has made some and found them successful in wintering bees on the summer stands. She also thinks that Mrs. Cotton's book is a plain and practical work. In justice we give the above, as we have published several complaints. Three dollars is still very high for a "pencil drawing of a hive."

Making Honey Vinegar.—Mr. C. F. Muth gives these instructions in *Gleanings*:

When making vinegar, one must know that water will turn into vinegar providing it contains the necessary quantity of sugar stuff, and is exposed to fresh air and a warm temperature. The warmer the temperature and the better the circulation of air, the sooner vinegar forms. A barrel is laid down, and an inch hole is bored in the upper end of each head, near the upper stave. This admits of a good air-passage over the body of the honey water. Tins with fine perforations nailed over these holes, with the rough side outward, exclude flies and skippers. Take about one pound of honey to one gallon of water, thoroughly mixed up, and nail a perforated tin on the bung-hole. We take 35 to 40 pounds of honey for a barrel containing 40 to 45 gallons of water. The warmest place in the yard is the best place for the barrel. If the sun shines on the barrel all day, it requires from the beginning of April to the end of October to make vinegar satisfactory for all purposes. If not sour enough by fall, it will be all right by Christmas or spring, if placed in the cellar or a warm room.

Kissing Bees.—In a woman's convention lately held, Mrs. Thomas, of Tacony, Pa., when speaking of the subject of "bee-keeping for women," said she had kept bees "for 25 years, and her earliest memory was of bees and tubs of honey," and then stated that she "had learned all the practical operations of bee-management before she ever saw a man lift a comb or transfer a colony." It will be seen that she was a wonderful woman, but her bees were still more wonderful! She added: "My bees know me, and often *kiss my hand*." We know of hundreds who would prefer not to have any such familiarity exhibited by bees—Bro. Clarke, for instance! When they kiss him, his lips swell up and he is apparently filled with poison!

But Mrs. Thomas has a splendid honey market, as well as wonderful bees. She says that when she began, she "received 50 cents a pound for comb honey in eight and ten pound boxes, and never had to go out after buyers." Two years ago she had 3,000 pounds of surplus from 25 colonies, and sold \$750 worth of honey! Prodigious! Honey 50 cents a pound! Profits, \$30 per colony! Wonderful bees—market—woman—and all!

Now see how unselfish she is. She wants every other woman to become an apiarist too, and puts it thus: "A woman who can obtain money to buy her bees and fixtures, may count on a return of \$200 to \$300 the second year, beside paying for the stock!"

This is clinched by the following: "Miss Angie Creed borrowed money and bought her stock, and two years after exhibited at the State Fair beautiful honey which sold at 40 to 50 cents a pound. It paid off her outlay and left a balance."

This rosy account is being extensively copied into the papers, and will, no doubt, induce many to embark in the business only to become disgusted when they find that the price of honey is less than one-fourth of that quoted above; and much of the rosy speech at the convention proves to be but a "delusion and a snare!"

Feeding Bees in May.—Mr. Wm. B. Treadwell, in the *American Agriculturist* for May gives these instructions for beginners:

Large quantities of brood are reared in May, and after the red buds of the soft maple have put forth their heads there will be plenty of natural pollen for the bees to gather. If there are no maples or willows near, take some unholted rye-flour, mix it with sawdust or cut straw, and set in a sunny corner, sheltered from the wind, when, if the bees require it, they will carry it freely. In localities where there is honey in the blossoms at this season, the bees will gather it very rapidly, and the more honey they get the faster the colony increases. Where there are not enough honey-producing flowers, by all means feed, at the entrance, say about a gill of hot feed every night. By feeding thus, your colonies will increase very rapidly, and when the honey commences to flow, they will be strong to gather it. Again, should there be honey in the blossoms, and cold and rainy weather set in, feed as above, for should the weather continue cold, the bees would naturally commence to destroy the work already accomplished, by tearing out and destroying the hatching brood. If bees are kept for increase alone, feed them every night, and continue to do so until honey can be gathered in abundance.

Bee-Catalogue of Thos. L. Thornton, Dividing Ridge, Ky., is received.

Building Air-Castles.—How often this is done, and how disappointed is the "builder" when light, truth and facts cause the air-castles to vanish. Mr. J. W. Sanders, of Le Grand, Iowa, writes us as follows concerning what he is pleased to call a "silver-plated air-castle":

During the social talk of our last bee-meeting, there was a person present from some out-of-the-way rural district. He wanted to know how we fixed sugar to feed bees in order for them to make it into honey. He said there was being lots of it fed now for that purpose, and money could be made at it.

We told him he was mistaken, that sugar was not fed for that purpose, and could not be, with profit, even if desired. He thought it could, and said that parties in the East were doing it.

In order to prove it to us, he took an old circular from his pocket, handed it to me and said to me: "Read that," referring to a particular item in the circular.

The part referred to gave the great advantages of a bee-feeder, and how easy it was to feed bees with it. I turned the paper over, and found that it was James Heddon's circular, and the item referred to his bee-feeder.

A general smile came over those present. We told him what was meant by a bee-feeder, and what they were used for. I advised him to take the *AMERICAN BEE JOURNAL*, and invited him to attend our bee-meetings.

A disappointed look came over him, and he failed to make his appearance at our meeting in the afternoon. We think he returned home with his silver-plated "air-castle" all vanished!

Many prefer to do a fraudulent business rather than one which is honorable and honest. This man had no idea of "keeping bees"—but he wanted to "make honey!" He snapped at the idea of using a feeder (which was intended to keep bees from starving), when he supposed it could be used to feed the sugar, and have the bees make honey! But when he found that the bees must gather the honey from the flowers, ready-made, distilled drop by drop in Nature's laboratory—pure, healthy, and nourishing—then he wanted none of it! He must have a fraudulent article or nothing!

Bumble-Bees and Clover Blossoms.—Prof. W. J. Beal, of the Michigan Agricultural College, writes thus on this subject in the *Farmer's Advocate*:

An inquiring friend would know "why the first crop of clover has no seed; whether it is possible to distinguish the difference, if any, between the blossoms of the plant bearing the seed and that which contains the fertilizing quality; and has the bumble-bee anything to do with it." So far as examined—the blossoms of the first crop of red clover have good stamens throughout, and good stamens, with plenty of what we should call good pollen. In other words, we cannot see why they are not just as capable of fertilization as those which come later. Experiments, repeated on the second crop for six years, give varying results, but in all cases they show that bumble-bees in Central Michigan increased the crop from 100 to 400 per cent. Other insects may also help in this matter. In Kansas they tell me bumble-bees are scarce, but clover seeds freely. Honey-bees at the Michigan Agricultural College, without any question, increase the yield of seeds of white clover enormously, in one case as 236 exceeds 5. I am satisfied that in some locations at least bumble-bees should be encouraged for the good they do to red clover. Now the problem is this: How can the entomologists rear and keep over winter large numbers of fertile queens? It seems to me not probable that the time may come when bumble-bee queens will be reared, bought and sold for their benefit to the crop of clover seed.

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Removing or Renewing Brood-Combs.

Query 409.—1. How often should the brood-combs of a hive be removed or renewed? 2. When is the best time of the year to remove them so as to get good, full sheets of worker-comb? 3. What becomes of the wax in those old brood-combs? Melting it gives very little wax to me.—A. J. F. CALIF.

I have had no occasion for renewing my old combs in all of my 18 years' experience with bees.—G. M. DOOLITTLE.

I have not yet been confronted with this problem. I do not know what becomes of the wax, but I do know that old combs have yielded but little wax for me.—W. Z. HUTCHINSON.

1. Not oftener than 15 or 20 years, if it is good straight worker comb. 2. In the spring, using full sheets of foundation in their place. 3. Perhaps the wax in old combs decays.—G. L. TINKER.

1. Not until you experience a difficulty with them that their removal will remedy. 2. During the brood-rearing season, when there is not much honey being gathered. 3. There is very little in them.—C. W. DAYTON.

Once every 15 years is often enough to renew the combs. They might as well remain even longer, if not too dirty. There is just as much wax in those combs as ever there was, but it is a little more difficult to get it out.—DADANT & SON.

1. I have seen prosperous colonies on combs 20 years old. 2. After swarming is all past. If before swarming, drone comb will be built in large quantities. 3. The wax seems to be held back among so many cocoons.—JAMES HEDDON.

I cannot say, as I have kept bees only about 20 years. Good frames of straight worker-comb may be kept indefinitely. If to be changed, it may be done at any time, though only when colonies want bees, and not room to store, if we desire worker-comb, as we always do unless we use worker foundation. 3. The wax is all there; the comb is very thin.—A. J. COOK.

1. I remove old combs gradually as they become inferior. I never remove a whole set at once, because they do not all become inferior at once. I gradually work out the worst combs. I have not kept bees in movable frames long enough to know how long good combs will last; I have combs over 15 years old that do good service yet. 2. The best time to have

combs built is during the best honey flow. 3. I think the wax is there—the trouble is in separating the wax from so much refuse as collects about the wax in old combs. With the improved sun wax separator, I get a good turnout of wax from old combs.—G. W. DEMAREE.

1. I do not know. I have some now that have been in use for over 16 years, and they are as good as ever. They should not be renewed as long as they are good. 2. Early in the season as possible. 3. The wax becomes amalgamated with the "cocoons" lining the cells, that are left after the bees emerge, and so closely that but little can be obtained by melting down very old combs. Old combs, therefore, are far more valuable as combs, than the wax that can be extracted from them.—J. E. POND.

1. I do not know. Some of mine must be 20 or 25 years old, and I would not think of renewing them. 2. I get worker-comb at any time by using full sheets of foundation. 3. Is it not possible that the wax is still all there, but soaked into the cocoons, as it were, so as not to be easily separated?—C. C. MILLER.

1. If the combs are all right what do you want to remove them for? 2. In the fall, when looking over all the colonies for winter, I take out all defective frames and replace them with perfect ones. 3. I do not know.—H. D. CUTTING.

If they are not damaged, and contain sufficient worker-cells, they should be good for a quarter of a century or longer. Old brood-combs contain so many "cocoons," accumulating from the myriads of bees born in them, that they are unprofitable to melt for the wax.—THE EDITOR.

Getting New Brood-Combs Built.

Query 410.—In moving my bees last spring on a farm wagon, over rough roads, the combs were more or less broken and damaged, so that the frames are now stuck together. I wish to get new combs built by furnishing wired foundation. 1. Shall I invert the old hives and put the new ones containing the wired foundation on top of them? Or put the old hive on top of the new one, and force the bees to pass in and out through the lower story? 2. When should this be done, and how many frames of wired foundation should I put in at first? 3. How long will it take the bees to transfer their stores?—Bellevue, Ky.

I should put into practice what has been styled "modern transferring," as advised by Mr. Heddon.—W. Z. HUTCHINSON.

1. Put the new hives on the top. 2. At the beginning of the honey harvest. Gauge the number of frames by the size of the colony.—C. W. DAYTON.

I should say that about your best plan would be to wait until the swarming season arrives, and then transfer the bees to "those wired frames of foundation" by the Heddon plan.—G. M. DOOLITTLE.

1. Wait until fruit bloom, and then transfer by the Heddon method, and feed the stores to the bees in the top of the hive. The brood can be cared for in the old hive, *à la* Heddon, and can be transferred temporarily into

frames, and put in the top of the hive until the bees emerge from the cells. 3. It will depend upon the weather. Probably but a few days. The trouble will be with the brood, which will require 21 days from the last egg before all leave their cells.—J. E. POND.

Put the new hive on top of the old one. It will take more or less time for the bees to move up, depending upon the season. A better way would be to transfer the worker-combs during apple bloom, and thus save all that were worth saving.—DADANT & SON.

1. Try both ways. I should place the new frames on top. 2. As soon as the bees are strong enough to build the combs; give them all you wish them to have at once—a super full. 3. Very much depends, as regards all these questions.—JAMES HEDDON.

I should give the bees wired foundation in new hives as soon as strong at swarming time; then let brood develop, and when the three weeks had passed, melt up the old comb, after extracting the honey. In changing to reversible frames I have done just this, and very successfully. If desired, we can use only starters in brood-frames, and add sections at once. This gives the maximum amount of honey.—A. J. COOK.

When the bees get to be strong in the old hives, I should place the new hives on top with full sets of frames. 3. After the bees have drawn out the combs in the upper story, the queen could be smoked into it, and a queen-excluding honey-board put between the hives. After 21 days the lower hive could be extracted, and the combs melted into wax.—G. L. TINKER.

1. I doubt if the bees will occupy the frames of foundation in either case until their old brood-nest is filled, and they are crowded for more room. Without seeing them I am not sure what I would do, but I think I would straighten up all the combs I could in the old frames, or transfer them into new, and supply the deficiency with frames of foundation added as the bees could occupy them.—C. C. MILLER.

I should want to transfer by any well defined method. You will get no satisfaction unless you do. 2. Just as fruit blossoms begin to open, put in all the frames the bees will cover. 3. If left in the old hive they will not transfer their stores at all, in the way you propose.—H. D. CUTTING.

You can do as you say, and the best time to adjust the frames of foundation is right at the commencement of the early honey harvest. But your plan would not pay me. I would cut loose and straighten up all the best of the old combs, and supply with foundation what is lacking. I cannot afford to melt up good old combs because they are out of shape, as long as I can save money and time by putting them in order. 1. Why invert the old hive? 2. Why not put on an upper story with a full set of frames, with foundation on the brood-chambers just as it is, at the beginning of

the honey season? 3. Perhaps never. If I wanted to throw away the old combs, I would drive the bees about May 1 into new hives filled with foundation, like we used to drive them into empty hives 30 years ago.—G. W. DEMAREE.

If you must use "wired frames," you should put the new hive on the old one, but the bees will be slow to go up there until they have filled up below. Would it not save time and trouble to transfer them during fruit bloom, and save all the combs that are worth saving?—THE EDITOR.

Spring Management of Bees.

Query 411.—My hives last fall, when put into winter quarters, were full of honey, and I left all the frames in them. The combs at the sides of the hives now (March 12) are still full of honey. Would it be better to leave them in, or take out one or two on each side, and put in division-boards, or put in frames of foundation in their place?—Kankakee, Ills.

Leave the combs of honey as they are by all means.—G. L. TINKER.

Let them alone where they are.—JAMES HEDDON.

I should leave them in, in this locality.—G. M. DOOLITTLE.

Take out and crowd by use of the division-board. This is the sovereign remedy against spring dwindling.—A. J. COOK.

For cold climates, take out extra combs and make the hive snug and warm.—C. W. DAYTON.

Most likely your bees will need that honey before the clover crop. But if they really have too much, it had better be taken out.—DADANT & SON.

I do not know how many frames are in your hives, but I think it a fine thing to have full combs of honey in a hive on March 12.—C. C. MILLER.

Much depends. If there are center frames without brood, remove them, and replace with the full ones, putting "dummies" on the sides of the hives. Contract to as few frames as the bees can cover, and feed if necessary. Do not remove brood in any case.—J. E. POND.

A solid frame of honey is the best division-board ever made. For all practical purposes, if the colonies are strong in bees, leave them as they are.—H. D. CUTTING.

If there is more honey in the hive than the bees will use, it is just so much dead capital; if you can make any use of it, take it out and put in division-boards or "dummies." Do not put in frames of foundation, as they will be filled with honey in very poor shape for market, unless extracted; and then it is more convenient to have the surplus stored in an upper story. Why use hives so large?—W. Z. HUTCHINSON.

I would leave the honey where it is. If the queen needs the room below to enlarge her brood-nest, the workers will carry the honey above. This is one of my objections to sugar feeding, and a very serious one. When my brood-chambers are full of honey except the room occupied by the queen

for her brood, I am sure of the surplus being conveyed to the surplus department. In other words, a hive full of brood and sealed honey is "contracted" to as good effect as if division-boards occupied the place of the sealed honey, and with this advantage the bees do not have to be fed at the close of the season at a loss of bees and stores.—G. W. DEMAREE.

You risk nothing by leaving the frames of honey in the hives until honey is being gathered; then if there is too much for immediate use, remove it.—THE EDITOR.

For the American Bee Journal.

The Medicinal Properties of Honey.

G. P. HACHENBERG, M. D.

Since the publication of my article on the "Medical Properties of Honey," in the AMERICAN BEE JOURNAL for April 26, 1886, I have received several letters asking for further information. The subject appears to have received special attention, by the profession in particular.

D. C. Spencer, M. D., of Augusta, Wis., makes this request: "Will you please to give, in the AMERICAN BEE JOURNAL, a list of authorities for the positions taken in your article, and also state how much and what parts were from original observations, and what were your data on which these were based?"

I reply with pleasure, and hope what I may be able to say in answer to the questions on the subject will prove satisfactory.

The general recognition of honey in the pharmacopoeias shows its high official position. The United States Dispensary necessarily had to receive it as an official remedy, but unfortunately blotted it with a great error. It says: "Honey possesses the same medical properties with sugar, but is more disposed to run off by the bowels, and to occasion griping pain." What an unhappy contradiction by so high an authority! The deleterious effects referred to show at once that honey is something more than sugar. It may safely be assumed that all remedies that betray an untoward effect on the system, may be turned to a medicinal advantage. This explains why some of the most powerful "poisons" may serve us as the most efficient means to subdue disease. A tisanne is no medicine—it may serve as a nutritive; but it is soon subverted by physiological operations; where, on the other

hand, it is the medicine that controls these operations.

There is another reason for regarding honey as something more than sugar. If the two were isomorphous, although identity of composition by no means implies identity of character, we would be less inclined to assail our august authority, but honey has one more equivalent of oxygen than has sugar, as established by Praut, Gay Lussac and Thenard; therefore the two are not alike to produce the same physiological effect. According to Draper, we have specific chemical tests to distinguish one from the other. Leibig's analysis of honey and sugar stands as follows:

	Carbon.	Hydrogen.	Oxygen.
Honey.....	36.36	7.09	56.55
Sugar.....	42.30	6.38	51.31

The chemists named, previously render the oxygen in sugar only about 50.00, giving still a greater excess of it to honey. I have no doubt, that on the law of chemical affinity, if the analysis could with strict accuracy be made, it would amount to one whole equivalent 8.013.

Honey has two specific effects in its route through the system in which it differs from other saccharine substances. The mellic acid in the honey (it is evidently this acid which is referred to in the American Cyclopaedia on the subject of honey), is an irritant, often distinctly felt in the throat after eating it. It is not always of uniform proportion in the honey. It has its beneficial function to perform, but when in excess, it poisons the honey, and like the Trebizond honey, may be dangerous to use. I know that poisonous honey is supposed to be derived from poisonous flowers, but of this I have my doubts. When honey is taken in the stomach, the mellic acid unites with the gastric acids and will excite and favor digestion. Especially advantageous, too, are its antiseptic properties, which, being more positive than sugar, tend little to gastric fermentation.

It is well enough to observe in cases of dyspepsia and idiosyncrasy, where the mellic acid does not receive the co-operation of the gastric acids to favor digestion, it may develop a strong, untoward effect, even to cause sickness. But such cases are not common, and upon the whole, honey is a wholesome diet, a good, mild medicine, and even a potent prophylactic of diseases. But the most important physiological action of honey in passing through the system, is its election for the liver, on which organ it expends the whole of its glucose material. Starch and sugar follow the same route, but only by means of a highly complicated operation. In the glycogenic process of the liver on honey, no special reconstruction is needed as is the case with starch and sugar. The latter have first to be converted into glucose, much like that of honey, before its assimilation in the liver. It is self-evident that this economy of labor on the part of the liver on honey, makes it an excellent hepatic with laxative and diuretic effects. There is perhaps no other

hepatic like honey, all others stimulate the liver into action at a certain vital expense; honey facilitates its operation on a reverse principle, that is, by lessening its labor, and still perform the normal amount of work.

It may here be proper to state that the mellic acid is hardly ever conveyed to the liver, but decomposed by the alkalinity of the chyle. Should it be taken to the liver, it would serve as an irritant to that organ, causing violent bilious vomiting and purging. The history of some cases that may be confounded with idiosyncrasy, I think will establish this as a fact. Honey leaves its highest blessing not only on the liver, but through its easy but thorough assimilation in that organ, it necessarily holds a healthy sympathy with the operations of the kidneys. By some fault of the liver, it may turn starch and sugar into glucose, but fail in the elimination, throwing the burden on the kidneys, often a most dire disaster, unfortunately too common, which would not take place by the use of honey.

In my article on the "Medical Properties of Honey," is given a full list of the same, both as a local and constitutional remedy. Perhaps the list has appalled Dr. Spencer. Of course they are not all of an immediate character, some are primary, some secondary and reflex, and of such nature as only Dr. S. and other medical scientists can determine. In determining the medical properties of a remedy, much depends upon circumstances, and the way a skillful physician prescribes it. For example, take ipecac. What is it? An *emetic*. Yet it cures vomiting, and thereby becomes an *anti-emetic*. In a disease of the lungs, you put the patient in bed, and it is administered as a diaphoretic and expectorant. Give it to one, and turn him out-doors, and it is likely to prove diuretic and hepatic. In fever, as a febrifuge; in cholera and convulsions, as an antispasmodic; in labor, as a parturient; in dyspepsia, as a tonic; in constipation, as an aperient; in diarrhea, as a sedative; in hemorrhages, as a constitutional hæmatostatic; in intermittent fever, as an antiperiodic; in hysteria, as a nervine; and in many forms of chronic diseases as an alterative, etc. It is often the case that the physician with suitable cases will mould his remedy to his purpose, as a potter does his clay; not only this, but doctors may all prescribe the same remedy for the same purpose, and they be like so many musicians playing the same instrument and the same tune, and yet no two play it alike.

It will be perceived now in what way I passed judgment on the medical properties of honey. The nature of a case often is as important a factor to determine the properties of a remedy, as the remedy itself.

Let us briefly refer to some of the authorities on our subject. Prof. John J. Reese, in his "American Medical Formulary," gives honey as a "demulcent and laxative, and used as a vehicle for other medicines." In Dungleson's Dictionary: "Honey is

employed as aliment, condiment, and medicine. It is demulcent and aperient, and is prescribed as an adjunct to gargles in *cynanche tonsillaris*, etc. It is used as a detergent to foul ulcers." The oxymel of the London and Dublin Pharmacopœias (made of honey and vinegar) is recommended as a "pleasant addition to gargle, and is sometimes used as a vehicle of expectorant medicines, and to impart flavor to drinks in febrile complaints." I know of a Texas physician that uses the oxymel, and nothing else, in the treatment of croup and other throat diseases, and, I am told, with wonderful success!

Where honey is used as an adjunct, it often has very fine and pleasant effects, such as the "Honey of Roses," "Honey of Borax," "Oxymel of Squill," etc., and other formulæ of the kind found in the Pharmacopœias of the medical profession. It is interesting and suggestive to see the different preparations of honey that may now be found in the drug-market. In connection with the few already given, there is the Acetomel, Aloe, Anaphromel, Aquamel (Honey-Water), Aquamelis, Ægyptomel, Ceromel, Depurated Honey Ph. Ger., Honey of Elder Flowers, Glycerated Honey, Hydromel, Rhodomel, Honey of Rhatany, Honey of Borax and Roses, Honey of Violets, etc. *Vide*: Frederick Stearns & Co's "Pharmaceutical Catalogue."

The place honey frequently takes in authenticated prescriptions demands our attention. I have had special facilities to examine this part of the subject. Having been for many years engaged on a "Consultation Prescription Book" which contains a full list of all the remedies with their posology and properties, etc., so far as I could, by large resources at my command, procure them; and many thousand authenticated prescriptions nosologically classified to cover not only each disease, but every stage and complication it may have. In this voluminous collection of material, I have carefully observed as author, physician and apiarist, in what manner honey was prescribed by the master minds of the medical profession. I may have perhaps a hundred formulæ in my book, where honey was prescribed, in many cases as in the oxymel that could not well be replaced with any other saccharine material. It is with some pique, I have to say that nearly all of these honey prescriptions, like the oxymel, originated in Europe. It is evident that the honey in these prescriptions take the place both of a menstruum and a medicine—a chemical agent no other solvent has, except those of a violent nature. I have noticed in these formulæ, that honey with Kusso, as an electuary for worms; with pepsin, as a tonic in preference to saccharated pepsin; with chlorate of potash, for gargles; with mindererus, as a diaphoretic and febrifuge; with opium and assafetida, as an antispasmodic sedative and nervine; with sulphur and senna, as a laxative, hepatic and carthartic. In the analgesic prescriptions of Prof. Fenwick, of

England, in his "Outlines of Practice," there are several that contain honey in some form.

Now when, where, and why is honey used as an adjunct and solvent by choice? There are two reasons, one is to favor the assimilation of the base in the prescription, and the other is to associate it with remedies that in some way or another have, more or less, some analogous principles with it, either physiologically or chemically. The object is to maintain a compatibility of the different remedies in a prescription. Take any of the above examples where honey is given in connection with other remedies, we find that each is modified in its physiological force. It may give a keener edge to honey, and blunt the acidity of its associates. Here is a principle that involves the construction of all scientific prescriptions. For many reasons there is often a necessity of uniting remedies, as disease is a complex affair; but at the same time we must see the folly of polypharmacy, or what in common parlance is called "shot-gun medication."

In domestic practice, honey has been used for ages as an independent remedy for the treatment of some diseases. Physicians in the present age with their armamentarium of over four thousand remedies, make better, quicker, and surer work by associating it with other remedies.

But what is its actual physiological force as a curative agent? In referring to my "Consultation Book," where with the labor of years I made a proximate estimate of the "force" of each remedy, I find that I have assigned to honey 14, sugar 6, and starch 1. The scale runs from 1 to 100. The higher the figure the more powerful the medicine. The force of Prussic acid is represented at 97. Honey here stands rather high in the scale as a mild remedy, but mainly on account of its local effects. Constitutionally administered, on Leibig's theory of the disposition of sugar in the system, I would make it 10, leaving it still higher than sugar, on account of the behavior of its mellic acid in the stomach. But without the acid in its assimilation, which is much more readily effected than sugar, it would fall below sugar and stand at 4! The importance of this arrangement is clear, as it greatly lessens the chances of making a mistake in prescribing powerful remedies. A glance is sufficient to make an intelligent estimate of the power of any drug, and with full security, which the reading of many pages on the subject may not always do, to say nothing of the loss of time.

The biblical history of honey leads us to think that it is not held in the same general estimate in the present age that it was in the earlier ages of the world. But from the present condition of things, we have every indication that it is about to regain its former appreciation from mankind. I am no prophet, nor the seventh son of the seventh son, yet I cannot resist the temptation to show you the chick that lay in the egg, in my last article

on this subject—when speaking of honey as a prophylactic. Honey is destined not only to take an important place in medicine, but in *state medicine* in particular. As a prophylactic, it will turn up as a giant in the way to stay the march of epidemics. Why this extravagant idea? You know well enough, Dr. S., that in the case of a victim of cholera, yellow fever, or of any other acute malignant malady, it is the liver that receives the first blow—the glycogenic process is stopped or greatly impaired, suppression of the urine follows with a dire train of symptoms all pointing to the grave. If our theory is correct as to the behavior of honey in the liver, honey is to the liver what oil is to machinery; the wear and tear of epidemic influences on it will do it little or no harm. Of course the protection is only secured by the daily use of honey as a diet, previous to the exposure of sickness. When the damage is once done, honey or any other remedy may fail to save the patient. The golden rule in medicine is, "Prevention is better than cure."

For the American Bee Journal.

An Experiment on Ventilation.

C. W. DAYTON.

Last fall I prepared an apiary of 112 colonies for wintering, by covering them first with forest leaves, and then with 8 inches of earth. A passage-way was provided from the entrance to the outside air, and a small space of the leaves at the top of the mound were left uncovered with earth, to allow upward ventilation, and the escape of moisture. The open space of leaves was protected from snow and rain by a hive cover. I should have said that 72 colonies were arranged in this way, and the remaining 40 were the same except that the leaves were entirely covered at the top, so that all chances for upward circulation was cut off.

They were doomed to a confinement of 150 days. On making examination on April 2, the 40 colonies were found dead, and 69 of the 72 were alive to enjoy a flight. Such long winters are almost enough to disgust the apiarist, and drive him from this northern country to continue his avocation; but when he realizes that it is so benefiting to the honey market, he is considerably relieved.

In many of the dead colonies I believe there had not been live bees for months, as but little of the honey had been consumed. Several combs where the honey had been taken out, contained 4 or 5 pounds of water. Four colonies that were in one end of long hives, while the other part of the hive was stuffed with leaves, showed the good effects of the space into which the moisture escaped. A few of the dead colonies left the combs and hive clean and nice, but the majority befouled the hive and combs that affords a chance for "frame scraping," and

the microscopist to charge his instrument for large game.

There was but little if any signs of brood-rearing. Those colonies that had the most upward ventilation seemed to have fared the best. Their cold and devitalizing condition brought them out all right; however, I hardly think they suffered much with the cold, as I think they were able to generate sufficient warmth for comfort, and some to spare.

It should be remembered that the more porous the coverings are, the requisite amount brings equal warmth and a drier condition.

Combinations for Honey-Producers.

J. M. HICKS.

When viewed from a practical stand-point, this seems to me a step in the wrong direction, especially so if we are allowed to judge of other combinations, such as Boards of Trade, Railroad Corporations, and many others I could mention of which I do not wish to leave unnoticed, the Coal Oil and Express Combinations, all of which have and are still continually sacrificing every principle of justice in order to accomplish their cunningly devised plans of injustice toward the many. These things will, at some future time, be more fully noticed and properly managed by the masses. Such corporations seem to flourish like the "green bay tree" for a while, but *God is just*, and will, doubtless, put it into the hands of His people to rectify these inhuman wrongs now exercised by almost every organization in existence. It has for many years been the custom of many honey-producers to consign their crop to some commission dealer in some city, for instance, one C. O. Perrine, of Chicago, who used to deal heavily in pure honey as furnished by the bee-keepers, as well as much of his own bogus production added, in order to make more extended sales. More than once have we seen his bogus productions in glass jars and tumblers for sale in the grocery stores of our own Hoosier State. Mr. C. O. Perrine was not alone in such dealings, as well as quoting honey at certain figures, far below the actual sales made.

We also find for several years past the quotations of honey (not glucose) have been very low, by the various commission men in many cities, especially in Chicago and Cincinnati; at the same time I retailed all the honey I could produce at 20 cents for extracted and 25 cents per pound for comb honey. And at this writing I have disposed of my 1886 crop at 20 cents per pound, something over 4,000 pounds, all of which has been sold direct to the consumer, and not a pound went into a grocery store or to a commission merchant.

I have long since found that it takes industry to produce, as well as to sell honey at a paying price. The former

commodity (industry) does not in a very great degree abound among the commission men of the present day, except at the expense of the producer, hence every producer can well afford to be his own salesman, provided always he desires good and reasonable returns for his honey. It seems to me after many years of close observation and contrasting the past with the present state of things, that it would be vain for the bee-keepers of America to try such a scheme as heads this article. It is a true saying, and worthy of full consideration, that even in all such combinations, the big fish eat up the little ones, and the stock goes up or down as the case may be. But one thing is sure, that the little fish soon find themselves far in the rear of the sharks, which has been, and is yet, the order of the day among all combinations, and the many suffer at the hands of such organizations; hence I for one, am opposed to all movements, especially so, when they have such a strong tendency of becoming a monopoly, which, if once organized, would have no other object in view than to control the honey trade, as against the consumer and directly in the interests of such organized monopoly. In fact, so far as our commission honey dealers at this date are concerned, it almost amounts to the same thing; a few of whom have control of the trade now in their locality, and we often hear of sad complaints from parties who make consignments, failing to receive enough in return to pay ordinary expenses of production.
Battle Ground, © Ind.

Well done, friend Hicks, you need no combination to boom price for you. We wonder how many more of our bee-friends will see the necessity of establishing a home market, by allowing no person, whether rich or poor, to go without a supply of honey, at all times of the year, if effort, honest dealing and good honey will secure it. Bee-keepers have been giving their attention too much to cities and towns, and allowing the rural population to go without. We have never known an instance, where the proper effort was put forth and the best management adopted, that honey could not be sold in much larger quantities. There is not one quarter of our territory where honey might be sold, occupied to-day. In one district where a house-to-house canvass is being practiced, the sales are increasing at every round; in fact the canvasser is himself astonished at the large quantities he is able to sell, and after paying the ordinary wholesale price for it, finds he can make more money in that way than he could by hiring by the day or month. Of course he is well suited to his occupation. How many thousands of ladies and gentlemen have we idle at the present time, or earning very small wages, who, if they could embark in the sale of honey and apply themselves with the same diligence, might secure a much better living? and who could refuse to buy honey from a lady? Any who embark in this business and en-

deavor to succeed, will be conferring a benefit on the bee-keeping public. What you say in reference to placing our honey in the hands of men who adulterate, cannot be put too strongly, for, no doubt, great injury is done to our market by these men. It is quite a common thing in London to see large shipments of honey from America and other places sold at 3 to 5 cents per pound.—ED. C. B. J.

[There are two sides to all debatable subjects. The above presents good reasons for doing what the AMERICAN BEE JOURNAL has for years advised—that of building up local markets in every village and hamlet in America, and we still believe that to be the true solution of the difficulty.—ED.]

From Gleanings.

Gilbert M. Doolittle.

A NEIGHBOR.

G. M. Doolittle was born April 14, 1846, near his present location, in the town of Spafford, Onondaga County, New York. His parents were natives of Connecticut, and moved to this State a few years before he was born; hence the thoroughness, energy and activity of the "Yankee" are largely manifested in the subject of this sketch. From his earliest youth, Mr. D. has been an admirer of the busy bee, taking great interest in them when kept by his father. Later on, nearly all the bees in this section of country perished with foul brood, so that from 1856 to 1862 a colony of bees was a rarity. After this the disease

seemed to abate, so that, in 1868, bees were quite common again.

As 1868 was a splendid honey season, bee-talk was rife in this locality, which again brought to life old ambitions which had been crushed out by the former loss by disease among the bees, so that the spring of 1869 found Mr. D. with 2 colonies of bees of his own, as the starting-point to his present apiary. Wishing to know for himself all of the minutiae of this (to him) interesting pursuit, he procured nearly all the bee-books of that day, and subscribed for the bee-papers. As his ambition led him toward the practical side of bee-keeping, Quinby's "Mysteries of Bee-Keeping Explained" was his favorite, the pages of which were as familiar to him as a nursery rhyme. His intense desire to learn and investigate the bees in

claiming that around the queen centered all there was in bee-keeping, which has caused the subject of this sketch to study along the line of queen-rearing to a much larger extent than any other part of this interesting pursuit, and it is believed by him that much of his success as a honey-producer has come from this, and his ever-anxious care to get the hive filled with brood at such a time that there would be multitudes of field-bees at the opening of the honey harvest.

[Mr. G. M. Doolittle, whose likeness is on this page, is one of the most successful and practical of American bee-keepers, and has a world-wide reputation as such. He is well-known as a writer for all the American bee-periodicals, and faithfully gives his plans and methods to the public year after year. He is genial and companionable, and one of America's sons that she is proud to own and honor.—ED.]

For the American Bee Journal

Sections Filled with Comb.

C. H. DIBBERN.

I have carefully read the articles of Mr. Hutchinson, on page 200, and Mr. Thielmann, on page 201. Mr. Hutchinson has hit the nail on the head squarely, when he says: "I can think of one reason why honey stored in drawn comb might remain longer unsealed, than that stored in foundation, that was drawn but slightly in advance of the filling; i. e., the drawing out and filling were both in progress at the same time. The opportunity for ripening is greater when the honey is not very deep in the cells." That is just the conclusion I came to, after years of experimenting. But the fact, that honey stored in full, drawn comb is more apt to sour than that built by the bees or drawn from foundation, is not my only objection to the use of such combs.

In an apiary that is run on correct principles, there will be few or no combs built during the white honey harvest to carry over to another year to be refilled. Then it is the combs mainly built late in the season that are extracted and carried over. Now it is well known that comb partakes largely of the color of the flowers on which the bees are working at the time. Such combs are usually dark or yellow, and heavier than those built in the white clover season. Then, too, the wood of the sections is always more or less soiled, either by propolis, honey that has leaked out, dust, bleached out by light, or stained by getting wet. It is almost impossible to get such sections to look as neat and clean as new ones.

Mr. Thielmann seems to think that my trouble with old comb arises from the fact that I did not have the bees clean them up immediately after extracting. Now if this was the one

every particular has been such that he has dreamed of them at night, and thought of them in his working hours to almost an absorbing extent, and to-day he is still a student, believing that there are many unexplored regions, and much room for the deepest thought, even on the practical part of this pursuit.

In the first years of his apicultural study, Elisha Gallup, then living in Iowa, gave him by letter much practical instruction, which, together with Gallup's articles in the different papers of that time, so grew into his life that he went by the name of "Gallup" among bee-keepers about him for several years; and to-day he is often heard to say that there never has, to his mind, been a greater man in the realm of bee-keeping than E. Gallup. Gallup, in his private letters, laid great stress on good queens,

thing needful, then Mr. Thielmann and other writers should always state this, as other wise bee-keepers, who have not "progressed" as far as he thinks he has, might ruin their honey crop, as he admits that honey will sour in the combs unless cleaned by the bees the previous fall. Well, I tried that plan some years ago, but I could see no difference between combs cleaned up by the bees in the fall, or cleaned but by the bees in the spring, as they will clean them up thoroughly before they will put a single drop in. I also found it a nice job to get the bees out of the sections a second time in the fall. Sometimes they would literally pack themselves into these empty combs, and neither smoke nor shaking had much effect on the benumbed bees, during cool days. Now as I could see no particular advantage of fall-cleaned-up combs over spring-cleaned ones, I concluded that this extra work was very much like "puttering."

My only object in calling attention to this subject is to induce bee-keepers to be more particular, and produce a better quality of honey. Since I have discarded the use of old combs, I use nothing but new white wood sections, with separators between each comb, I have built up a demand for my honey that is far beyond my ability to supply. During the past season I could have sold many thousands of pounds after my 10,000 was gone, could I have obtained such honey as I produced.

Mr. Thielmann seems to think that I could not distinguish the sections that had been filled with old comb, but I venture to say that with me, nine out of ten would grade "No. 2." Mr. T. says that in extracting he shaves down all uneven or bulged combs, which shows he does not use separators, another fatal defect in a progressive bee-keeper. Now if he would shave these combs down so they would not be over $\frac{1}{4}$ -inch thick, it would be about equal to good foundation, and would do away largely to my objections to old comb.

