So much is being said about implements, apparatus and improved methods, one would naturally think that success depended upon a certain kind of a hive, frame, section, section-case, or some other apparatus or a certain method of manipulation. New apparatus, fixtures, and methods are all right, but it is not wise to lose sight of the one important fact, that the queen is the mother of the colony and it is upon her that the strength of the colony depends. Truly, the key-note of success is struck only when the bee keeper sees to it that each colony has a good, young, prolific queen. It is upon the queen that the greatest success is hinged, and until the apiarist awakes to the true value of the queen, just so long will it be until he becomes the most successful. To me it is a plain fact that in no one thing in bee-keeping does quality count for so much as it does with the queen or mother-bee. Of course, if we only desire to count our colonies, then a poor queen is better than none; and then there are other times when she may hold a colony together until we can get a better one; but let me repeat, that an apiary with all poor queens is worse than no bees at all. When we come to the full realization of the great achievements which can be obtained with a really good queen, we, as apiarists, will put forth more energy along *this line* of our pursuit than we ever have done before.

Some may ask why the best colonies did so well. Because they had a large working-force of the right age, at the right time, to take advantage of the honey-flow. This is simply due to a good queen—one doing her part at the right time, and at no other time. The poor colonies failed to do so well because they did not have a full working-force—due to a poor queen or because the bee-keeper failed to have the queen do her duty when she should have done it. Some may ask, "Can I get all colonies to do as well each year as my best colonies do?" I will answer the question by asking, Why not? If all of the colonies are of the same strength, having a full working-force, why will not all do as well as the best colonies? This being true, the trouble lies in not having all the colonies of equal strength, and this condition devolves primarily upon the queen. We may not have all exactly alike, but we may have them approximately alike—if we work for that object.

Many queens are bred for beauty rather than quality. If we want superior stock we must breed from the superior workers, and by careful selection and breeding one can greatly improve the stock of bees. Pardon for referring to our own apiaries, but we take pride, if I may say so, in giving special attention to the careful selection and breeding of our queens for quality, and for this alone we are well paid in our honey-yield.

Then, too, the wintering problem may be greatly rectified by keeping close account of the age of the queens. We find that we have much better success in wintering with young queens than with old ones. Here is a value of queens that many have overlooked. But a great deal of the success

for the coming season depends upon the queens we have put into winter quarters.

INTRODUCING QUEENS.

Perhaps no other one subject connected with bee-keeping has received so much attention in our bee-papers and manuals as has the subject of introduction of queens. Yet, after reading the methods and discussions given, it is plainly to be seen that success does not always attend the efforts. On the contrary, many losses arise from the fact that bee-keepers in general do not discriminate between queens taken from one hive and placed in another, and those which have come long distances by mail. In introducing queens from one hive to another in the same apiary, it does not require one-half the care that must be given to a queen coming from a distance.

In introducing a queen from our own apiary we very frequently use the following methods:

We go to a nucleus from which we wish to get a queen, and, when she is found, we take the frame of brood she is on—bees and all—together with another frame from the same hive, carrying them to the hive from which we are to take the superannuated queen, placing the combs so the queen will be between the two combs; then we secure the poor queen and dispose of her; then we take out two frames brought from the nucleus in their place, puff a little smoke over the top of the frames and close the hive. The object in taking two frames with the queen is so that while waiting outside of the hive she and most of the bees may cluster between them, thus becoming quiet. When placed in the hive both are put in together, thus leaving the queen quite among her own bees. This is a very easy and safe method.

To introduce a queen that has come to me from abroad, or one which I consider of more than ordinary value from our own apiary, we proceed as follows:

First catch the undesirable queen and let the bees remain queenless from 24 to 48 hours. In the meantime prepare a cage as follows: Cut a piece of wire-cloth 4x6 inches, bend up sides (after cutting out a piece one inch square in each corner), forming a tray-like cage; ravel down the edges one-half inch. Then we take the shipping-cage containing the queen and escort bees and release all the escort bees—we do not allow any of the escort bees to go with the queen. Select a comb of hatching brood with some unsealed honey above the brood; place the cage, previously made, on the comb over some unsealed honey and hatching brood, and let the queen to be introduced run under the cage. Press the cage into the comb until firmly imbedded into it, and in 48 hours more, if the bees have not released the queen, she may be released.