Mr. T. makes one extraordinary statement, viz: "Many times the bees will fill a case before they would enter one with only foundation in the sections." Now I will admit that the bees will fill the empty combs a little quicker, but when filled they seem to hesitate about sealing it up, seeming to know that it is not sufficiently ripened to be capped. I have watched combs, side by side on the same hive, one of foundation and the other comb, and the first would have every cell capped the soonest. Indeed, the bees often persistently refuse to cap cells near the wood at all, in these comb-filled sections.

I am glad that I have attracted attention to this subject; we want to get at the truth of the matter. I want to hear from Mr. Heddon, Dr. Miller, Mr. Pond, and also further from Mr. Doolittle, Mr. Dadant and others. I have no interest in the matter, only that I desire the production of the very best comb honey. The trouble is in old sections and combs; we first use the best, and

soon those that are not so good, and by-and-by we are found using the bad. We all know the result—dirty sections, bulged combs, honey souring and running all over everything, disgusting dealers, low prices, dissatisfied consumers, and "blue" bee-keepers.

Milan, Ills.

Irish Farmers' Gazette.

Races of the Honey-Bee.

H. W. LETT, M. A.

I submit the following description of ten different varieties of the *Apis mellifica* which are kept in hives:

I—BLACK OR BROWN—The ordinary hive-bee or honey-bee, called by the way of distinction, the black or brown, from being almost one uniform brown-black color, with slight indications of paler bands on the abdomen, and clothed with grayish brown hairs. Until within the last fifteen years, no other bee was known in north or west Europe. This bee, after escaping, has made itself wild in the American and New Zealand woods.

II—ITALIAN ALP—The Italian Alp bee, sometimes called Ligurian, is indigenous to the mountainous district that lies in the north of Italy round about the lakes Maggiore and Como. It is of a light orange yellow color, with two orange red bands on the abdomen, and is longer and more slender than the black. They are better honey gatherers, more hardy and prolific, and very courageous in defending their own hives, even from the ravages of the wax-moth.

III—CYPRIAN—The Cyprians are natives of Cyprus and part of Turkey in Asia. They are yellow, quite slender, wasp-like, and smaller than Italians. They always have a yellow shield mark on the back between the wings. They are strong, excellent honey gatherers, winter better than any other race, and are proof against being robbed by other bees. But they are easily excited, and most revengeful stingers.

IV—SYRIAN—The Syrian bees are found on that part of Asiatic Turkey which lies north of Mount Carmel. They are of the same size, qualities, and temper as the Cyprians, from which they differ in showing less yellow, and being on the whole of a grayer color over their whole bodies. They are quite distinct from the next variety.

V—HOLY LAND—The Holy Land, or as the natives call them, the Holy Bees, are found in Palestine, south of Mount Carmel. They are marked like the Cyprians, but their hair is so light in color they appear to be beautifully striped. Their size is smaller than Italians, but larger than Cyprians. They are very active and far-flying, most wonderful cell builders, and get honey from red clover; but they are ready to sting, become furious at the least smoke, and run off their combs when one is lifted from the hive.

VI—TUNISIAN—Tunis, on the north of Africa, has a peculiar race of bees. They are the same in size as the Cyprian and Syrian, but their color is dark brown—even darker than the common black or brown. They are active workers, keep on the combs when being handled, and bear smoke better than other Eastern races; but they are liable to attack a person coming near them, even though not interfered with.

VII—CARNIOLAN—The Carniolan bees are natives of Carniola, in South Austria. They are longer and thicker than the black or brown, being the largest domesticated European bee. The color is a rich, dark brown, nearly black, while each ring of the abdomen is clearly marked by whitish-gray hairs, giving it a silvery look. They are equal to Italians in honey gathering, fecundity and hardness, while they are of a most remarkably gentle disposition, never attacking the manipulator, except when they are treated with improper roughness.

VIII—HUNGARIAN—The bees peculiar to Hungary are the same size of, but far blacker than the common brown. They are very fair honey gatherers, and as gentle as Italians, but their propensity to swarm renders them very uncertain and unprofitable.

IX—EGYPTIAN—The Egyptian bees are like Syrians in size, but quite yellow, like the Italians. They abound, both wild and in domestication, along the valley of the Nile, and while famed for good honey gathering qualities, are without exception the most ferocious bees known outside of India.

X—SOUTH AFRICAN—There is an excellent race of bees, both wild and hived, in the Cape Colony, which it is to be hoped will soon be introduced to our bee-keepers. They are the size and color of Italians, but grayer, while they are more tractable, and at the same time very prolific, and of remarkable working powers; where honey is to be gathered, they keep at it early and late, and often are at work even by moonlight.

It is from the best of these races that the advanced bee-keepers of the world are now endeavoring to concentrate in one strain those characteristics which commend themselves as desirable in the best bred bee. And it may be safely stated that the honey-bee of the future will be as superior to the bees known to us twenty years ago, as a pure Shorthorn is to an old brindled cow.

County Down, Ireland.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

SELECTIONS FROM OUR LETTER BOX

Successful Wintering of Bees.—I.
 A. Travis, Lyons, Wis., on April 13, 1887, says :

I put in the cellar last fall 110 colonies of bees, and on April 2, 1887, I took out 109 colonies, all in good condition. The one that died, starved but a few days before I put them out. Is this not doing well ?

Feeding Honey in Musty Combs.—
 A Subscriber at Prophetstown, Ills., asks the following :

I have lost several colonies of bees from diarrhea, their combs being left in a musty, bad condition. Is there any danger of the bees contracting disease, if this honey is fed to healthy colonies ?

[No; it will be as good as any for spring feeding.—ED.]

**Gathering Pollen.—S. Burton, Eu-
 reka, Ills., on April 16, 1887, says :**

My bees have wintered on the summer stands all right, except one colony that I neglected to pack as I did the others. I had 15 colonies, and I now have 14 that are good and strong. They have been gathering natural pollen for several days. My bees are pure Italians, hybrids and blacks, in separate hives.

**Spring Protection of Bees.—Mrs.
 H. Hills, Sheboygan Falls, Wis., on
 April 14, 1887, says :**

If the Rev. Wm. F. Clarke could look in my hives to-day, he would see how the uninstructed mind was obliged to solve that problem, "spring protection," and did succeed in "killing two birds with one stone," by securing, at the same time, "contraction of the brood-chamber." I had 2-inch chaff division-boards at both sides and ends of ordinary Simplicity

hives, with frames crosswise, and frames hung lengthwise in winter and spring. It took all my first year to climb that (to me) almost insurmountable obstacle. The plan involves a world of work and bother, but it is perfectly successful. No dead bees or moldy combs are in the hives, and no spring dwindling!

Building up Starving Colonies.—
 T. F. Kinsel, Shiloh, Ohio, on April 14, 1887, says :

Last fall when putting my bees into the cellar I found 8 weak, light colonies. These were set aside by themselves, so they could be fed, if necessary. The middle of February I made an examination and found these 8 colonies starving. I took a frame of sealed white clover and basswood honey and inserted it in the centre of the cluster. They soon became quiet again, and are as good to-day (put out of the cellar on April 2, and on April 8 I finished) as any. All my bees spotted their hives when put out; these 8 certainly no more than the others. My cellar can be kept at 35° to 42° Fabr. All the colonies had brood when put out of the cellar, and some of it was capped.

**Swarming Expected Soon.—F. L.
 Merrick, Waldron, Ills., on April
 14, 1887, says :**

My bees were packed on the summer stands, and all came through the winter in fine condition. They are bringing in pollen lively. They had an abundance of honey, but I commenced feeding in February. I think some of them will swarm within 30 days.

**Wintered without Loss.—L. Reed,
 Orono, Mich., on April 14, 1887,
 writes :**

On Nov. 15, 1886, I put 54 colonies of bees into the cellar in good condition. I have been putting them out, a few at a time, since April 9; to-day I put the last out, all having come through in splendid condition—no disease, no light colonies, and all strong in bees. We have had a steady winter, with sleighing up to April 1. We are having nice weather now, the mercury being up to 70° in the shade to-day, and has been there a few days before. Bees are carrying in pollen to-day. White clover is starting nicely, and prospects for a good honey season are fair.

**Favorable Spring for Bees.—Mrs.
 L. C. Axtell, Roseville, Ills., on
 April 14, 1887, writes :**

My 202 colonies of bees are in fine condition for this time in the spring. Five colonies were lost from out-door wintering, but all except one that was stolen was due to carelessness in preparing them, as all that were prepared properly, and had queens, are in good condition. There was no loss in the cellar-wintering of 113 colonies; 4 are queenless, but fair colo-

nies, and I shall not unite them with others, but supply them with eggs from other colonies, as I shall soon need to make up nuclei, and they are fair colonies. I secure excellent results in giving a space of an inch or more below the brood-combs in winter, as then they never get clogged up as they formerly did. Of those wintered in the cellar, we raise the front board of the hive, giving a large entrance. The bees taken out of the cellar on March 1 have from 3 to 4 combs of capped brood, and plenty of bees to keep them warm. Those just taken from the cellar have but very little brood, and about the same number of bees. This spring has been very favorable to putting bees out early, as there has been but very little severe weather since March 1.

**Disagreeable Weather, etc.—Abe
 Hoke, Union City, Ind., on April 19,
 1887, says :**

This is a beautiful morning; but yesterday was a very disagreeable day, as it snowed all the afternoon. It was cold last night; the snow was 3 inches deep. In my letter on page 235, I am made to say that I had not lost an entire colony in three winters. It should have read, "in three winters in straw hives;" for I lost 13 colonies in wooden hives during the winter of 1885-86, which I reported to the BEE JOURNAL.

["In straw hives" was omitted, by an oversight of the printer.—ED.]

Honey and Pollen Yielding Trees.
 —In reply to a question in a private letter from Mrs. H. Hills, of Wisconsin, in regard to alder, soft maple and poplar yielding honey and pollen, Prof. A. J. Cook says :

The alder yields some honey and much pollen. The maples—all of them—yield richly of both honey and pollen. Had we populous colonies at this season of the year, we should find the maples among our best honey-plants. Poplars and willows certainly furnish nectar as well as pollen.

**My Experience with Bees.—Frank
 Andrews, Smethport, Pa., on April
 18, 1887, writes :**

I commenced keeping bees in 1882; got my start by taking 4 colonies on shares. I kept them only one year, as the owner would not furnish half the hives. We divided them, and I had 3 colonies of my own in the spring of 1883. The spring of 1886 I had 22 colonies, and last fall I had 42, and 2,756 pounds of honey, about half of it being comb honey in one-pound sections. I have lost no bees in wintering, had one colony given to me, and now have 43 very strong colonies. I winter my bees on the summer stands, and do all feeding in the fall. I keep them as warm as possible through the winter and spring until they swarm. I obtained 185 one-pound sections of honey from one

colony; this being the largest amount from one colony ever secured in this locality. This colony is a black one; I got it 2 years ago last September from a tree which had been cut down and the honey removed. Their queen is still alive. The colony has never swarmed. I have 12 of this queen's daughters; they are very gentle. I also have Italians and Holy Land bees, but none of them ever produced more than 124 pounds of honey. The Holy Land queens mated with black drones are the crosest bees I ever saw. I have one colony that I always chloroform. I worked them for extracted honey last year, and the honey of this one colony sold for over \$20. I shall kill the queen of this colony if I can ever find her again.

Losses of Bees in New York.—O. L. Whitcomb, Argyle, N. Y., on April 15, 1887, says:

There is a fearful mortality among bees in this section this winter. Our cold weather and snow covers a period of 5 months already, with May to hear from. I started in the fall with 8 colonies, and have 2 colonies left. "Eighty colonies out of 150" is one man's loss within two miles—a discouraging outlook.

The Cappings over Honey.—C. P. Dadant, Hamilton, Ills., writes:

Mr. Hutchinson (on page 232) now bases his arguments, mainly, on the reports of some distinguished apiarists who found "honey so thickened that it did not fill the cell more than half full." I do not wish to be understood as disputing this statement, but I do say that I believe it comes from mistaken observations. Let Mr. Hutchinson take a can full of honey, no matter how thin, when sealed by the bees, and whenever he succeeds in evaporating it, by whatever process, until the can is only half full, I will silently, and willingly, give up.

Bees Packed in Sawdust.—W. Z. Hutchinson, Rogersville, Mich., on April 14, 1887, says:

Bees have come through in excellent condition. I have 110 colonies; 80 are packed in sawdust, as recommended in the first chapter of my little book.

Protecting Sections from Propolis.—Mr. J. J. Roe, Buchanan, Mich., writes:

While taking off honey last summer I saw the desirability of a section-case which would better protect the sections from propolis. I thought of a blank strip to correspond with the sections, and had some of that kind made. I then made up a hundred cases, and thought I would not give the invention to the public before testing it in my own apiary. This spring I received a catalogue from the dealers in bee-supplies, who made my cases, which advertised my invention. I thought *perhaps* the

dealers got the idea from the work they did for me. I thought I would get a patent, and so I sent a model to Washington. On page 232, Messrs. J. W. Powell & Son have illustrated almost exactly my invention. My case is reversible, and for Simplicity of construction I do not think it can be excelled. If Messrs. Powell & Son invented their case before I did mine, I willingly make my bow to them; if not, will they please make theirs, etc.

[It is only a waste of money to attempt to patent the "blank strip to correspond with the sections," to keep the sections free from propolis. As we stated in an editorial item on page 147 of the AMERICAN BEE JOURNAL for March 9, 1887, we have several of such "protecting strips," in different patterns, in our Museum, which have been there for years, and antedate both Mr. Roe and Messrs. Powell & Son—the only difference being the use of one of these strips at the top as well as on the bottom of the "cases" by Messrs. Powell & Son. The "cases" in our Museum were each described in the BEE JOURNAL, when received.—ED.]

White Clover in Bloom, etc.—John H. Christie, Dyersburg, Tenn., on April 18, 1887, writes:

Bees have wintered pretty well in this part of Tennessee. The winter has been very mild. My bees brought in pollen on Jan. 31. They got along very well until the last cold spell, then the most of the colonies stopped breeding, and some of them run short of stores so that I had to feed them some. I have had 4 swarms so far, all from one colony. It cast the first swarm on April 2, then one on April 10, another on April 12, and the last on April 14. They are about $\frac{3}{4}$ Italians. I saved all of the swarms, and they are all doing well. I have heard of a good many swarms throughout the country; I had ripe strawberries on April 15, and saw some white clover bloom to-day—both in the open country. I am 68 years old to-day, and have kept bees about 25 years. I have about 100 colonies in all.

Two Feet of Snow on the Ground.—J. F. Latham, Cumberland, Me., on April 14, 1887, writes:

At this date there is a greater body of snow on the ground than I have ever known at any corresponding date before. Although bare spots are beginning to appear in the open land, there is still about 2 feet of snow in the woods. The past winter has been of unusual severity, cold and blustering. Feb. 9 was fair and mild, as was also Feb. 16 and 19; then it was very severe until March 12, when it began to moderate again. On March 13 and 14 all of my colonies of bees, that seemed to need it, enjoyed a cleansing flight. About a dozen colonies

remained quiet. Three colonies have evinced no desire to fly during the winter, but are apparently in a most satisfactory condition, dry, cozy and comfortable. Six colonies soiled the entrances to their hives before their flight, but not badly. Everything considered, I am well satisfied with the status of all of my colonies at the present time, as they have been working "with a will" on rye-meal for the past five days, from every hive. Pollen on the willows is beginning to make its appearance, which makes me feel like reporting "50—50," but as it is I will wait until spring, and then see how many colonies I have.

No Rain for Two Years.—W. G. Ponton, Corwin, Tex., on April 9, 1887, writes:

"Texas against the world for honey," is what one of our Lone Star bee-keepers has said. I really do not know whether this is correct or not, but I would state it thus: Texas against the world for drouth. We have not had a good rain since the spring of 1885, and 1887 is coming in more gloomy than ever. Wheat and oats are considered a complete failure; there is yet hope for corn, should we get a good rain this month, and yet, considering the great drouth, bees are doing remarkably well, owing to the peculiar flora of this country, which makes it *par excellence* for the production of honey. All we need is enterprising apiarists. Bee-Keeping is conducted here according to the log-gum system. Every Saturday a very spicy visitor calls about 11 a.m., in the shape of the AMERICAN BEE JOURNAL, heaping full of good news.

Wintered Well in the Cellar.—F. A. Gibson, Racine, Wis., on April 18, 1887, writes:

My bees have wintered in splendid condition, having lost none. They were confined from last Thanksgiving Day to April 9, without having a flight. They did not spot the hives any when put out. There were such large clusters of bees hanging from the combs that I had to shake them off to get the bottom-boards on. They commenced carrying in pollen the next day after being put out. The temperature was at 41° in my cellar when I put them in, and continued so until I removed the bees. The cellar is under the honey-house, bricked up, with an air-space all around it, and 10 inches of sawdust on top, between two floors. The bottom floor is of cement, closed by double doors from outside.

The Western World Guide and Handbook of Useful Information, contains the greatest amount of useful information ever put together in such a cheap form. The printing, paper, and binding are excellent, and the book is well worth a dollar. To any one sending us two new subscribers besides his own, with \$3.00, for one year, we will present a copy of this valuable book.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for a year, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x1¼ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

System and Success.

☞ All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

Leaflet No. 2, entitled "Alsike Clover for Pasturage and Hay," is now ready for delivery. This should be scattered into every neighborhood, in order to induce farmers to plant Alsike, that the bees may have the advantage of it for pasturage. We send them by mail 50 copies for 30 cents; 100 for 50 cents; 500 for \$2.25—all postpaid. It will pay bee-keepers to scatter these Leaflets, even if 9 out of 10 avail nothing. If ten farmers out of a hundred plant Alsike in any neighborhood, the bees will reap a very substantial reward.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the **AMERICAN BEE JOURNAL** for one year, will be clubbed for \$1.25.

The Production of Comb Honey, as practiced and advised by W. Z. Hutchinson, can be obtained at this office, for 25 cts.

☞ **Sample Copies** of the **BEE JOURNAL** will be sent **FREE** upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Do you Want a Farm Account Book? We have a few left, and make you a *very tempting offer*. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the **Weekly BEE JOURNAL** for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal1 00..	1 00..
and Gleanings in Bee-Culture2 00..	1 75
Bee-Keepers' Magazine1 25..	1 25

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the **BEE JOURNAL**. It is now so *cheap* that no one can afford to do without it. We will present a **Binder** for the **BEE JOURNAL** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

By Using the Binder made expressly for this **BEE JOURNAL**, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Dr. Miller's Book, "A Year Among the Bees," and the **BEE JOURNAL** for one year, we will club for \$1.50.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax :

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12½@13c.—**BEESWAX**,—25c. R. A. BURNETT, 161 South Water St. Mar. 28.

DETROIT.

HONEY.—Best white comb, 11@12c. Market is improving.
BEESWAX,—23c. Apr. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4@4½ cts. Comb, white, 7@13c. Market firm.
BEESWAX,—Scarce at 19@22c. Apr. 4. SCHACHT & LEMCKE, 122-124 Davis St.

CLEVELAND.

HONEY.—Choice white in 1-lb. sections, 12@13c.; second quality, 10@11c.; and buckwheat unsalable at 8@9c. Extracted, 3@6c.
BEESWAX,—25c. Apr. 20. A. C. KENDEL, 115 Ontario St.

ST. LOUIS.

HONEY.—Choice comb, 10@12c. Strained, in barrels, 3½@4½c. Extra fancy, 4 more than foregoing prices. Extracted, 3½@6c. Market dull.
BEESWAX,—Firm at 21c. for prime. Apr. 21. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: White comb, 12@14c.; amber, 7@9c. Extracted, white, 4½@5c.; light amber, 3½@4½c. Market quiet.
BEESWAX,—19@22c. Apr. 16. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 13@15c.; 2-pounds at 11@13c. Extracted, 5@7c. Sales slow.
BEESWAX,—23 cts. per lb. Apr. 22. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 3@7c. per lb. Best comb brings 11@14c. per lb. Demand fair.
BEESWAX,—Good demand, —20@23c. per lb. for good to choice yellow. Apr. 21. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 11@12c.; 2-lbs., 10@11c. No call for dark. White extracted, in barrels and kegs, 8@6½c.; in small packages, 6½@7c.; dark, in barrels and kegs, 4@5c.—Demand good.
BEESWAX,—25c. Mar. 28. A. V. BISHOP, 142 W. Water St.

Convention Notices.

W. Z. HUTCHINSON,

Rogersville, Genesee Co., Mich.,

HAS the permission of the writer to publish the following:

"Forest City, Iowa, March 28, 1887.

"W. Z. Hutchinson, Rogersville, Mich.—Dear Sir, and Friend: I am in receipt of your pamphlet—'The Production of Comb Honey.' It is the nearest little thing I have seen lately. As a work of art it is as near perfection as printers in 'country offices' usually attain to. I venture the opinion that that cover was the work of a bee-keeper, or at least originated in his (your) creative brain. Nobody but a bee-keeper would have thought of such a unique and appropriate covering. The subject is treated in a very readable and creditable manner. I have been practicing substantially the same method, except the non-use of foundation. I shall try that this season.

Respectfully Yours, **EUGENE SECOR."**

☞ Reader, if you wish to enjoy the same pleasure as did Mr. Secor, send 25 cts., and a copy the book will be sent postpaid.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x18 "	8 00
For 3 " " 10x18 "	10 00
For 4 " " 10x18 "	14 00
For 2 frames of any size, 13x20 "	12 00
For 3 " " 13x20 "	12 00
For 4 " " 13x20 "	16 00

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIII. May 4, 1887. No. 18.

May shall make the world anew ;
Golden sun and silver dew—
Money, minted in the sky,
Shall the earth's new garments buy.

May shall make the orchard bloom ;
And the blossoms' fine perfume
Shall set all the honey-bees
Murmuring among the trees.

May shall make the bud appear
Like a jewel, crystal clear,
'Mid the leaves upon the limb
Where the robin lilted his hymn.

May shall make the wild-flowers tell
Where the shining snow-flakes fell ;
Just as though each snow-flake's heart,
By some secret, magic art,

Were transmitted to a flower
In the sunlight and the shower.
Is there such another, pray,
Wonder-making month as May ?
—St. Nicholas.

Mons. Eugene Francois Jonas, father of the late celebrated Leon Jonas, died at Amiens, France, on March 27, and was buried on the 30th. He was the oldest member of the Apicultural Society of the Department of the Somme, France, and is deeply mourned by his numerous friends and acquaintances in Northern France.

Promptness and Regularity.—Mr. Charles Solveson, of Nashotah, Wis., on April 24, 1887, writes us as follows :

Last week's BEE JOURNAL was lost in the mails. Please send another. It is the first one that failed to arrive at our office in time during the past six years. It is the most "regular" periodical to arrive, of all that I ever subscribed for.

Should a number fail to come on time, we hope our subscribers will notify us at once, and we will with pleasure send another copy. If this is neglected for months, we may not have any left to send another.

Our systematic care in mailing, and promptness in putting them into the post-office here, are the causes of every copy arriving by just the same train on the same day, every week. Our subscribers know just when to expect them, and are but rarely disappointed—once in half a dozen years or so ! We do not think that one in a thousand goes astray or is lost ! So perfect are the postal facilities in America.

Price Lists are received from J. P. Moore, Morgan, Ky. (Bees) ; J. B. Hains, Bedford, O. (Bees and Supplies) ; A. G. Hill, Kendallville, Ind. (Bees and Supplies.)

Not Over-Production! but imperfect distribution, is the cause of low prices and slow sale of honey ! This we have many times stated in these columns, and we do not fear any contradiction of the position we have taken. As corroborative evidence, we would ask the reader to refer to the article of Mr. W. Z. Hutchinson, on pages 280 and 281 of this issue.

In reference to our suggestion to defer the proposed convention on marketing our crops of honey, until early in the fall, Mr. H. says :

I think that Mr. Newman's suggestion, on page 227, is a good one, viz : to defer holding a convention until the meeting of the North American Bee-Keepers' Society, next fall, in Chicago. As Secretary of this Society, I would suggest that at least one day (and the best day at that) be devoted at the next meeting to a discussion of this vital topic.

We fully endorse this suggestion, and refer it to the President, Dr. Miller, who, in the absence of any objection, we think will "declare" that to be the decision of the Executive Board of the society, and provide for the full discussion of the items named by the Secretary, viz : "the cost of production, prices at which honey can be sold at a profit, methods of putting up honey, commission men, cash buyers, home markets, city markets, foreign markets, development of markets, distribution of our products, associations, corners, etc."

Then let us have a full attendance of representative apiarists, and give the matter an exhaustive discussion. There is time enough between this and the meeting, for every one to perfect plans of thought in order to present *matured* projects for deliberation.

Dispensing with Middle-men.—At a recent meeting in London, Mr. Jones opened a discussion upon the co-operative distribution of the products of the farm.

Mr. Jones, like others who deal with the subject rationally, did not call for the extermination of all present distributors ; but he contended, and with reason, that there was a superfluity of middle-men, and that the producer and the consumer stood at the opposite ends of a line of persons who handed the goods from one to the other, each taking a bite on the way. The consequence was an enormous disparity between the price paid by the consumer, and the price the producer got for it.

Apiarists should place themselves in a position where they can use the middle-men to their own advantage—not allowing them to *make prices* for honey, or compete with one another to break down rates already established, but to handle the product under the supervision of competent apiarists who are cognizant of the amount produced, the state of the market, and the prices it should bring at wholesale and retail. The producers of the world seem to be awaking up to the magnitude of the work before them. "Let there be light !"

"I want to look at a pair of eye-glasses, sir, of extra magnifying power." Dealer—"Yes, ma'am ; something very strong?" "Yes, sir ; while visiting in the country last summer I made a very painful blunder, which I never want to repeat." "May I ask what that—er—blunder was?" "Oh, yes ; I mistook a bumble-bee for a blackberry."

Falsely Accused.—The poor bees seem to be arraigned almost daily upon some trumped-up charge. While it is annoying to have it so, yet it is in the interest of the pursuit, rather than otherwise. Any attorney will admit that he enjoys the work of proving that a charge made against his client is "false and malicious." So is it in the case of the bees—the more unreasonable the things charged against them, the better does the case appear to all thinking and honorable persons !

In the BEE JOURNAL for April 20, page 243, we recorded the charge made by Dr. B. F. Dunkley, that the bees *ate out the hickory pins* with which he secured the combs to the frames. Now, on page 279, some malicious person has charged the bees of Mr. Clark, in Arkadelphia, Ark., with *eating up his young ducks !!* as well as eating up the peaches !

This is making the thing ridiculous enough ! Were it not for the friendly action of insects to fertilize the flowers of fruit trees, there would be no fruit ! Bees are the fruit-growers' best friends ; but instead of appreciating their services, some of them are abusing the bees, and trying to prejudice mankind in general against them !

Middle-men are getting into diarepute. The peach-growers as well as honey-producers are now wreatling with the subject of marketing their products without the aid of commission men. The peach-growers are to meet at Dover, Del., on Thursday, May 12, 1887. The call sets forth the object of the meeting thus :

There is now a prospect of a most abundant crop of peaches, and it behooves us to use timely action to have it properly distributed throughout the country. If sent to a few large cities a glut in those markets must necessarily ensue. We are as competent to place our fruit in the right market as the city commission men, and by a wise and judicious distribution to avoid the disastrous evils of low prices by overstocking a few places. Many other questions conducive to our interests will come before this convention, such as the invitation of dealers to buy directly of us at home, the establishment of a fruit market of our own in New York and other places.

We must have lower freights. We must develop more new markets. We must imitate all the great and successful industries of our country by co-operating with each other for our own good. We must cease shipping at hazard. We must have system.

Men of Honor.—An old mercantile authority says that a man violates the laws of honor when he takes advantage of another's unskillfulness or inexperience, or the technicalities of the law, to impose on him. A man acts dishonorably when he does not make sacrifices to pay his debts promptly ; when he sells below the market price to get away his neighbor's customers ; and in all cases in which he does acts which if thoroughly understood, would tend to lower him in the estimation of his customers, or any good man.

Tried by this standard, how many dishonorable persons exist, even in apiarian circles, and yet, is it not a fair statement of the case? Men of *honor* and sterling *integrity* are always at a premium in every pursuit ! Their opinions and advice are ever of value, and worthy of the generation and country in which they live !

Our Queries

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Honey in Brood-Frames or Sections.

Query 412.—All other conditions being equal, how much more comb honey will one colony or 50 colonies of bees store in brood-frames than in one-pound sections?—Ohio.

Not any.—JAMES HEDDON.

In the way you state it, there is no difference.—C. W. DAYTON.

I do not think they would store any more.—W. Z. HUTCHINSON.

They will not store a pound more if side-opening sections are used.—G. L. TINKER.

If the sections are properly adjusted, the difference in quantity of honey will not be much; though "how much more" is difficult to determine.—J. P. H. BROWN.

It will depend upon the bees; some colonies will work much better in sections than others.—H. D. CUTTING.

There is not enough to make up the difference in price that it would have to be sold at; or to pay for cutting it out and fitting it into sections, as some do.—G. M. DOOLITTLE.

I have no means of knowing for certain, but should guess there would be no great difference.—C. C. MILLER.

With an expert, no more; with a novice, often a third more, or even sometimes a much greater per cent.—A. J. COOK.

This is an impracticable question. Different seasons and localities will so operate that no answer of value can be given. As a rule, double the honey is stored in the frames here. Mr. Heddon does not find much if any difference in his locality.—J. E. POND.

I have never tried the experiment in the way you suggest. If you mean that the bees must build the combs in the brood-frames as well as in the sections, there will be but little difference, and the little difference will be in favor of the sections; because bees store honey with the greatest economy in thick store combs.—G. W. DEMAREE.

In cool seasons the difference is not very great. In hot seasons here, with a short crop, we have known the bees to refuse altogether to work in the sections. Some of our Eastern bee-keepers have a different experience, probably owing to the difference of the climate. At any rate no rule can

be laid down. Much depends upon ventilation in hot weather.—DADANT & SON.

If the bees are to build the combs, there may be some difficulty in getting them to work in the sections in cool seasons. If combs or foundation are supplied in each place, and if the season is warm and honey is plenty, there will be no difference.—THE EDITOR.

New or Old Combs for Winter.

Query 413.—Will bees winter better on old than on new combs?

I think not.—G. L. TINKER.

I think they will.—C. C. MILLER.

There is no difference.—C. W. DAYTON.

I have seen no evidence in that direction.—W. Z. HUTCHINSON.

I see no reason why they should.—A. J. COOK.

We have never seen any difference.—DADANT & SON.

I prefer combs that have contained several litters of brood hatched in them.—J. P. H. BROWN.

Probably yes, if any difference; but this is the "gnat" and not the "camel" in the case.—JAMES HEDDON.

It is generally thought they will, but I do not know this to be a fact.—G. M. DOOLITTLE.

On old combs; and for the reason that they are warmer and stronger. The reason is obvious to all.—J. E. POND.

It is laid down that bees will winter better on old combs. For my part I have seen no difference.—H. D. CUTTING.

I have never seen any difference, if they fare alike as to quarters and stores. I used to winter many colonies that not only had new combs, but part of them were built only part of the way down.—G. W. DEMAREE.

We do not see why there should be any difference.—THE EDITOR.

Extracting from the Brood-Chamber.

Query 414.—Is it essential to extract from the brood-chamber in the production of comb honey?—T. P., Va.

No.—J. P. H. BROWN.

No.—G. L. TINKER.

No.—W. Z. HUTCHINSON.

No.—C. C. MILLER.

No.—A. J. COOK.

I seldom do.—H. D. CUTTING.

It is not, in proper management.—C. W. DAYTON.

I never take honey from the brood-chamber unless I have a special purpose for so doing. A brood-chamber full of brood and honey will give as good results as if the entire brood-chamber is full of brood alone, and I

much prefer that condition of things, though many others think differently. To have an apiary in a starving condition at the close of the honey season, is the greatest misfortune that can well be imagined, even though a large honey crop has been harvested.—G. W. DEMAREE.

No. I never do, and any arrangement requiring such extracting to be done, I should consider very faulty.—G. M. DOOLITTLE.

No rule can be established, for much depends upon the season. We would advise to extract only if the bees are crowded for breeding room.—DADANT & SON.

No. Neither is it advisable. It complicates and increases labor, and does the bees and brood no good, to say the least.—JAMES HEDDON.

Much depends. Prevention of excessive swarming is a necessity to a large yield of comb honey, and the particular circumstances of each individual case must govern. No rule can be given that will apply to all cases or conditions; care and judgment must be used in the matter.—J. E. POND.

It is neither essential nor desirable to do so.—THE EDITOR.

Convention Notices.

The next regular meeting of the Cortland Union Bee-Keepers' Association will be held in Union Hall at Cortland, N. Y., on May 10, 1887.
D. F. SHATTUCK, Sec.

The next meeting of the West Lake Shore Central Bee-Keepers' Association will be held on May 26, 1887, in Koekring Hall, at Kiel, Wis.
FRAN ZASTROW, Sec.

The May meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held at Rockton, Ill., on Tuesday, May 24, 1887.
D. A. FULLER, Sec.

The Keystone Bee-Keepers' Association will hold its next annual meeting on Tuesday, May 10, 1887, in the Court House at Scranton, Pa. All are welcome; come and bring your knotty questions. Interesting and instructive essays are promised by noted apiarists of the country.
ARTHUR A. CLARK, Sec.

The semi-annual meeting of the Progressive Bee-Keepers' Association will be held in the Town Hall at Bedford, O., on Thursday, May 5, 1887, at 10 a.m. Manufacturers of supplies for bee-keepers are requested to bring with them, or send, samples for exhibition. There will be a "picnic dinner." All interested in apiculture are cordially invited to be present.
MISS DEMA BENNETT, Sec.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them)

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Bees and Grapes—Some Observations.

G. M. DOOLITTLE.

For several years I have been interested in the discussion of the bee-and-grape question, and have many times wished I might add a few lines of proof that bees never injure sound grapes; but until the present season I had no grounds to work on, save that I had grape-vines scattered all through my bee-yard, yet bees had never attacked them. This and much which has been written on the subject is only negative proof that bees do not injure sound grapes. Negative proof is not what we want, but proof of a positive nature. During the past season I have had some experience along the line of bees eating grapes, and while it is not as positive proof in favor of the bees as I might wish for, yet it sheds some rays of light upon the subject.

On any warm afternoon during the month of September, a casual observer would have said, "Doolittle, your bees are destroying your grapes;" and at first I almost so believed myself, but after carefully watching I found out wherein the trouble lay. The Concord and Worden suffered the worst among the black varieties; the Agawam and Salem among the red, and the Lady and Belinda of the white. A close examination of all these revealed that the Concord, Worden and Belinda burst open during a damp night or warm, moist spell; for I would find scores of them at such times cracked about and near the stem of a fresh nature, so that I knew that no bees had been at work upon them the day before, while such examination was made early in the morning before the bees were out. This, of course, cleared the bees from doing aught but sucking the juice from the fruit, so that instead of being the cause, they came in as an effect.

But an examination of the Lady, Agawam and Salem, at first appeared to convict the bees; for on examination these tougher skinned varieties showed a triangular piece of skin of about 3-32 of an inch on each side torn right out of the side of hundreds of perfectly sound grapes. Through these holes the bees were putting their tongues and sucking or lapping up the sweet juices, for all of these grapes are very sweet. I carefully watched the grapes in the morning to see if any appeared freshly cut, as if it was done during the night, but none was so found, and at this time there was nothing on the grapes ex-

cept a few squash bugs or stink bugs, while a long time watching of these convinced me they were not the cause of the holes.

I next watched the bees, feeling almost sure that they did really bite open the grapes, but after watching a long time I failed to see one make any attempt at aught save sucking through holes already made. In fact I soon became convinced that they were not the cause, for where several were collected about one of these torn places, so that no more could get at them, others tried to push in, and failing, would run frantically about in search of some other opening, when to cut a hole through would have been but a short job, if such had been the object. Thus they would continue to run around over different grapes till a torn place was found not fully occupied.

So far I had watched in the forenoon, when the bees first came on the grapes, or had been on but an hour or two, thinking that if the torn places were the work of the bees, they would be more apt to commit their depredations at this time of the day. Finally I thought to watch about 2 o'clock, and later, when on almost the first bunch I looked at was a wasp, such as build paper nests about our houses wherever a secluded place affords shelter. Upon looking further I saw many of them, and a few moments watch gave me the privilege of seeing a grape torn open; for what purpose I could not tell, unless for mischief, for I failed to see any wasp act as if sucking the juice of the grape. They seemed to work upon the piece of torn skin for awhile, and then leave that grape and tear open another. If a bee came near, the wasp would put out a foot or bring out a wing and drive it away, so that no bee could get at a freshly-made hole until the wasp had left.

These wasps I have often seen about the entrances of the hives on warm October afternoons, where they will sit and keep the bees away from them, unless perchance several bees attack them, when they will quietly withdraw a little way and parry with a single bee, not stirring an inch for it. I never knew that they did any harm before, save to annoy the housekeeper when they had their nests behind the window blinds, or in some such place, when they would sting if disturbed. But now I know they are a most prolific source of loss to our ripening grape crop, and to the defamation of our bees. These wasps and the cracking of the grapes has resulted in the loss of at least one-half of my grape crop. However, I am glad to know that the bees have no part in causing the trouble.

There is an item wherein the bees give offense, and that is in gathering the crop. If done when they are on the grapes, care must be used or the gatherer will get stung; for at this season of the year the bees are very sluggish, and will sting on the least provocation by way of squeezing. Again, they will crawl down into the baskets or boxes so that many will be carried to the store-room to be an

annoyance there. Of course a bee-keeper will overlook all of this for the sake of the bees, but such care and annoyance is anything but pleasant to a person who is not a bee-keeper, or especially to a timid person.

Borodino, ⊙ N. Y.

For the American Bee Journal.

Working for Extracted Honey.

M. A. GILL.

While reading Mr. J. J. Waller's article on page 216, I find his management so different from my own that I concluded to give a brief of how I manage extracting. His first objection is to robber bees, while taking combs away. I am never bothered in this way, and in out-apiaries where I have moved for basswood, I frequently extract in the open air, and on two occasions I have seen the bail break and spill a pail of honey in the apiary, and it was not visited by a single bee. Of course this was in the height of the basswood yield.

Mr. W. mentions "stooping" as an objection. Well, it is, but he would need about two men to help him "straighten" if he carried some of my colonies into his honey-house. Remember I allow no increase when working for extracted honey, and have my hives tiered from three to four stories high; and I have had them on the scales when they would weigh from 180 pounds to 225 pounds. You will see the straightening up with them would be harder than stooping. I can imagine what kind of a muss I would have, should I take one of those colonies into the honey-house. Think of from 16 to 20 pounds of bees turned loose thus; of course a large per cent. would be young bees, that could not get home in any way except on "foot with a guide." These young bees do not know enough to fly to the window, and could not if they did. The little, soft things only know enough to feed a young larva, or crawl into a person's ear.

Another reason why I could not afford to do as he says, is, the bees would lose too much time. Our main crop is gathered in from 9 to 14 days, and when the bees are bringing in from 5 to 30 pounds per day, they should be kept at work, and by using little or no smoke, their work goes on with but very little interruption. By tiering up and keeping one or two frames with "starters only," in the lower story, bees can be kept from swarming. About two weeks before basswood blossoms, I examine my bees, and take the queens away, forming a good nucleus colony. By doing this three important points are gained—one which concerns the nucleus, and two concerns the main colony.

It will be seen that in two weeks after (at the beginning of basswood), the nucleus will have a working-force of its own, and will work wonders in the next two weeks. Next, if the work of cutting out queen-cells has been thoroughly done, swarming is

up for the old colony; and last, but not least, they have no brood that is of any value to them; that is, their brood is all sealed up, and who has not noticed what a colony of nearly all *old* bees, with no brood, plenty of empty combs, and a *large* entrance, can do in the way of storing honey?

To return to the matter of extracting: Where hives are 3 stories high, there will be two sets of combs to take off. By having a box with a cover, handles and legs, two men will take them to the honey-house and extract them with as little stooping as if the hive was taken. I imagine that what would do in my location would not be advisable in Mr. Waller's. I suppose his yield is slow, and lasts for months, while ours comes in floods, usually about 10 days of white clover, and about the same of basswood, with less honey but a longer flow from buckwheat and goldenrod.

Where bees have been in 3 and 4 stories through the basswood flow, they should all be removed but one super, as soon as the yield is over, and, in fact, worked into the brood-chamber as early in the fall as possible. The big colony is gone; the three weeks used in rearing a queen, and the three weeks before her brood hatches, together with the fearful mortality incident upon a large honey-flow, makes the difference.

Do Bees Really Hear?

ELIAS FOX.

In regard to Mr. Brimmer's article on page 240, I would say that I am as much of a lover of the truth as any one. I do not wish to be understood as saying that bees *cannot* hear, but I do not *think* they can; and so far I do not think that Mr. B. has furnished any proof to the affirmative. I did not say that bees are wholly guided by the sense of sight, but by sight and scent both. Now I *do* claim that the sound is produced *wholly* by the wings, whether they are in a person's hair or under his coat collar. A bee in the act of stinging moves its wings with lightning rapidity, which we all know they cannot do without emitting a buzzing sound, and at the same time we can smell the formic acid which attracts other bees. We cannot hold a bee in our fingers tight enough to prevent its wings from moving, unless the bee is crushed.

I do not claim that a colony going to the woods can see the tree from the time they leave the hive, but I think they start out and go into the first suitable tree they find. If they do not, why is it that they are frequently found clustered on trees and bushes, after going miles in search of a suitable tree, some even traveling until with dwindling and storms they are worn out and never find a place to get into? Several years ago I found a colony clustered in the top of a tree at 7 o'clock in the morning, and they remained there until 3 p.m., when I

cut the tree down, hived them, and took them home. I know a man who, two years ago, found a colony clustered on the underside of a limb of a small basswood tree, and had comb enough to fill an American hive. So it looks plain enough to me that they do *not* know where they are going to locate; and I do not think they carry flags of truce either. I do not believe that Mr. B. has reared a sheep, or he would not say that a flock is attracted by the bleating of the leader.

I would advise Mr. B. to try running ahead of an absconding colony without his milk-bell, and see if he does not succeed just as well. I have noticed young and old queens piping on the comb, and I am *just* as positive that it is their wings which causes the sound: for if you are a close observer, you can see their wings move in accordance with the sound. Let a bee alight on the hand, and set up a buzzing, such as they do at the entrance of the hive, and if you cannot feel the vibration I will admit outright that bees can hear. They scent a virgin queen as readily as a fertile one. Now let us not have so much guess-work, but if bees can hear, let us have some good, solid proof, as I am open to conversion.

Hillsborough, +o Wis.

For the American Bee Journal.

Storing Surplus Honey, etc.

G. W. DEMAREE.

The enthusiasm of the old class of bee-keepers found vent in swarms; but since we have learned how to breed and multiply our "live stock" at will, the direction of the outlet has turned in the opposite direction. We now want to know how to keep increase in proper bounds. A few years ago we were advised to work our apiaries on the "prime swarm" plan, *i. e.*, just take one good (first) swarm from each colony; but we asked, "where is this thing to end?" We were told to sell our surplus bees, and we asked, "where or to whom, if every bee-keeper must double his stock every year?" I could find no solution to this problem except to let the overplus of colonies consume two or three dollars worth of honey, and starve at last, or be over-run with more "live stock" than was profitable to keep.

This perplexing quandary set me to experimenting to find a plan that would turn the energy of the "prime swarms" into surplus honey, and turn the swarms into mere nuclei and into non-existence, if desirable, at the close of the season. To accomplish this the necessary manipulations may be varied considerably. The gist of the plan is to draw from the parent colony after casting the first swarm so many of their mature workers as will prevent after-swarms, and throw these into the hive containing the swarm; an essential feature of which is to have the swarm on the old stand, so that there will be no returning to the old or parent hive to keep

up the swarming impulse. Another essential feature is, the queen's apartment in the new hive containing the swarm must be so contracted as to be in the condition of a mere nucleus brood-chamber—thus throwing nearly the whole force of workers into the surplus department. In my locality two or three weeks of time immediately after the swarm issues, must give all the results that can be expected from a swarm, and if I can get 100 pounds from a good swarm, I consider that the swarm was turned to a good account.

My plan is to so manage my bees under the swarming energy that their entire force will be spent in storing surplus honey, instead of being permitted to turn their force into increase of bees. I cannot prevent my bees from swarming, and keep the colonies in a normal condition, but I can convert the strength of the swarms into surplus honey, and the swarms themselves into non-existence by "contracting" all the honey into the surplus departments, and removing it to the honey store-room.

While practicing my system of preventing increase, I have had ample opportunity to observe how the "contracting system," first brought to light by Mr. Doolittle, and later systemized by Mr. Hutchinson, will work in my locality. Such treatment would bring my apiary to ruin in an average season, unless I should feed the colonies through the heated months of summer, and supply them with winter stores in the fall, in which case I would lose rather than gain in the operation. Some seasons the bees would survive such management because of favorable conditions, but favorable conditions are not certain here, and therefore the contracting system is unsafe, if our bees are to be kept in good condition without feeding the profits of the apiary back to the bees. Nature seems to have laid tribute on all things. Every pound of honey costs the life, energy and death of a great number of bees. Brood represents honey, and honey represents brood.

My experiments, and my practice to keep down increase, shows that to so manipulate the hive arrangements as to throw all the honey into "surplus," costs the life of the colony. Now if we feed back to counteract the loss on the side of the bees, we have gained nothing—nay, lost in the operation. Ten pounds of sealed honey in the brood department is worth more to the bees than 15 pounds of liquid honey or syrup, unless the experiment is made for stimulative purposes, and then you must account for the loss of life and vitality of the bees caused by the labor and excitement while re-storing it.

How easy it is for a man to work himself up into the conceit that he has discovered "something new under the sun," when his peculiar environment, or perhaps his ignorance of past history, or of the laws of nature, is all that is in it. This is a great country of ours, and there are many places where bees will do as well and apparently better, with mere

starters in the frames, than if supplied with full sheets of foundation or with empty combs. An extra good season now and then has turned my head in that way; but when it comes to running an apiary from year to year as a business, comb foundation and empty combs cannot be dispensed with in the majority of the apiaries of the country, and their judicious use must be profitable everywhere.

Our bee-literature is in a muddled condition, and is likely to get worse since in "book making there is no end." One of the worst and most vicious tendencies in the would-be authors of the times, is to lionize somebody, or some bee-hive, or some theory, instead of writing directly to the matter in fact, as indicated by the title of the book.

Christiansburg, 3 Ky.

For the American Bee Journal.

Bees and Fruit—Removal Desired.

Z. A. CLARK.

The following appeared in our local paper, the *Standard*, concerning my apiary:

"As some dissatisfaction has arisen in this place tending to and developing into a somewhat organized effort to have the apiary of Z. A. Clark declared a nuisance by the city authorities, and forcibly ousted from the city limits, we deem it pertinent to discuss the matter. A veritable howl has been raised against Mr. Clark's bees, and it is said on account of the fact that the little workers were attacking and actually destroying the growing fruit of the town. The idea was really a new one to us; and besides believing that the man engaged in apiculture on his own premises had rights to be respected and protected as much so as the followers of other avocations, we believed they were mistaken as to the ability of the bee to do the damage it had been charged; so investigation showed that the opinions of the citizens as based on their experience and observation in such matters, were widely divergent. But the matter we feel is fully settled by the official report to the United States Entomologist, by N. W. McLain. From it will be seen that it is impossible for bees to puncture the skin of sound, unbroken fruit. Let the enemies of the industrious bee read it."

Then follows the report as already published in the BEE JOURNAL.

No one in this immediate vicinity is cultivating fruit as a business, and from May 10 to June 3 it was extremely dry, and no rain—something very unusual in this locality—and in consequence, the bloom was all destroyed. From June 3 until July 1, it rained incessantly, and the early peaches began to ripen when a rain would come. Hot sunshine upon the fruit would cause it to break, rot and collapse, and there being no honey, nor bloom for the bees to work upon or gather honey from, and in con-

sequence of the drouth preceding, and followed by rain every day for a month, the bees were starving, and so they took to the juice exuding from the decaying peaches. From ignorance, the populace—the "cranky" part of them—set up a veritable howl that Clark's bees were eating up all the peaches! One party even went so far as to say they ate up his young ducks. As for this I cannot vouch, as they were not brought into the apiary.

This is the only move ever heard of this kind in any town or city in Arkansas. Our town has about 1,800 inhabitants, not crowded, and bees have been kept here for 50 years.

The chronics are a minority, and last year, as soon as the flora grew, the bees left the fruit, and there was no more complaint. They want to have the bees moved this year before fruit ripens. I do not know what steps to take. I have no other land in this county but what my bees are on, and I have no money to buy any, and want to make a living, if I am allowed to, from my bees.

Arkadelphia, 9 Ark.

[The Manager of the Bee-Keepers' Union, by request, has advised Mr. Clark as to what course to pursue. The false accusations against the bees, about their breaking the skin of grapes, when thus refuted, will be advantageous to the apiarist. All he needs is to treat the subject with calmness, be courteous to his adversaries, and await the reaction which will surely come in due time.—Ed.]

For the American Bee Journal.

The Prevention of Swarming.

OTIS N. BALDWIN.

This topic seems to be agitating the minds of the wide-awake apiarists of to-day, and well it might; considering the close competition and prevailing low prices of honey it behooves us to make every "corner cut" in producing the most honey with the least labor and capital expended. It is unnecessary to state that the quality must be gilt-edge to compete now-a-days, for every live apiarist has discovered that ere this. But to the point:

It is a fact beyond dispute that if the bees of a colony can be kept together with all its increase, and made to work in the sections from the commencement of the harvest, and produce an impulse for gathering honey equal to a swarm just hived, without destroying any of the fundamental rules necessary to produce harmony in the hive, more honey can be obtained by such a non-swarming plan than is possible to obtain by letting the bees increase naturally. But some will say that such a thing is impossible; that the greatest entomologist, and the most learned apiarists in the world have not discovered it, and therefore it is impossible; and should

a common bee-keeper proclaim that he could accomplish it, he would be at once put down as a fraud, trying to swindle the fraternity out of a few dollars.

In this day of frauds and humbugs, we cannot be too careful. While this is all true, we should not cry down a thing that might be worthy an investigation, without knowing something of the footing upon which we stand. I have read Mr. Gresh's article on page 167, and I am inclined to think that he will still look in vain for the desired method. He states, too, that he is glad that Mr. Simmins has given his non-swarming method to the public, etc. If I am rightly informed, Mr. Simmins did not give his method to anybody; he published a pamphlet on the subject, and it is for sale. Let some man ask Mr. Gresh to give him a hundred pounds of honey; would not Mr. Gresh be a little non-plussed? Would he not say, "my honey is my labor, and must bring the cash." Then he would cast a smile at the stranger, as much as to say, "you are awful green!" It is just the same with a non-swarming plan that is genuine; it costs money, and takes labor to experiment, and the man that discovers such a plan as is mentioned above, will not give his time, labor and money for unappreciated glory.

Many bee-keepers, too, want increase in their apiaries, and think that a non-swarming plan prevents increase. This is just exactly as the bee-keeper wants it. He can have all the increase he wants, or none, and can always have his bees in good condition, which is impossible where swarming and contraction is practiced. I have tried the contraction method to my sorrow, and consider it the most impractical plan in apiculture. It is unnatural, and ruination to an apiary for at least a year thereafter. Any plan of manipulation that is calculated to violate the God-given laws of nature in handling bees, will prove a failure every time. Let the bees follow their own instincts, arrange the hives accordingly, and you have the non-swarming plan described above; and I will insure your bees not to cast 4 swarms in 100 colonies, in a normal condition, and get every pound of honey in the surplus departments, if you want it so. It does away with two-thirds of the labor, and makes happy bee-keepers.

A hundred years ago railroads, telegraphing, telephones, and thousands of other wonderful inventions were unknown, and if any man could then have looked into the future and revealed the wonderful things that have transpired, he would have been looked upon as in conspiracy with the evil one. In all the literature on bee-culture of the present day, there is not a single process recorded where artificial fertilization of queen-bees has been made a success, and most of the authors claim it is an impossibility to produce fertile queens in confinement.

I have queens that were hatched in cages, and their wings were clipped before they ever had the possibility of a chance for a flight. They were

operated according to a plan of nature's own laws; they are as prolific layers as any other queens in my apiary of 75 colonies, and they did not go through the absurd, scientific monstrosity mentioned on page 65 of "A B C of Bee-Culture." It is my opinion that all bee-keepers who claim to have ever observed such wonderful nonsense, were laboring under a delusion, or looking through the wrong end of the microscope.

Practical bee-keepers are testing the methods, reports of which will appear in due time. Any plan of operation that is a success will work in one apiary as well as another, if the normal conditions are properly observed. A man that has passed his opinion beforehand is unfit for a jurymen; the same rule holds good in apiculture. It is the investigator that takes the lead, and reaches the *ultimatum* of success.

New England Homestead.

Securing Apple-Blossom Honey.

SAMUEL CUSHMAN.

Under the usual management, surplus honey is rarely taken from this source. Bee-books generally teach that apple honey is dark, inferior in flavor, and is of use only in building up colonies. A prominent New York bee-keeper once said: "We could get as much honey from apple-blossom as from basswood, if we had the workers at that time to gather it. But with plenty of bees, a failure of the yield, or cold and rainy weather, will prevent success, as many have found."

In southern New England, honey from this source is often obtained in large quantities in the brood-chamber without special management. A Massachusetts apiarist had one colony gather "72 pounds of surplus honey in four days from apple-bloom."

Last season I acted on the above suggestion, and by special management obtained a nice lot of apple honey in pound sections. It was the thickest and finest flavored honey I ever tasted, and when gathered and capped quickly, it was nearly equal in appearance to the best white clover honey. It was not quite so white, but was bright and clear, and the apple-blossom flavor was very distinct. This honey was exhibited at the Rhode Island State Fair, received the first prize, and was sold to a dealer at a better price than is given for white clover. The judges and bee-keepers generally who tasted it, pronounced it equal or superior to anything they had ever eaten.

My management to obtain this honey in sections was as follows: Early in the spring I fed warm syrup, artificial pollen and uncapped stores, and added empty combs, etc., to get a force of workers in time for the bloom, which I expected about May 20, but which opened on May 10, as the season was early. Just before the height of the bloom, I filled out the brood-chambers of several colonies with capped brood from weaker ones,

leaving only combs of capped brood, and also united a few colonies where two stood side by side. One was removed; the other placed between where each stood. Nearly all the bees from the removed colony were brushed in front of the remaining one. The one removed had the queen, combs of honey and uncapped brood, and enough bees to cover the brood, and were in a condition to build up. They were placed on a new stand. The prepared colonies had combs full of capped brood, an extra lot of young and field bees, and were obliged to occupy supers for want of room, and had no other place to store honey. The surplus cases contained rows of sections of empty comb, alternating with those having full sheets of foundation.

The result was from 20 to 30 nicely capped sections per hive. This was nearly all gathered in three days. One colony furnished 32 sections of honey and did not swarm. Without this apple honey I should have had little choice comb honey last season, as clover was a failure, and there was little fall honey. Under this management, honey is produced at a greater cost of bee-power than that from clover or a later crop, and therefore must bring more to be profitable. This is but the experience of one season in taking honey from this source; it may vary in quality in different seasons. Those who try this plan and succeed will, I think, be well repaid by the quality of the product, but I would suggest that it may be safer to work but 1 or 2 colonies in this way.

Pawtucket, § R. I.

For the American Bee Journal.

The Honey-Producers' Association.

W. Z. HUTCHINSON.

Not many years ago bee-keeping was a bonanza, in one respect, at least; and that was in the selling of its products. The pursuit is a fascinating one; its beauties have been painted in the brightest colors; its ranks have been filled to repletion; and the active minds of its bright devotees have all been brought to bear upon one focus—*production*.

The bonanza is a bonanza no more; the beautiful, pastoral pursuit has been forced down to a business level—*yea*, below the business level of some occupations. In overcoming the difficulties of production it seems as though success had ended in *over-production*. The wiggings, twistings, and frantic attempts of the "boomers" to attribute the low price of honey to something, *anything*, than *over-production*, are really pitiful in their ludicrous inconsistency. It must be admitted that the demand has not kept pace with the production. Once the honey-buyers sought the honey, now the honey must seek them; and it is a tedious task to find them, as the commission man has sprung up and the cash buyer faded away. The commission merchant has been ter-

ribly abused of late; and, mingled with the abuse, it is quite likely there were some unpleasant truths. Personally, however, I have nothing but praise for this class of men.

Bee-keepers are not the only class, however, that has suffered from over-production. Many strawberries were sold last season for scarcely enough to pay for picking, transportation and commission. Last September I attended a meeting of the American Horticultural Society, held at Cleveland, Ohio. The president of the society, Parker Earle, the "strawberry king" of Illinois, in his annual address, went straight to the heart of this problem. He said:

"Many as are the enemies to conquer in every line of horticultural effort—and sometimes it seems as if all the forces of nature were combining against our success, when insects deface, and blights wither, and drouths burn, and frosts destroy—yet the ingenuity, the energy, the enthusiasm of the horticultural producer are found sufficient in most cases to overcome all obstacles so far as to provide enough, and too much. In fact, the difficulties of production have been so far overcome that most branches of the business seem to be suffering from over-production.

"Looking at this question from the stand-point of a commercial grower of fruits, it appears to me that one of the chief problems for our fraternity to solve is, how to distribute our products more perfectly—how to reach wider markets... There is as yet no over-production of good fruits; but there is defective distribution. There were not too many apples grown in New York, Michigan and Missouri last year, although apples sold in many of our large markets for prices far below the possibilities of profit; but our system of distribution left half of the families in America with few or no apples to eat last winter. When one or more barrels of apples go into each farm-house and laborer's cottage all over the South; to each miner's cabin among the mountains, and to all the new homes building on the wide plains of the West, the supply of apples will not be found too large. There have not been too many oranges grown in Florida and California for the last few years, though many orange-growers have gotten little profits from their crops; for three-quarters of the people within a practicable commercial distance of these orange-orchards have eaten scarcely any oranges in these years. If all the American people were to eat apples and oranges daily in their season, the quantity produced would not supply their wants. A more thorough system of distribution will render this approximately possible....

"Hence it appears to me that we are not producing too much, but are marketing too poorly, and that the question of distribution is the one most important to the commercial grower. Its successful solution will result in infinite benefits to the people who consume, and in living profits to the often-discouraged class who produce."

I think that Mr. Earle has most clearly covered the ground upon which lie the troubles of the *honey-producer*; but exactly how to wipe away these troubles—to place a barrel of apples (or a crate of honey) in "each miner's cabin among the mountains"—he left unsaid, except that we are to market better and distribute more widely. Excellent advice, but *how*? It is to wrestle with this question that would be the legitimate work of a honey-producers' association.

I very much doubt if any association of honey-producers will ever be successful in getting up a "corner" on honey. Very many producers would not join the association, and while the members were "cornering" the honey, holding it and fixing prices, the outsiders would be selling *their* honey. There are too many bee-keepers; too many varying circumstances; it will be impossible to combine them and secure uniformity of action. While I have no faith in the "cornering" scheme, I do not belong to the class that says that nothing can be done.

The production part of the bee-keeping industry has been studied now for years. With rare exceptions it has been the only theme in bee-papers and at bee-conventions. It is almost impossible to say anything new upon this branch of the business; in fact, until lately it was scarcely necessary to touch upon any other department. The time has now come, however, when to produce a good crop of honey is *one* thing, to sell it to advantage is entirely another. To cheapen production may possibly help us, but the other end of the problem—that of securing good prices for honey—will bear the most working. The problem can be solved much more quickly by beginning at this end. A few have tried working at this "end." Mr. Muth has called the attention of bakers, packers of pork and pickles, and tobacco manufacturers, to the using of honey in their business; Mr. Bingham has told us how to make the best of vinegar from honey; Arthur Todd uses honey in making candies; Mr. Newman and others have furnished us thousands of leaflets for distribution; J. H. Martin has just brought out a new and peculiar small package for extracted honey; our Canadian brothers went over to England last summer and showed our cousins across the "big pond" the superiority of American honey; tasteful exhibits of honey have been shown at Fairs, etc., but more, *much* more must be done in this line, or else a radical change made in the methods of marketing, ere the palmy days of old will return even in a measure.

I think we owe Mr. Baldrige a vote of thanks for having started a discussion upon this subject. Much good has been done; and while I think that a meeting devoted to a discussion of this subject would work to the advantage of bee-keepers, I doubt the wisdom of calling such a meeting this spring. Reform movements and changes come about slowly. Many bee-keepers seem to have rather vague ideas in regard to what will be or can

be done at such a meeting; they will wait and see what is *done*. We can get no reduced rates, and this, combined with the apparent lack of enthusiasm, would, I believe, result in a very slim attendance. Very few bee-keepers would spend any great sum of money just now to attend a meeting that is to discuss only this one topic, broad and all-important though it be. I think that Mr. Newman's suggestion, on page 227, is a good one, viz: to defer holding a convention until the meeting of the North American Bee-Keepers' Society, next fall, in Chicago. As Secretary of this society I would suggest that at least one day, and the best day at that, be devoted at the next meeting to a discussion of this vital topic.

This meeting will probably be a "rouser;" composed of representative men; and the cost of production, prices at which honey can be sold at a profit, methods of putting up honey, commission men, cash buyers, home markets, city markets, foreign markets, development of markets, distribution of our products, associations, "corners," etc., can all receive such a discussion as they never before have received.

In my opinion this is a live question—it is *the* problem that now confronts bee-keepers; let us study it well the coming season, then meet in Chicago next fall and see if associations will help us to solve it.

Rogersville, δ Mich.

For the American Bee Journal.

Our Honey Crop for 1886.

C. W. DAYTON.

The honey crop of Chickasaw county, Iowa, for 1886, was close to 100,000 pounds. A good many thousand pounds was shipped to distant markets, and mostly remains unsold; nearly as much was brought from other States and sold here.

The general complaint, or "howl," rather, is that there was not half enough honey produced to supply the home demand. The honey-producers of the county are located usually 2 or 3 in a place near some town. The inhabitants in and near those apiarists obtained enough for their bread and cakes during the fall, but when winter came the honey was "played out." From 6 to 8 months in the year the consumers of honey in this county are forced to abstain from its use. If all the families in the county could use, and knew where to get what honey they would be glad to pay cash for, it would be equal to 1,300,000 pounds, and we cannot boast of a very populous or wealthy county either. There is a great demand for it at present; but the demand will be supplied when we get another crop.

Some bee-keepers have a greater demand for honey than others. It may be that it is because those bee-keepers usually leave it on the hives the longest—so long that their customers get very hungry for it. Then they let them have it all at one dose.

I do not think the bee-keepers around here are very sharp. When they are nearly sold out, so there is not much on hand, they always cling to the same price. Where honey is scarce they ought to do as other folks do: ask a big price. Honey always gets lower and lower, but the price does not fluctuate around here. If the price would change, then a customer would not be so likely to question the price and buy somewhere else. As it is, once posted, he is fitted for life.

I always find good sale for comb honey in sections where there is some bee-bread in them. That is when I am selling to private houses, but it does not work very well with the merchants, as they expect to get it for 2 or 3 cents per pound less on that account. Sometimes, where people are used to adulterated or poor honey, it would be hard work to sell if it was not in boxes or frames that showed the roughest work of the bees. It is not always the appearance of honey that makes it sell, any more than the dealers are the best customers. I once sold 14 two-pound sections of excellent comb honey to a man who dumped them hither-skilter into a grain sack which was thrown across his horse's back, and carried 8 miles home.

I do not sell honey to those who do not want it, but sell to those who do want it. A good place is to keep some honey in the combs till spring, then extract it and give the neighbors a taste. Do not try to sell them any. They will buy it of you sooner than you could possibly sell it to them. The greatest fault in bee-keeping in this county is that we cannot get enough honey to meet the demand. We cannot get enough to feed one-tenth of those who would like it.

Bradford, δ Iowa.

From Gleanings.

Disposing of our Honey Crop.

MRS. L. HARRISON.

There is no subject that comes nearer to us all than the best way and means of disposing of our honey. If a bee-keeper ships his honey to a large city, and sits down to smoke, he will, in many instances, have time for a pretty long smoke before he has any returns for his season's labor.

There are few localities where there are not more than 100 colonies kept, which would not be able to consume all the product. I once stopped at a farm-house, five miles from any town, where 40 colonies were worked for extracted honey. The proprietor said: "I never take away a pound of honey; the neighbors come with their jars and pails, and take it away, and I could sell much more if I had it. I cannot half supply the demand."

Farmers formerly, in Illinois, consumed large quantities of molasses. They bought it by the barrel or in kegs. Emigrants from Pennsylvania missed their fruit-butters, for which they are so famous, and the large family of "spreads" scoured through

the woods in search of wild plums, grapes and berries, and finally succumbed to the inevitable, and ate molasses. Since the advent of glucose-factories, molasses and syrups have "gone by the board." Fruit is more abundant than in the early settlement of the country, but it does not entirely fill the gap. This class of consumers are almost entirely neglected by producers. They think honey is something to be sold to town-folks. How one of our Western farmers would laugh if you should ask him to buy a pound of honey! "A pound of honey? Why, that wouldn't be a lap. Bring me 50 or 100 pounds." He has no use for a 10-cent package.

Those who farm here have large families; if not many children, they have work-hands, comers and goers, and there are few days when strangers do not sit down to their tables—agents, peddlers, etc. What a bonanza would honey be to the over-worked wife! It needs no cooking; she does not have to stand for hours, either, over a hot stove or by a fire out-of-doors, with smoke or ashes in her eyes, moving a stirrer back and forth all day, and at night till the clock strikes the "little hours," to finish it off as it boils and sputters. This class needs instructing in the use of honey, and they could be easily taught, if it were only brought to their notice.

We never shipped any honey more than once, and that was owing to the severe illness of Mr. Harrison; and if we had employed the young man who packed and shipped it, to have peddled it out, we should have saved money and worry, as he had been in the peddling business. During the winter, in most localities, there are plenty of young men out of employment, well fitted, with a little instruction, to sell honey. It would be better to trust them with our property than to ship it to entire strangers.

I am not ashamed of the business, but proud of it—glad that I am a producer of a pure sweet. In peddling honey, the better way when it is sold from house to house, would be to go forth as the apostles did, "by twos." One could drive the team, and abide by the stuff, while the other could exhibit the honey and solicit orders. The best assistant would be one who has been over the ground before. A honey-route, in time, would have a commercial value the same as milk-routes now have. A family that uses honey at all buys a good deal, while there are others who cannot be induced to use it; and in going over the ground the second time these could be left out.

Large producers must, of course, seek distant markets; but "it is the little foxes that spoil the vines." Small producers must sell their own honey at home, if they would succeed; make honey legal tender for everything they buy.

Peoria, © Ills.

[About selling honey on commission, Mrs. Harrison is quite right in saying that it is vexatious and very unsatisfactory. A case in point oc-

curred in Chicago this month. A small lot of the best white clover honey ever produced was put into the hands of a commission merchant as a trial lot, to ascertain whether it would be advisable to let him have 50 tons more to sell. The commission merchant made returns at 5 cents per pound, less commissioner's expenses, etc. As it will not do to sell at such ruinous rates, the rest of the crop will be "held" from the commission men.—Ed.]

Local Convention Directory.

1887. *Time and place of Meeting.*
- May 5.—Progressive, at Bedford, Ohio.
Miss Dema Bennett, Sec., Bedford, O.
- May 10.—Keyatone, at Scranton, Pa.
Arthur A. Davis, Sec., Clark's Green, Pa.
- May 10.—Cortland Union, at Cortland, N. Y.
D. F. Shattuck, Sec., Homer, N. Y.
- May 13.—Sheboygan County, at Hingham, Wis.
Mattie B. Thomas, Sec., Sheboygan Falls, Wis.
- May 24.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
D. A. Fuller, Sec., Cherry Valley, Illa.
- May 26.—West Lake Shore Central, at Kiel, Wis.
Ferd Zastrow, Sec., Millhome, Wis.
- Dec. —.—Michigan State, at East Saginaw, Mich.
H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER-BOX

Expecting a Good Harvest.—Geo. W. Moore, Golden City, 9 Mo., on April 22, 1887, says:

Bees have wintered finely. I had packed 10 colonies on the summer stands in the Langstroth hives; on Feb. 7, they had brood hatching; on March 10 they gathered pollen and honey from elm and maple. Fruit bloom is almost gone. It has been so windy that the bees have not had a chance to do much in the way of gathering honey. They are very strong in numbers. I look for a good honey harvest this year.

An Apiary Roughly Handled.—Jno. C. Peden, Lawrenceburg, © Ky., on April 20, 1887, writes:

For 5 years I have had from 15 to 20 colonies of bees near the Kentucky river, between 2 and 3 miles from home. During that time they have been protected from harm by being near the house of Wm. Skelton, who had charge of the landing and elevator there; but last February he moved away, and that left my bees without protection, except in the daytime. On Tuesday, April 12, I made arrangements to remove them, but on that night some evil-disposed person turned them all (24 hives, 19 containing bees) down the river bank where

it sloped toward the river at an angle of 45°, was very rough and rocky. I heard of it early the next morning, and went to them, and by noon I had most of the bees back in the hives. Upon examination I find 13 queens left, which seems almost impossible, considering that many of the hives rolled for 50 to 75 feet down the bank. The surplus combs were stored in the upper stories of the hives, making nearly 500 combs in all. These, along with the bees, brood, combs, stores and hives were scattered in the utmost confusion, and that 13 queens were yet alive is much better than I expected.

Encouraging Outlook.—Ira Barber, De Kalb Junction, 3 N. Y., on April 22, 1887, writes:

So far as I have learned, bees were put into winter quarters in poor condition, as a rule, in northern New York, and the result is a heavy loss to many bee-keepers. I carried the last of mine out to-day, and all occupy their old stands but 3 out of 147 colonies carried in last November. About 80 per cent. of them are in good condition for business. Clover has wintered fairly well, and the outlook for a crop of honey is favorable.

Long Winter Confinement of Bees.—G. M. Doolittle, Borodino, © N. Y., on April 21, 1887, writes:

The first pollen was brought in by the bees to-day, and that in very small pellets from skunk-cabbage. The old snow-banks are still 3 feet deep in places in my bee-yard, with freezing nights nearly all the while, which does not tend to diminish them very fast. As near as I can get at it, the date of the first pollen was never so late as April 21 before in all my 18 years' experience with bees. Bees wintered out-doors had their first flight on April 3, which was just 5 months from the time they flew last fall. My loss is 10 per cent. of this class. Those in the cellar are quiet and nice yet, and I am glad of it, for it looks as if they are to be confined 6 months—180 days. Who beats that?

Sowing for Bee-Pasturage.—James Jardine, Ashland, © Nebr., on April 22, 1887, writes:

In this part of the State we have had rather a hard winter for bees that were out-of-doors. Many bee-keepers have lost almost all the bees they had. I put 101 colonies into a bee-cellar on Nov. 15, 1886, and took 101 colonies out on April 2, 1887. I kept the temperature at about 40° to 50° the most of the time. My hives are all 8-frame Langstroth; I gave them plenty of ventilation, and have been very successful so far with cellar-wintering. My bees are doing nicely now, and are breeding very fast. I hope we will have a better year for honey than last year. It was then too dry for them in this part of the State. I have induced many farmers here to sow Alsike clover this spring, and I think

if I had had plenty of the "Alsike Clover Leaflets" to show, I could have been still more successful; but the Leaflets were issued too late for me. I am trying the Chapman honey-plant this year; also the white mustard, which will be ready for the bees in June; and sweet clover. I mean to keep sowing bee-plants until my bees can have something else than the heart's-ease to get honey from. The basswood last year yielded honey pretty well for a few days, but when it came there was plenty of bees starving. Now I hope that the Alsike clover that has been sown this spring will furnish lots of honey in June next year. My apiary is out of town a little ways, and the bees were killed in the store windows, in June, by the thousands every day, and a good many store men were getting sick of their company. The only way "to keep peace in the family," is to do just as I have been doing this spring.

Breeding up Nicely.—B. W. Peck, Richmond Centre, O., on April 22, 1887, says:

My bees have again come through the long, cold winter, and are breeding up nicely. Bees in this locality generally have not wintered as well as they did last winter. My loss was 3 colonies out of 38.

Bees in Prime Condition, etc.—F. M. Taintor, Coleraine, Mass., on April 25, 1887, writes:

I am happy to say that our bees (those of Mr. W. W. Cary and mine, as we are in company) have wintered extremely well. We think we have some of the largest colonies we ever wintered. Every colony that was out in chaff hives are in prime condition. The spring is quite backward here, but we hope for warmer weather soon, as we have considerable transferring, and other important work to do. The valuable old AMERICAN BEE JOURNAL is worth more to me than all the rest, for the good commonsense which it contains.

Terrible Mortality among Bees—Late Snow Storms.—Geo. A. Wright, Glenwood, Pa., on April 20, 1887, writes:

It seems to be the impression that bees have wintered well all over the country, which I think can hardly be the case. In this locality, at least, the mortality among bees has been terrible, and for bee-keepers to report only the bright side, and leave the dark side untold, is to give the business a false coloring, which will surely operate against us. As far as I am concerned, I want the public to know how I have succeeded in wintering my bees. I began the winter with 106 colonies, 57 in chaff hives and 49 in Simplicity hives. Out of the 106 colonies 56 are dead, 6 are queenless, and more than 40 are weak. They all had plenty of stores, and were well packed with chaff; in fact, I put them up with greater care than

ever before; but, alas! I do not think that 20 per cent. of the bees in this locality can possibly survive. We have had a few warm days, and bees began to breed very fast; but day before yesterday we had one of the worst snow-storms of the season, and last night the mercury lowered to 10° above zero. So that I think the brood must surely have been chilled. Many small bee-keepers have lost all of their bees, and in every case where bees were not thoroughly packed, they are all dead. This has been the hardest winter on bees in this locality since the winter of 1880-81. The clover has not been injured by frost, as it has been protected by the snow; so what few bees are left will stand an excellent chance to get a good harvest. I want to hear from the dark as well as the bright side of bee-keeping.

Bloom Frozen.—Mr. Eugene Secor, Forest City, O., on April 26, 1887, writes:

The weather is bad for unprotected bees outside. The fine weather of a couple weeks ago, which brought out the soft maples and all early blossoms, received a sudden setback last Saturday. One of the worst snow-storms of the season reached us. I finished taking bees out of the cellar on April 19. They came out in good condition generally, but I fear the effects of the late cold weather. If they were inside I should feel glad. I hear of heavy losses in some localities; and we are not "out of the woods" yet, since all the pollen and honey-bearing plants in bloom are frozen.

Unfavorable Weather for Bees.—F. A. Snell, Milledgeville, Ill., on April 26, 1887, writes:

The weather being very fine, and soft maples in bloom, I removed my bees from the cellar on April 7, in good condition. Every colony was alive and strong, and the combs were bright and free from mold. The hives and combs were as dry, apparently, as they would have been in the sitting-room or kitchen. I placed them in the cellar on Nov. 23, 1886. I have wintered my bees on natural stores for years, with excellent results; in fact just as good or better than on granulated sugar syrup, which I gave a good trial 15 years ago. The weather for the last two weeks has been very unfavorable for bees. It has frozen for the last few nights quite hard, ice forming as thick as window glass. I prefer a late opening of spring for bees.

Great Mortality of Queens.—O. B. Barrows, Marshalltown, Iowa, on April 22, 1887, writes:

On May 1, 1886, I had 54 colonies of bees—50 were strong and 4 were weak. I increased them by natural swarming to 98, gave away 2 colonies, and found 2 queenless in October. I put 94 into the cellar from Nov. 12 to Nov. 16, 1886, and a slow fire was kept

constantly burning in the cellar from Nov. 22 to April 1. The bees were put out from April 6 to April 8, and I found 2 queenless colonies and the bees all dead; since that I have found 9 more queenless, making 13 queenless colonies out of 96 colonies, since Oct. 1, 1886, and more than half of them were the old colonies having queens reared in 1886. The hives were all dry, with no moldy combs, and had plenty of honey. Was not this an unusual mortality among queens? If so, from the above data, wherein did I err? Two or three thicknesses of burlap over the brood-chamber was all the cover they had.