I will not mention any other ways of introducing queens. There are probably as many different methods as there are bee-keepers, and with precaution almost any method may be used with success. I will simply start the ball rolling, that we may gather ideas from others.

Richland Co., Wis.

Questions and Answers.

CONDUCTED BY

DR. O. O. MILLER, Marengo, Ill.

The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Management of a Queenless Colony.

In looking over my small out-apiary I found a very strong colony with only drone-brood in worker-comb, and some drones already out; also one queen-cell containing a young larva. I moved it away a little distance and put a weak colony from a stand close by in its place. I then put a frame containing brood and eggs into the queenless colony by way of experiment, to see if they would get a queen fertilized with those drones, as there were no signs of any

drone-brood in any of the other colonies, and no other bees within 10 miles.

1. What would you have done under those circumstances?

2. If, as I think is most likely, there is no fertilized queen in about a month, how would you treat that colony?

3. If, about two or three weeks earlier in the season than this (April 6), you found a strong colony to be queenless, without laying workers, would you send for a queen, or unite it with a weaker colony? If the latter, how would you proceed? If you would not send for a queen, why not?

BRITISH COLUMBIA.

ANSWERS.—1. You do not give the time, but, of course, it was earlier than the date of your letter, which is April 6, and if the seasons are about the same as in northern Illinois (you are very much farther north, but you are on the Pacific Coast), I should have united the queenless colony with the weak one, or perhaps with two weak ones.

2. Unite it with one having a good queen.

3. Unite it with a weaker one, perhaps by simply placing one colony over the other with paper between, and a very small hole in the paper to allow passage from one story to the other. I would not send for a queen, because there would be only old bees in the colony very likely, and rapidly reaching the limit of their lives, so that the prospect of building up a good colony by adding a queen would be not the best, and in the long run there would be a greater gain to give some weak colony a better show.

Prevention of Swarming when Producing Comb Honey.

I have all the bees I want, and run for comb honey. How can I best prevent any increase?

Now, Doctor, I am sure you have about the same number of colonies year after year. Please give your best plan. I feel sure all big bee-men have a good plan, yet I have never seen a good explanation of any plan.

INDIANA.

ANSWER.—It is somewhat doubtful that any bee-keeper has a plan entirely satisfactory to prevent swarming when working for comb honey. One way is to allow the bees to swarm once if they will, then in the spring to unite so as to reduce to the desired number. Another way is to have all queens clipped, and when a colony swarms kill the old queen. About eight days later listen in the evening by putting your ear to the hive, and when you hear the young queen piping go to the hive the next day and destroy all remaining queen-cells. Another way is more radical, and prevents swarming: As late as you can without risking swarming, take from the colony all its frames of brood and leave it on foundation or starters.

Stimulative Spring Feeding.

I work for comb honey, and want my colonies strong when the honey-flow comes. The books say, "Stimulate brood-rearing by feeding." You said not long since, in answer to some one's question, that "spring feeding is a two-edged sword, a good thing for beginners to let alone." What is the danger? And how can I feed, if at all? or must I wait until I am a veteran?

OHIO.

ANSWER.—I don't know whether you should wait till you are a veteran, or whether you are in that class who should never practice stimulative feeding at all. If the latter, it will, I feel pretty sure, be some comfort to you to know that you will have myself for company. I do not feed anything in the line of honey or other liquid food to stimulate brood-rearing, and I do not believe I would gain anything by it. If my bees have enough stores, there is little danger but they will have all the brood the bees can cover, and what more do I want? But it would not be right for me to insist that every one should have his shoes made on my last, although I think it very likely that you and I are alike. Some, however, may have a week or more of nice, warm weather, when bees can fly freely, and yet gather nothing, and in such a case brood-rearing may cease entirely. For such persons it may be decidedly advisable to feed so as to keep up brood-rearing.