[I cannot account for your unusual loss of queens on grounds other than old age, or too high a temperature in your cellar, and the degree you did not state. When the temperature is kept too high, both workers and queens oftentimes leave the hive and never return.—JAMES HEDDON.]

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark unobtainable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10¢@12¢; choice, 12¢@13¢.—
BEESWAX.—25¢. R. A. BURNETT,
Mar. 28. 161 South Water St.

DETROIT.

HONEY.—Best white comb, 11¢@12¢. Market is improving.
BEESWAX.—23¢.
Apr. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4¢@4¼ cts. Comb, white, 7¢@13¢. Market firm.
BEESWAX.—Scarce at 19¢@22¢.
Apr. 4. SCHACHT & LEMCKE, 122-124 Davis St.

CLEVELAND.

HONEY.—Choice white in 1-lb. sections, 12¢@13¢; second quality, 10¢@11¢; and buckwheat unsalable at 8¢@9¢. Extracted, 5¢@6¢.
BEESWAX.—25¢.
Apr. 20. A. C. KENDEL, 115 Ontario St.

ST. LOUIS.

HONEY.—Choice comb, 10¢@12¢. Strained, in barrels, 3¢@4¼¢. Extra fancy, ¼ more than foregoing prices. Extracted, 4¼¢@6¢. Market dull.
BEESWAX.—Firm at 21¢ for prime.
Apr. 21. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: White comb, 12¢@14¢; amber, 7¢@9¢. Extracted, white, 4¼¢@5¢; light amber, 3¼¢@4¼¢. Market quiet.
BEESWAX.—19¢@22¢.
Apr. 18. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 13¢@15¢; 2-pounds at 11¢@13¢. Extracted, 5¢@7¢. Sales slow.
BEESWAX.—26 cts. per lb.
Apr. 22. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 3¢@7¢. per lb. Best comb brings 11¢@14¢. per lb. Demand fair.
BEESWAX.—Good demand, —20¢@23¢. per lb. for good to choice yellow.
Apr. 21. C. F. MUTH & SON, Fresman & Central Av

MILWAUKEE.

HONEY.—We quote choice 1-lb. sections at 11¢@12¢; 2-lbs., 10¢@11¢. No call for dark. White extracted, in barrels and kegs, 8¢@9¢; in small packages, 8¢@7¢; dark, in barrels and kegs, 4¢@5¢.—Demand good.
BEESWAX.—25¢.
Mar. 28. A. V. BISHOP, 142 W. Water St.

Issued every Wednesday by
THOMAS G. NEWMAN & SON,
 PROPRIETORS,
 923 & 925 WEST MADISON ST., CHICAGO, ILL.
 At One Dollar a Year.

ALFRED H. NEWMAN,
 BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Preserve your Papers for reference. If you have no **BINDER** we will mail you one for 60 cents, or you can have one **FREE** if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the **BEE JOURNAL**, and will send two or more free of cost to any one who will use them, and try to get up a club.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

One Dollar invested for the weekly visits of the **AMERICAN BEE JOURNAL** for a year, will richly repay every apiarist in America.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiarist printed on them—by mail, postpaid.

System and Success.

☞ All who intend to be systematic in their work in the apiary, should get a copy of the **Apiary Register** and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

Leaflet No. 2, entitled "Alsike Clover for Pasturage and Hay," is now ready for delivery. This should be scattered into every neighborhood, in order to induce farmers to plant Alsike, that the bees may have the advantage of it for pasturage. We send them by mail 50 copies for 30 cents; 100 for 50 cents; 500 for \$2.25—all postpaid. It will pay bee-keepers to scatter these Leaflets, even if 9 out of 10 avail nothing. If ten farmers out of a hundred plant Alsike in any neighborhood, the bees will reap a very substantial reward.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the **AMERICAN BEE JOURNAL** for one year, will be clubbed for \$1.25.

The Production of Comb Honey, as practiced and advised by W. Z. Hutchinson, can be obtained at this office, for 25 cts.

☞ **Sample Copies** of the **BEE JOURNAL** will be sent **FREE** upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Do you Want a Farm Account Book? We have a few left, and make you a *very tempting offer*. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the **Weekly BEE JOURNAL** for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

E. Duncan Sullivan, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising media. Mailed free. 52A40t

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

When Renewing your subscription please try to get your neighbor who keeps bees to join with you in taking the **BEE JOURNAL**. It is now so *cheap* that no one can afford to do without it. We will present a **Binder** for the **BEE JOURNAL** to any one sending us three subscriptions—with \$3.00—direct to this office. It will pay any one to devote a few hours, to get subscribers.

By Using the Binder made expressly for this **BEE JOURNAL**, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Dr. Miller's Book, "A Year Among the Bees," and the **BEE JOURNAL** for one year, we will club for \$1.50.

Fire.—As I have just had the misfortune to-day of having my residence burned, including all my books, letters and correspondence, I wish to say that I will esteem it a favor if my customers will please send me at once their addresses, including a repetition of their orders. All orders will receive prompt attention. The loss of the house, including its contents, is \$4,000, and not one cent insurance! We could not save a thing out of the house, as the wind was blowing a gale.
J. P. H. BROWN.
Augusta, Ga., April 29, 1887.

Should any Subscriber receive this paper any longer than it is desired, or is willing to pay for it, please send us a postal card asking to have it stopped. Be sure to write your name and address plainly. LOOK AT YOUR WRAPPER LABEL.

A Cheap Smoker.—Martinsville, Ohio, April 11, 1887.—Messrs. Bingham & Hetherington, Bronia, Mich.: Enclosed find \$2.50 for two Large 2½-inch Bingham Smokers (wide shield). They are for my neighbors. I have one of the Bingham Smokers that I have used six years, and it is as good as ever. Send ¼-dozen rates.—Respectfully, AMOS R. GARNER." 17A4t

Advertisements.

FOR Sale or Trade.—65 Colonies of BEES, principally Italians, on nice, straight worker-comb, mostly in 2-story movable-comb hives. Price, \$275.00, really worth \$350.00. Call on, or immediately address, H. J. SCHROCK, Goshen, Ind.

The prices quoted last week were an error of the printer.—Ed.

FOR CASH.—Pure Italian Queens in May and June: 1 Untested, \$1; ¼ doz., \$5.50; per dozen, \$10. For Tested Queens, double. Guarantee safe arrival.—Address, D. E. ALDERMAN, 18A1t Clinton, Sampson Co., N. C.

QUEENS for 75 cts.
I AM ready to ship choice Italian Queens, bred from select mothers. Untested, 75 cts.; Tested, \$1.50. E. F. LOCKETT, 18E1t COLUMBUS, MISS.

FRIENDS.—From many years' experience I find it to my interest, and to yours, to rear fine, well-developed QUEENS. I breed only Italians, and as I employ only experienced help to rear Queens, and making it a specialty this season, I will sell for cash till June 30, at \$9 per doz.; after June, special rates per doz. Will sell Nuclei & Bees per lb. cheap in June, as my honey-flow is over thee. Mention this paper, and write your address *very plainly*. You shall have my prompt and cheerful attention. This will not appear again. IRA D. ALDERMAN, 18A1t Taylor's Bridge, Sampson Co., N. C.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, we have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the cans leading to the honey gate, and moving sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00

NO TAB

AMERICAN
ESTABLISHED 1861
OLDEST BEE PAPER
IN AMERICA
BEE JOURNAL

THOMAS G. NEWMAN, Editor.

Vol. XXIII. May 11, 1887. No. 19.

Life is a Leaf of Paper White,
Whereon each one of us may write
His word or two—and then comes night.

Our Friend, G. M. Doolittle, is reported "on the sick list." We trust it will not be long before he may be reported as "fully recovered," and busy with his daily duties in the apiary.

A Pound of Bees, in early spring, with a good queen and a liberal use of comb foundation in the brood-chamber and sections, will rapidly build up into a good colony, and if the season is favorable, will store considerable honey during the summer.

A Damp Cellar is more deadly than dynamite! Do not live in a house with a damp cellar. In a family of seven, two have just died, and five are ill with typhoid fever—all from a wet cellar; the drain having become filled up.

Dr. Brown, of Georgia, lost his residence by fire on April 29. Loss, \$4,000; no insurance. We could hardly believe that Dr. Brown could be so very unmindful of his interests as to neglect to insure his property. That is a duty no one should neglect. Our sympathies are with our friend in his loss.

"Florida Bee-Keeping has had a setback," says a correspondent. "About one-half of all the bees here in January of last year are now dead. The 85 colonies brought here from Iowa by Mr. Poppleton, were nearly all dead at last accounts." This is very discouraging to apiarists in Florida.

J. C. Melcher, who inserted a small advertisement 5 or 6 times in the BEE JOURNAL recently, writes as follows: "I have received several hundred answers to that advertisement." This shows the value of judicious advertising in the AMERICAN BEE JOURNAL.

Liquid Honey.—In answer to a query on page 292, Mr. G. W. Demarco makes this announcement:

I have found by 8 years' experience, that the word "extracted," as applied to liquid honey, has damaged my trade in the article severely. In all these years I have failed to teach my nearest neighbors to adopt the misnomer. I have given it up in despair, and now call it *liquid honey*.

The only objection to calling it "liquid honey" is the fact that very soon after it is taken from the combs, it granulates, and then it is *not a liquid!* As well might you call ice *liquid water!* as to call this candied-sweet *liquid honey!* It would be an unfortunate misnomer!! At the convention of the North American Bee-Keepers' Society in 1879, the following resolution was passed unanimously:

Resolved, That the North American bee-keepers, in convention assembled, do earnestly ask the commercial reporters of the newspapers to use the words "extracted honey" instead of "strained honey" in their price-current reports.

Until a better name—one that can be truthfully applied to it—can be found or invented, we must stick to the name "extracted honey." Not that it is unobjectionable, but it is the best that has been presented so far! The chief objection to it is the fact that there are now so many "extracts" on the market, and some people think that this is the "extract of honey"—not the real thing! We would like a change—but it must be also an *improvement!*

No Patent Bee-Hives.—Some evil-disposed person in Indiana is reported to have stated that the Editor of the BEE JOURNAL had positively asserted "that there were no patent bee-hives in the United States."

We do not know who the person is, but the report to us comes from Warren County, Indiana. We now publicly deny ever having written or stated verbally any such thing! and demand the proof for such a charge!

More than any other publisher of a bee-paper have we said in favor of respecting patents, and the rights of individuals to their inventions, as guaranteed by the United States Government! Such a charge is not only a deliberate and *cruel falsehood*, but "made up out of whole cloth," devoid of any single thread of truth!

Our correspondent asks us if we do "not know that James Heddon, of Michigan, has a patent on a hive?" Most certainly we do! and we also know that hundreds of others have patents on hives! The total number of bee-hives patented in the United States up to this date, will not vary much from 850! Of these, 591 bear date prior to Jan. 1, 1874! The number of United States patents issued on bee-hives up to Jan. 1, 1886, were 810! The next malicious falsifier will please step to the front! Next!

An Apicultural Congress and Exposition is to be held in Hanover next fall. The Minister of State will award the premiums to exhibitors. The money prizes offered amount to \$1,500 besides the medals. German apiarists are a vigorous and pushing lot of individuals, and leave no stone unturned to make a large show of honey, and thus educate the people to eat honey in place of other sweets.

A Bold Trickster in St. Louis has been doing business on a very small capital and a mountain of "check!" He bought a very small stock of groceries of a wholesale firm for cash, and then used the wholesale firm's name without authority, for reference to those whom he proposed to swindle in large amounts.

From one man in Indiana he had ordered a car-load of butter-tubs; from another, willow-ware. Dun's and Bradstreet's agencies were overwhelmed with inquiries about him. They started an investigation, and learned that he had flooded the country with letters soliciting flour and other goods from millers and dealers, and giving them for reference. A number of millers believing his statements, shipped him large consignments of flour, some of which he has disposed of at half their value. They are still waiting to be paid, although the understanding was that the transaction should be conducted for cash.

This illustrates in some measure how producers are swindled out of their goods, by shipping them to irresponsible persons, who intend to *swindle* every one they can.

No one should send honey to be sold on commission without first finding out if the parties they ship to are reliable, and good for at least twenty times the amount of the goods to be shipped to them.

The moral taught in the above is—never to ship goods or pay money to any one with whom you are unacquainted, without first ascertaining whether they are responsible and have good credit!

Shade for Hives.—In the *Plowman*, Mr. C. H. Dibbern gives the following as his advice on the above topic:

There will be many hot days during this month, and the bee-keeper should provide some protection both for himself and the bees. Small trees, if not allowed to grow too thick, so as to obstruct the flight of the bees, furnish a grateful shade for both. The bees seem to appreciate the shade, as well as man, and will seldom leave a hive if placed in the cool shade of a tree. If no trees are at hand, then some protection by covering the hives with boards is desirable.

Failures.—Who make them? Why the men who lose heart and fail to continue the journey once begun. The man who starts for the city of Success, and gets part way and then returns to the starting place to take another road, and again pursues his journey for a little distance only to turn back, never reaching the city. It is only he who, setting out, keeps his face as a flint, and turns neither to the right hand nor to the left, that enters the city in triumph.—*Exchange.*

Beeville. In Bee County, Texas, situated about 25 miles from the bays that fringe the Gulf of Mexico, ought to be a good location for bees. It is generally rolling prairie, with a soil of dark, sandy loam. The county contains 900 square miles, and has a population of about 3,000. One-fourth of the county is covered with timber. We have often had letters inquiring about different parts of Texas as a location for bee-keeping. Our correspondent has resided there for 28 years, and will answer letters about that county, if addressed to "County Judge," Beeville, Bee County, Texas.

QUERIES

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—Ed.]

The Flavor of Extracted Honey.

Query 415.—1. Can extracted honey be put on the market of as high and delicate a flavor as comb honey of the same kind? 2. If so, give the best method of securing and handling the same?—N. J.

1. I think so. 2. Be sure that it is thoroughly ripened.—A. J. COOK.

Yes, sir. There is not space here to give my method of working for extracted honey.—JAMES HEDDON.

1. I hardly think it can. 2. I will let others answer the second question, as I have little experience.—G. M. DOOLITTLE.

1. Yes. 2. Your best method of handling and securing depends altogether upon what sort of a market and customers you have.—J. P. H. BROWN.

These questions hardly belong in this department. It would require a long article to explain the matter fully.—J. E. POND.

1. My experience is that it cannot. The finest quality of honey will ever be sold in the comb.—G. L. TINKER.

I think so. Leave it on the hive until thoroughly ripened, then extract and keep sealed up from the air.—W. Z. HUTCHINSON.

1. I think it can. 2. Take well-ripened honey, extract it, and seal it up at once. If it is exposed to the atmosphere for any length of time, it will lose its fine flavor.—H. D. CUTTING.

1. Yes. 2. Extract it as it is sold, and not as it is gathered. That is some more buncombe, some may say.—C. W. DAYTON.

1. I think it might. 2. I do not think I can answer this, and those who can, will, I think, need more room than they can have in this department.—C. C. MILLER.

Some say no; we say yes. Extract when the crop is ripe, and treat it as you would comb honey. If it granulates you may melt it over water. Extracted honey sometimes ferments, but some comb honey does too.—DADANT & SON.

1. I think so without doubt. 2. The honey should not be taken until it is thoroughly evaporated and sealed. Pass it through a cheese-cloth as it runs from the extractor, and let it have the air long enough for the imprisoned air to escape, and then close the vessel tightly and keep it in a dry place. I have samples of honey—ex-

cepting one or two years—running back to 1877, and every sample is well preserved. I have found by 8 years' experience, that the word "extracted," as applied to liquid honey, has damaged my trade in the article severely. In all these years I have failed to teach my nearest neighbors to adopt the misnomer. I have given it up in despair, and now call it *liquid honey*.—G. W. DEMAREE.

1. Yes. 2. Extract it after it is sealed over and fully ripened; then put it into kegs or small packages for the market.—THE EDITOR.

Frames for Extracting.

Query 416.—1. When the standard Langstroth hive is used for producing extracted honey, is it best to use full-depth second-stories or shallow supers on the tiering-up plan? 2. How deep should the frames for the latter be? 3. What thickness should the top and bottom bars be to prevent sagging?—New Jersey.

I use full-depth Gallup frames with 9-32 of an inch thick top-bar.—G. M. DOOLITTLE.

1. Full depth. 2. I use reversible frames with 1/2-inch top-bars.—A. J. COOK.

1. I see no advantage in shallow extracting stories, except the pleasure (?) of extracting twice instead of once.—C. W. DAYTON.

Both the standard Langstroth frame and a shallow 4 1/2-inch frame on the tiering-up plan work well. I prefer the latter. The top-bar is 3/8-inch, and the bottom-bar 1/4-inch.—J. P. H. BROWN.

1. I should prefer shallow supers, and work them on the tiering-up plan. 2. From 5 to 7 inches. 3. The top and bottom bars should be 3/8 of an inch to prevent all sagging.—G. L. TINKER.

1 and 2. In the early honey harvest I prefer a frame about 5 inches deep to start tiering-up. 3. The top-bars should be 3/8-inch; bottom-bars, 1/8-inch. If you use wired frames, make the bottom-bars 1/4-inch.—H. D. CUTTING.

1. I prefer full-sized frames. 2. The regular Langstroth frames are 9 1/8 inches deep inside. 3. I use wired frames with centre support, and find 3-16-inch top-bars and 1/8-inch bottom-bars sufficient.—J. E. POND.

After trying both styles largely, we much prefer a half-story super. We make the upper frames 6 inches deep; two such stories hold more honey than one full story, and are more easily handled. We make top-bars 5/8-inch thick, and bottom-bars 3/8.—DADANT & SON.

1. Perhaps locality has something to do with these things. I have used both the half depth and full size Langstroth frames for taking liquid honey since 1879, and the shallow frames on the tiering-up plan has given me the best results. My half-depth frames are 4 3/8 x 17 3/8 inches, the length being the same as the standard Langstroth frame. They are adjusted in cases the same size of the top of the brood-chamber, and are just bee-space

deeper than the frames, viz: 5 1/4 inches deep, and are made so as to be interchangeable. For taking liquid honey the frames should be worked 1 1/2 inches apart from centre to centre, and must be fixed in the case so that the cases can be handled without the frames becoming misplaced. 2. When foundation is used in full sheets, 1/4-inch will answer for the top and bottom bars.—G. W. DEMAREE

The shallow frames undoubtedly possess some advantages in this direction, but whether they are of sufficient weight to warrant their adoption for this purpose alone, I cannot say. I would suggest that the shallow frames be one-half the depth of the Langstroth frame, or a trifle deeper, and that the top and bottom bars be a good, plump 5-16 of an inch.—W. Z. HUTCHINSON.

1. Having used both for 16 years, I have the advantages and disadvantages between full and half depth frames to be about equal. Considering the important feature of uniformity, I have lately used and would advise full depth. 3. Every thing depends. Do you use full sheets of foundation or not. Do you wire the frames or not? Do you use metal standards or not? Do you make the frames of pine or poplar?—JAMES HEDDON.

Use full-sized Langstroth frames. The top-bars should be V-shaped, and cut out of inch lumber; then all danger of sagging will be avoided.—THE EDITOR.

Winter Repository for Bees.

Query 417.—Suppose an earth-roofed cave, half under and half above ground, frost-proof, well drained, well sub-earth ventilated, containing a trough holding 2 barrels of water, into which, and from which, by a sub-earth pipe passes 4 or 5 barrels of fresh water every morning and evening, from a well (the temperature of which water is 46 degrees Fahr.) 1. Would such a cave be a good winter repository for bees? 2. Will the trough of water be a benefit or an injury to the bees? 3. How many colonies will be safe in such a cave, the dimensions being 10x15 feet, and an average of 6 feet high?—S., Central Ills.

I see no great objections to such a repository. 3. From 50 to 75 colonies.—J. P. H. BROWN.

If the walls are dry, and you can give ventilation when needed, you can safely winter in it 150 colonies, or as many as it will conveniently hold.—DADANT & SON.

1. Yes, if the temperature was maintained at 44°, and the hives ventilated at the top. 2. Neither. 3. According to my experiments in even temperatures, 500 colonies.—C. W. DAYTON.

1. Yes. 2. I should say it would be a benefit by keeping an even temperature, if nothing more. 3. As many as it will conveniently hold.—G. M. DOOLITTLE.

1. I think it would be a good repository for bees. 2. The water would be a benefit; it will absorb impurities which would be carried out with the water.—H. D. CUTTING.

1. It would depend upon the temperature maintained in the cave,

whether it was a good place to winter bees. I think with fresh water flowing through it, a higher temperature would be required than in a dry cave. 2. I think the water would be a benefit if it kept the temperature at 45° and above. 3. If the conditions were right, you could not get in too many.—G. L. TINKER.

1. Yes, I think it would. 2. It may serve to equalize the temperature; it would have no other beneficial effect. 3. As many as can be stored comfortably. The above is theory with myself drawn from reading experiments of others; I have never wintered bees save on summer stands.—Jos. E. POND.

I think it would be a good winter repository for bees, and that the water would be beneficial. I have had no experience with very large numbers of colonies in cellars; but I should think this size of cellar would answer for from 100 to 150 colonies.—W. Z. HUTCHINSON.

1. I should guess it would be an excellent place, but you can tell better by trying. 2. Perhaps a benefit. 3. If it is really well ventilated, it is possible that it might bring through in good condition all it would hold; 150 colonies ought certainly to winter in it well, and a less number would probably do still better.—C. C. MILLER.

1. I should say capital. 2. Yes, because it will aid materially to control the temperature. 3. Just as many as you can get in, providing you can keep the temperature at 45° Fahr., in the coldest weather, which I believe would be possible with such an arrangement.—A. J. COOK.

1. If the temperature be kept at about 45° Fahr., the cave will no doubt answer well. 2. The water would be beneficial in equalizing the temperature. 3. It will do to comfortably all it.—THE EDITOR.

Convention Notices.

The next meeting of the Darke County Union Bee-Keepers' Society will be held at Greenville, O., on Friday, May 27, 1887.
J. A. ROE, Asst. Sec.

The next meeting of the West Lake Shore Central Bee-Keepers' Association will be held on May 26, 1887, in Kockring Hall, at Kiel, Wis.
FERD ZASTROW, Sec.

The May meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held at Rockton, Ills., on Tuesday, May 24, 1887.
D. A. FULLER, Sec.

The New York World says that many a dealer who places a \$10 advertisement in his village paper begrudges his investment when it is worth double to him what he pays for it. Advertising rates in city newspapers would astonish such business men. One column in the Chicago Tribune costs the advertiser \$26,000 per annum. The New York Herald receives for its lowest price column \$39,562, and for its highest price \$63,800. The New York Tribune for the lowest, \$29,754, and for the highest price \$85,648, and these papers never lack for advertisements to fill their columns.

Legislation on Priority of Location.

WM. F. CLARKE.

On page 251, under the side-heading, "Where is it found?" Dr. C. C. Miller writes: "On page 218, in the address of Rev. W. F. Clarke, occurs the following statement: 'It is proposed by some to pass a law securing to the first-comer as a bee-keeper into a neighborhood, the exclusive ownership of the bee-forage within certain limits!' Will Mr. Clarke kindly give the names of some who have made such a proposition, and also the place, if any, where it has been mentioned in any of the bee-papers?"

A civil question is entitled to a civil answer, and I shall do my best to give it frankly and fully. In my reference to "some," I had more particularly in view Dr. Miller himself, Mr. Heddon, and Mr. Betsinger. At the outset of the discussion, Dr. Miller was generally understood to advocate legislative protection to "the first-comer as a bee-keeper into a neighborhood." Mr. Heddon hailed his utterances at the Indianapolis convention as harmonious with those previously made by himself in favor of priority of location, but did not agree with the Doctor in trying to secure it by legislation. After the discussion had been going on for some months, Mr. Heddon, on page 138, withdrew his contention with some facetious hits at the Doctor, and said, "I give him the case for the present at least." Mr. Betsinger, who was at first inclined to oppose the Doctor's views, announced himself as a convert to them, on page 105. I reply, therefore, that all three of these gentlemen have advocated the proposition mentioned in my address, and, as requested, I will now proceed to cite quotations from the "place" where they have done so, viz: in the AMERICAN BEE JOURNAL.

The Doctor first aired his pet scheme of legislative protection for bee-keepers at the Indianapolis convention in October last. There was no verbatim report of his remarks in advocacy of the movement, and I will not pretend to quote him, but the impression made on my mind and on the minds of others was, that he wished legislative recognition of a right of pre-emption to territory in which to keep bees. Thus Mr. Heddon understood him. He says in the AMERICAN BEE JOURNAL for 1886, on page 709: "Only a few months ago I wrote on the subject of 'priority-right of location,' trying to show why

the prior occupant had the natural exclusive right... Surely, none have forgotten how malignantly my position was attacked... Imagine my surprise at noting that at the Indianapolis convention a committee was appointed to inquire into the desirability and feasibility of asking our Government to legislate this condition of affairs."

In the same volume, on page 743, Dr. Miller thanks Mr. Heddon for giving his view on page 709, and substantially endorses it. He says: "I understand Mr. Heddon to claim that the prior occupant has a natural exclusive right, and that such exclusive possession would result in the greatest good to the greatest number. In this we are very nearly, if not altogether in accord," and he goes on to specify as the point in regard to which they are not quite in accord, Mr. Heddon's "idea of a natural exclusive right of the prior occupant" securing of itself "the survival of the fittest." Instead of leaving the result to the operation of natural law, the Doctor would secure it by legislation. He says further: "However much thought Mr. Heddon may have given to the matter of rights as to 'priority of location,' I cannot believe he has given much thought to it with the possibility of legislation in view, but it seems to me that without much thought upon this branch of the subject, he has hastily settled upon the conclusion that because there was no legislation there could be none, etc." No legislation on what? "Rights as to priority of location" is the Doctor's own statement of the case, which Mr. Heddon would leave to the operation of natural forces, but which Dr. Miller would have regulated by law.

In the AMERICAN BEE JOURNAL for 1886, page 775, Mr. Heddon replying to the Doctor, contends that the "natural right of priority" is competent to take care of itself without such legislative aid as Dr. Miller proposes. On page 794 of the same volume, Mr. W. H. Osborne urges the following valid and strong objection to the Doctor's position: "There are persons in this village who have kept bees longer than I have, and if by reason of priority, I must surrender the business to them, such legislation might seem more desirable to them than to me."

In the AMERICAN BEE JOURNAL of Dec. 22, 1886, Mr. C. G. Beitel says: "Again, when we scan closely a law such as is contemplated, we cannot fail to perceive what a source of litigation it might prove. The question of priority of location would often be as difficult to establish as that of priority of invention, etc." In the present volume, on page 57, Mr. J. E. Pond, under the heading, "Legislation for Bee-Keepers," and evidently discussing Dr. Miller's proposition, says: "The question of priority of location of an apiary is one on which my views are so well known, that I need not, neither do I care to discuss it; but the question of legislation on that subject is one on which more light is needed, and for that reason

may have a small share of attention." In that issue of the AMERICAN BEE JOURNAL, Dr. Miller for the first time disclaims the priority idea, saying: "And now it is Mr. L. N. Tongue, on page 24, who sets up the priority question in order to knock it down. Has Mr. Tongue not yet found out that nobody ever asked for, or hinted at wanting legislation on the priority question?" I read that with amazement, but not being in the controversy, I did not care to bring the Doctor up with a sharp turn by quoting his previous utterances, and pointing out the drift of the discussion as I have now done.

On page 69, present volume, there is a long article of the Doctor's probably written before the brief reference to Mr. Tongue in the previous number. It is mainly in reply to Mr. Heddon, and mentions "priority of location" several times without any disclaimer of it as part of his scheme. He even says, "In the generality of cases I believe in the priority right." Further, in replying to Mr. Heddon's remark, that "priority of location gives one a natural right, *provided he is fit to hold that location,*" the Doctor proceeds to argue again against the natural "survival of the fittest," and pleads for legislation for the sake of those who try to crowd in but cannot, and are involved in loss by their futile attempt, which, he says, might have been prevented if the first comer could have said: "This territory I hold in fee simple as my own, and you must go elsewhere if you want to keep bees." Still arguing along the priority line at considerable length, the Doctor winds up by asking, "On all accounts, then, should not every man have a legal right to his own ground?"

On page 154, Mr. G. M. Alves thus defines the question at issue: "Mr. Heddon thinks that the claims of 'priority of location' are right in morals, but doubts whether legislative bodies could be induced to enact a law for the enforcement of the same. Dr. Miller not only accepts the principle as right, but goes further, and gives it as his opinion that it would be practicable to make it statutory."

On page 199, Dr. Miller is "aroused." He is replying to Mr. J. E. Pond, and asks that gentleman to name "a single person who has ever advised, requested, or desired any legislation on 'priority?' Getting still more "aroused," he says, "Why it is that everybody tacks on 'priority,' I cannot imagine." Again, as if fearful he has not been emphatic enough, he says, "Allow me to impress the fact that so far as I know, no one has ever advocated obtaining legislation in favor of 'priority of location.'"

I am forcibly reminded of an incident of my juvenile days. Our school was in a second story, and the stairway leading to it had a pair of banisters. One day some of the boys played a dirty trick on the master. They smeared the banisters with some filth, and seated serenely in the school-room, awaited his arrival. Just as they expected, he had run his hands along the banisters as he came

up-stairs, and got them sadly bedaubed. He hastened to his desk, and offered a reward of half-a-crown to any boy who would tell him "who had hands in this." A boy volunteered the desired information, and gave it by saying, "Please, sir, you had hands in it."

I am at a loss to know why Dr. Miller should wax so warm in his tardy disclaimers of the priority idea. As Mr. Pond very justly says, on page 233, "I cannot see how the question of legislation, as desired by Dr. Miller, can be divided from that of priority." Guelph, Ont.

For the American Bee Journal.

Wabash County, Ind., Convention.

The Wabash County, Ind., Bee-Keepers' Association met at the G. A. R. Hall, at North Manchester, Ind., on April 20, 1887. The meeting was called to order by the Secretary. The President and Vice-President being absent, J. C. Zimmerman, of Wabash, was chosen President *pro tem*.

The reading of the minutes of the previous meeting was heard and approved, after which a discussion followed on "When should sections be placed on the hives?" Messrs. Martin, Whitlow, Miller, Comstock and Zimmerman all agreed that they should be put on as soon as honey begins to come in; Mr. Singer would not put them on too soon, on account of too great loss of heat from a colony. "Can the pure fertilization of queens take place by drones from a miss-mated Italian queen?" It was decided that they could.

The following questions were taken up in order and discussed: "Which is the most profitable, comb or extracted honey?" "Can a man who runs his apiary for honey, combine it profitably with queen-rearing or *vice versa*?" "Is spring feeding to stimulate rapid breeding profitable?" (No.) "How can we keep our bees from bothering our neighbors?" (It was decided that there is no trouble when only a few colonies are kept). "Is it necessary to have bee-space between the cases?" "How do you prevent robbing?"

The following essays were read: Aaron Singer: "Do gentle bees gather as much honey as ill-tempered ones?" "What sized packages sell the best?" "When should we transfer?" J. J. Martin: "How do you get your bees to work in the sections where you want them to?" The following resolution was then passed:

Resolved, That this convention consider the Italian bees superior for all purposes, and each member endeavor to Italianize his apiary as rapidly as possible.

The following officers were elected for the ensuing year: J. J. Martin, President; Alex. Hess, Vice-President; F. S. Comstock, Secretary; and H. C. Whitlow, Treasurer.

The next meeting is to be held in Wabash next fall, the time to be decided by the executive committee.

F. S. COMSTOCK, Sec.

Read at the Wisconsin State Convention.

Honey Adapted to the Human System.

DR. J. W. VANCE.

The subject of honey ought to be of interest to the agriculturist, knowing as he does, that every flower which blooms on his farm and along the highway yields its delicious nectar to the busy bee that, with tireless wing, flits from flower to flower in quest of its food. From every meadow, orchard and forest the summer-wind bears away countless tons of this precious product that ought to be gathered for the good of mankind.

It is not of the importance of bee-keeping as a pursuit, or the progress of bee-culture, that I wish to descant, but rather to say a few words about honey—to speak of its constituents, and its perfect adaptation to the wants of the human system, and of its superiority as a saccharine product to all other sweets in common use.

Although honey has a very ancient history, both sacred and profane, having been in use from time immemorial, its praises sung by inspired and uninspired poets, yet in modern times it has fallen into comparative disuse, perhaps on account of the competition of cane and grape sugars, and syrups made from them. The use of honey has almost become a lost art. It seems to be regarded by most people as a luxury only, and seldom appears on the table except on great occasions. Away back in the annals of time, our ancestors used it as a common article of food, and in cooking.

Honey is a physiological sweet; in other words its constituents are such that it is absorbed into the blood without undergoing chemical change. Such is not the fact with regard to sugar. Sugar is indigestible, or rather not as susceptible of absorption and assimilation as honey, but it requires the action of the gastric juice to split or invert its elements, the muriatic acid element of the gastric juice being the chief agent in this chemical transportation. This change produces what is termed in chemistry dextrose and lævulose. I presume this explanation does not convey a very clear or definite idea of the nature of these products, for the names applied only indicate how they affect polarized light. After this change occurs, absorption takes place. If in any way it is hindered, or, on account of an excess of sugar above the capacity of the gastric juice to transform, there remains a residue, the result is decomposition into elements that irritate and inflame the mucus membrane of the intestinal canal, producing a list of ailments too numerous to mention here. Think of the legions of little ones who have been the victims of their universal fondness for sweets, and who so frequently suffer from gastric troubles which are, in a large degree, the result of sugar indigestion. How many, many children have perished from eating candy!

The importance of sugar as an element of food may be inferred from the large proportion of the elements of our food which is transformed by the action of the digestive organs, into the constituents of sugar. Consider the proportions of bread, potatoes and vegetables that we consume daily, all of which must undergo this saccharine change before they are suitable to be appropriated by the human system; it may give an approximate idea of the amount of these elements that are required to nourish our bodies.

If, therefore, the saccharine comprises so large a part of the elements of our food, does it not become an important question as to what form of sweet is the most appropriate and healthful for the nutrition of the human body? For the reasons I shall hereafter enumerate, it seems to me that you will agree with me that honey is the most important and the most healthful, because it is absorbed into the system without change, and, because, unlike sugars, it does not easily undergo fermentation. The formic acid which is an ingredient of honey, prevents chemical change and the morbid processes arising from decomposition of sugar.

Let me repeat the points of difference in ordinary sugars and syrups, and their comparative inferiority to honey as a saccharine food: Honey is an inverted sugar consisting of levulose (fruit-sugar) and dextrose (starch-sugar) and readily absorbed into the system without being acted upon by the gastric juice. Sugar and syrup require the action of the gastric juice, converting, or as it is expressed in chemical language, inverting it into dextrose and levulose, before it is susceptible of absorption and assimilation in the blood. When thus acted upon by the digestive organs, it is assimilable, but in case of weakness of digestion, this action does not occur, and decomposition is sure to follow. Honey is not only a delicious form of sweet, but is a very healthful and nutritious form of food. It aids the natural functions of the alimentary canal. It is recommended, by those who have thus used it, as a refreshing drink, diluted with water in the proportion of from 2 to 5 per cent.

As a remedy for croup and sore throat, it is quite efficient. It is highly useful as a vehicle in the administration of medicine in the treatment of diseases of the mouth and pharynx, in the form of a gargle.

It would require too much time and space to enumerate the many valuable uses to which honey is adapted in medicine and surgery, as well as a most nutritious and healthful food. If these hints may tend in even a small degree toward bringing back into general use that sweet which comprises so large a part of the food of our remote ancestors, I shall be glad. Let us hope the people of our country will recognize the presence of such a perfect natural product, as will induce them to make a larger use of it as a food as well as a luxury.

Alfalfa as a Honey-Plant.

W. L. PORTER.

On page 248, Mr. A. J. Foss refers to the proceedings of the Colorado bee-keepers' convention of last March. The report referred to was one taken from the Denver daily papers. I did not have the pleasure to be present at the meeting, but it was evident that the reporter aimed to make something very pleasant to read—something like "Wiley's pleasantry." While we have many ladies in Colorado who are engaged in bee-keeping (and they deserve to be complimented highly), still they are not in the majority, and not the most extensive apiarists in the State.

I am in one of the greatest alfalfa sections in the State, and I have made bee-keeping a business here for the past six years, yet I must say that I am not able to declare alfalfa a honey-plant of any note. I have observed with my best observing powers, since I have been here, to ascertain the value of alfalfa as a bee-feeding, and as yet I am not able to sing its praises; and if a person would exhibit a pound of honey and call it pure alfalfa honey, it would be exclusive evidence that he was not an "observer," or did it for "pleasantry."

There is no time in the season when alfalfa is in bloom, that other flowers do not figure largely as honey-plants. The latter part of June, when the first cutting of alfalfa blooms, there is an abundance of Colorado-mint on which the bloom lasts about four weeks, and it produces an abundance of beautiful white honey; raspberry is also in bloom at this time. At the time the second and third crops bloom, there is an abundance of cleome, and it is certainly from this that we get our greatest yield.

When we have the mint in abundance, it is rare to find a bee on alfalfa; the same is true when we have cleome and other valuable plants in bloom. The bees seem to take alfalfa as a make-shift—work on it when they can find nothing better. There are times when the bees fairly swarm on the alfalfa, but it has been my experience that when they are working the strongest on it, they are at a standstill in the sections.

One great draw-back with the alfalfa—if it is a honey-plant—is that when raised for hay, it is cut as soon as the first bloom opens. When farmers leave it to get a crop of seed, it gives the best chance for honey, and it might be that the latter part of the bloom is richer in nectar; but on this I have not had a fair chance to observe. Since I came to the State I have produced over 25,000 pounds of honey, and I never have had an ounce that I could call alfalfa honey. I can recognize the mint, cleome, raspberry, and certainly the rosin-weed; but what alfalfa is like, I have not yet learned.