As to the danger, there is danger that the inexperienced will feed and excite the bees to flying at a time when it is chilly and windy so that too many bees are lost. If advisable to feed at all, and the feeding is done at a time when it is warm and bees can fly freely, it does not matter such a great deal how you feed. A good way is to uncup or mash down the capping of the sealed honey in the hive.

I said I do not need to give any liquid food, but I do often offer the bees a substitute for pollen, and I am not sure but it stimulates as much as the liquid food, at the same time being safer. If I didn't do it for any other purpose, I'm not sure but I would do something at it for the fun of seeing the bees tumbling around in the meal. You may take almost any kind of ground grain—I use mostly ground corn and oats, which is easy to get—put it in a shallow box, have the box tipped a little to one side, and as often as the bees work down the feed to a level turn the box around. When the fine part is worked out, the cattle or horses can have the rest. As soon as the bees can get plenty of natural pollen, they will desert your meal.

Spraying Near End of Blossoming.

There are a number of orchards near my apiary, and as soon as the bloom falls they are going to spray with arsenic. Now, as a matter of course, there will still be more or less blossoms on the trees that the bees can get at. Is there anything I can do to prevent their being poisoned? I have thought of closing their entrances with wire netting; and I might, if it is absolutely necessary, take some of them to the cellar.

COLORADO.

ANSWER.—It is possible that removal to the cellar would be advisable. If the owners of the orchards are intelligent, however, nothing of the kind will be necessary, for it has been decided at the experiment stations most conclusively that it is only a waste of time and material to spray while any blossoms are yet on the tree—not only a waste, but absolutely detrimental to the blossoms without doing any good whatever.

Management for Extracted Honey.

I am working for extracted honey, and use supers the same as bodies, that is, 2-story hives with an excluder between.

I have about 50 colonies in hives one story only, to top out with empty hives. No comb foundation.

Would you recommend putting the empty hive above or below? Or would it be better to give some combs and some empty frames to each story?

CALIFORNIA.

ANSWER.—I don't know. Something depends upon what you want. If you would rather not have any swarming, then put the empty story below with the queen in it. If you would rather have the bees swarm, then put the empty story above, leaving the brood below with the queen there. Another thing ought perhaps to be considered: It is claimed by some, and denied by others, that you will have finer honey if you extract from combs in which brood has never been reared. There is probably little doubt that there is a difference, however little the difference there may be, and if you want the finest quality of extracted honey you may prefer to put the foundation above, leaving the queen below.

Equalizing Colonies in the Spring—Increase.

I would like to get your best method of equalizing colonies in spring, and the best method of making increase without swarming.

I have 40 colonies—some at home, others scattered through the country—which I propose to run this season for increase only. I want to increase to 200. I am willing to feed some, if profitable. We have fruit-bloom, perhaps white clover, always sweet clover, and a fall bloom if seasonable. I would like to increase early, about May, so as to build them up strong.

INDIANA.

ANSWER.—The quickest way to equalize colonies is to take from the stronger ones all the brood and bees they have above the average, and that will yield enough to bring the weaker ones all up to the same level. But unless your colonies are strong enough to average at least four Langstroth frames of brood to the colony, I should strongly advise against that method of equalizing. Instead of that it is better not to equalize all at once, but to take the stronger ones first. Suppose your colonies vary from weaklings having only one frame of brood each, up to those having 7 or 8 frames of brood. Take brood from the strongest, reducing them to 4 frames each. Then give a frame of brood to each colony that has 3 frames, and, after that, if you have any left, give two frames to each colony that has two, so

long as the brood lasts. Two weeks later you can repeat the operation, not doing anything to strengthen the weakest colonies till all the stronger are brought up to the mark.