Two years ago I read an article in the BEE JOURNAL, from one of Colorado's most flowery writers, setting forth the great honey-resources of the State. He said that the cactus was one of the best of honey-plants, from which the most of our honey was gathered. There are many hundred acres of the cactus within a mile of my apiary, and it is a beautiful sight to see it in bloom; but I never have seen a bee either gathering honey or pollen from it. It is evident that the writer pictured vividly in his imagination. He perhaps thought from its abundance, beauty, fragrance and uselessness, that it ought to be a honey-plant! Perhaps this is the way the conclusions about alfalfa have been obtained. I am not prejudiced against it, for it certainly will produce more hay to the acre than any other plant, and I should be glad to be convinced that it is the greatest honey-plant. But the foregoing is my sincere observations.

Greeley, 6 Colo.

For the American Bee Journal.

Hiving Swarms—Building Drone-Comb

G. M. ALVES.

Mr. Hutchinson's book, entitled "The Production of Comb Honey," I have read with very much interest. The clearness with which the author states his ideas, together with his enthusiasm, raises his performance at times to some considerable degree of brilliancy. A work of this kind, coming from a man practical in details, as Mr. Hutchinson undoubtedly is, never fails to strongly interest.

Upon the last page, the reader is freely invited to candid criticism. I wish here to take advantage of this frank invitation.

The central idea of the little book is "hiving swarms on empty frames." Mr. Hutchinson's arguments in this direction, are given with such vigor and clearness, and the facts upon which they are based are so abundant and so strongly vouched for by him, that I feel compelled to accept his conclusions, provided along with them it is insisted that the swarms should be in a normal condition, *i. e.*, that they should be natural ones, or if "made up," they should satisfy the general conditions of natural ones. My observations are, that a "made-up" swarm indiscriminately treated in this manner, will as a rule give unsatisfactory results. I take it that Mr. Hutchinson intends this treatment only for natural swarms, but he does not plainly make this distinction, and hence the novice might conclude that if it was well for a natural swarm, it would be equally well for one "made up." The gist of my objection to treating "made up" swarms indiscriminately in this manner, will appear in a discussion of his observations to be found upon page 33 of his book. He raises the question *why* bees build drone-comb, and then answers: "I believe they always are actuated by one of two rea-

sons, viz., to rear drones in it, or to enable them to store honey more rapidly."

I hope it will not be considered hypercritical when objection is raised both to the form of the question, as well as the answer given. *Why* bees do any given thing, would seem to presuppose a power of reason and volition which they by no means possess, and I have not found that bees construct much drone-comb "to store honey more rapidly" when conditions are normal.

It seems to me preferable to put the question in this form: Under what conditions do bees build drone-comb? To which I would answer: When drones are likely to be needed, and when during a honey-flow queens are inactive, either from superannuation or from being in a recuperative state. My observations have been so numerous, and the results have been so uniform. I accept it as a natural law, that bees with a queen in a prolific state, are impelled to construct little drone-comb, and with a queen in an unprolific state (it matters not how fruitful she may be normally) will be impelled to construct a considerable amount.

I have always found that for a certain time previous to casting the first swarm, the queen becomes quite unprolific, and remains so until the swarm issues, by which time she has recuperated, and then again becomes prolific. I have noticed this so repeatedly, and it is so in accord with similar phenomena in natural history, that I would much question the accuracy of any observations to the contrary. Therefore, in using Mr. Hutchinson's method when dividing for increase is resorted to, great precaution should be taken that the queen should not be in or near her resting state; and we are very liable to get such an one in the old way of dividing or driving just before the season of natural swarming. In dividing colonies for increase it would seem that the only proper way of using this method would be in employing only young prolific queens.

In a merely scientific point of view, there are some passages scattered through the book, besides the one already pointed out, that are inaccurate and tend to indefinite ideas. For instance, after mentioning the fact that when an empty frame was inserted in the centre of certain colonies before swarming, it was filled mostly with drone-comb and drone-brood, whereas after swarming the same queens and bees when hived upon empty frames, filled them with worker comb and brood. The reason for their different action is then given as follows: "Before they swarmed the bees knew that drones must be provided for the fecundation of the young queens, etc." Now we may not attribute to bees such power of reasoning, nor may we conclude that they are not impelled by laws over which they have no control, and in which they have no volition.

The fact is, the bee is but a product of natural law. In the first instance, the colonies were in a state of more

or less inactivity, in which if the queen laid at all, she must deposit mostly drone eggs, which even the workers are at times able to do. In the second instance, recuperation had been accomplished, and the queen and all were impelled to active duty. In both instances the queen and her bees were merely the *subjects* of natural laws; and because these laws of rest and activity are beneficent in all directions to the perpetuation and well-being of the bees, we are not allowed to conclude that the bees themselves do any intellectual planning, but rather that their *very existence* is only to be accounted for by the fact that they are the merely passive subjects of these (to them) impelling and immutable natural laws.

However, as before said, the book is filled with contagious enthusiasm and pointed suggestions, and I hope all will read it. It will certainly be to their interest to do so.

Hives for Comb Honey.

J. H. ANDRE.

During the season of 1886-87 I described a new hive; I still think now, more than I did then, that it was *the* hive for comb honey and for wintering bees, but one objection is its cost, and another is its difficulties in manipulating its frames. One reason that I made it was, I did not like a large frame, and also I thought if the frames were deep enough to contain honey in the tops all of the time, the bees would enter the sections quicker than they would from dry combs, and the sections would be cleaner than they would be if they run across old black comb. In both of these I believe I am correct, but taken all in all, cost and everything into consideration, I would not advise any one to try them, as I wish to be fair, and not mislead in the pursuit of bee-keeping.

I had not decided until a day or two ago to throw them aside, but while cleaning out a hive that the bees died in the past winter, I saw that their objections over-balanced their good points.

I shall use a hive in the future 14x17 inches, Simplicity depth, frames crosswise, two 6-inch entrances on the side (cut out of side instead of bottom), case of 32 sections, no division but to rest on strips, and if it troubles to remove the case entire, I will remove the sections. With a division-board a colony can be hived in one-half the hive as two in one hive. I like a loose bottom, but if I cut the entrance in the side of the hive, and place the frames as high as will be practicable, I think I can clean out the *debris* in the winter, and save something there in the way of claps, etc.

Bees have gathered but little pollen yet; it is the most backward season for bees that I ever knew.

Lockwood, ♀ N. Y.

For the American Bee Journal.

Sections Filled with Comb, etc.

W. Z. HUTCHINSON.

I have just read the article of Mr. Dibbern, on page 264. I fear he does not use the right kind of sections, nor take the proper care of them, as he speaks of their becoming soiled by honey that has leaked out, by dust, bleached by the light, or stained by getting wet.

Basswood sections are easily soiled by any honey that may become daubed upon them, but white poplar is free from this objection. Mr. Dibbern takes Mr. Thielmann sharply to task, as not being a progressive bee-keeper, because he does not use separators; it seems to me that allowing sections of comb to become covered with dust, bleached out by the light, and stained by getting wet, are not exactly signs of progression, but rather of neglect and carelessness. Of course sections treated in such a manner could scarcely be classed as "number one." I always put my unfinished sections into cases in the fall, and pile them up carefully, putting a tight-fitting cover at the top and bottom of each pile, being careful that there is not a crevice left large enough for even a spider to enter; and in the spring they come out just as sweet, clean and fresh as when put away. It is possible that the fall-built combs of some localities are dark or yellow, but such is not the case here. Of course *dark* combs ought not to be used for white honey.

Mr. D. says: "In an apiary that is run upon correct principles, there will be few or no combs built during the white honey harvest to carry over to another year to be refilled." Of course if the bees are crowded near the close of the honey harvest, a greater proportion of combs will be finished, but I have never found it profitable to do this, especially as I find empty combs so valuable in the spring.

In regard to getting the combs cleaned up: There is no necessity for putting the sections on the hives and leaving them until the weather is so cool that there is difficulty in removing them. They may be placed upon the hives in the forepart of a pleasant day, and will be ready for removal before night. If left upon the hives several days, the first pleasant day should be improved by their removal. The bees may be gotten out of the cases in the same manner as from cases of honey. Smoke as many bees as possible down into the hive, then remove the case and shake it vigorously in front of the hive, which shaking will dislodge most of the bees, when the case may be carried to the screen-house and placed upon end, where the few stragglers will seek the light and escape. To attempt to perform such operations upon a *cool* fall day would be folly, but upon warm days, such as *always* come after the close of the honey harvest and before cold weather, it can be managed without *any* trouble.

There is still another method, viz: that given by Dr. Miller in his book: Pile up the cases of sections out-of-doors, or in some place accessible to the bees, then adjust the cover in such a manner that only one or two bees can pass in or out at once, and the combs will be cleaned up with no further trouble.

THE CAPPINGS OVER HONEY.

It seems to me that Mr. Dadant, on page 267, offers to yield the palm upon peculiar grounds; viz., if I can succeed in evaporating honey to one-half its former bulk, he will admit that the cappings over honey are not impervious. I fail to see how this would be satisfactory proof. I presume that the ground that Mr. Dadant desires to take is this: If honey *cannot* be evaporated one-half, then the "distinguished apiarists" were mistaken. It is quite probable that they did not take the trouble to measure the amount of evaporation; they probably saw that the honey occupied considerably less space, and used the expression "one-half" without intending to be *exact*. Such expressions are often used, colloquially, in this manner. I believe, though, that Mr. Poppleton did not say "one-half"—he simply said: "The honey in the dry atmosphere will become thicker and occupy less space."

So far as the question under discussion is concerned, it is immaterial whether the honey evaporated to one-half or only nine-tenths of its former bulk.

How to Market Honey.

W. A. PRYAL.

The following article I wrote for the San Francisco *Chronicle* last August, and thinking that it might be of interest to the readers of the AMERICAN BEE JOURNAL, as the subject of marketing our honey crop is now being discussed, I send it as my contribution on this interesting and important matter. The article is substantially as follows:

"Every year, no matter whether the season has been favorable for a heavy production of honey or not, the same complaint is heard from the bee-keepers—that the prices netted for their product are not sufficient to more than pay expenses. For years the price has been steadily going downward, especially for the extracted article, until it seems now to have reached a point beyond which it is impossible to sink. One desperate apiarist in southern California, who has been netting $2\frac{1}{2}$ cents or less per pound for fine white-sage extracted honey, says that he will ship no more, but has commenced feeding the honey to his hogs, confident that they will fatten readily upon it, and that he can convert them into a choice article of honey-fed bacon. This seems to be the first instance on record where it has been found more profitable to

dispose of so delicious an article in such a manner. The same man is also experimenting by mixing extracted honey in the feed of his cows, and thinks that good results are bound to accrue from such a source.

"It is a great pity that bee-keepers should not receive a fairly remunerative price for their honey, and the whole trouble lies in the fact that people in large cities, like San Francisco, are not educated to its use, and do not have it brought to their attention in such a manner as to lead them to make it a regular portion of their daily diet. It is not necessary here to go into a dissertation upon the subject of the healthfulness of honey as a regular concomitant of the table. From time immemorial this fact has been recognized by writers and physicians.

"Honey enters largely into the preparation of many excellent remedies, particularly those which are adapted to the cure of throat and lung troubles, and many who have cured such affections in their own persons, can testify to the marvelous healing-powers of honey when freely consumed. What is needed is to have the honey—both extracted and comb—brought directly to the attention of house-keepers, especially of the middle and poorer classes, in such shape and at such a price that it will be within the reach of the most limited purse. Even at the low prices complained of by the producers, it is a fact that by the time the honey is offered at retail, the rate asked is such that it is regarded as a luxury, instead of, as should be the case, a common article of diet.

"Extracted honey is the purest and cheapest sweet that is known. It should displace molasses in every household, and may be made to take the place largely of sugar. There are many bee-keepers in this State who do not consume a pound of sugar from one year's end to the other. The better grades of white honey are used in all culinary operations, and even for sweetening coffee and tea, and one cannot detect the difference between food so prepared and that into whose composition the best grades of sugar have entered.

"Many Eastern bee-keepers have solved the problem of a profitable market for their honey by fitting up wagons and making regular trips from door to door in the towns and cities, and as soon as the excellence of their products becomes known, they have no difficulty in disposing of all they can produce at good prices. There is any opening, or rather any number of them, in any large city for such an enterprise. The extracted honey should be carried in a tank, from which it may be drawn in any desired quantity, and the purchaser not be obliged to pay a high price for the glass or tin vessel in which, as is now the case, extracted honey is sold. The comb should be in sections without glass, so that when a person buys honey he gets as little of anything else as possible with it. By offering the honey at such moderate prices as may now be done, and still save a

profit, a great many tons of the article might unquestionably be disposed of in any city at a good profit, and a steady demand thereby created where now not a hundred pounds finds sale in a twelve-month."

North Temescal, Calif.

For the American Bee Journal.

Reports on Wintering Bees.

G. W. DEMAREE.

Mr. Gilliland's statements on page 249, places the question of the natural condition of bees in winter quarters beyond all philosophical argument. Were I to attempt to reply to his "facts," it would be a dead-set case of "'tis and 'taint."

The case which he cites, however, of a hive-cover being blown off, must be ruled out, as that was a case of disturbance, not a natural condition. But it happens that I, in the same winter (1885), wintered a large colony without any protection over the tops of the frames, only what a 10-inch super with a flat hive-cover on top of it might be supposed to afford. That colony endured a swoop of 20° below zero in the month of January, 1885, the coldest weather here of which we have any record. When the hive-cover was raised to peep in, the bees could be seen sandwiched between the combs, silent as the dead. They never "roared" until spring-time, and until the proper conditions were present.

My love for the honey-bee has bordered on infatuation for over 40 years, and in all these years when I have kept bees, I have missed the gentle hum of the bees in the winter months. But when spring-time would come, with sunshine and flowers, and the bees would begin to breed up, a joyous "roar" would begin to be heard in the apiary after the day's toil. Every apiarist knows how this state of things gladdens the heart, touched by the spring resurrection. But now Mr. Gilliland reverses the whole thing, and has the bees "roaring" in zero weather, and silent when the "sun warms things up." This difference in matters susceptible of proof, must be settled, if at all, by the preponderance of the evidence, and I propose, the Editor concurring, that this question in bee-science be settled in that way. I will suggest that all bee-keepers who feel inclined to do so, write on a postal card, addressed to the AMERICAN BEE JOURNAL, in substance like the following, according to the facts and their experience:

BLOOMFIELD, Ind., April, 1887.

I wintered my bees on the summer stands, protected and unprotected. At a temperature of zero and lower the bees "roar" until they can be heard "10 feet from a hive."—JOHN C. GILLILAND.

CHRISTIANSBURG, Ky., April, 1887.

I wintered my bees on single-walled hives, on the summer stands. When the temperature approaches zero, or goes below, no sound issues from the hives, if the bees are in good health.—G. W. DEMAREE.

If a great number of such reports should be sent in, they could be con-

densed and put in tabular form so as to occupy but little room. Who would not like to see the result? - Let us have the evidence.

Christiansburg, 3 Ky.

Western Plowman.

Apicultural Notes for May.

C. H. DIBBERN.

Of all the months of the year May is perhaps the most important to the successful apiarist. Of course this statement would apply to April in the States south of "Mason and Dixon's line." It is yet too early to expect to secure much surplus honey, and I find it more profitable to direct all my energies to building up my colonies to a uniform, strong condition. If the bees are worked for extracted honey, some extracting may be done to advantage during fruit bloom; but for comb honey, I do not think it desirable to greatly increase the bee space. Then, too, honey stored so early in the sections is somewhat dark, and in my locality not much can be secured, and that only by the use of ready-built combs, which I have not found desirable. Such combs will, generally, only be partly filled, if touched at all, in patches and sealed over rather dark, to be finished later, during the white clover harvest, thus securing only second grade honey at best.

A better plan for the bee-keeper to pursue is, to equalize his colonies, by taking a comb of brood or two of such colonies as would store a little honey, and give them to such as would otherwise not build up sufficiently to store any surplus during the white honey harvest. After all the equalizing has been done that is practicable, some colonies will be found that are not up to the standard, and in such cases, the best way is to confine the bees to only as many combs as they will cover, taking the surplus combs away and contracting the space by division-boards. As the bees increase and more space is needed, give them an empty comb or two, and place them near the centre of the brood-nest. If there should be a lack of honey, a full comb may be given by placing it at the side of the brood-cluster. Of course a great deal of judgment must be used in doing this kind of work. It is not best to be forever breaking the hives open and disturbing the bees in cold weather; neither is it advisable to open the hives when there is no honey coming in, and thus induce robbing. If hives must be opened at such times, do it in the evening when but few bees are flying, and stop as soon as many robber bees appear. There is no necessity to be forever opening hives and exposing honey to robber bees. The experienced bee-keeper is able to look through an apiary of hundreds of colonies when the bees are flying, and by simply watching the movements of the bees, almost invariably can tell the exact condition of every hive.

Right here a novice is often misled. I was once called to see a very

strong colony, that was supposed to be gathering honey at a fearful rate. Of course I recognized the shrill sound of the robber bee long before I came near the hive. There was quite a falling in the hopes of the bee-keeper when I told him that instead of his bees gathering honey, about all the bees in town were carrying it away.

Another case I remember: I was called to see a colony where there seemed to be plenty of bees, but were lazy, as they were clustered about the entrance doing nothing, while other colonies were piling over each other carrying in honey and pollen. When I told the owner that about all the bees in that hive were at the entrance, and that the colony was queenless, he seemed incredulous. Upon opening the hive, however, I soon satisfied him that I was right.

The bee-keeper should ever remember that he cannot expect a large honey crop without plenty of bees to gather it. In this locality, May is the month that we want to produce bees by the millions, as they are the ones that will gather the honey in June and July. Everything should be done that can be done this month to build up every colony strong in bees, and next month will be the time to work for all the honey that can be secured. If we have the bees at the right time, and the season is at all favorable, and we attend to the necessary work of placing on the surplus arrangements, there need be no fear about getting the honey.

While in this latitude but little swarming need be looked for in May, yet hives should be in readiness, for there will be plenty of other work when swarming-time comes. Indeed all the work that can possibly be done, while the weather is cool, should be attended to now. Sections should be made up, foundation placed in them and put in cases ready to go on the hives. Hives should be neatly painted, as they last much better, and help very much in giving the apiary a pleasing appearance. Everything in the shape of sections, cases or other material likely to be needed during the busy time, should be on hand. If not, order at once, as you cannot always get it at the moment wanted. Remember when you are busy with the bees, supply dealers are doubly so, and disappointment and loss are often the result.

Milan, Ills.

For the American Bee Journal.

U. S. Honey-Producers' Association.

W. H. STEWART.

I am decidedly in favor of organizing the proposed "United States Honey-Producers' Association." The truth is, that something must be done that will effectually protect the interests of honey-producers, or they will be compelled to go out of the business. A man may keep a few bees in connection with some other more lucrative business, and be lay-

ing up every year something more than the cost of living from his entire business, and not know whether the production of honey is profitable at the market price or not.

If a bee-keeper is engaged in the rearing of queens, or furnishing bee-keepers' supplies, and having a brisk trade, he may be saving some money, but if he were to leave off all other branches of business, and make the production of honey a specialty, and have to take our present chances for a market, he would find it very hard to support a family in a respectable and comfortable manner.

It will be remembered that I have before stated in this paper that our honey should be handled only by commission men that were approved, or chosen by bee-keepers; and that it would be the business of those commission men to keep well posted as to the market value of honey in all parts of the civilized world; to know what rates of freight could be secured, and that they should keep the bee-papers and bee-keepers posted in the matter; thus enabling us to ship our honey direct to the best markets. These commission men should also have a good understanding with each other, so that a surplus that may be found in one market may be forthwith shipped to another that is not well supplied.

How is it now with the honey market? Not one bee-keeper out of a hundred that ships his honey to the great markets, has ever seen the man to whom the honey is sent. We know not, and have no means of knowing, whether the merchant is responsible or not; or whether he is honorable or dishonest. Again, let us suppose that a merchant reports that my honey is sold at 6 cents per pound. How am I to ever know for a certainty that it was not sold for 10 cents per pound? I can do nothing about it. Yet this is not all. Many a poor, hard-working bee-keeper has shipped away as best he could, his entire crop, and never got one cent in return!

Much has been said about home markets for honey. It is true that a given quantity may be sold at home, but to talk of us all disposing of a good crop near home, is utter nonsense! Honey is mostly produced in the rural districts, and those who use it are mostly in the towns and cities, and the product *must* be carried to the consumer.

Here in the West is in operation an organization called the "Farmers' Alliance," and farmers here in Dakota can get, at the present date, 7 cents more per bushel for wheat from the "Alliance," than from merchants that are shipping to commission men in the large cities. Farmers that are in want of immediate cash, are allowed to draw a portion of the worth of their crop from a fund kept for that purpose by the "Alliance," and the balance when the wheat is disposed of. This would be a good arrangement with our proposed honey-producers' association.

Some propose to discontinue the publishing of the honey-market re-

ports for commission men of the cities. I would say that if we have our own salesmen in the cities, then no honey would go into the hands of the former commission men, and they would have no reports to publish; but our own salesmen would give us reports that would be valuable.

How easy it is for the present commission men to "put their heads together" and report that extracted honey is worth only 6 cents, and all agree to get all they can from consumers and only report to the producer, "sold at 6 cents!" It is very plain to me that the commission men are now fixing our wages, which is all wrong! and in this, as in all other important matters, the "fittest will survive." If our fraternity has less brains than our present commission men, then we must "perish;" but if we have enough common-sense to do our own business in a proper manner, then we may yet survive.

Kimball, ♀ Dak.

For the American Bee Journal.

Items in Bee-Keeping.

W. H. STOUT.

Some years ago (say six or eight), after reading many "gushing" articles on bee-keeping and its profits, I started in, expecting from the flattering reports to be rich enough to retire in about two seasons; but I was doomed to disappointment, and after the other years added I fail to see that my wealth has increased to any great extent in consequence of keeping bees.

ALSIKE CLOVER FOR HONEY.

But I have it now, as I noticed in some bee-periodical that an acre of Alsike clover will yield 500 pounds of honey in a favorable season. I have now 25 acres seeded with Alsike, which ought to make 12,500 pounds, which, even at the present low prices, ought to net a clean "thousand." I have 40 colonies of bees which contain (by estimate) 15,000 bees each, or 600,000 bees; requiring each one to store only $\frac{1}{2}$ of an ounce, and they must be lazy bees, indeed, that cannot gather above what they need to the extent named.

If this catches the eye of some speculative individual, I wish to state that a liberal discount will be made for cash on the prospective honey crop.

BEE-LEGISLATION.

In regard to bee-legislation, suggestions are made, and some advocate taxing bees and getting them recognized as personal property. In this State we can keep chickens, ducks and geese without being taxed, yet they are recognized as personal property, and why any one should be anxious to pay taxes on bees, when pigs and poultry are free, is not very clear!

HONEY-PRODUCERS' ASSOCIATION.

So also in regard to forming a honey-producers' association; it is

perhaps possible to regulate the price of honey, but scarcely probable, as there are too many to unite for the purpose, and we Pennsylvanians are from principle opposed to combinations, monopolies and pools, since we who are out of them have to pay dearly on coal, coal oil, and other things controlled by such combinations, reaching far into other States, and regulating mainly the prices of necessities, and not luxuries, like honey.

If the articles could be dispensed with, the combinations would soon be "busted;" but honey can be dispensed with, and the prejudices already existing are sufficient, without adding "monopoly" to the weapon of bee-keepers' enemies.

MY LOCAL HONEY MARKET.

Before this year I had the honey market in this vicinity almost to myself, but now the stores are full at low prices, with only little demand, simply because wages are low and business was dull, but shows signs of revival.

As I have no honey to offer, owing to the light crop last year, I let them sell all they can, brought here from other States, but if I succeed in producing any surplus, I mean to have this market, as legitimately mine, and no family shall be missed in canvassing for the sale of my honey when the proper time comes.

By working my home trade I have always succeeded in disposing of my crops at fair prices, and I think I can, by saving commissions and freight, make a little more out of my product than others at a distance.

Pine Grove, Pa.

For the American Bee Journal.

Swarms Locating a Home.

GEO. POINDEXTER.

When people "go West," some have a home located, and others stop and look around for a home after they arrive.

So it is with bees—some have the home located, and the hollow or hive cleaned up before leaving the parent hive; others leave the hive not knowing where they are going, and fly until they alight on some bush or tree, and then they begin to look for a hollow or hive, sending out spies from the swarm in every direction to discover the most favorable place. There the bees will continue to come until everything is clean; then the main swarm is notified, and all come off the tree and follow the house-cleaners direct to their new home. After the swarm has left the tree, back comes a lot of spies, only to find themselves alone.

Some swarms remain where they alight, and if a home is not found in a short time, being full of honey they start combs, and remain there until Jack Frost drives them into winter quarters.

SELECTIONS FROM OUR LETTER BOX

Removing and Renewing Brood-Combs.—Chas. Hill, Mt. Healthy, O., writes:

I have read the answers to Query, No. 409, but none who answered seem to have used my method of cleansing old brood-combs. It is very simple, and consists only in using them in the second story for extracting combs. Old brood-combs do not yield much wax, but the oldest and blackest combs, after being used for extracting one season, will be as clean and fresh as new ones; and hence there will be no need of having new combs.

The Great Drouth in Texas.—J. M. McDaniel, Peoria, Tex., on April 25, 1887, says:

Bees have done well here this spring, and the prospects are favorable, provided we can have sufficient rain. The drouth that has prevailed in central and western Texas for the last two years, has been very disastrous to bee-men. We have had some rain lately, which would be sufficient, but for the fact that the drouth has penetrated deep down into the earth. Our chief source for honey is from horse-mint, which was almost a failure last year, and there is a bountiful supply this year. It does not bloom until June.

Compelling a Swarm to Cluster.—Dr. A. B. Mason, Auburndale, O., writes thus on May 2, 1887:

My bees have been out of the cellar 8 days only, and are in splendid condition, some of the colonies having built quite large pieces of new comb. The last 3 weeks have been quite cold. Yesterday the temperature was 72°, being the warmest day for some time, and the bees had a regular jubilee.

A few days since, a friend was spending the day with me, and asked if I knew of a good way to make a swarm of bees cluster quickly. I told him that I knew of nothing better than to shoot sawdust among them, as told me by H. D. Cutting, of Michi-

gan. He then related the following incident: His father kept bees in Westchester county, N. Y., and 60 or more years ago (when the narrator was about 15 years old) a swarm came out and started to leave, and an older brother shot into it with a shot-gun and it alighted immediately. Two or three days after, the same bees swarmed out of the hive they had been hived in, and circled around, going higher and higher until nearly out of sight. A clap of thunder coming just at that time, the swarm dropped to the ground, alighting within a short distance of the former place of clustering. They were again hived, and in two or three days more they came out again and took a "bee-line" for a house 10 miles away, and went directly into a knot-hole in the side of the house, being the fifth swarm that was seen to go into that knot-hole that summer. The bees occupied the spaces between the chamber floor and the ceiling below. When winter came the floor was taken up, and several barrels of honey were taken out. The foregoing seems like a pretty big story, but I have known the narrator several years, and have never known his word to be doubted.

Losses in Wintering.—H. M. Seeley, Harford, ♂ Pa., on April 30, 1887, says:

I had 4 colonies last fall, and have 4 now, 3 strong and 1 weak, the latter being caused by the mice getting into the hive. I have a record of 770 colonies in the fall, of which there are now alive 381 colonies. Some beekeepers lost all they had.

Death of an Old Subscriber, etc.—J. E. Boyles, Nelsonville, ♂ Ohio, on May 2, 1887, writes:

My father, T. M. Boyles, died last fall, and it leaves me in charge of the bees, with a limited experience. I have sold some, and have 35 colonies now, the most of them being in good condition. Father had kept bees about 40 years, was quite successful, and was without a total loss at any time from the first. He had taken the AMERICAN BEE JOURNAL during nearly the whole time of its existence, and was very fond of both his bees and the JOURNAL.

Bees doing Well, etc.—W. Mason, Fillmore, ♂ Ind., on April 28, 1887, says:

A neighbor of mine, who commenced keeping bees two years ago under my supervision and instruction, has been very successful both in summer and winter management. He had a colony in March, during a warm spell, that acted as though it was swarming. On looking at the entrance of the hive, he saw a queen dead, and looking a little longer he found another queen about dead. He returned her to the hive, and the bees returned again. He saw nothing wrong after that, until this week he found no brood or the appearance of

brood, and the colony was somewhat dwindled. He put in two frames of brood and bees, and awaited results. This was a colony that had cast 2 or 3 swarms, consequently the queens were young. Whether they were improperly wintered, or whether it was a case of superseding, and they destroyed both queens, I do not know. Bees are doing well, although the weather is very changeable. We had considerable snow on April 1. Plums and pears are in full bloom, and bees are working hard on them.

No Loss in Wintering.—J. N. Ginn, Brooks, ♀ Maine, on April 27, 1887, says:

Spring here is unusually late. The snow is deep in the woods. The roads are a mixture of snow-drifts and mud falling in where the frost goes out. We had fine weather from April 19 to April 23, a few poplars blossoming so bees brought in pollen. Since then the weather has been bad; last night it rained like a flood. My 50 colonies of bees have wintered without the loss of a single colony, in the cellar, and most of them are there yet. I shall put them out as soon as "Old Sol" shows his face.

Working with a Will.—H. J. Rogers, Stanard's Corners, ♀ N. Y., on April 28, 1887, writes:

I have kept bees for 5 years, commencing with one colony in a box-hive. Last spring I had 36 colonies, and increased them to 52 during the season. Of these all have wintered finely except two, one of which was queenless last fall, and the other had the diarrhea. I first found sealed brood on April 1. The combs are now well covered with young bees, and the bees are working with a will. I have fed them since March 15, although there was plenty of honey in most of the hives. My surplus crop last season was 2,800 pounds of comb honey. With us the season was dry, and most of the honey came from raspberry in June.

Expecting Early Swarms, etc.—Wm. Ford, Marshalltown, ♂ Iowa, on April 30, 1887, writes:

I put 25 colonies into the cellar last fall, and on March 22 I took out 22 strong colonies and one that was weak. The two that died were queenless. The temperature of the cellar ranged from 40° to 45°. All are breeding very rapidly. I spread the brood-nest as directed by G. M. Doolittle, in his pamphlet called "The Hive I Use." My bees carried in the first pollen on April 2. Drones are flying now every day. I expect to have early swarms. The apple blossoms will be out in a day or two. I think we will have a good honey season this year. I am experimenting with a new kind of entrance-block to stop robbing. It works like a charm so far. I will report and give a description of it later.

Encouraging Prospects.—R. B. Woodward, M. D., Somerset, ♂ Ohio, on April 27, 1887, writes:

All of my 18 colonies of bees wintered finely on the summer stands. I have heard of no losses in this section from persons who follow the modern methods of preparing their bees for winter. I have Italians, Syrians and Cyprians, and I see no difference in their wintering, but the Syrians and Cyprians are rearing brood more rapidly, and have drones flying now. The clover is looking well, and plenty of fruit bloom and locust is near at hand. The prospects are encouraging for an excellent honey crop in this locality.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c.—**BEEWAX.**—25c. R. A. BURNETT, Mar. 28. 161 South Water St.

DETROIT.

HONEY.—Best white comb, 11@12c. Market is improving.
BEEWAX.—23c. Apr. 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4@4½ cts. Comb, white, 7@13c. Market firm.
BEEWAX.—Scores at 19@22c. Apr. 4. SCHACHT & LEMCKE, 122-124 Davis St.

CLEVELAND.

HONEY.—Choice white in 1-lb. sections, 12@13c.; second quality, 10@11c.; and buckwheat unsalable at 8@9c. Extracted, 5@6c.
BEEWAX.—25c. Apr. 20. A. C. KENDEL, 115 Ontario St.

ST. LOUIS.

HONEY.—Choice comb, 10@12c. Strained in barrels, 3½@4½c. Extra fancy, ¼ more than foregoing prices. Extracted, 4½@6c. Market dull.
BEEWAX.—Steady at 20c. for prime. May 7. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: White comb, 12@14c.; amber, 7@9c. Extracted, white, 4½@5c.; light amber, 3½@4½c. Market quiet.
BEEWAX.—19@22c. Apr. 16. O. B. SMITH & CO., 423 Front St.

MILWAUKEE.

HONEY.—We quote: Finest white 1-lb. sections, 12@12½c.; choice white 1-lb., 11@12c.; choice 2-lb., 10@11c.; dark not wanted, and imperfect slow. Extracted, finest white in kegs, 6½@7c.; good white in kegs and barrels, 6@6½c.; dark, 4 to 4½c. Demand good and market firm.
BEEWAX.—25c. May 4. A. V. BISHOP, 142 W. Water St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 13@15c.; 2-pounds at 11@13c. Extracted, 5@7c. Sales slow.
BEEWAX.—26 cts. per lb. Apr. 22. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 3@7c. per lb. Best comb brings 11@14c. per lb. Demand fair.
BEEWAX.—Good demand, —20@23c. per lb. for good to choice yellow. Apr. 21. C. F. MUTH & SON, Freeman & Central Av.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

BEE JOURNAL

Issued every Wednesday by

THOMAS G. NEWMAN & SON,
PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO, ILL.
At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

The Production of Comb Honey, as practiced and advised by W. Z. Hutchinson, can be obtained at this office, for 25 cts.

The Convention History of America with a full report of the proceedings of the Detroit and Indianapolis conventions, and the AMERICAN BEE JOURNAL for one year, will be clubbed for \$1.25.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office, or we will send them all to the agent.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of a printer printed on them—by mail, postpaid.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Home Market for Honey.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them)

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

System and Success.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages).....	\$ 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

We will Present Webster's Dictionary (pocket edition), and send it by mail, postpaid, for two subscribers with \$2. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Do you Want a Farm Account Book? We have a few left, and make you a very tempting offer. It contains 166 pages, is printed on writing paper, ruled and bound, and the price is \$3. We will club it and the Weekly BEE JOURNAL for a year and give you both for \$2. If you want it sent by mail, add 20 cents for postage.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. As each separate fiber extends the whole length of the handle as well as the brush, they are almost indestructible. When they become sticky with honey, they can be washed, and when dry, are as good as ever. The low price at which they are sold, enables any bee-keeper to have six or more of them, so as to always have one handy. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Should any Subscriber receive this paper any longer than it is desired, or is willing to pay for it, please send us a postal card asking to have it stopped. Be sure to write your name and address plainly. LOOK AT YOUR WRAPPER LABEL.

Dr. Miller's Book, "A Year Among the Bees," and the BEE JOURNAL for one year, we will club for \$1.50.

E. Duncan Sniffen, Advertising Agent, 3 Park Row, New York, inserts advertisements in all first-class Newspapers and Magazines with more promptness and at lower prices than can be obtained elsewhere. He gives special attention to writing and setting up advertisements in the most attractive manner, and guarantees entire satisfaction. In all his dealings, he is honorable and prompt. Send for his Catalogue of first-class advertising mediums. Mailed free. 52A40t

A Cheap Smoker.—"Martinsville, Ohio, April 11, 1887.—Messrs. Bingham & Hetherington, Abronia, Mich.: Enclosed find \$2.50 for two Large 2½-inch Bingham Smokers (wide shield). They are for my neighbors. I have one of the Bingham Smokers that I have used six years, and it is as good as ever. Send ½-dozen rates.—Respectfully, AMOS R. GARNER." 17A4t

Simmins' Non-Swarming System is the title of a new English bee-book. The author claims that it will inaugurate a "new era in modern bee-keeping," and states that "it is based upon purely natural principles, and is the only system that can ever be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the desired result—a total absence of any desire to swarm." It contains 64 pages; is well printed and illustrated. Price 50 cents. It can now be obtained at this office.

Advertisements.

W. Z. HUTCHINSON,

Rogersville, Genesee Co., Mich.,

DESIRES to briefly outline the contents of his little book,

"THE PRODUCTION OF COMB HONEY."

The "Introduction" gives a concise sketch of the author's experience in producing comb honey, and explains how the book came to be written. The first chapter, "Securing workers for the harvest," sets forth the advantages of cellar-wintering combined with spring protection. "Aside from food in abundance, warmth is the one great thing needed to promote safe, early breeding." The cheapest and best method of securing this is given in detail. Under the head of "Supers" the author names his favorite surplus case, and gives reasons for the preference.

The next topic is that of "Separators." Their advantages and disadvantages; the conditions under which they are needed and the methods necessary to their abandonment are briefly told. Then "Sections" are taken up; the good and bad qualities of the different kinds mentioned; the time for putting them on given and the advantages of having them filled with comb, especially in the spring, fully explained.

The next three pages are devoted to "Tiering-Up," in which the operations of this system are explicitly described, showing the ease with which it enables a bee-keeper to handle a "honey-shower." Then follow: "Hiving swarms on empty combs; Hiving swarms on foundation; and Hiving swarms on empty frames;" in which the question of profitably dispensing with full sheets of foundation in the brood-nest when hiving swarms is made perfectly clear, and thorough instructions given for its accomplishment.

"The building of drone-comb."—This appears to have been the great stumbling-stone in the road to success with starters only, hence six pages are given up to this subject. Why bees build it, is well considered, and the way to prevent its construction made plain. The next page we enter the "Sections" are taken up; the good and bad qualities of the different kinds mentioned; the time for putting them on given and the advantages of having them filled with comb, especially in the spring, fully explained.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the American Bee Journal.

It contains 220 profusely illustrated pages is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. Bound in cloth, \$1.00, postpaid.

A Liberal Discount to Dealers, by the Dozen or Hundred.

THOS. G. NEWMAN & SON,

923 & 925 West Madison St., CHICAGO, ILL.

1880. 1887.

Notes from the Bright-Band Apiary.

I WILL send Pure Untested Italian QUEENS, reared from imported mothers, to any address, at 80 cents each; or Tested for \$1.25. Satisfaction guaranteed. Send for terms on large numbers.

CHAS. KINGSLEY,
BENTON, LA.

18A4t

NEW ONE-POUND HONEY PAIL.

THIS new size of our Tapering Honey Pails is of uniform design with the other sizes, having the top edge turned over, and has a bail or handle, making it very convenient to carry. It is well-made and, when filled with honey, makes a novel and attractive small package, that can be sold for 20 cents or less. Many consumers will buy it in order to give the children a handsome toy pail. **PRICE, 75 cents per dozen, or \$5.00 per 100.**

THE BRITISH BEE JOURNAL

AND BEE-KEEPER'S ADVISER,

IS published every week, at 10s. 10d. per annum. It contains the best practical information for the apiarist. It is edited by Thomas Wm. Cowan, F.G.S., F.R.M.S., etc., and published by John Huckle, King's Langley, Herts, England.