Unless you have had a good deal of experience you may make bad work increasing 40 to 200, and you are just about sure to make a bad mess of it if you get up to the 200 in May. Here is one way that I have successfully used: Suppose No. 1 has your best queen. Wait until your colonies are at least fairly strong, and until honey is regularly yielding, and by that time build up No. 1 very strong. Take from No. 1 all its brood with all the adhering bees, leaving the queen to welcome home the returning field-bees. The brood and bees you have taken from No. 1 are to be put on the stand of No. 2, or some other strong colony, setting No. 2 on a new stand. Then go to the remaining colonies, and take from each one all the brood it has beyond 4 or 5 frames, but taking no bees, and give this brood to No. 1. About 9 days later—certainly not more than 10 days later—go to the queenless colony that was left on the stand of No. 2, and divide it up into nuclei having 2 or 3 frames of brood each, making sure that each nucleus has 2 or more good queen-cells centrally located so there shall be no danger of chilling. Then take all brood and bees from No. 1 and put as before on the stand first occupied by No. 2, and fill up No. 1 with brood from other colonies, but no bees. Repeat this every 9 days so long as the flow continues, or until so late that there will not be time to build up. As the work continues you will need to add stories to No. 1, and equally to the pile of queenless brood and bees on the stand of No. 2. If there is danger of having the piles too high, you can start a second plant to working the same as Nos. 1 and 2.

Uniting in the Fall—Extracting Late.

1. I let my bees swarm once, then build the new colonies up strong at the expense of the old. If I have 100 colonies in the fall, and want only to winter 50, what would be best, to kill off the surplus colonies, or unite in hives that hold 11 Langstroth frames?

2. Can I extract honey as late as October?

MINNESOTA.

ANSWERS.—1. I should prefer to unite so as to have strong colonies for winter.

2. Yes, but not without taking special pains to warm the combs before extracting. For 24 hours before extracting keep them in a hot room; all the better if hung up near the ceiling. No danger of having them too warm if you do not melt the comb.

Early Queen-Rearing in Pennsylvania.

I opened a 10-frame hive April 5 (as the bees were flying) to ascertain their condition. I found plenty of capped brood but no young larvæ, eggs or queen. But I found a queen-cell nearly ready to cap containing a large larva.

Now what I want to know is, whether I could safely and profitably get that colony in good condition for the honey season, which commenced about July 10 last year. Drones commenced flying May 23, last season.

I have been a bee-keeper since 1898 and have lost only 2 small colonies in box-hives.

Now I have 3 strong colonies besides the one mentioned, in 10-frame hives.

I do not care for any more colonies—all I want is a large amount of bees to store honey. The honey crop last year was poor; year before, good. PENNSYLVANIA.

ANSWER.—If I understand your question rightly, it is this: With drones flying May 23, will a queen reared from a cell nearly ready to seal April 5 be able to bring up a colony strong for the harvest by July 10? I should say she will not be likely to do so. The queen will issue from her cell by April 15 or sooner; May 23 she will be 38 days old, and the chances for her being fecundated at that age are not worth considering. Very likely some drones will be flying before that time, but hardly early enough, for she will probably fly out on her wedding-trip about a month before May 23. In general you will find that in the latitude of Pennsylvania a queen emerging as early as the middle of April will not be a good one. Perhaps your best plan is to destroy the young queen and get a laying queen from the South, or else break up the colony and divide its forces among the other colonies.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

SERVING UP "REPORTS."

And so John M. Davis wants the reports well-digested and intelligible—size never stated as, "as big as a piece of chalk," and distance never "a right smart piece," and the keystones never left out from the arches of testimony. He seems reasonable in his desire and request; and yet most certainly nobody is going to fill the great yearning chasm in his soul to any satisfactory degree. Brief, lucid statement of things when they write—why, you might as well ask Algebra and Greek of a great majority of intelligent people. An editor can't do more than he can do. He can't scold continually about rambling and unintelligibility without frightening off the reports altogether. I expect if we knew how carefully he carves, and how deftly he fixed things that *must* be fixed, we'd send up a vote of thanks, and refrain from asking anything more. Page 171.

THE "MUSLIN SANDWICH" COVER.

Doubtless a coat of paint with a thickness of muslin in the middle of it would make an excellent surface for some climates, providing you get *enough* paint both above and below, and also providing you keep putting it on as fast as the weather beats it off. Such a live-roof would, I judge, fit best a climate of fierce sunshine and occasional violent rains. In a climate of little sunshine and endless drizzle there might be danger perchance that the surface would disintegrate. Page 173.

BARRELS FOR COMB AND EXTRACTED HONEY.

The chaps that can't stand barrels for honey, and the chaps that want all their honey in barrels, can be reconciled by the method of C. A. Deadman, page 173: Make your honey secure in tin, and then fill barrels with the tins—for security and convenience in handling. Guess he's right, that no big package ever was or ever will be devised that will handle as nicely as a barrel. If second-hand barrels at ten cents each can be had, the expense ought not to frighten one—in fact, the greater expense of crates is one of the items pro.

MELTING GRANULATED HONEY EXPEDITIOUSLY.

Pshaw! Didn't everybody know that? Then let them hear and heed that the melting of a mass of honey is very greatly expedited by frequent punchings and whirlings and subdivisions of it. Page 174.

CARNIOLANS FOR INCREASE—THEN ITALIANIZE.

Here seems to be a winning kink which Mr. Coveyon of the Michigans gave: Premising that you start with a few bees, and want to build up a big apiary, keep Carniolans till you get your number, and then Italianize. Page 180.

BLEACHING COMB HONEY.

On page 181 we have more about the unfamiliar subject of bleaching comb honey. Sulphur vapor and sunlight both. One bath of the former equals somewhat less than a week of the latter. But look out the sulphur doesn't "green" it; and look out the sun doesn't melt it. In Mr. Crane's experience 500 pounds out of 6,500 could not be completely bleached. Just one-thirteenth. I should call that encouraging success.

THE SEMI-MOVABLE FRAMES OF YEARS AGO.

Exactly so, Mr. Greiner, the semi-movable frames of long years ago, and centuries ago, would not have benefitted us any. We should never have heard of them had not an inventive mind of our own age put the thing in actual working shape—not merely old-time working shape but modern working shape. Should the next great inventor find out how to fly to an adjacent planet we should directly hear about Elijah and Enoch. Soon the recondite literature of the world would contribute dozens of Iliawathas and Laou-Tzes who had made such trips before.

Wonder what Solon thought he was after when he went to Egypt in the interests of bee-keepers, 500 B. C. Could hardly have hoped to copy the floating apiaries on the Nile. Might have sought an improved manipulation and a better kind of bee. Page 182.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nehr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Pine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested.....	1.50	8.00	15.00
Selected Tested.....	2.00	10 50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Quirin the Queen-Breeder,

PARKERTOWN, OHIO.

33A 1f Please mention the Bee Journal.

Here we are again with a larger line of Incubators and Brooders than ever. They are the **HAWKEYE** brand and the kind you can depend upon. They are made three walls best grade poplar, 12 oz. cold rolled copper water pipe heating system, metal lined deflector, our patent safety lamp, patent regulator and a thoroughly first-class machine. This is our large size \$10.00 proposition, the best incubator ever offered for that money. We sell all our incubators on **30 Days' Free Trial**. We do not ask you to buy a "Fig in a poke." Do not buy the machine until you try it. This is our *Tubular Lamp Hawkeye Brooder*; roomy and so constructed that little chicks cannot crowd, smother, nor trample each other. The lamp is guaranteed not to blow out in the harshest wind storm. Our handsome new catalog (all paying covers) "Profitable Poultry." Is now ready, sent free. Or send 10 cents in stamps for book and a year's subscription for leading poultry paper. Write at once. **HAWKEYE INCUBATOR CO., Box 17, NEWTON, IA.**

Please mention Bee Journal when writing.

ITALIAN QUEENS and the WARFIELD STRAWBERRY ...