JUST PUBLISHED,

"PRACTICAL TURKEY RAISING"

By **Fanny Field.** This book tells all about turkey raising, from the setting of the eggs to the maturity of the young turks. If you follow the directions in this book you need not lose a bird. **Fanny Field** has had more experience and succeeds better in raising turkeys than any other person in America. She clears hundreds of dollars yearly on them, and will tell you how she does it. Price, 25 cents. Stampstaken. Address **R. B. MITCHELL,** Publisher, 69 Dearborn St., Chicago, Ill.

AMERICAN
ESTABLISHED
in
1861
BEE JOURNAL
OLDEST
BEE PAPER
in
AMERICA

THOMAS G. NEWMAN, Editor.

Vol. XXIII. May 18, 1887. No. 20.

Sunny May Day, with whitest clouds,
And twittering swallows high in air,
A timid zephyr from the South,
And fragrance, fragrance everywhere.
Young grass, pink buds; all bees astir;
With plow, afield the swain I spy,
And, in her door, the young, good wife
To baby singing lullaby.

—C. G. Blanden.

Fanny Field's "Practical Turkey Raising" is a new book which tells all about rearing turkeys from the egg to the mature bird. If you want to make it profitable to rear these birds, send 25 cents to this office for the book.

Rain came very opportunely last week in this locality. Nature responded promptly to the baptism, and appears in its gayest dress, flowers decking field, hillside and valley, and the bees are apparently enjoying the anticipation of a plentiful supply of the nectar which they so much enjoy, gathering and hoarding up, in their waxen cells of virgin comb.

Bees Roaring in Winter.—On page 297, Mr. Demarce proposes that those interested in the settling of this question, should write a postal card to the BEE JOURNAL to be tabulated and published, giving the result of their actual knowledge or experience on the subject. By an oversight, this was omitted last week. We now approve of the method proposed, and will give the letters space and attention. Send them in at once.

Royal Jelly.—A correspondent desires us to explain the composition of royal jelly and its uses and effects upon the larva-queen. At the quarterly *Converazione* of the British Bee-Keepers' Association held in London, on April 20, 1887, Mr. T. W. Cowan, editor of the *British Bee Journal*, gave a very interesting address on this subject, which will be found on page 310. It will be read with more than ordinary pleasure by progressive apiarists.

Be Patient!—How often do we find some impetuous soul growling about the delay of receiving goods ordered, when there has not been sufficient time allowed to transport them from the dealer to the customer! Quite often, even before the complaint has had time to get to the dealer, the purchaser has received the goods, then he feels badly (if he has any conscience) for having used the unkind words, and has then to sit down and write an apology.

These things are aggravated, when in his impatience he has also written a complaint to the bee-paper where the dealer's advertisement appeared, and leads to still greater complications!

We now have a case in point. A purchaser wrote to us a long and bitter complaint, using very uncomplimentary language about the delay of receiving goods from one of our advertisers. We wrote to the advertiser and obtained a full statement of the case—saying he had positive proof that the goods were at the station as ordered by the purchaser, and the railroad company had notified the shipper as well as the consignee of the facts.

We wrote several letters to both parties, as there was also a financial dispute about it, and the upshot of the whole is a letter just received from the complainant, stating that he withdraws all complaints against the dealer, who has made a settlement in full with him.

Now, we protest against such impetuosity and carelessness; as well as against burdening us with complaints against our advertisers, which are merely the result of carelessness on the part of the customer, or a want of exercising due patience for the arrival of the goods ordered. We have enough to do with our legitimate business, and we have no relish for such unthankful and unnecessary work.

Then, again, many mistakes occur from not writing names and addresses plainly. We have a letter before us now, with the name of the writer so indistinct that we cannot read it at all. Another, with an order for goods without any attempt to give the name of the writer. Such carelessness is inexcusable, and is the cause of much confusion.

Small Loss in Winter.—The *Leader*, of Arcadia, N. Y., gives the following item about its apiarist:

On Nov. 19, 1886, E. D. Keeney put into winter quarters 316 colonies of bees. On May 2, 1887, after their confinement of 165 days, he took out 311 colonies, all in fine condition, there being a loss of less than 2 per cent. We doubt very much if there has been its equal in wintering in the State.

The losses have been very light both in winter and spring, and if the weather continues favorable, a good crop of honey may be expected.

Frank Leslie's Sunday Magazine for June completes the twenty-first volume of this much esteemed family visitor. The number is full of interesting contributions, and is as usual, beautifully illustrated. Among the important articles is one entitled: "A Visit to the Azores," which is accompanied by ten illustrations. Many miscellaneous articles of merit help to make up a number which ought to be welcomed heartily everywhere.

The Century Plant.—From California we learn that bees work on the flowers of *Agave Americana*, commonly called the century plant, and seem to be in great glee while thus occupied. It is a misapprehension that this plant has to be a hundred years old before it blooms. It is a common occurrence to see them bloom in California when they are from 10 to 15 years old. When once the flower stalk or shaft puts forth its asparagus-like head it shoots up rapidly, so that in a few weeks it is 25 or 30 feet high. To those who have not seen the plant, we do not know how we could better describe it than to say that it looks something like the Yucca mentioned in another column, with this exception, however, there are not so many leaves, and they are much more fleshy; the flowers are not borne in whorls as in the Yucca, but the shoots starts out like those of the Yucca, and from them again start out smaller shoots taking about the same curve as the main one. On the latter the flowers appear. The main flower-stalk has the appearance of a huge lamp-post, and the flower stems look like chandeliers, and when in bloom the bees, when humming about its flowers, reminds one of moths flitting about the lights of a chandelier.

It is pretty certain that in California it will never be considered as a honey-plant of much importance, but we suppose that in Mexico, where they grow by the acre, it is valuable for the bees. In that country, we learn that by tapping the plant, it yields profusely of its sap, which the natives ferment into a beverage, and after partaking thereof, become good-natured and jolly to an inordinate degree.

Bees were Declared a Nuisance by the City Council of Arkadelphia, Ark., on May 5. This matter was referred to on page 279, where it was stated that some crank had charged the bees with eating up his young ducks, as well as eating up the peaches!! In the published report of the City Council meeting, the following occurs:

A resolution, introduced by Councilman Spencer, was adopted, to the effect that the rearing of bees within the city limits was a nuisance, and an ordinance was accordingly passed declaring the owning, keeping or rearing of bees in the city limits to be unlawful, and notifying all persons keeping or owning bees in the city to remove the same within thirty days from the passage of the ordinance, and fixing a fine of not less than \$5, nor more than \$25, for each day of refusal to so remove them.

A resolution also passed, instructing the City Marshal to notify all bee-keepers of the passage of the foregoing ordinance, and of their duty under it.

Major J. L. Witherspoon, ex-Attorney General of Arkansas (who stands at the head of the Bar of the State), has been employed to attend to the matter on behalf of the bees. He "enjoined" the City Council on the 9th inst., and the trial probably came up in "Chancery" on Monday, May 16. The National Bee-Keepers' Union backs up Mr. Z. A. Clark to fight the case on its merits. More anon.

The Kenton Bee-Hive is the name of a new monthly bee-paper of 12 pages published by Smith & Smith, Kenton, O., at 50 cents a year. The first number is on our desk, and makes a good appearance.

QUERIES

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Wintering Bees under a Kitchen.

Query 418.—Mr. A wants to try wintering his bees in his cellar, which communicates, by a stairway, with the kitchen above. 1. Will it be in any way a detriment to the health of his family to have his bees in the cellar? 2. How large a room must be partitioned off for 30 colonies? 3. Will it be any benefit to whitewash the room before putting in the bees?—H. D. S., Pa.

1. No. 2. 10x10x6 feet. 3. Yes.—J. P. H. BROWN.

1. It might prove to be a sad affair. 2. Large enough to contain them; and larger for future wants.—C. W. DAYTON.

1. No. 2. Ten or twelve feet square will do. 3. It would if there was a bad odor in the cellar.—G. L. TINKER.

1. I think not. 2. Large enough to get them in handily. 3. I think not.—W. Z. HUTCHINSON.

1. I think not. 2. It will depend upon the size of the hives. 3. It will be no detriment to whitewash it.—H. D. CUTTING.

1. I should say not, but I am not posted on hygiene. 2. I should not partition it off at all, as the whole cellar is as good if the temperature is right. 3. I do not see why it would.—G. M. DOOLITTLE.

If the bees are kept dry and in good health, I should have no fears of their presence under the kitchen doing any harm.—G. W. DEMAREE.

1. No, if decent ventilation is given. 2. As large as will allow of storage, depending upon the size of the hives. 3. It is always a benefit, sanitarially, to whitewash a cellar.—J. E. POND.

1. No. 2. Let him put the bees in, and partition the space afterwards with a heavy curtain, old carpets or anything. 3. It will not injure, but it is not of any particular benefit.—DADANT & SON.

1. No, if the air in the cellar is good as it ought to be for the bees. 2. It depends upon the size of the hives. I should want it large enough so that when the hives are piled up, I could get at the front of each. 3. I think it might.—C. C. MILLER.

1. No. 2. I cannot say. It depends. The temperature must be kept at 45° Fahr. 3. No.—A. J. COOK.

1. It would to some, but probably not to him, as there are very few persons who are injured by breathing the odor from bees. 2. Two or three times as large as the space occupied by the hives. 3. I guess it would not

do any harm or good to the bees.—JAMES HEDDON.

1. Probably not, if ventilated. 2. Hives vary in size; a sure plan would be to put in the bees first, and then partition them off; but why not have it large enough for future increase? 3. Any cellar may be whitewashed to advantage, but so far as the bees are concerned, it would make no difference.—THE EDITOR.

Dividing Colonies—Locating the Queen.

Query 419.—In dividing colonies for increase, or building up colonies in the spring, on the evening before transferring a frame or frames from hive to hive, should I place such in an empty body over the centre or side of the brood-nest, and leave them there all night, and put them in other hives before 9 o'clock in the morning? Would I be in danger of taking queens along? 2. What is the status of the queen in a hive, or on what frames may she be found at different times of the day?—W. B., Iowa.

1. No. Why? 2. There is no rule as for that.—JAMES HEDDON.

1. Some, but very little. 2. There is no rule. Some queens are easily disturbed, and when disquieted they often pass rapidly from one to another.—A. J. COOK.

1. No. 2. In the morning when it is cool, the queen will usually be on one of the middle frames of the brood-nest; but in the afternoon when warmer, she is oftener on one of the outside frames.—J. P. H. BROWN.

I would rather make the colonies in the evening than in the morning. Your plan is too much bother for me. Find the queen, then you will know where she is. That is my rule.—C. W. DAYTON.

It is always easy to find queens in dividing colonies, and to place them where wanted. The queen will nearly always be found on the frames of brood. It is even rare to find her on the sealed honey of a brood-comb. If the hive is carefully opened, always look for her first on the combs in which eggs are seen.—G. L. TINKER.

1. You would be in danger of making a complete failure of the whole business. 2. When you make a business of producing honey on business principles, you will not care on what frame she is just at each particular moment.—H. D. CUTTING.

1. I hardly know what you would gain by so doing. It would depend upon existing conditions whether the queen might be on one of the frames. 2. I do not know in what part of the brood-nest to look for a queen.—C. C. MILLER.

1. Your best way would be to find the queen, for she might not leave the frame by your proposed plan, and by using it the brood might be in danger of being chilled. 2. From 10 a.m. to 4 p.m. the queen is usually on one of the outside combs of brood, but not always.—G. M. DOOLITTLE.

1. I do not understand the object of leaving the frames in such a position over night. Queens must be looked up before removing the frame. 2. I have seen it stated that the queen

made the circuit of the brood-nest once in 24 hours, and at such and such hours, she might be found in such and such places. I have never noticed anything of the kind.—W. Z. HUTCHINSON.

1. I can see no reason for so doing. My advice is to adopt the nucleus plan of increase; the plan I made public some years ago, and which I believe is now generally used for increase. By that plan the maximum both of honey-gathering and brood-rearing is constantly kept up; this cannot be done by ordinary division. 2. This is one of those impracticable questions that "no feller" can answer. Ordinarily she will be found on or near empty cells.—J. E. POND.

1. Before removing frames of brood with adhering bees, I first look up the queen so as to make no mistakes. When I divide a colony with the view of making a new colony of one of the divisions, I do the work early in the morning, and at once. When selecting combs to make nuclei, or new colonies, I take such as out of which the young bees are cutting or hatching, as we say, in great numbers; in this lies the secret of forming nuclei or new colonies. I confine the bees to their new quarters the first day, releasing them just after sunset. 2. It depends upon the condition of the brood-nest. She will ordinarily be found wherever her duty leads her. If I always knew the precise condition of the brood-nest, I could guess pretty well where she might or might not be.—G. W. DEMAREE.

1. No. 2. Any one can guess, but no one knows. When you find the queen, you will know where she was each time, and probably not twice in the same place.—THE EDITOR.

Number of Frames for Comb Honey.

Query 420.—How many frames of the Gallup size would be best for producing comb honey, where the honey harvest continues from the last of May until the last of July, with generally a fall crop?—B., Iowa.

Nine frames—G. L. TINKER.

About 12.—J. P. H. BROWN.

About 9 in the spring, or before swarming; and 5 or 6 after.—W. Z. HUTCHINSON.

I have never used the Gallup frame, but I should think about 9 frames.—H. D. CUTTING.

I use 9, and consider them ample for any locality. With new swarms I use only 5.—G. M. DOOLITTLE.

We say 13 or 14 frames. Make your hives the same size as Doolittle's. See his pamphlet on "The Hive I Use."—DADANT & SON.

Ten until the harvest begins; 4 during the harvest; and 10 after the harvest, is my practice.—C. W. DAYTON.

Twelve frames before swarming, and 6 afterwards, as a rule. Comb honey production without the contraction system, would be to me like the play of "Othello" with Othello left out.—JAMES HEDDON.

I should prefer 12 frames, but should reduce—a *la* Heddon—to 7 or 8 when I added sections.—A. J. COOK.

I do not know. I use the standard Langstroth. Mr. Doolittle can answer understandingly, as he uses the "Gallup frame."—J. E. POND.

I think Mr. Doolittle uses Gallup frames, and I should place confidence in his answer. I do not think any of us yet know all we might about this matter.—C. C. MILLER.

I would want not less than 12 for such a honey harvest as you seem to have. By using a hive of the largest size, you could have it large or small, to suit the conditions, by simply using division-boards. A 10 frame Langstroth hive, properly made to "tier up," would just "fill the bill," if I had to make the choice for you.—G. W. DEMARRE.

Probably about 9 or 10 frames.—THE EDITOR.

Introducing Queens—Making Bees Stay

G. M. DOOLITTLE.

As the time of year for introducing queens is at hand, I wish to give a very simple plan of doing the thing, and one which so far has proved successful with me in every instance. If I had a very choice queen coming a long distance to me through the mails, I should use the "nucleus box" as described in a back volume of the BEE JOURNAL; for with this I do not consider a failure possible, although out of the thousands who have tried that plan, one has reported a failure with one queen. However, the nucleus-box plan is not quite as convenient as the one about to be described, nor can the whole operation be done at the same time as can this. The plan I wish to speak of is as follows:

Go to any hive from which is desired to remove the queen, and smoke the colony only enough to keep the bees quiet during the finding and removing of the queen, after which the frames are to be put back, and the hive closed. Before disturbing the hive at all to find the old queen, the bee-keeper should get the one to be introduced and have her with him in a cage. Having closed the hive, blow smoke into the entrance until the bees are heard roaring greatly, which shows that the light is all taken out of them, when the smoking is to cease for a moment, and then pound on top of the hive with the fist about ten times. Now blow smoke again

as long as pounding continued, when the bee-keeper is to pound the same number of strokes again, and so on until the smoke has been given five times, and the same number of poundings are done.

In doing this pounding, only strike with force enough to thoroughly jar the hive, which is easily done without at all hurting the hand. As soon as the last pounding is finished, unstop the cage having the queen to be introduced, and hold the mouth of it to the entrance of the hive, when she, hearing the roaring of the bees inside, will immediately run in. As soon as she is well inside of the hive, give them another liberal smoking, and the operation of a direct and safe introduction is finished. If in time of scarcity of honey, this should be done about sundown, otherwise robber bees would gain access to the hive while the bees were in a defenseless condition. In fact I prefer to perform the operation near sundown at all times.

If all has worked as it does with me, the queen will be found laying the next morning, just as if that had always been her home.

My theory regarding why the plan is so eminently successful is, that the bees realize that they have had a "terrible shaking up, the same as would happen in their primitive state if the tree containing their home should be blown over. Their first anxiety then, after coming to their senses, would be for the queen. Well, before coming to their senses, in this case, the queen is run in and followed by smoke so that she assumes the same scent that the bees, hive and combs smell of, so that when they find her they do not realize that a change has been made.

MAKING DRIVEN SWARMS STAY.

Many seem to suppose that when a swarm of bees is driven from a hive, that the driven part must be put on the old stand, placing the old hive and contents on a new stand, otherwise the driven bees would mostly go back to the old hive. With no precaution this would undoubtedly be the case, but it is a very easy matter to make a driven colony of bees stay wherever one wishes. I often make swarms by driving, and as some of the readers of the BEE JOURNAL, who can be with their bees only in the morning or evening, may wish to do the same, I will describe how I manage. It is thus:

Go to any hive whose colony is about ready to swarm, and if in a box-hive, drum out the bees in the way given in any of the books while treating on transferring, but if in a movable-frame hive, as they will probably be, proceed as follows: Open the hive to see if there is plenty of unsealed honey, and if not, shave off the cappings of the cells along the top-bars of the frames, so the bees can easily fill themselves with honey, finding the queen at the same time and caging her on one of the frames. Now close the hive, and after blowing smoke in at the entrance, pound on it with the fist, as I stated in in-

roducing queens, except that it is to be kept up for three or four minutes, with no smoke except the first.

As soon as you have finished pounding, place a box and an inch board close to the hive; or, better still, have the box there to start with, when you are to open the hive and shake about three-fourths of the bees from the combs down in front of the box, into which they will readily enter. When you come to the frame having the queen, uncage her and let her run into the box. Having the queen and what bees you wish in the box, close the hive and take the box to the shade of some tree where it is to be left with the mouth or open side facing up and out, which is best accomplished by leaning it against something. Leave it thus for three-fourths of an hour, when the bees will be clustered the same as a swarm would be.

They can now be hived the same as any swarm, and will stay and work the same as if they had issued naturally. The old colony can be allowed to rear its own queen or have a queen-cell given them, the latter being preferred, as that does away with after-swarming.

If the bees are "drummed" from a box-hive, they are to be treated after they are in the box the same as the other. In some respects I like this plan for securing increase better than any other.

Borodino, ⊙ N. Y.

For the American Bee Journal.

The Next Michigan State Convention.

At our last annual meeting at Ypsilanti, in December, 1886, the desire was expressed that our next meeting be held in conjunction with that of the State Horticultural Association, and preferably at East Saginaw, Mich.; though it was left optional with the committee to change place and arrange time, if to consummate the joint meeting it was found necessary.

The arrangements favoring this plan are as follows: Many of our members are also interested in fruit culture. Such an arrangement would enable them to secure the benefits of both meetings with the least expenditure of time and money. Again, many topics are alike interesting and important to fruit-men and bee-keepers; such as the relation of bees and fruit, bees as fertilizers, etc. Thus it would be profitable to have at least one or two joint meetings, in which both societies should take an equal part. Lastly, with both associations meeting in one week at one place, we could almost surely secure reduced rates on the railroads. Last fall the fruit-men accomplished this, though the bee-men failed. Such commutation induces larger attendance, as seen at our Flint meeting three years ago; and so adds to the value and interest of our discussions.

I am happy to state that the arrangements have been fully and most satisfactorily made. Both associa-

tions will meet at East Saginaw, Mich., the second week of December, 1887. The State Horticultural Society will meet Monday evening, Dec. 5, and close Wednesday noon, Dec. 7. On Wednesday afternoon, and possibly evening, there will be a joint session of the two societies. The bee-keepers will continue in session all day Thursday and possibly Friday.

In publishing its own programme, each association will give a brief abstract of that of the other association; thus each association will be very widely advertised.

The East Saginaw people will furnish a free hall; will secure reduced rates at the hotels, and, more than all, will give a royal welcome. All this with reduced railroad rates will aid to make this a meeting of unusual importance. A hearty invitation is extended to those of Ontario and other States, to meet with us.

Will other bee-periodicals and agricultural papers please copy this, or give a notice of the arrangements?

A. J. COOK, Com.

Read at the British Bee-Keepers' Convention.

Food of the Queen-Larva, etc.

T. W. COWAN.

There is an important question I should like to bring before the meeting, and upon which a very interesting discussion might be started. It has reference to the food of the queen-larva (royal jelly), the food of the other larvæ, and also with respect to the digestion of such food. I am now in a position to give some recent investigations which will, I think, clear up those points conclusively.

We have been taught for some time that the food which is given to the worker and others is partly digested in the chyle-stomach of the worker-bee; for this digestion, and the providing of this food, the young bees act as nurses. Dufour was one of those who taught this, although Swammerdam alluded to it before; and we have always accepted the idea that the larvæ were fed with this semi-digested food. Leuckart was also a partisan of this theory. However, when the glands were discovered, Leuckart thought he was not quite satisfied with this theory of semi-digestion, and he suggested that the larvæ were fed with a secretion from the different glands.

In the honey-bee there are four pairs of glands; three pairs in the head, that is, two pairs in the upper part, and one pair in the jaws, and one pair in the thorax. Leuckart supposed that these glands furnished the food for the larvæ as well as the food for the queens. Schiemenz, who was a pupil of Leuckart, was induced to take up and investigate the matter thoroughly. He did so, with instructions from Leuckart to examine specially the functions of these glands in relation to the food, and he published the result of his researches in 1883. I have his work with all the drawings. He went into the subject very fully indeed, and it is the most

complete description of the glands we have. He came to the conclusion that the food was a secretion produced from the glands.

For some years since 1853 Schonfeld has been at work likewise on this subject. He described the digestive system of the honey-bee particularly in the *Bienezzeitung*, and his discoveries from 1854 to 1883. Below the honey-mouth (*Magenmund*) there is a neck which connects the honey-stomach with the chyle-stomach, and from this mouth into the chyle stomach there is a prolongation through which the honey and pollen passes from the honey-stomach into the chyle-stomach; and Schonfeld, by experiments and microscopical examination, showed that this internal prolongation could be turned inside-out or inverted so that the bee could discharge the digested food from its stomach by way of the œsophagus into the cells.

These alleged discoveries were thought to be very singular by Leuckart, Fischer, Vogel, Dzierzon and others, but they continued to insist that the food of the bee was a secretion; some were going so far as to call it *Milchsaft*, or milk food.

Leuckart says that the food of the larvæ of the queen, workers and drones is exactly the same. But Leuckart, in 1858, discovered that the food of the larvæ of worker-bees was subject to some variation, that it was not always the same during the whole of its larval existence. For the first three days the food was liquid, and appeared like a secretion. After that pollen and honey were added to it, which could be detected by the microscope. The queen-larva, on the contrary, was fed with the same food throughout its larval existence, that is, from the very first day of the larva leaving the egg to the day it was sealed up; and he said it was owing to this that the queen was produced instead of a worker.

The weaning took place on the third day, and it was exactly at this time that the ovaries began to make their appearance in the female bee, and by changing the food in the case of a worker, this development was arrested and a worker produced, whereas by continuing the same food a queen was produced. The same took place with regard to the drone, except that of three days, the drone was fed on the same food for five days.

We have always hitherto been led to believe that this food was alike, at any rate during the first three days, and that the greater abundance given to the queen-larva produced the development more rapidly.

Dr. A. de Planta has been at work for two years in trying to settle the question by analyzing this food, and has had considerable difficulty in carrying out his investigations. Some idea may be formed of the magnitude of the work he has been engaged on when I say that he has had to operate upon 120 queen-cells, 4,000 drone-cells, and 10,000 worker-cells. I believe only one chemical analysis of the food has been made prior to this,

namely, by Schlossberger in 1871. He took all the food he could get hold of, put it together and analyzed it on the supposition that the food was the same all through. Dr. Planta was not satisfied with that, and wished to settle the point by analyzing the different foods separately, and his chemical experiments have confirmed step by step the observations of Schonfeld, and have shown him to be right.

Dr. Planta analyzed the substances contained in the queen-cells, worker-cells, and drone-cells, and the result of these investigations showed, as regards the different ingredients of the different foods, the following proportions:

Albumen.....	46.5	¢	for queens.
“	50.16	“	workers.
“	39.91	“	drones.
Fatty Matters..	12.62	¢	for queens.
“	6.84	“	workers.
“	7.85	“	drones.
Sugar.....	17.90	¢	for queens.
“	27.65	“	workers.
“	1.17	“	drones.

The above tables refer only to dried food. As regards the water contained in each food, there is not a very great difference. The proportions are as follows:

66.64	per cent.	for queens.
71.09	“	workers.
72.75	“	drones.

These figures show that the food of the queen contains less water than that of the drones or workers; and I dare say all of you know that the food in a queen-cell is much stiffer in substance, and is able to stick to the top of the queen-cell hanging down and to support the grub.

With regard to albumen, you see the worker stands at the head, whilst in respect to fatty matter the queen is first, and the drones and workers in nearly equal proportions. In regard to sugar, the workers are first, then comes the queen, and the drones have very little indeed. Drones are the fewest in the hive, and I think we must not grudge them the small quantity of honey they take, seeing that they get so little sugar during their larval existence.

The figures I have given may not convey much to you, but with regard to richness of the food I may tell you that in 100 queen-cells there are 356 times more dry nutritive substances than there are in 100 drone-cells, or 232 times more than in 100 worker-cells.

Then Dr. Planta tried another experiment, namely, in order to judge upon an equal basis he compared the dry substance in 100 grammes of fresh food. In this he found that it contained 4.92 grammes more of dry nutritive substance than 100 drone-cells, and 3.26 grammes more than those of workers. Testing in every way the food of the queen, there can be no doubt that it is the richest and best from the commencement.

Now, if the food were a secretion similar to milk, it would always be the same, or at least it would vary to a very trifling expense; but as it varies as greatly as Dr. Planta has

shown, and has chemically proved to be different in its composition, there can be no doubt that it is a digested food elaborated in their chyle-stomach, and that the bees at will vary the ingredients thereof to suit their particular purpose. They can voluntarily add the necessary ingredients, such as pollen, honey, and nectar, more or less diluted with water.

So far as can be ascertained there do not appear to be any particular bees set apart for the purpose of feeding particular grubs, but that up to a certain age the feeding capacity is the same in all cases. We suppose that the bees must have the voluntary power of supplying one kind of food or the other as may be wanted.

This subject is a very important one, because upon it, to a great extent, is based the rearing of queens. The question naturally arises, are queens that are reared by natural means as good or better than queens reared otherwise? Now, I always maintained, and I think I have good reason for maintaining, that queens should be reared from eggs, because they get the better food from the very first day when the eggs hatch. The analysis of Dr. Planta, and the conclusions he comes to, go a great way in favor of that theory.

Queens must be better if reared on the best food from the commencement. I have known queens started on larvæ four days old. If a queen-cell is started after the fourth day, there has been one day in which the development of the ovaries has been arrested, and she can never make a good queen. Also microscopically Dr. Planta has been able to show that the worker larvæ receive this digested food for the first three days, and after that pollen and honey; drone larvæ are reared after the fifth day; while the royal food is always a chyle food, and never has either pollen or water mixed with it.

I think I have now placed this matter before you as fully as I am able to do. It appears to me that we may now look upon this question as decided, namely, that the food is produced in the chyle-stomach of the bee, and is not a secretion. I do not wish it to be understood that the secretion of the glands has nothing to do with the food, because Schonfeld, Holtz, and others admit that the secretions from the glands are added to the chyle-food, but are not the actual food itself, which consists of digested pollen and honey. The results of the investigations referred to will be published in Germany in about a fortnight's time, and I hope then to be able to say something more on the subject in the columns of the *Bee Journal*.

It is supposed that the workers that became fertile had received an extra large proportion of rich food. Instead of being weaned at the proper time, the rich food had been continued to them beyond that period. If a worker were fed thus for four days, the organs would have one day's development. In an ordinary worker they were stopped on the third day.

The Voice of Spring.

MISS EDNA A. THOMPSON.

Now we hear the voice of spring
In the song the blue-birds sing;
Hear the "humming of the bees"
Through the budding forest trees,
Going to and from the flowers
In the morning sunlit hours.

Watch the cleaning of the hive,
Where the busy workers thrive;
How they guard their little store,
From the robbers at the door;
Working on from day to day,
Stopping not to rest or play.

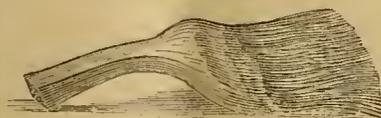

When the linden comes in bloom,
Then they work from morn till noon,
Thankful for the light or shower;
And obey their Sovereign Power,
Something as the human race;
Though, perchance, with better grace.
Clark's O.

The Yucca or Spanish Bayonet.

W. A. PRYAL.

These plants are quite numerous on the mountains and foothills in the southern part of California, and when in bloom, their white crests can be seen for miles, towering above all else. The early Catholic missionaries, when they first came to California, called this plant "Our Lord's Candle Stick." W. W. Bliss remarks thus:—I have seen it stated that the bees gather large quantities of honey from this plant, but I do not think that this

YUCCA BRUSH.

is the case, although I have seen bees at work on the flowers. The most important use of this plant to beekeepers, is the brushes which are made from the leaves that grow at the bottom of the plant. These brushes are decidedly the best thing that has yet been discovered for brushing bees off from the combs in extracting; they are a vegetable fiber, soft and pliable, yet almost indestructible, and never come loose in the "handle," no matter how much they are exposed to the weather.

There are several varieties to be found growing through California, Arizona and Utah. There is one variety found in Arizona, and though not so stately as the above described, it is, nevertheless, more useful, as the fiber of it is now being made into paper of a very fine quality, which commands a high price in the market. We have not learned that it is yet to be had in large quantities in the market. Several other important uses are made of this last-mentioned variety. North Temescal, Calif.

For the American Bee Journal.

Cost of Cellar-Wintering of Bees.

W. Z. HUTCHINSON.

I believe that one of the unwritten laws of literature is, that no author shall defend his own works. I also believe that we bee-keepers are a law unto ourselves—we care more for truth than for some of the hair-splitting rules of authorship—and so strong is my faith in this belief that, in the conclusion to my little book, I announced that I should hold myself in readiness to explain and defend my views, or, if necessary, acknowledge my errors. I will now fulfil this promise.

First, I wish to thank my friends Clarke and Cook for having noticed my little book so kindly and so fairly. As one of the principal criticisms is that I have placed the cost of cellar-wintering at too low a figure, I will "explain and defend." Before doing this, however, let me show Mr. Clarke what good company he has. I have received a good, long letter from (and a sprig of orange blossoms) Mr. Poppleton, of Florida. After stating how completely his views agreed with mine in regard to the importance of spring protection, even going so far as to say, "I would no more think of trying to keep bees without spring protection in the short, changeable seasons of northern Iowa or Michigan than I would without movable comb hives," he also says: "Ain't you a little careless or wild in the statement that 'the saving of stores in cellar-wintering will pay for the expense four times over?' Compared with unprotected, out-door wintering, you are correct; but so far as my experience goes, the difference in the consumption of stores between the cellar and a thoroughly-packed colony out-of-doors, is too small to be considered. The only reliable statistics that I have seen upon this subject are those published by A. G. Hill, of Indiana. If I remember correctly, these tables cover several years of experiments, with an average of say 50 to 75 colonies each year; and the average difference between cellar and out-door wintering was, I think, not far from only one pound per colony. This, of course, applies only when hives are properly protected; not where the work is only half done."

W. F. Clarke says: "Let Cyula Linswik, A. G. Hill, A. I. Root, and other successful out-door winterers give us their figures, and I do not think they will sustain this strong assertion."

While Cyula Linswik has been successful in wintering bees out-of-doors, her experience in cellar-wintering is, I believe, limited to a single experiment with only one to two colonies; hence she has been unable to make any comparisons upon the point under discussion. Of course if her bees consume but little if any more honey than the cellar-wintered bees of somebody else, such testimony would be in point, *provided* other things were equal; but there are so

many varying circumstances that, to my mind, the only satisfactory evidence is that obtainable by comparative experiments in the same apiary, similar to those made by Mr. Hill.

As we approach the equator less protection is needed by bees, until a point is finally reached where chaff hives and cellars never come. Before this point is reached, however, there is another point where *some* protection is needed in winters; where chaff hives and the various kinds of packing are probably a sufficient shield against the cold; and by means of which bees can be wintered to better advantage, and it is likely, with no greater consumption of stores, than in a cellar; but it must not be forgotten that Messrs. Root and Hill live nearer this point than do Mr. Clarke and myself.

I met Mr. Root last March at the home of Prof. Cook, and as the wheels rattled over the frozen earth, and the frosty air nipped our ears and noses when on our way to the station, Mr. Root exclaimed: "Well, I declare, if this is the kind of weather you have up here, at this time of the year, I don't know but I, too, *should favor cellar-wintering* if I lived here. Why, the frost has been out of the ground at our place for two weeks." I will admit that the weather *was* unusually severe just then, but it was two weeks later before the frost was out of the ground at this place.

At the Michigan State Bee-Keepers' Convention held at Lansing in 1884, the question of "Saving honey by cellar-wintering" was thoroughly discussed; and the weight of the testimony indicated that wintering bees in a cellar effected a saving of from 5 to 10 pounds of honey per colony. Mr. Root suggested that a good chaff hive would give almost as good results as a cellar, but was told by quite a number that he was mistaken.

Judging from my own experience, which I will admit, is not so decisive as it might be, consisting as it does only of general observations, and of several times being obliged to take honey from cellar-wintered colonies, and give it to those wintered out-of-doors, I should place the saving by cellar-wintering at about 4 pounds per colony.

Mr. A. G. Hill has given us some excellent tables showing the amount of stores consumed during the winter, when the bees were protected; but, according to the table in his paper for April, 1886, he has been wintering bees in the cellar only since the winter of 1883-84. Comparing the three years of cellar-wintering that are included in this table, with three corresponding years in the table showing the results of out-door wintering, I find that the saving by cellar-wintering averages 2 pounds and almost one ounce per colony.

The next step is to decide in regard to the expense of cellar-wintering. I had a cellar under one-half of my house. Last fall I dug out the other half at a cost of \$5, which enlargement furnished room for 100 colonies. The soil was hard clay, and as the

walls were given a slant of about 60°, no stone wall was needed. As the hatchway to the other part of the cellar also furnished an entrance to the new part, it is perhaps fair to assume that the bee-cellar cost \$10. The interest upon this amount is 70 cents, or 7 mills per colony. To carry the bees in and out the cellar, counting a man's time one shilling an hour, cost 2 cents per colony, and the apiary was 15 rods distant; hence, to winter my bees in a cellar costs 2 cents and 7 mills per colony.

Knowing that Mr. R. L. Taylor, of Lapeer, Mich., had built a new honey house having a cellar under it for wintering bees, I wrote him asking in regard to cost, etc. Here is what he says:

"My new bee-cellar, which will accommodate 250 colonies, should not be figured, I think, to have cost me to exceed \$50. Of course circumstances would make the cost vary greatly. I can easily put the bees into the cellar and take them out again for 2 cents per colony. Your plan of spring packing is all right, but can it be made popular?"

The interest upon the cost of Mr. Taylor's cellar would be 1 cent and 4 mills per colony; making the cost of cellar wintering to him 3 cents and 4 mills per colony.

Perhaps some one will say: Well, this is cheap enough, but how will it be if a cellar is built independent of any building, and expressly for wintering bees? In reply I will say that each bee-keeper must have a house, also a shop or honey-house, and the bee-cellar may be under one of these; but special, independent repositories need not be so very much more expensive. Mr. J. H. Robertson, of Pewamo, Mich., has an out-door cellar for wintering bees. It is double-boarded, and the space between the boards filled with sawdust. If I remember aright it cost about \$40, and will hold at least 350 colonies. The interest would be 8 mills per colony, carrying in and out, 2 cents, making the cost of cellar wintering to him, 2 cents and 8 mills per colony.

I know that bees can be carried into and out of a cellar for 2 cents per colony, and to the best of my knowledge a wintering repository can be furnished, in most instances, at a cost not greatly exceeding one cent per colony.

Fellow-bee-keepers, I may yet be compelled to put the saving by cellar wintering at a lower figure than I have, but I was neither "wild nor careless" when I placed it where I have; as, before making the assertion, I went over the ground fully as carefully as I have in this article, and felt that I spoke within bounds.

I presume few of the readers of my little book would imagine that I devoted a whole month exclusively to its writing. Each point was gone over with great care, and so hard did I work to have everything exactly correct, that I could scarcely sleep nights from waking to "think."

Since I have proved the importance of spring protection, I, too, have thought considerable about house-

apiaries, but that they should have been so almost universally abandoned is pretty nearly a knock-down argument against them. Perhaps Messrs. Vandervort and Foster have found some new "wrinkle."

There are two or three other points in Mr. Clarke's review that I should be pleased to notice, but this article is already too long, and I must wait until another time.

Rogersville, 6 Mich.

For the American Bee Journal.

Bee-Keeping a Healthful Occupation.

MRS. L. C. AXTELL.

All the way through my last letter in the BEE JOURNAL, I am made to say "my" when it should have read "our," as Mr. Axtell is the bee-man here, or rather, he and I are in partnership, as I think all husbands and wives should be if possible in all business, especially in the bee-business if they wish to succeed.*

But Mr. A. does not care to write any of his experience in bee-culture, and I rather like to write, and take a great deal of pleasure in reading communications from others. We have now 202 colonies of bees—not so many as formerly. It takes much of his time to make racks, hives, sections, shipping-crates, etc., besides overseeing work on the farm. I take it upon myself to do all the bee-work I can, partly for the out-door exercise, as it has been a great benefit to my general health. Before we kept bees there was 10 years and more that I suffered everything with indigestion. I had but little pleasure in my food, from the suffering that followed. I tried many remedies, but *nothing* helped me until I became interested in the mysteries of the bee-hive. I read everything I could get hold of far and near, trying to commit as much of it to memory as I could, and watching every chance to read what I could find to my husband, or mark for him to read. From that day when I began to forget myself and live for the bees, I began to have better health, and food digested better, until now for years I have been troubled but little with indigestion, and life has taken on a new beauty. I find I can be as successful, too, in the care of our home apiary as my husband can of our timber apiary.