D. J. BLOCHER, Pearl City, Ill.

Ask for our price-list and testimonials. As we are spending the winter in North Dakota, all our correspondence, whether social or business (until further notice) should be addressed,

D. J. BLOCHER, Denbeigh, N. Dak.

Please mention Bee Journal when writing.

DAIRYMEN ARE DELIGHTED to meet those who work for us. Cow keepers always have money. We start you in business. You make large profits. Easy work. We furnish capital. Send 10 cents for full line of samples and particulars. **DRAPER PUBLISHING CO., Chicago, Ills.**

Please mention Bee Journal when writing.

Weekly Budget.

THE APIARY OF ALBERT ROZELL, of Los Angeles Co., Calif., is shown in the picture on the first page. In it are over 150 colonies. Last year a car-load of honey was extracted in this apiary, and several hundred-weight of beeswax was obtained besides. The location of this apiary is a beautiful one, with the grand old mountains in the distance.

ALL FOREIGN SUBSCRIBERS will please remember that our queen or other special offers, whether in this journal or in others, do not apply to them. It really ought not to be necessary to say this, but occasionally some thoughtless foreigner desires to take advantage of our offers, and almost invariably forgets that there is extra postage for mailing from here to his home.

Please remember that we do not send queens to foreign countries—only the American Bee Journal, and that with the extra postage added to the yearly subscription price of \$1.00.

A CITY GIRL'S BEE-STORY.—Miss Jean Stirling is a little Chicago girl, 11 years of age. Mrs. J. J. Glessner, a prominent society lady, who is also greatly interested in the subject, gave a lecture on bees, and afterward "Jean," who was one of the select audience, wrote out the following from memory, and also copied the bees and cells as shown in the illustration accompanying:

BEEES.

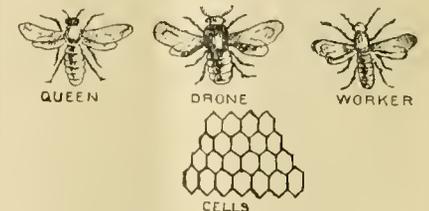

The bee, or, as the Indian calls it, the white man's fly, is a very interesting insect to study. There are three kinds of bees—the drones, the queens, and the workers. Each hive has only one queen, which governs the others, and also lays the eggs. The drones do no work, so, in the swarming season, the workers, which do all the work, kill them.

A bee can see a long distance. After gathering as much honey as she can carry, she rises in the air till she sees the hive, and flies the shortest way toward it. The word "bee-line" is derived from this fact.

A bee will not sting unless bothered. Drones have no sting, but queens and workers both have.

The poison of bees is so deadly that if they sting an insect it will die very soon. Sometimes animals and men also have been known to die when a swarm of bees have attacked them.

The queen-bee, after pairing with one of the males or drones, begins to lay eggs. Sometimes in one day she lays two or three thousand. The queen lays worker-eggs in one set of cells, the drone-eggs in another, and the queen-eggs in a third. After three days small

worms, called larvae, come out of the eggs. In about five or six days—during which time the workers feed and care for them—they spin a cocoon. In 21 days the workers come out of

the cocoons, in 21 days the drones appear, and in 16 days the queen-bees come.

The old queen stings all the new queens to death if the hive does not happen to be full; but if the number of the inhabitants is large, the old queen and some workers start to find a new home.

The working bees supply the wax for the hives. In the back of their bodies there is a little pouch in which the wax increases, little by little. When this pouch is full, the wax sticks out in little scales. Then it is taken off and made into cells. These cells are six-sided, so as no space will be wasted.

When we eat honey it is difficult to realize how much patient labor is spent in making it.
JEAN STIRLING.

We think that is very well done for a city little girl who had just heard the story of the bees told, and then wrote it out as she remembered it. Of course, there are some little twists in it, but in the main it is fairly correct. Who knows but "Jean" may be a bee-keeper herself some day! Stranger things than that have happened.

We hope our little girl friends in the country will read Jean's story, and see if they could do as well at copying pictures of the three kinds of bees and the honey-cells.

THE A. I. ROOT COMPANY have a Branch Store at 10 Vine St., PHILADELPHIA, PA.,

Where they have direct steamboat connections with Massachusetts, Rhode Island, Connecticut, New Jersey, Delaware, North Carolina, South Carolina, Georgia and Florida, and low freight-rates.

As this is a main branch, order from any catalog or quotations given from Medina.

Also booking orders for healthy ITALIAN BEES shipped this month. Full colonies, 8 frames and queen, \$6.00. Wholesale rates on application.

30 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 30 cents a pound—CASH—for best yellow, upon its receipt, or 32 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

GENERAL ITEMS

Peppermint Oil for Bee-Stings.

For the benefit of "Penn" (see page 218) and other bee-keepers who may not know of this remedy for bee-stings, I would say that I use peppermint oil; it will stop the pain and swelling instantly. MINNIE GREENMAN.
Van Buren Co., Mich., April 13.

Favors Ordinary Italians.

All my bees came through the winter safely. I have not lost a colony for several years, except some of the "yellow" order, which die with plenty of honey around them. I believe for all-around workers nothing can beat the ordinary Italians.

EVAN E. EDWARDS.

Madison Co., Ind., April 15.

Spraying Fruit-Trees While in Bloom.

This subject, like most others, has two sides to it, or it is seen from different points of view, and different opinions are formed as to the effect it will have upon the pollen in the bloom and the crop of fruit. The American Bee Journal of November last quotes from the Farmers' Review on this subject:

"It has also been discovered that the poison is equally destructive to the life of the pollen, even when the amount of poison is only 9 to 10 parts to 10,000. Even 2 parts in 10,000 has been frequently found fatal to the pollen."

The writer quoted does not tell us what "the poison" was that was used in the spraying mixture that was so fatal to the fruit crop; and we must take it for granted that he refers to the usual "Bordeaux" spraying mixture. If so, then his conclusions are very different from the experience of some others.

I have always avoided spraying trees when in full bloom. I have heard that it would kill bees, and also injure the fruit-bloom. It looked reasonable that it would do both, and I did not believe that it would be of any special benefit at that time if the spraying was done just before and just after blooming. I accepted these conclusions without making any personal investigation. But there are others who believe that it is of great benefit to the fruit crop to spray the trees when in bloom; and, through the influence of bee-keepers laws have been passed in several

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you."—Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30) I never found these bees to show the least indication of unrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

Out of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chilly winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, Ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italians and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

States and in the Province of Ontario to prevent them from spraying while trees are in bloom. There are those of an investigating mind who believe in the old adage, "Try all things, and hold fast to what is good," who are not willing to take hear-say evidence without personal investigation, especially in matters pertaining to their own business and interest. Of this class I have a friend living on a neighboring island, over in the State of Ohio, who has almost a national reputation as a successful fruit-grower. There are no bees on that island to be killed, and he was willing to run the risk of losing the fruit on a few trees, or even the trees themselves, in the interest of the knowledge gained; so he made a test of the effect of spraying some trees while in full bloom, and comparing the result with trees sprayed after blooming. On July 27, 1901, he wrote to me as follows:

"I experimented with a half-dozen peach-trees just in full bloom, with Bordeaux mixture—4 pounds sulphate of copper, 5 pounds lime, and 4 ounces of green arsenoid, to 50 gallons of water. I thoroughly saturated the trees, every portion, until the mixture dropped from them. I saw no ill effect. The trees so treated had more fruit on them than any other six trees adjoining them that were not sprayed until after blooming. One seedling was so full that I had to take off more than half the fruit."

And there were no bees there to fertilize the bloom, and it was too early in the season for other insects to be out; if any had chanced to have been there such a dose would most likely have killed them.

It will be noted that "green arsenoid"—a virulent poison—was added to the usual formula for Bordeaux mixture, and that the writer simply states facts, and does not claim that the spraying in bloom was the cause of there being no fruit on them; he leaves us to our own conclusions. But such evidence ought to go a long way to establish the truth that the "poison" does not injure the pollen, or spraying in bloom prevent a crop of fruit. This witness is thoroughly reliable, and one of the most intelligent, up-to-date, successful fruit-growers in this country. It may require further investigation and experiments to settle this matter fully.