But this spring, feeling rather better than usual, I have, with the help of an inexperienced girl, worked all of our 202 colonies, through clipping all the queens' wings except a very few that I could not find on the first trial; and preparing the bees for sections. The girl and I have taken pleasure with our 3-year-old black horse in a buggy, and having an early dinner, drive down to our timber apiary, 4 miles away, work through 12 to 18 hives, turning the frames around, as we winter them placed lengthwise of the hives (Quinby), and set up one inch from the bottom-board in large chaff hives; hunt out queens and clip wings, give more

brood-combs full of honey; return the chaff until time to put the sections on; and then go home tired but strengthened. We enjoy the trip more than if we had been to a picnic.

If we got no pay for bee-work, I fear it would after awhile become insipid and tiresome, but the honey—such piles of honey that always reward faithful work with the bee—seldom fails us, and what to be desired more even than honey is the cash that it brings to do good with. It is a real luxury—a luxury worth living and laboring for. Those of us who have learned to love God for all he has done for us, and what we expect to receive in the future, do not or ought not rest content to enjoy this knowledge alone, while there are millions of our fellow beings who have no knowledge of Him who made them, and are groping through this world in midnight darkness. I say it is a real luxury to have the wherewith to do a little for such people, and hope many of our brothers and sisters in bee-culture are also enjoying this blessed privilege.

Roseville, Mo. Ills.

[*It is all right to say "our" when there is a partnership, of course; but the clerk who prepared your letter for the press, knew nothing of your family history or connubial partnership. If you had slipped in the words, "My husband and I are the apiarists," all would have been plain.—Ed.]

For the American Bee Journal.

Transferring Bees from Box-Hives.

W. W. BENTON.

MR. EDITOR.—I wish you would give us a good method of transferring bees from old box-hives to frame hives. I have been looking for such an article for some time. Please do not refer us to printed books, but give it in detail in the AMERICAN BEE JOURNAL, for the benefit of its new subscribers.

Newry, Pa., May 3, 1887.

[The best time to transfer bees from the common to movable-frame hives is about the season of swarming, though it may be done on any warm afternoon, when the bees are actively at work.

A transferring board about the size of the frame should be prepared in advance, by making grooves of about $\frac{1}{2}$ an inch wide and $\frac{1}{4}$ of an inch deep, and about 2 inches apart. The spaces between these grooves should be cushioned with several thicknesses of cloth, to prevent the brood from being injured when the comb is laid upon it.

Transferring sticks should be prepared from some light, tough wood,

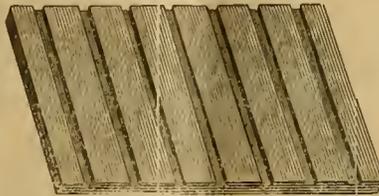

about $\frac{1}{2}$ inch longer than the frames are deep, and about $\frac{1}{4}$ of an inch square. Fasten two of these sticks together with a piece of fine annealed wire, so as to leave about one inch of

Wired Sticks for Transferring.

space between them; attach a piece of wire to the other end of one of the sticks, to be used in fastening when placed around the frame of comb. A small notch should be cut to admit the wire, and prevent slipping. These sticks should be made in pairs, and be kept ready for use.

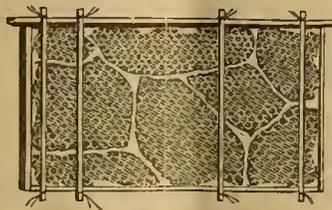

After smoking the bees at the entrance of a box-hive, remove it some distance from the old stand, leaving an empty hive or box in its place, to receive the bees that return from the fields; invert the hive, place an empty box or hive over it, of the same size and shape, wrapping a sheet or cloth

Transferring Board.

around where they come together, leaving no cracks large enough for a bee to escape. By gently tapping the hive for some time, most of the bees, with the queen, will enter the upper box. When they have nearly all left the hive, place the upper box with the bees on the old stand. Being alarmed and filled with honey, they may be handled without fear.

The old hive may now be removed to a convenient room or building and taken to pieces, by cutting off the nails with a cold-chisel and prying off

Frame of Transferred Comb.

the end, cutting the combs when taken out as near as possible to the size of the frames to be used. The transferring board should be placed upon a table or box, to be in a convenient position for working over it.

The pieces of combs containing honey may be placed at one side till some with brood are found; this should be put upon the transferring board, so that when the frame is placed in position over it, the brood may be nearly in the same position as it occupied in the old hive, and near the top of the frame, as that will be the warmest position in the hive. With a honey-knife cut these combs to make them fit. If more are wanted to fill the frame, use the combs of honey first removed from the hive. Then push the ends of the sticks, that have no wire attached, through the grooves, from the bottom of the frames, where the combs may need support; the other sticks attached, place on the top of the comb, and fasten the ends together at the top of the frame, to match the fastenings below. Place this frame in the hive, and proceed in the same manner with the next brood-comb, and let it occupy the adjoining position in the hive, giving the frames containing honey the outside position on either side. The honey from pieces of comb not used, and especially from all drone comb, should be removed with the extractor.

Carry the new hive to the old stand, and empty the bees out of the box on a sheet, in front of the hive. See that the queen, as well as all the bees, enter it. To prevent robbing, the entrance should be contracted; and in two or three days, when the bees have fastened the combs, the transferring sticks should be removed. Always work slowly with the bees, and avoid jarring.

As several have asked to have Mr. Heddon's plan of transferring repeated, we give it below:

About swarming time I take one of my Langstroth hives containing 8 frames of foundation, and with smoker in hand, I approach the hive to be transferred. First, I drive the old queen and a majority of the bees into my hiving-box. I then remove the old hive a few feet backward, reversing the entrance, placing the new one in its place, and run in the forced swarm. In two days I find 8 new straight combs with every cell worker, and containing a good start of brood. Twenty-one days after the transfer, I drive the old hive clean of all its bees, uniting them with the former drive, and put on the boxes, if they are not already on. If there is any nectar in the flowers, the colony will show you comb honey. About the queens: I usually kill the forced queen as the bees run in.

I run them together as I would one colony in two parts. Now to the old

beeless hive; of course there is no brood left, unless a little drone brood, and we have before us some combs for wax, for more foundation, and some first-class kindling wood.

If you have no method by which you can use a full hive of frames, of full sheets of foundation, running a full swarm into them at once, by all means procure it without delay.

We hope this will be sufficiently "detailed" to oblige our correspondent. It should be remembered that every beginner ought to have a good "book" for convenient reference at all times.—ED.]

Translated from *Bienen Zuechter*.

Honey Cakes, Cookies and Gingerbread.

J. DENNLER.

I consider honey as a food second to none, on account of its solubility in the blood, its power of providing for heating the body and maintaining life.

I strongly recommend honey as food for children, especially for those who are growing quickly, as it provides easily-digested food, changing their pale faces and languid condition to a ruddy hue and sound health.

To the old it gives heat. Do they wish to enjoy a green old age? Let them eat milk and honey. Crumble up white bread and pour on it liquid honey and cream. This is the most healthy, the most nourishing, and the most relishing breakfast.

In the following recipes the metrical system of weights and measures are changed to the English for convenience. The gramme (grm.) contains nearly fifteen and a half grains, the kilogram (k. g.) is two and a half pounds, and the litre nearly a quart.

Alsation Gingerbread.—1 lb. (half k. g.) honey, 1 lb. (half k. g.) flour, 2½ drams (10 grms.) of bicarbonate of potash. The honey must first be put on the fire in a sauce-pan till it begins to boil. It is then taken off the fire, and the flour well stirred up in it, and last of all the potash. If sweet gingerbread is wanted, you must whip up the white of an egg, and stir in ¼ of a pound (125 grms.) of syrup or honey.

Basle Cookies.—Prepare some dough as in the above (which will keep for a year in a cellar); mix it with ½ pound of shredded almonds (5 grms.), 1¼ drams of orange juice (3 grms.), ¾ dram of lemon juice, 2 grms. of cinnamon, together with (1 grm.) ¼ dram of finely pounded cloves. The whole must be carefully kneaded together and sifted, so that there are no lumps, and then baked.

French Honey Cakes.—Heat in a sauce-pan 4¼ ounces (150 grms.) of pure sugar, and ¼ pint (½ litre) of milk. When the sugar is dissolved add 12 ounces (350 grms.) of honey and boil, mixing with it 1 pound (half k. g.) of fine flour, and 30 grains (2 grms.) of bicarbonate of potash. Knead the dough thoroughly, and

make a thick dough of it, and put it in a dish sprinkled with some flour, and bake for an hour.

English Honey Cakes.—Take 2 lbs. (1 k. g.) of honey, ½ pound (250 grms.) of fresh butter, the juice of two lemons, and some ground nutmeg. Melt some butter and well mix the ingredients together. Take 2 pounds (1 k. g.) of flour and make a dough, which must be lightly and carefully rolled out into cakes about ½ of an inch thick. Cut it in pieces, and bake them lightly in butter.

Honey Fruit Cakes.—Take 4 eggs, 5 tea-cups of flour, 2 tea-cups of honey, 1 tea-cup of butter, 1 tea-cup of sweet milk, 2 tea-spoonfuls of cream of tartar, 1 tea-spoonful of baking soda, 1 lb. (half k. g.) of raisins, 1 lb. of currants, 1 tea-spoonful of cloves, 1 tea-spoonful of cinnamon, 1 tea-spoonful of nutmeg. Bake in an oven with a slow fire. These cakes will keep good for months.

Honey Tea-Cakes.—1 cup of strong honey, ½ cup of thick white cream, 2 eggs, ½ cup of butter, 2 cups of flour, ½ tea-spoonful of soda, 1 tea-spoonful of cream of tartar. To be made into dough and bake slowly.

For the American Bee Journal.

Honey on Commission—My Experience

R. V. MUIR.

I shipped to a large city 16 Heddon cases of comb honey, and received returns for the same at 14 cents per pound for a certain amount, and 10 cents per pound for the balance, which was termed in the returns as "damaged sections." I was offered 15 cents per pound at home before shipping it. The retail price in that city was 25 cents per pound.

Some months after I had occasion to visit the same city on business, and found some bee-keepers who had wholesaled their honey at 20 cents per pound. Now the question naturally arose, why was not my honey sold at the regular wholesale price, provided it was as good in all respects as the other? It was a very fine article of pure linden honey.

Since then I have not shipped any honey, and never intend to do so. I have worked up my home market, and on March 7 I had not a single pound of extracted honey, and only a few sections filled with fall honey. My extracted honey sold at 10 cents per pound, and the comb honey at 15 cents per pound. I called this my wholesale price to grocers, and all others I sold more extracted in 50-pound kegs than in any other way. All that came to the apiary purchased at the above prices, without regard to quantity. Three-fourths of the crop was sold at home. Some may think that it was unfair to deal in this way with the grocers, but my object was to make the farmers come and buy of me instead of the grocers (as they charged 15 cents per pound for extracted honey, for which they only paid 10), and I succeeded. My honey

was genuine, and my customers knew it.

BOOMING THE BUSINESS.

What would we think of a banker who, after he had bought State or county bonds at a certain discount, and then sent them to New York or some other commercial centre, and sold them for 10 or 15 per cent. advance, and then rush to a printing office and have it put in the first daily paper issued? Would not the community as one man say that he was a fit subject for a lunatic asylum? Certainly, and the verdict would be correct. Well, this is just what many bee-keepers are doing, ignorantly perhaps, especially those who have just commenced the business—mere tyros in the art—and "happened" to have "good luck" from 2 or 3 colonies, not considering for a moment the average difference between 2 or 3 colonies and two or three hundred colonies.

All have doubtless often seen something like the following: "From 35 to 55, and 3,000 pounds of honey." While such reports may be true, it is an indirect way of "booming" the bee-business, which is at least misleading. The country is strewn with apiarian wrecks, then why "boom" the bee-business to the detriment of those who wish to follow it as a pursuit?

I have been a reader of the BEE JOURNAL for years, and intended to keep silent, and let other correspondents do the "gushing" and "booming;" but I thought the time had come to say something on the other side.

Watson, Mo.

Read at the Oneida Co., Convention.

Can we Control our Honey Market?

JOHN ASPINWALL.

This subject seems to be agitating the minds of many (or I might better say a few) of the prominent bee-men at the present time. It is an important subject, and one worthy of much thought. We may, by combining to control the market, do ourselves some good, but the chances are that we may do ourselves much harm. To assert that we can so control the honey market as to place the price where we please, is proposterous; and to my mind so far from possible, under the present condition of things, as to lead me to think that some other motive prompts the discussion.

Let me put the facts more plainly before you: What is it that regulates trade? What is it that causes fluctuations in any business not controlled by a speculative board, as in the case of stocks and grain? I answer that it is supply and demand. Coal is controlled, we know, by great combinations who place the price where they please to a certain limit, until some firm drops out, and cut-throat prices are the order of the day, to the detriment of all concerned. But is it to be supposed that because this combination owned all the coal

fields in a certain very large district, that it could put the price of coal to \$10 per ton? No, they could not hold those prices three days before coal would be coming in from West and South and North and East to fill the markets at such a price as the market will allow. Controlling a market is a preposterous proposition, if we have not demand to act as the chief factor.

The honey interest has not the advantages which exist in other industries, such as iron, coal or petroleum; for in the first instance mines and wells can be bought outright and controlled, but who can buy up the flowers of the field, or who control the flow of nectar? Only He, under whose providential care bee-culture always rests.

Suppose that the members of the Oneida Bee-Keepers' Association were combined together, and declare that section honey should be sold by the members for not less than 20 cents per pound for the best quality, and I was an outsider not belonging to your association. Is there any law to prevent me from bringing my own honey, and as much more as I chose to buy in other parts, and selling it under your very noses at 18 cents a pound? Where would you get your money from to continue your business, if you found buyers loath to pay 20 cents per pound for the same article they could obtain from me at 18 cents? I leave the answer to yourselves.

What would you think of a lot of enthusiasts getting together to control the egg market, in country towns and elsewhere? How many farmers' wives would they control when it came to the question of selling a dozen eggs to pay for a new shawl, or to buy bread for the children? In this case the egg men have an advantage over the honey men, in that eggs are a far greater necessity than honey, and consequently there is a constant demand.

Suppose that a man depended on honey production for a living, and the combination of bee-keepers, to which he belonged, should say the honey market must be 20 cents, and some fellow comes along offering honey at 18 cents in this man's market, and gluts it. Where is the member to get bread from? He will go out of the bee business next year, and the fellow will reap the harvest in a market which the first bee-keeper has toiled so many years to create. Combination, you see, would be a curse there, instead of a blessing.

I offer the following suggestions, not as a solution of the problem, but something toward a solution: I would propose the formation of a honey company headed by some experienced men in the honey business, and the establishing of head-quarters in New York city with branch establishments at the different centres of commerce. This to be a stock company that shall buy honey outright and not sell on commission, and whose principal work shall be the creation of a market by circulating pamphlets tending to educate people to the numerous uses to which honey can be put, and above all, inspiring the minds of the general

public with the absolute confidence that when honey is bought from this company and labeled "pure honey," it is "the truth, the whole truth, and nothing but the truth."
Barrytown, N. Y.

For the American Bee Journal

Moving Bees on the Cars.

ESAU RUSSELL.

I moved my apiary from Tiffin, Iowa, on April 6, to this place. The weather being cold when I started, I simply nailed wide boards on top of the hives tight, and placed screens in front, so that the bees could all come out if they wanted to; but very few bees came out until the next day; then the weather got warm and lots of bees would crowd the ventilators. I piled the hives 6 high in the car, and then packed tight, giving free circulation of air. I used a stock-car, and scarcely a comb was broken, as I placed little bunches of straws between the hives to prevent the sudden jar of the cars. The bees are doing well now, are building up rapidly, and some hives are half full of brood.

Ida Grove, Iowa, May 7, 1887.

Practical Farmer.

Honey as a Tooth-Preserver.

DR. W. G. PHELPS.

From a hygienic stand-point the value of honey is scarcely realized by the masses. Were it the case the use of it would have kept pace with the increased use of sugar for the past 25 years, which it has not. Years ago honey was to a great extent the sole sweetening medium, and the general health of civilized people was better than of the same classes to-day. The price of honey has gradually placed it among the luxuries, while sugar from its cheapness has been substituted in its stead. "Had the science of bee-keeping," says one writer, "been in its present advanced stage when the sugar-cane industry began its rapid growth, the use of sugar would have been considerably retarded by the contemporaneous march of its more wholesome competitor, honey, which then held the field."

By modern methods employed in bee-keeping, the purity and perfect cleanliness of honey is guaranteed, and had the rational culture of bees marched along with scientific sugar-making at an early date, we should have heard less of cheap and nasty substitutes (as the glucose mixtures for instance, manufactured potatoes, sawdust, rags, etc., frequently) for pure sugar and wholesome honey. The latter would have been produced at so low a rate that it would have held its own as the most delicious food, sweet-meat, and saccharine diet, either rich or poor could possess."

As some are already aware, honey is a perfect substitute for cane sugar in preserving fruits, in wine and beer

making, and for cider in manufacture of vinegar, while as a medicine in many forms, it is invaluable.

A leading medical and scientific journal advances the following good points in reference to its use: "But for cane sugar there would most probably not be so many millions of artificial teeth in daily use. As there are, the grape sugar of honey being at once fit for assimilation, whereas cane sugar (one has noticed how the eating of sweets increases thirst!) calls on a laggard saliva to convert it into grape sugar, and rests in nooks and corners among the teeth, fit food and breeding-ground for caries, schizomycetes, sphaeromycetes, and what not, which turn it into acid, the said acid acting upon the lime of the teeth and dissolving them."

Because cheap cane sugars have been taken into the stomach in unreasonable quantity, the liver has been unable to transform them, resulting in disordering both organs.

Dyspepsia and biliousness are probably caused more by the use of cane sugar than most of us think; indeed, Dr. Cheshire tells us that if cane sugar be injected into the blood, it is at once excreted, which is not the case with grape sugar. Let us then remember that it is only grape sugar which the system can at once use as heat-giving, fattening food, and this it is which honey supplies ready prepared for us by the bee in Nature's laboratory.

Honey will carry along with itself into the stomach for digestion more bread (starch, etc.) than butter, each helping the other; and a pound of honey at 8d. or 9d. per pound, will consequently go as far as 2 pounds of butter, costing 3s. Here then is decided economy.

It can be used for almost every purpose we now use sugar for; and by the principles of modern bee-keeping, it is becoming more plentiful and cheaper year by year. A great objection to its free use in past years was its comparative high price, owing to the restricted supply caused by the annual destruction of bees. This is now removed.

Another serious objection was the fact that honey disagreed with many people. The wonder is that it agreed with any one, for a common way of obtaining it (after smothering the bees) was to cut out the combs containing young bees and pollen, besides honey, and squeeze the whole in a cloth, straining the result for use.

It will thus be easily seen, without entering into details, how much objectionable matter was thus imported in the honey, which would tend to disorder delicate stomachs. All this is now changed. No brood (young bees) is now allowed by the bee-keeper to be hatched in the clean, snow-white sections of white bass-wood we see in the shop-windows of fruiterers and grocers who sell the honey, the whole of which honey and comb may be spread on bread and eaten, the cells being so thin that it takes six cell-walls to equal the thickness of ordinary note paper.

Bees in Excellent Condition.—Charlie W. Bradish, Glendale, & N. Y., on May 9, 1887, says:

My bees have come through the winter in excellent condition. They were taken from the cellar on May 3 and 4. After examination I have found 100 colonies good and strong, and a few weak ones. They are at work to-day on maple blossoms. Clover has wintered well, and the prospect is good for a honey crop.

Results of the Winter in Vermont.—John H. Larrabee, Larrabee's Point, & Vt., on May 9, 1887, writes:

The past winter here has been unusually severe, and like other bee-keepers in this region, we have lost heavily. Personally, I have been very fortunate, having lost only 2 out of 33. The spring is very backward, and fruit has not yet blossomed. One lady has only 9 colonies left from 25; another apiarist lost 40 colonies out of 130. Mr. Manum has met with his usual success, but has lost a little heavier than usual; I think about 50 colonies out of 800. I am of the opinion that the Inter-State Commerce law will operate to the discouragement of large bee-associations, and all other organizations of a like character, but it may aid local societies. The bees are booming at present—making up lost time.

Finding the Queen in a Hive, etc.—Mrs. L. C. Axtell, Roseville, & Ills., on May 5, 1887, writes:

Our bees (my husband and myself are the apiarists) now are doing finely. Both those wintered out-of-doors and those in the cellar are still packed with straw, and will be until we put on sections. They are increasing in young bees very fast. We always aim to clip the queens' wings before many of the young bees are hatched out in the spring, as it is so much easier to find the queen, for young bees are so apt to run, pile up and fall off in bunches. When bees get to running we give up the search for that time, as it is not very safe to have the bees run, for there is more fear of loss to the queen. The queen is more

easily found at the first or second time the hives are opened in the spring; then with care she is in nearly every hive found the first time the combs are looked through. Use as little smoke as possible, and get to looking for the queen as quickly as possible after opening a hive.

Colonies Strong and Cross.—E. Pickup, Limerick, & Ills., on May 11, 1887, says:

Last fall I made a bee-house for my bees, and the result is that this spring my colonies are stronger than usual. It has finally become warm, so to-day I took from the hives the winter packing of sawdust and chaff, and the bees were soon outside. Some think I was foolish for keeping my bees packed until now; but I do not think so, as my bees are now strong and cross, and not weakened by poverty.

The Blank-Strip Section-Case.—J. W. Powell & Son, Mankato, & Minn., write:

In reply to Mr. J. J. Roe's letter on page 267, we wish to say that we do not desire to argue the matter of "priority" of the invention of the blank-strip section-case. We do not remember just the exact date when we first thought of making surplus cases that way, but we made a number of them last season, and gave them a thorough test, leaving some of them on the hives all of the fall; and we never have seen sections come off of the hive so clean. We never have intended to try to get a patent, however, but give other bee-keepers the benefit of our thought, in part payment for the many thoughts and ideas that have been so freely given to us. We hope this short explanation will satisfy Mr. Roe and all others; and thus we will leave the matter where it is.

Bees are Booming.—Lewis Werner, Edwardsville, & Ills., on May 8, 1887, writes:

Bees have commenced working on white clover. I am expecting a fine crop of honey this season. Bees are strong, and ready to swarm at any day. Swarming will be a little later than it was last year.

Non-Progressive Bee-Keepers.—E. W. Alexander, Esperance, & N. Y., writes:

I have kept from 50 to 300 colonies of bees for the past 25 years, and expect to continue in the business the remainder of my life, and I know that there has never been anything that stood so much in the way of selling our honey at a paying price, as that class of slip-shod bee-keepers who give their bees little or no attention, and put their honey on the market in any shape, for any price they can get offered for it. I do not think there are many bee-keepers who keep 50

colonies or over, but what would be glad to have a law passed prohibiting bees from being kept within 25 rods of our public highway. That would wipe out all of these slip-shod bee-keepers who will not Italianize their bees nor have their honey in a suitable condition for market; consequently they are a nuisance to the business. A man who cannot attend to his bees as they should be, 25 rods from a highway, ought not to keep bees.

Honey and Beeswax Market.

The following are our very latest quotations for honey and beeswax:

CHICAGO.

HONEY.—Sellers ask from 7 to 10 cts. for anything off in comb honey; this includes dark undesirable and crooked combs, and 2-pound sections. Good 1-lb. sections, 10@12c.; choice, 12@13c.—**BEE SWAX.**—25c. R. A. BURNETT, 161 South Water St. Mar. 28.

DETROIT.

HONEY.—Best white comb, 11@12c. Market is nearly bare, awaiting the new crop.
BEE SWAX.—23@24c.
 May 11. M. H. HUNT, Bell Branch, Mich.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 4@4½c. light amber, 4½c.; amber, 4½c. Comb, white, 12@14c.; amber, 7@9c. Demand good.
BEE SWAX.—23c.
 May 8. SCHACHT & LEMCKE, 122-124 Davis St.

CLEVELAND.

HONEY.—Choice white in 1-lb. sections, 12@13c.; second quality, 10@11c.; and buckwheat unalable at 8@9c. Extracted, 5@6c.
BEE SWAX.—25c.
 Apr. 20. A. C. KENDEL, 115 Ontario St.

ST. LOUIS.

HONEY.—Choice comb, 10@12c. Strained, in barrels, 3½@4½c. Extra fancy, ½ more than foregoing prices. Extracted, 4@6c. Market dull.
BEE SWAX.—Steady at 20c. for prime.
 May 7. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: White comb, 12@14c.; amber, 7@9c. Extracted, white, 4½@5c.; light amber, 3½@4c. Market quiet.
BEE SWAX.—16@22c.
 Apr. 16. O. B. SMITH & CO., 423 Front St.

MILWAUKEE.

HONEY.—We quote: Finest white 1-lb. sections, 12@12½c.; choice white 1-lb., 11@12c.; choice 2-lb., 10@11c.; dark not wanted, and imperfect slow. Extracted, neat white in kegs, 6½@7c.; good white in kegs and barrels, 6@6½c.; dark, 4 to 4½c. Demand good and market firm.
BEE SWAX.—25c.
 May 4. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—We quote: White comb, 9@12c.; dark 5@7c. California comb, 8@9c.; extracted, 5@6c. Sales large and demand good.
BEE SWAX.—23@24½c.
 MCCAUL & HILDRETH BROS.,
 May 10. 28 & 30 W. Broadway, near Duane St.

BOSTON.

HONEY.—1-lb. packages of white clover honey at 13@15c.; 2-pounds at 11@13c. Extracted, 5@7c. Sales slow.
BEE SWAX.—26 cts. per lb.
 Apr. 22. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote for extracted, 3@7c. per lb. Best comb brings 11@14c. per lb. Demand fair.
BEE SWAX.—Good demand, —20@23c. per lb. for good to choice yellow.
 Apr. 21. C.F. MUTH & SON, Freeman & Central A.V.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for examination every day in the year. We have reduced the price to 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

DRAKE & SMITH,

Successors to A. E. Manum, Bristol, Vt.

MANUFACTURERS of the BRISTOL Bee-Hive, the Standard Hive of Vermont.

SECTION HONEY BOXES,

made from white poplar, (the best timber in the world for honey-boxes), Clamps, and a Wood Thumb-Screw for Clamps. Separators and Wood Sides. LIGHTNING GLUERS Shipping-Crates, Bee-Escapes, Bee-Feeders, and

MANUM'S BEE-SMOKERS,

all made of the best material and in a workman-like manner. Send stamp for Sample SECTION and Price-List. 2E12t

BEAUTIFUL.

ALL-IN-ONE-PIECE Sections, smooth inside and out. Comb Foundation, Alsike Clover Seed, and everything needed in the apiary.

Send for free price list, and samples of Sections and Foundation.

M. H. HUNT,

BELL BRANCH, Wayne Co., MICH.
10Etf Near Detroit.

HOW TO WINTER BEES,

ELEVEN Essays by eleven prominent bee-keepers, sent to all who apply.
Address, HENRY ALLEY,
11Atf Wenham, Mass.

FOUNDATION

STAPLE brand, first quality, cannot be excelled. Satisfaction guaranteed. My Foundation is used and endorsed by Prof. J. H. Comstock, of Cornell University, G. W. Stanley, and many others. For Brood, 6 ft. to lb., 40c. Light, 45c. Every sheet equal to sample; orders filled in rotation.
18E2t WILBER G. FISH, Ithaca, N. Y.

QUEENS for 75 cts.

I AM ready to ship choice Italian Queens, bred from select mothers. Untested, 75 cts.; Tested, \$1.50. E. F. LOCKETT,
18E1f COLUMBUS, MISS.

100 COLONIES of Italian and Hybrid Bees for sale at bottom figures. Write for prices.
A. J. & E. HATFIELD,
12E1f SOUTH BEND, IND.

BEES for SALE, Cheap.

100 Colonies of American-reared Italian Bees, best strain, strong, and in 10-frame wired Simplicity hives; for sale at \$8.00 per Colony.
Z. A. CLARK,
8E1f ARKADDELPHIA, ARK.

SECTIONS.

WE make a specialty of the manufacture of DOVE-TAILED SECTIONS. The White Poplar, the whitest and best wood for the purpose. We make all styles and sizes, but recommend the Side-Opening Sections as superior to any other. The great accuracy and fine finish of our Sections are the admiration of everybody. Sample 3 cents Price-List of Supplies free.

Address, DR. G. L. TINKER,
8E1f NEW PHILADELPHIA, O.

Western BEE-KEEPERS' Supply House.

We manufacture Bee-Keepers' Supplies of all kinds, best quality at lowest prices. Hives, Sections, Comb Foundation, Extractors, Smokers, Crates, Honey Buckets, Veils, Feeders, Bee-Literature, etc., etc. Imported Italian Queens, Italian Queens, Bees by the lb., Nucleus or Colony, "Bee-Keepers' Guide, Memoranda and Illustrated Catalogue" of 48 pages FREE to Bee-Keepers. Address JOSEPH NYSEWANDER, DES MOINES, IOWA.

huck's Invertible Hives & Cases. 1 make L. hives all styles. Greatly reduced prices.-506 Walnut st.

"Boss" One-Piece Sections,

MANUFACTURED BY

J. Forncrook & Co., Watertown, Wis.

Patented June 28, 1881.

WE will furnish you SECTIONS as cheap as the cheapest. Write for price-list. Watertown, Wis., May 1st, 1887.

Thos. G. Newman & Son, of Chicago, sell the one-piece Sections manufactured by us.

ESSAYS

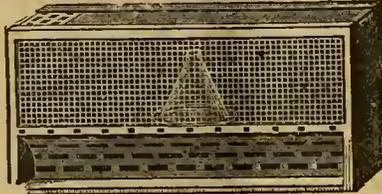

ON THE PRODUCTION OF COMB HONEY

WILL be given in the June issue of the AMERICAN APICULTURIST, by G. M. Doolittle, Dr. G. L. Tinker, Dr. C. C. Miller, and other prominent and well-known bee-keepers. Ready May 25. Price, 10 cts. Address, AMERICAN APICULTURIST, 18A4t WENHAM, MASS.

100 Colonies of Italian Bees,

Strong, first-class in every respect, For Sale at reduced prices.
15A1f E. C. L. LARCH, Ashland, Mo.

Alley's Drone and Queen Trap.

Price, by Express, 50 cts.; by mail, 65 cts.; 12 in the flat, and one nailed (13 in all), \$3.50; 50, in the flat, \$12.00. Address,

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

500 Heddon-Langstroth HIVES

-FOR SALE.-

WITH slotted honey-board, eight brood-frames, crate filled with 28 sections, all put up in good shape and painted 2 coats.

In lots of five, \$1.00 each. (Price-list free on application.)

J. W. BITTENBENDER,
18A1f KNOXVILLE, IOWA.

BEES! 300 COLONIES ITALIANS

READY for spring delivery at 60 cts. to \$1.00 per pound, according to time. Choice Queens and Brood cheaper in proportion. Also ADJUSTABLE HONEY-CASE and other Supplies. Circular free. OLIVER FOSTER,
11A1f Mt. Vernon, Linn Co., Iowa.

1880. 1887.
Notes from the Bright-Band Apiary.

I WILL send Pure Untested Italian QUEENS, reared from imported mothers, to any address, at 80 cents each; or Tested for \$1.25. Satisfaction guaranteed. Send for terms on large numbers.

18A4t CHAS. KINGSLEY,
BENTON, LA.

Chapman Honey-Plant Seed

(Echinops sphærocephalus.)

We can supply this seed POST-PAID at the following prices: One-half ounce, 50 cents; 1 ounce, \$1; 2 ounces, \$1.50; 4 ounces, \$2; ½ pound, \$3; 1 pound, \$5. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

THE NEW HIVE.

I have many more testimonials like the following, from Leading Bee-Keepers of this country. See 1887 Catalogue, to know what Prof. Cook, W. Z. Hutchinason, F. P. Stiles, T. L. VonDorn, F. Boomhower, and Doctors Tinker, Mason, Miller and others think, after many of them have thoroughly tasted the New Hive:

ST. CHARLES, Ills., Feb. 7, 1887.
JAMES HEDDON—Dear Sir: Your letter dated Feb. 3rd, is received. In reply I can say that I have watched closely, and with interest, the discussions pro and con in our bee-periodicals in regard to your New Hive. Although I have not as yet been prepared, as you are aware, to give your New Hive a personal test, yet I can say, in harmony with Dr. Miller's declaration, that your invention is one that requires no practical experience, on the part of any one familiar with the art, to recognize it at once as a hive of very superior merits. Having, during the past year, given your New Hive and its management very careful thought and study, I am constrained to say that I believe it to be as far in advance of all other hives as the well-known Langstroth is in advance of the old box or beehive. I say I believe this, and in keeping with that belief, it is my present purpose to adopt your New Hive just as soon as I can spare my place to that end. In short, I feel as though I CANNOT AFFORD to use any other hive. Having used the Langstroth, with its best modifications, since the spring of 1858, it is with a feeling of considerable regret that this resolution will compel me to bid this old friend a final adieu.

It is apparent to me that the novelty of your New Hive is as wide a departure as its utility is superior to all others. Notwithstanding there have been hives with features resembling parts of your New Hive, still I have never seen a combination, nor am I aware of any that possesses its functions. And right here is just where the invention and patentability exist, without which you certainly would never have received the many strong and well merited testimonials which I find in your Catalogue for 1887. Having for the past 25 years given the laws relating to patents more or less attention, I have no hesitation in repeating the word of Prof. Cook and G. M. Alves, that the "rubbish" which is already "lugged forward," in futile attempts to anticipate your claims, does not "deserve a critical man's attention."

As you seem to desire the foregoing for publication, I have taken especial pains to say nothing that I might possibly regret in the future.

Fraternally yours, M. M. BALDRIDGE.

FOR WINTER.

HARTFORD, N. Y., April 9, 1887.
We have had sleighing 134 days, and we are on runners yet. This is the first general flight my bees have had, and I had to dig the hives out of deep drifts in order that the bees might have fair sailing. Eighty-five wintered in my old chaff hives came through with a loss of half, and many more weak. Nine in your hives packed in 6 inches of chaff, and setting 2 inches from bottom-board, not having a general flight in over 130 days, are all in good order. Four wintered on a single case are in best shape, with sealed brood. Stores the same in all the hives. Bees in the cellar are dying.
J. H. MARYIN.

No Circulars sent out, unless asked for. Send address (plainly written) to

James Heddon,
DOWAGIAC, MICH.

THOMAS G. NEWMAN, Editor.

Vol. XXIII. May 25, 1887. No. 21.

May Sun is bright—the air is clear,
The darting swallows soar and sing,
And from the stately elms I hear
Blue-birds and bees salute the spring.

We Regret to learn that Mr. C. Schindler, of Perryville, Mo., lost his wife and child on the 6th ult. This leaves him with four small, motherless children to care for. We condole with him in his affliction.

A Great Bee Show will be held at Vienna, with the main object of establishing a honey market for the convenience of the inhabitants of the Austrian capital, and a means of facilitating the sale of honey now being produced in that country.

A. O. Crawford, South Weymouth, Mass., has sent us his new Carton case for a one-pound section of comb honey. It has a piece of mica covering a hole (nearly 2 inches) through which the honey can be seen. It is a nice thing for grocers' shelves to keep the honey clean, and yet show it to customers.

Apiculture at Cornell University.—A course in apiculture under Prof. Comstock has just been added to the regular work. This course is intended to supplement the Professor's lectures on the subject. Each student is given a colony of bees, and is expected to attend to it himself. The bees given to the students are Italians, and are the property of Prof. Comstock. The students taking this course have just had some practical work. A swarm of black bees had taken possession of a tree near Fall Creek, just opposite the Professor's house, and had to be taken care of to prevent them from hybridizing the Italians. The tree was cut down, the bees hived, their queen and drones destroyed, and an Italian queen given to them, making them now harmless neighbors.

Thus it will be seen that progressive and scientific apiculture is now being taught as a practical pursuit in several of the colleges of America.

Indiana now presents a case of antagonism to apiculture. Mr. F. C. Barrett writes to us that the City Council of Fort Wayne, Ind., has passed the following ordinance against bee-keeping :

BEES—It shall be unlawful for any person to keep within the limits of the city, more than two hives of bees upon any one lot at a time, and said hives must not be nearer than 50 feet to any street, or 20 feet to any alley, or division line between lots or parts of lots of another. Any person who shall violate any or either of the provisions of this chapter, or any section, clause or provision of any section of this chapter, or who shall neglect or fail to comply with any or either of the requirements thereof, shall, on conviction, forfeit and pay a fine of not more than one hundred dollars.

This ordinance practically wipes out the pursuit of bee-keeping within the corporate limits of Fort Wayne—if it is enforced.

Of course a similar plan may be pursued to the one in Arkansas, mentioned last week on page 307. So far we are not advised as to the result of the trial, which was expected to take place on the 16th inst. We await that news almost impatiently.

LATER.—Since the above was put "in type," we have another letter from Mr. Barrett, stating that a bee-keeper being arrested there, it was rumored that it was under the provisions of the above ordinance; but, upon examination, it proved otherwise. Such a pressure is being brought to bear upon the City Council, that it is expected that it will repeal the obnoxious ordinance at the next meeting.

Bee-Keeping in Russia.—Mr. G. Kandratieff, has 500 colonies of bees, and has just visited Italy in order to study the apicultural methods of that country. One of his apiaries containing 300 colonies is located in the Caucasus, and the other of 200 colonies is located in St. Petersburg. The Italian bee-periodical *L'Apicoltore* says:

According to the *Apicoltore*, Mr. G. Kandratieff, Director of the Imperial Opera of St. Petersburg, has availed himself of a short visit in Italy in order to make an inspection of the most important apiaries. Mr. Kandratieff is the proprietor of two large apiaries in Russia, one of about 300 colonies in the Caucasus, and another of about 200 in St. Petersburg. Notwithstanding the great difference of climate between the Caucasus, where winter is almost unknown, and St. Petersburg, where it is both most severe and long, Mr. Kandratieff obtains, it appears, almost the same amount of profit in proportion from the one as from the other. It appears that Mr. Kandratieff is a perfect master of the Italian language, and a constant reader of the *Apicoltore*, which has been his guide in his apicultural pursuits.

More Rain Needed.—Dr. C. C. Miller, Marengo, Ills., writes on May 17, 1887: "Bees are doing nicely, but unless we have rain soon there must be a failure of the clover crop here."

Here in Chicago we have had several good rains, and things are consequently looking prosperous, but in many parts of the country rain has been much needed for several weeks. Now, however, the scene has changed; for the past three days copious showers all over the northwest have revived vegetation, and good crops are now assured.

F. H. Scattergood's price-list of Italian queens is received on a postal card from Winona, O.

Foolish Warfare Against Bees seems now the rage! The idea that fruit suffers because of the presence of bees is simply ridiculous! The good they do in fertilizing the fruit trees far outweighs any possible evil that may follow from their presence.

Some time ago we noted the fact that in New England, so strong was the belief that bees injured the fruit, that an ordinance was passed obliging the bee-keepers to remove their bees to another locality. After a year or two the fruit-growers decided to have the bees brought back, as so little fruit set upon the trees in proportion to the blossoms which appeared!

While the "good" the bees are doing to fruit is so apparent, and most fully demonstrated, the injury to fruit charged against them is the work of other insects and birds, and is a senseless and ignorant howl by those who know nothing of the possibilities of the bees' organism, and vehemently charge the bees with puncturing fruit when their jaws are too weak to puncture the skin of the most delicate grape. All the bees do is to gather up the juice after the damage is done, and save what is going to waste! All bee-keepers wish they would even leave that juice ungathered.

The Flavor of Honey.—Mr. G. W. Brodbeck writes as follows on this subject in *Gleanings*:

In all discussions in regard to ripening honey, one essential fact has been entirely ignored, and yet the quality, if not entirely, is more dependent on it than on any other. That honey must be of a certain consistency, is conceded by all; so quality first, and quantity next, is what we are all in pursuit of; and how to get the latter without failure of the first, is yet an open question. Admitting proper consistency, quality, then, is due to its peculiar flavor, which is derived from the nectar of the flower.

All flowers and plants possess a peculiar and distinct odor, which is due to a volatile, or essential oil, peculiar to itself, and this same oil we find in the nectar of the flowers; this it is that gives honey its distinct flavor. When flowers are macerated in water, then distilled, the essential oil of the flower passes off with the steam, and, if condensed, the oil is found in minute quantities floating on the water; and this, as its name indicates, is very volatile, and, if exposed to the atmosphere, in time all evaporates. Thus the flavor of the honey is dependent on the quantity of this oil present in it. Some flowers possess more of it than others; and, as a natural result, we find some honey with more of a distinct flavor. If the retention of this oil is desirable, then that method by which there is the least loss is the one we are in search of. That we have not yet attained this, is evidently a fact; but that it is attainable is beyond question, and I doubt not but that careful experimenting will yet give us a standard to go by.

We have Received the Illustrated Catalogue of G. Stoddard, of Welwyn, Herts, England. It contains 48 pages descriptive of his stock of bee-keepers' supplies.

Warm Days tell us of approaching summer, and an article that takes us to the woods and mountains has an attractive appearance. Mr. Charles Bacon allures us all to follow him in his sketch, "Camp-Life Among the White Hills," in *Frank Leslie's Popular Monthly* for June. Miss Lily Higgin tells something about the "Jubilee of Queen Victoria." The many articles are all well illustrated, and the stories, six in number, are very clever and worth reading. The whole number is most attractive in matter and picturesque effect.

QUERIES

With Replies thereto.

[It is quite useless to ask for answers to Queries in this Department in less time than one month. They have to wait their turn, be put in type, and sent in about a dozen at a time to each of those who answer them; get them returned, and then find space for them in the JOURNAL. If you are in a "hurry" for replies, do not ask for them to be inserted here.—ED.]

Rearing Queens and Italianizing.

Query 421.—I want to Italianize my apiary the coming season, rear my own queens from an imported mother, and work my apiary for comb honey. What is the best way to proceed, and at the same time procure the best results in honey, with no desire to rear queens for sale?—L. R., W. Va.

This is like asking a carpenter how to build a house.—JAMES HEDDON.

I should proceed as recommended by Mr. Hutchinson in his new book; then rear queens from Italian stock, and supersede by use of these.—A. J. COOK.

Have queen-cells built in full colonies, transfer them to nuclei, and when the queens are laying, introduce them to the full colonies.—W. Z. HUTCHINSON.

This space is too small to give any good method. Procure "Bees and Honey," read it carefully, and you will obtain the information you want.—H. D. CUTTING.

As Prof. Cook says, "Consult the books," and back numbers of the BEE JOURNAL, and you will probably find better answers than I can give. Queen-rearing must interfere with honey-gathering to some extent.—C. W. DAYTON.

Set aside a few colonies for the purpose of rearing queens, and then proceed according to the rules laid down in any standard work on bee-keeping.—J. P. H. BROWN.

Form as many nuclei as you think you will need, and as fast as you get queens to laying in them, introduce them to your full colonies, using the same nuclei till the required amount of queens are secured.—G. M. DOOLITTLE.

I am not sure that I know the best way for any one, and without knowing your experience, etc., I could not say what would be best for you. One good way might be to rear queens at the beginning of the honey harvest, and then as fast as swarms issue, give queens or queen-cells to the colony in the old hive, and change the old queen toward the close of the harvest.—C. C. MILLER.

In my locality it interferes less with the honey-field to change the queens at the close of the honey season. I sometimes rear the queens in nuclei and introduce them, but more frequently I remove the black queen and give the colony a maturing queen-cell, 3 days after removing the queen.

Last season I introduced hundreds of virgin queens after the colonies had been queenless 3 or 4 days, by caging some of them and leaving the bees to release them by eating away the plug of soft candy with which the cage was stopped, and by simply running them in at the entrance of the hives.—G. W. DEMAREE.

Break up enough colonies into nuclei to give you the number of queens you want. Then rear a lot of queen-cells in a full colony; when they are sealed transfer them to the nuclei to come out from the cells, and to fly on their wedding tour. Let the colony the queens are reared from have from ten days to two weeks rest before rearing a second lot of cells; and three weeks, sure, again before rearing the third. Be sure and keep the air full of drones during the mating season.—J. E. POND.

I would not Italianize and try to work for comb honey at one and the same time, except to introduce queen-cells to all colonies casting swarms, if convenient. After the principal honey flow has ceased is the best time to Italianize, in my experience. Then take out all undesirable queens, and on the third day after take out the larvæ of the queen-cells and introduce very small larvæ from the select stock; mark the cells, and afterwards destroy the other cells made. Another good plan is to take out the queens, and in nine days all the cells, then introduce just hatching larvæ in a bit of comb, and let each colony rear a queen.—G. L. TINKER.

To Italianize an apiary, it will be necessary to catch and destroy all the drones, or the young queens you propose to rear will be impurely mated. Take away the queens to be superseded, and after 24 hours cage the Italian queen and insert it between two combs containing honey, which the queen may be able to reach at pleasure. In about 48 hours release the queen upon one of the combs. If she is molested by the bees, return her to the cage for another 36 hours, after which she will no doubt be accepted. If queen-cells have been started, destroy them. This need not interfere with honey-gathering to any great extent. There are other methods, and it will be well to consult Alley's book on queen-rearing. Select a method, and then follow the directions given.—THE EDITOR.

Worker-Comb and Drone-Eggs.

Query 422.—If an 8-frame Langstroth hive is filled with all worker-comb, and no drones hatch during the season, what becomes of the drone eggs, if it is not the size of the cell that causes the impregnation of the egg?—G. P.

They remain unladen.—C. W. DAYTON

I suppose the drone-eggs in that case are all impregnated and become worker eggs.—C. C. MILLER.

According to our best authorities, the eggs are all alike until impregnated, then they produce workers; otherwise they produce drones.—W. Z. HUTCHINSON.

Your "if" is hardly possible. I have yet to see a strong colony pass the swarming season without drone-brood.—G. M. DOOLITTLE.

There are no drone-eggs laid, that's all. If you imagine that a queen has a certain number of drone-eggs to lay in a season, you had better read what the modern writers say about parthenogenesis.—DADANT & SON.

It is bee-nature to rear some drones during the swarming season, and to accomplish this object they will alter and change worker-cells around the margin of the comb into drone.—J. P. H. BROWN.

I have never seen any trouble about bees rearing drones in worker-cells when they have no drone-cells. Drone-eggs, if they hatch and mature, make nothing but drones in all cases. I do not think the size of the cells has anything to do with the impregnation of the eggs.—G. L. TINKER.

All I know about it is, that where I have no drone-comb in my hives, I see no drones in the hive at any time of the year. I was not aware that any "drone-eggs" were laid.—JAMES HEDDON.

I presume that there are no drone-eggs to "become of," if the queen has none but worker-cells to lay in. I know that queens can lay eggs that hatch out drones, in worker-cells, for I have seen the like several times. I think that the preponderance of the evidence is on the side of the theory that the queen lays male and female eggs at her own option. Still I believe the matter has never been demonstrated.—G. W. DEMAREE.

If there is no place for drone-cells, you will have no drone-eggs, unless the hive contains an old queen; then they will make a place for drone-cells. The size of the cell has nothing to do with the impregnation of the egg. In other words, if there are no drone-cells to put drone-eggs into, all the eggs will be impregnated by the queen and produce workers.—H. D. CUTTING.

They are deposited in worker-cells, and the drones emerge therefrom the same as from drone-cells, but are much smaller. There is no difficulty in the matter at all. Every bee-keeper of experience has seen drones emerge from worker-cells, and thousands of them also at times; this particularly where a virgin queen has been kept for experimental purposes.—J. E. POND.

I should say that the queen controls this matter, and knows better than to lay drone-eggs in worker-cells, and so she lays no drone-eggs in the case mentioned. The fact so often witnessed, of a queen laying worker-eggs in cells but partially completed, some times only just fairly commenced, utterly refutes, it seems to me, the compression theory.—A. J. COOK.

Before impregnation occurs the eggs are all alike; after that they produce worker bees. If no drone-comb is provided, the queen impregnates the eggs and uses the worker-cells. This shows the value of using

full sheets of comb foundation in the brood-chamber—to prevent an excess of drones.—THE EDITOR.

Honey for Bees in Winter.

Query 423.—Having a few light colonies of bees last fall, I gave each full combs of honey from strong colonies, and put them into the cellar on Nov. 19. Upon examination recently, I found the combs filthy with the excrement of the bees, with lots of honey in the hive, but the bees were dead. Is it practical to winter bees in solitary confinement on honey gathered by other colonies?—B. S., New York.

Yes.—G. L. TINKER.

It is practical in many cases. Read my article on page 184, in regard to small colonies.—C. W. DAYTON.

I should say the temperature of your cellar was not high enough, rather than a fault of the honey.—G. M. DOOLITTLE.

It is practicable to winter bees on combs of honey gathered by other bees, but weak colonies are liable to dwindle and perish with the best of stores, if the cold is protracted.—J. P. II. BROWN.

I do not understand your meaning of "solitary confinement." Bees will winter on good honey whether they or some other colony gathered it.—H. D. CUTTING.

The honey of other colonies has nothing to do with the question, if it is wholesome. But outside of this the circumstances in which your bees were placed may have been unfavorable. We could not say what was wrong, unless we were acquainted with all the particulars.—DADANT & SON.

Most assuredly; I have done it repeatedly. The probable reason of your loss is that your cellar was too cold, and your bees to few in numbers.—A. J. COOK.

The bees died with the diarrhea. That the honey was gathered by other colonies probably made no difference. Perhaps they were not strong enough in numbers to keep up the requisite heat.—W. Z. HUTCHINSON.

I am not sure I understand the question, but I believe that combs of honey upon which the bees that gathered it would winter well, would be just as good for any other colony.—C. C. MILLER.

To the last part of your question I say yes, most certainly so. But if you give the bees a new supply of stores and put them in confinement at once, they are likely to gorge themselves to their ruin, unless they can have a flight in the open air till they resume a normal condition. Continued confinement with low temperature will destroy any colony of bees, but conditions may vary the time all the way from successful wintering to the worst sort of failures.—G. W. DEMAREE.

Yes! most certainly, if preparation is made at the proper time. Honey is honey; comb is comb, and bees utilize both at all times, whether their own or of other colonies. You must look deeper for the source of

your troubles. You do not say that it is so, but I judge that you put the bees on strange combs on the day you put them into the cellar. If such was the case, it should have been expected the bees would die, as they had no opportunity to construct a brood-nest before cold weather.—J. E. POND.

Your bees have that disease known as bee-diarrhea. It was not caused by "solitary confinement," nor the transferred honey. It was caused by the consumption of pollen, and that consumption was caused by some condition present with your colonies, which is not known to me.—JAMES HEDDON.

"Solitary confinement" may do for criminals; but for bees, never. They need company for warmth. It makes no difference as to what bees gathered the honey, so long as it is "come-at-able" for the nourishment of bees in winter quarters. Your colonies were evidently too "weak" to keep up the necessary temperature, and therefore "succumbed to the inevitable."—THE EDITOR.

Housekeeper.

Weighing the Baby.

EUGENE SECOR.

"The baby is three months old to-day;
We want to see what the cherub will weigh—
So if papa has leisure,
I know he'll take pleasure
In bringing the scales containing the tray."

'Twas mamma, who thus from my book
Enticed me, with speech and with look
So happy, so winning,
I had surely been sinning,
Had I not left, with pleasure, my nook.

The clumsy scales to the room were brought;
The same by which fish and potatoe were bought.
As if, in one measure
And just at one's pleasure,
A bushel of turnips could balance a thought.

As if with grocers' scales could be weighed
A sunbeam, a joy—or a reckoning made
In pounds, to a fraction,
Of the subtle attraction
Of a lily, in all its beauty arrayed!

The treasure was wrapped in mamma's shawl,
The little pink toes and fingers all—
'T would not do to chill her
With the scales from the cellar—
For 'twas cold, cold weather late in the fall.

The balance was turned at ten and four,
Nor could we make it a fraction more;
When she looked up so smiling,
So bewitching, beguiling,
That in our estimation the weight was fourscore.

Then for those dimples add at least eight,
For blue eyes that twinkle a sum twice as great;
'To the crowing and cooing—
Like wood-pheasants wooing—
Add the charms unseen that to mama have weight.

And what do you guess is the total amount?
'Tis a sum too large for papa to count.
So back with these cumbersome
Scales to the lumber room—
To weigh Heaven's gifts they're just no account.
Forest City, Iowa.

Contraction of the Brood-Nest.

W. Z. HUTCHINSON.

On page 278, Mr. Demaree, in speaking of the contraction system, says: "Such treatment would bring ruin to my apiary in an average season, unless I should feed the colonies through the heated months of summer, and supply them with winter stores again in the fall, in which case I would lose rather than gain by the operation."

Farther on he says that "to so manipulate the hive arrangements as to throw all the honey into the 'surplus' costs the life of the colony. Now, if we feed back to counteract the loss on the side of the bees, we have gained nothing—nay, lost in the operation."

Let us consider for a moment what contraction of the brood-nest really does. Perhaps I cannot explain the matter more clearly than I have in "The Production of Comb Honey." I quote as follows: "To rear the great army of workers needed for the harvest, there must be, in the forepart of the season, a good-sized brood-nest—not larger, however, than an ordinarily prolific queen will keep well filled with brood—but when the bountiful harvest has finally arrived, and been ushered in by swarming, then we wish the *now existing* workers to go into the *fields*, to gather in the nectar and cure and seal it, instead of wasting their time, vitality and stores in rearing another army of workers that will come upon the field when the harvest is over and gone. Fortunately, our desire and the bees' instinct are exactly parallel in this instance. Give a swarm a large brood-nest and the bees will fill it—partly with brood, but mostly with honey; put a swarm into a hive with a small brood-chamber, allow the bees to build their own combs therein, at the same time give them access to a super furnished with comb, and they will fill the super with honey, and the brood-nest—slightly with honey, but mostly with brood."

Contraction carried to an extreme will curtail the production of brood, but increase the *immediate* production of honey; moderately employed, it will not lessen the rearing of brood nor augment the amount of honey, but effects a comparatively complete separation of brood and honey; *i. e.*, the brood will be in one apartment and the honey in another. This is what contraction does, it secures nearly all of the white honey in the most marketable shape, leaving the brood-nest filled with brood instead

of honey. Now what is there about this that will "ruin an apiary in an average season," or that "costs the life of a colony?" Just as much, or, at least nearly as much brood has been reared, and the only difference is that the honey has been stored *above* the brood-nest instead of *in it*. What is there about this that is detrimental to the "life of the colony?" There are just as many, or at least sufficient bees, and they are healthy and strong, and exactly as good in every respect as though they had stored *all* their honey in the brood-nest. Why then say: "The apiary is ruined?"

Of course they must be furnished with food. There is usually enough in the corners of the frames to last them until fall. I have been practicing the contraction system now for four years, contracting to five Langstroth frames or their equivalent, and have never yet been obliged to feed my bees through "the heated months of summer." Before cold weather sets in, all that is necessary is to put on feeders and feed sugar syrup, which is not only unvarying in character, but as a winter food for bees is equal, if not superior to the best honey; and at present prices, can be used at a profit. And right here I wish to again quote from "The Production of Comb Honey:"

"Those who for any reason do not wish to use sugar, may still take advantage of this system by putting the unfinished sections back on the hives in time for the honey to be carried down and stored in the brood-nest for winter. . . . As some may ask what is to be gained by this management, I will explain that the number of *finished* sections is increased thereby; in other words, it enables us to virtually exchange the *honey* in our unfinished sections for nearly its weight in *finished* sections, leaving us the *combs* to give the bees a 'send off' in the spring."

I do not say it boastingly, but few bee-keepers have experimented more than myself in "feeding back" extracted honey, and one thing that I have discovered is, that the loss in weight, when the bees have *empty combs* in which to store it, is comparatively slight. If the bees have to construct combs in which to store the honey, there is then a decided loss in weight, so much so that it is unprofitable. When bees are gathering honey in the fields, there are times when they may build combs to advantage, but when they get their honey from a feeder, paradoxical as it may appear, they must have combs in which to store it, if the work is done at a profit.

The idea advanced by Mr. Demaree, that the labor and excitement caused by feeding the bees for winter causes a great loss of life and vitality, does not agree with my experience. The feeding of from 10 to 15 pounds of syrup occupies, upon an average, about two days' time; it is done at a season when brood-rearing is on the wane; and it is so soon over that it has no great stimulating effect; but, far better than all theorizing, colonies so treated winter better, as a rule,

than those that have nothing but natural stores. Each year I have left some colonies uncontracted and unfed, and they have shown no superiority over those that had been contracted and fed in the fall, while the profits have been considerably less. My only object in leaving some colonies in this manner was to make a comparison. A neighbor living two and one-half miles away, who did not "believe in contraction," nor in "starters only," bought my empty combs one year ago, and hived his swarms in 10-frame Langstroth brood-nest, and left his bees their natural stores, now mourns over a loss nearly twice as great as my own.

Mr. Demaree says: "But when it comes to running an apiary from year to year as a business, comb foundation and empty combs cannot be dispensed with in the majority of the apiaries in the country, and their *judicious* use must be profitable everywhere." (Italics mine.) Although this was probably intended as a criticism, I must say that I agree with him *entirely*. So many seem to misunderstand my views upon this subject; they seem to think I would banish foundation and empty combs, while I only plead for a "judicious" use of them, and it was to make clear what I considered, and what my experience taught, was a judicious use of them, that I wrote my little book, the last paragraph of which, preceding the "Conclusion," reads as follows:

"In my locality, and with *my* management (and I can see no reason why the same rules and laws will not hold good in other localities), I know that the use of full sheets of foundation in the brood-nest, when hiving swarms, is attended with loss; and I do not think the matter stops *here*. I think there are still more advantages to be gained by utilizing the natural wax secretion, and it is possible that it would be profitable to *encourage* wax secretion and comb-building. What is needed is, I believe, an abundance of empty comb in the supers at all times, and the bees at the same time allowed to indulge in comb-building."

Rogersville, Mich.

Shipping Honey to Commission Men.

MRS. L. C. AXTELL.

We have for perhaps ten years shipped honey to Chicago to be sold by commission men. One year 30,000 pounds went from our apiary to Chicago. In our state of health it is almost impossible to sell all our honey at home, but Mr. Axtell and I believe in developing our home market all we possibly can.

As to commission men, I fear we think too harshly of them. No doubt some of them are dishonest, as there are those in all kinds of business who are dishonest; but there are good, Christian commission men, as well as rogues. Send your honey to them, or to men with a good reputation, and if

you should fail in getting returns in time, get a competent lawyer to collect for you, with an understanding that he shall have such a per cent. on the hundred for collecting. Never take a note from a commission man, as it is a State's prison offense to sell on commission and refuse to pay over the money and keep it to do business with.

When sending the honey, give instructions as to what price you are willing to take for it, and if it does not sell for that, say you will not take less than a certain price, but to get all they can for it. We have never had trouble but once, and then we gave the case into the hands of good lawyers, and they had a few talks with the commission men, and told them they had committed a State's prison offense, and the commission men were glad to pay up without going to law with it. It cost us some \$30 to collect the \$550, but the lawyers threw off, in our case, ten or twenty dollars from their usual fee.

Write kind letters to your commission men occasionally, get their confidence, as it is to their interest to do business honestly. We never pay but 5 per cent. commission, and always send our honey by freight. We never had but two cases lost by railroad, and it was in due time paid for. At home we have to give 2 cents per pound for selling.

Roseville, Ills.

Gleanings.

Mr. James Heddon—Biography.

PROF. A. J. COOK.

I am very glad to accede to the request to give a brief account of the life and work of Mr. Heddon. True merit should always be rewarded; and as I am acquainted with no more able, thoughtful, studious, and hard-working bee-keeper in the United States than Mr. Heddon, it is with no little pleasure that I call attention to his life, his work, and to the valuable results of his careful experiments and thoughtful, studious labors in the apiary.

Mr. Heddon was the first specialist in bee-keeping in Michigan, and one of the first in the country, and thus his fertile, active mind has ever been directed toward the "pocket-book" side of bee-keeping; and so, as we should expect, all his work, experiments, and influence are in the spirit of this intensely practical age. Best of all, from a long and intimate acquaintance with him I feel assured that all his labor, both of hand and mind, has ever been impelled by an honest purpose and sincere desire to advance the vocation of his choice.

He was born in Genesee Valley, N. Y., Aug. 23, 1845. Thus he is now 42 years of age. In stature, Mr. Heddon is below the average, while his form is slight and wiry. He is extremely nervous, and has a keen, intense expression. He is gaunt and lean, because he has a twenty-horse-power nervous organism in a ten-

horse-power physique. His nervous tension and mental energy have always been vexed that their dwelling-house were not bigger and stronger, and are determined to destroy it; and it behooves our friend to look sharply or they will succeed.

Mentally Mr. Heddon is exceptionally vigorous and gifted. The Rev. Mr. Gage once told me that he was especially interested in a certain young man in his village, who with an opportunity, would certainly make a scientist. Years after, I became acquainted with this same promising young man in Mr. Heddon.

As a speaker, Mr. Heddon is unusually vigorous. His sentences are always to the point, and his figures and illustrations are often irresistible. I have known him at our State convention to hold every person spell-bound as he explained, often at great

He has had as many as 550 colonies of bees at one time, which were kept in three separate apiaries. He now has 450 in two apiaries. In 1877 his Glenwood apiary, worth \$1,500, and numbering 99 colonies, gave him a cash income of \$1,070, and increased to 207 colonies, all but two of which came through the following winter in good condition. The expense in caring for this apiary that year was \$200.

One year, with 16 colonies, he increased to 33, and sold \$800 worth of honey. All of the 33 colonies wintered well during the succeeding winter. At that time honey sold for a very high price. His largest yield for one season, of a single colony, was 410 pounds, all but 48 of which was extracted. He once secured 29 pounds and 13 ounces of unripe extracted honey as the result of a single day's gathering of a single colony.

His modification of the Langstroth hive, omitting the portico, the telescopic upper story and cover, and the bevel of the Simplicity, have so pleased me, after a two-years' trial, that I would never think to return to the old styles. Those who condemn, surely have never tried it. The shade-board is also much superior to a tree, evergreen or grapevine.

Like myself, Mr. Heddon used sections before he ever saw them elsewhere. Though original with us, their use in our apiaries may not have priority.

Mr. Heddon's shipping-crate, as I state in my book, is neat and cheap, and was the first substantial improvement in that article.

The section-crate, with bee-space above, will probably never be excelled in securing comb honey without separators. After two years' use I pronounce it simply perfection. It is in his new hive.

I have already reviewed his new book, and there spoke of his new hive and system. There can be no question of the originality of these, and hardly less that they are a marked improvement, and will soon come into general use. I have never tried these, but the experienced bee-keeper does not need to try every invention to be assured of its excellence.

Mr. Heddon has also practiced the principles of breeding, as followed by our successful breeders of other domestic animals; that is, he has crossed two valuable breeds, and by selection has secured a strain with the excellences of both the original races and without their undesirable qualities. He claims this; and while I have not tested his improved strain, I am certain that the above is the method which must be employed to secure the best bees.

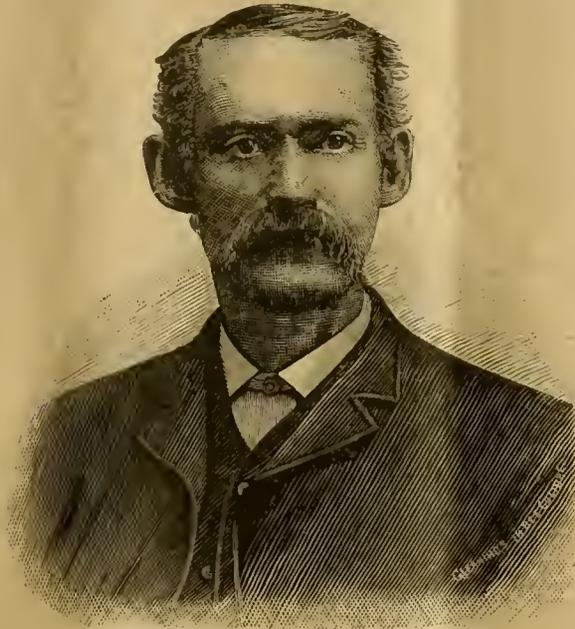

Lastly, Mr. Heddon suggested the "Bee-Keepers' Union," which may and will be of great service to our industry. Each of us is liable to prosecution by those ignorant and prejudiced, and we need just such an organization to aid us in protecting our rights, and in maintaining the high position which our industry deservedly holds among the pursuits of the world.

Mr. Heddon has been President of the Michigan Association, and a very poor one he made. A President must be staid and serene, and without nerves, which does not describe our Dowagiatic friend.

When at his house, some years since, among the many attractions I saw, were three beautiful children, those best ornaments in every home.

Agricultural College, 9 Mich.

[Mr. Heddon is well known the world over, as a successful apiarist who has thoughts and methods of his own, and that he is not afraid to express them, even if the multitude favor the opposite. His fort and special success lies in the direction of mechanical invention. Nearly all of his devices are practical, and will live after he is gone.—Ed.]

MR. JAMES HEDDON, DOWAGIAC, MICH.

length, his experiments, views and methods. The same spirited, forcible style characterizes his writings, as all who read the bee-periodicals know. His nervous energy, excessive love of fun, and desire for hard-earned victory, make him an eager controversialist. He fairly grows fat (mentally) in a good, square, honest, intellectual wrestle.

Mr. Heddon told me that he commenced bee-keeping with nothing except a stout heart. He has been a specialist all the time, except for a brief period of late, when he has sold supplies. This diversion, he has told me, was a loss to him. Now he is worth thousands of dollars. He went into the supply business in 1879, in hopes that, by a circular, he could answer many of the questions that now came to him in letters, and save time to his business. His present capital he credits almost exclusively to honey production.

Mr. Heddon is very neat and methodical. It is a very great pleasure to visit his place. I think I never visited an apiary where more taste and good judgment were displayed in all the arrangements of the bee-yard.

The valuable improvements which Mr. Heddon has given to our industry are many, and will most interest the readers of this sketch. All that I shall name, I feel certain are original; and nearly all I know to be excellent from actual experience.

I have found the slatted honey-board a very valuable adjunct to the Langstroth hive. This, when made just right, keeps the sections perfectly neat. The spaces must be just over the centre of the top-bars of the frames in the brood-chamber, and the spaces between the top-bar and slats no more nor less than a bee-space. This prevents the brace-combs, and such a honey-board needs only to be tested to be retained in every apiary.

Translated from the French.

Honey Necessary to Produce Wax.

G. DE LAYENS.

In making the experiments which I am going to describe, I have not made it a point to ascertain whether or not bees build their combs more economically with one kind of sugar than with another, my object having been simply to arrive at the quantity of honey used by bees working in an apiary at their free will, and at a season when they take to comb building with more readiness than in any other.

The experiments hitherto made in this direction differed so much among themselves that it was impossible to arrive at a reliable conclusion. It is this fact which induced me to recommence these experiments, taking for basis the various plans previously adopted. But at the very outset two questions arise which in practice have often been confounded, but which must be distinctly separated, viz:—

1. Even when honey is plentiful, it is not advantageous to induce bees to produce wax, although it may be done at a small cost, because, in the first place, if only a few empty frames are given to a strong colony among a good supply of ready-made combs, within which to store the incoming harvest, and yet to find sufficient scope to give vent to their comb-building propensity, they would be almost sure to build drone-comb. On the other hand, if plenty of comb building is given them by reducing them, as it were, to a combless colony, they would no doubt build numerous worker-combs, but they would not have sufficient cells wherein to store the incoming honey, the production of wax not being in proportion to the collection of honey. Therefore, at the time when honey is plentiful, it is not advisable to set bees to comb building.

2. When, on the contrary, the honey yield is great, is it advantageous to have bees produce wax? This is the point I have tried to solve.

The basis of what was considered to be the best experiments made consisted, briefly put, of selecting 2 colonies, say A and B, of the same strength, one of which—A, for instance—was supplied with empty frames, and the other, B, ready-built combs. A little later on, the honey gathered by B is weighed; the same with that found in A. This done, the quantity of wax produced is ascertained; the difference between the weight of the honey compared with that of the wax produced represents the proportion between the honey and the wax. This method is, however, incorrect in several respects.

1. Even supposing that by some chance one queen were as prolific as the other, they would not lay the same number of eggs within a certain number of days, because one of the hives afforded, from the very first day, all the desired accommodation for egg laying, which would not be

the case with the colony whose combs are built at a slow pace. Therefore, at the end of the experiment there will be more brood in one than in the other; hence a difference also in the consumption of honey, a difference which is left out of reckoning, and—

2. It was generally supposed that by choosing from an apiary 2 colonies, apparently of the same strength internally, and of similar activity externally, one could compare the work done by either of them without risk offering to any great extent; but very frequently this is not the case as I will presently show.

Having examined 2 colonies, which for the present purpose I will call No. 1 and No. 2, and having, moreover, ascertained that the strength of the latter was about twice that of the former, I reduced them both to the condition of a swarm. The bees, finding themselves now free to set about bringing in their harvest, under identical circumstances—for both colonies had been deprived of their brood—at the closing of each favorable day I used to take the exact weight of the honey brought in. No. 1 had stored kilos 2,140, and No. 2 kilos 2,030, that is, nearly as much as No. 1, whereas it ought to have gathered only about half that quantity.

This year Mr. Bertrand witnessed results similar to this, in the opposite direction. A colony of his had gathered kilos 37 of honey, whilst another, of about the same strength, had brought in, during the same interval, kilos 18. The question with me now is, not to find how to explain this, but rather to show that all experiments having for basis the simple comparison of actual work done by 2 colonies of the same strength cannot be relied upon.

I will now explain, therefore, what were the circumstances I placed myself in when I undertook my experiment.

1. My colonies had been allowed to work freely in the apiary, without interferences, so that nothing could be altered in the natural order of their duties.

2. My experiments were made at a season when temperature was high (maximum at least 20° Centigrade), this being the temperature which bees, in their natural state, choose for the production of wax.

3. I had also selected for my experiments a season when honey was rather scarce, so as to be sure that the colonies which were building, as well as those which were not, had sufficient room in their combs for storing all the honey they could bring in.

4. I experimented on 2 colonies in my apiary which differed in strength as well as in quantity of brood, but which, judging from external appearance, both worked with about the same amount of energy.

Now, these 2 colonies, which I will here call A to the strongest, and B to the less stronger, were both reduced to the condition of a swarm. To A, seven built frames were given, between which I inserted empty ones. This I did in order to feel that the bees were obliged, as it were, to build,

and that at the same time there was a sufficiency of built-combs to receive the incoming honey, and that, moreover, the egg-laying propensity of the queen would not be checked for want of room. To B, I gave eight ready-built frames; here the bees could not build combs for want of space.

5. I made two experiments, one after the other, and each one lasted exactly eight days. At the end of the eighth day all the combs were taken away from the hives and replaced by others, but the order was reversed; here, then, B was placed in the necessity of building combs, whereas A was prevented from doing so. This crossing system is an important one, as it permits, whilst experimenting on any two hives, of obtaining data for comparing, by simply adding, at the end of the experiment, the differences which are noted between them.

6. At the conclusion of the experiments, the honey collected by the colonies A and B (which did not make any wax) was added together; so was also the honey of the colonies A and B (which made wax). Lastly, the quantity of wax made by the 2 colonies was added together. Owing, however, to great dampness, the honey gathered during the sixteen days of the experiment contained a considerable quantity of water, consequently at the end of the time none of the cells had been sealed up. The honey, which was very thin, contained, therefore, more water than that in the sealed-up cells. In order to neutralize this misleading circumstance, I ascertained the thickness of the sealed-up honey as well as that of the thin liquid one (honey) which had just been brought home. This done, I added a sufficient quantity of water to the honey which had been sealed up by the bees, until it had been brought to the same degree of thickness of that which had not been sealed up. By these means I was enabled to arrive at the extra quantity of water contained in the honey which had just been gathered, and I deducted this quantity of water from my calculations. Finally, the difference in quantity of honey gathered by the colonies which built combs and that of those which did not build, indicated the weight of the honey consumed in the production of a given weight of wax.

7. During the sixteen days my experiments lasted, the queens did not lay a uniform number of eggs, as they were not of identical fecundity. Nor did it happen that during the same period the laying of eggs by these two queens did progress with the same disproportion; as a result of this, in the colonies which had not been building, 16,064 eggs were laid, whereas in those which had been building, the number of eggs laid was 16,634, or as near as possible the same number. This small difference of brood represents a quantity of honey consumed the weight of which must be added to that gathered by the colonies which had been building comb. But as the eggs did not open until the end of three days, and that it was only then that they began consuming honey,

the number of larvæ which had been fed was 358. It is the honey consumed by these that must now be arrived at.

According to the investigations made by Berlepsch, 47 grammes of honey and pollen would have sufficed to feed these 358 larvæ until they closed themselves up in their cell. Other experiments, made by myself, show that to feed their brood bees use about as much honey as pollen, consequently 25 grammes will be the maximum quantity of honey used up by my bees in the partial feeding of this brood, of which only a few cells were sealed over.

We find, therefore, that the difference in the quantity of honey gathered was one kilo and 202 grammes. That of wax produced 191 grammes. My bees had, therefore, used 6 grammes, 3 of honey in order to produce one gramme of wax.

In previous experiments my bees had started comb-building on eight frames, and as the honey yield was an indifferent one, with the exception of the first day, they built almost worker comb throughout—I say almost, or nearly so, because in a corner of the largest comb there were to be found a few drone-cells; the latter had been built the first day, when the honey yield was greatest, almost two kilos having been brought in.

It will be seen, therefore, that in practice it is possible to get bees to build worker-combs rather economically by feeding them with a cheaper kind of honey, say some of the foreign kind, to be had on the Havre market at from 50 to 60 francs the kilos. But, to obtain this result, three things are essential, viz:

1. A rather poor yield of honey.
2. The removal of all the brood-combs of a hive, to be replaced by empty frames, the latter to be placed between the full ones. The brood-combs removed, will be given to a weaker colony.
3. Never to induce comb-building unless when the temperature is high.

Plowman.

A Plea for Better Bee-Keeping.

C. H. DIBBERN.

While I am free to admit that much has been accomplished in the past twenty years to place this industry on a higher plane, yet we cannot shut our eyes to the fact that very much still remains to be done.

Perhaps the best way to get an idea of the present condition of bee-keeping, is to visit some of our larger towns, and inspect the honey offered for sale by dealers. I made such a visit recently, and this is about how I found things:

Calling at a large grocery house I inquired if they had any comb honey. I was assured that they had some that was very nice, and followed the clerk in the back room, was shown some boxes apparently made from old fence boards, without planing. The honey was of good quality, but in sections about 7 inches square, and made of material varying from $\frac{1}{4}$ to $\frac{1}{2}$ of an

inch thick. They had not been scraped of propolis, and some of them had evidently been used a number of years. It was easy to see that no separators had been used to compel the bees to build straight combs, as it was very much bulged, and in handling and shipping some of the combs had got jammed together, or the cappings were scraped off in trying to get the sections out, and the cases were leaking all over the floor. When I objected to the honey on the above grounds, I was told that it could not be helped, that the honey was all right and clean, and that the people did not eat the boxes, anyway.

The next place I visited, I found some California honey in Harbison sections. This was nice and white, but it had evidently been roughly handled. A dozen crates were piled upside down in a tub, and were leaking a good deal, as the 2 or 3 inches of honey (and flies) in the bottom of the tub testified. I objected to this as not being what I wanted, and they then told me they were disgusted with the honey-trade and thought of giving it up.

Next I tried the much-abused commission man, and, seeing a large pile of nice, new crates with some very fine honey showing through the glass, I thought, "now I had found honey that I would find it hard to find fault with." Getting into conversation with the man in charge, he kindly showed me around, and on my request looked into several shipments. The first lot was of one-pound sections, in nice, new cases. Opening a case, the honey was nice and straight in white-wood sections, cleaned of every particle of propolis, and the sections resting on little strips of wood, placed inside of little paper pans in the bottom of the case, to catch any dripping honey, but there did not seem to be any.