Ontario, Canada. THADDEUS SMITH.

[All the same, it is good advice *not* to spray while in bloom. Good crops of fruit have been secured when no spraying at all had done.—EDITOR.]

Only a 2 Percent Loss.

Bees have wintered with a 2 percent loss of colonies, and perhaps 10 percent of the remainder will require careful handling to build them up in shape for the white clover honey-flow.
MORLEY PETTIT.
Ontario, Canada, April 14.

Plenty of Rain.

Bees are doing well here. We have had plenty of rain to insure a good honey crop. My bees are working on the fruit-bloom and gathering some honey from filaree. White sage will soon blossom.

This is my second year with bees. I built up my apiary last year, and have now 52 colonies, spring count.

I have the bee-fever pretty strong. I am running for both extracted and comb honey.
EUGENE DUMAS.

San Bernardino Co., Calif., April 10.

Report for 1901.

I have kept bees for about 30 years, on a 100-acre farm. I never had a bee-book or a bee-paper, the American Bee Journal being the first one I have taken.

I have been very happy in bee-keeping. My apiary now consists of 49 colonies. I had 30 colonies last year, spring count, from which I secured 8500 pounds of extracted honey; half of the lot I sold for 7 cents per pound, and the rest for 8 cents, without any cans. I in-

creased to 50 colonies. I have always wintered my bees in the cellar, with a temperature from 48 to 50 degrees. I put them in the cellar in good condition and plenty of winter stores. I have never lost a colony during the winter.

We had a fine day yesterday, and put the bees out, but to-day we had a big snow-storm, and put the bees into the cellar again.

THEODORE STEGER.
Washington Co., Wis., April 7.

Bees Wintered Well.

I have been interested in the reports published in the American Bee Journal. I put 48 colonies in last fall, and took out 48 all right this spring. One year ago I took out 25 colonies. I kept them from swarming all I could by cutting out drone-comb, or cutting the heads off. I fed two sacks of sugar in April and May, and got the bees ready for business when clover came into bloom. I got 2150 pounds, mostly comb honey, which I sold at home at 13 cents per pound.

I had no ventilation to the bee-cellar, only as I might open the door from the rest of the cellar where I kept the vegetables, but I found the bees got quite uneasy, and I took them out a week earlier than usual this year.

WM. CLEARY.
Kossuth Co., Iowa, April 7.

Later Day Merchandising has many houses in the mail order business, "selling direct to the consumer," and "saving agent's profits." A very large percent of these are themselves taking the agent's profits, having themselves received their goods at second and third hands. Among this smaller class, who in truth and in fact manufacture their own goods and sell directly from the factory to the consumer, is the famous old Elkhart Carriage and Harness Mfg. Co., of Elkhart, Ind. These people handle only goods of their own manufacture, and they have no jobbers, agents, or middlemen. Everything you purchase from them comes directly from their factories. There is no doubt about agent's commissions being avoided in their case. The mammoth proportion to which their business has grown proves that the people realize that there is a great saving to them in dealing direct with this firm. Every kind of light vehicle and harness is in their line. They publish a large illustrated catalog which our readers should have. They will be pleased to mail it to any one writing for it. Please mention the American Bee Journal when asking for the catalog.

SWEET CLOVER
And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

Add 25 cents to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

GEORGE W. YORK & CO.
144 & 146 Eric Street, CHICAGO, ILL.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Apr. 18.—The season in which comb honey sells prior to the new crop is now practically at an end; therefore prices are more or less irregular, as some sections in a case will be graded more or less and others free. The best lots of basswood and clover sell at 14@15c; other kinds of white at 10@13c; ambers are not in heavy supply and sell at 9@12c. Extracted is dull at 5@6½c for white, and 5@6c for amber, depending upon flavor and other qualities. Beeswax scarce at 32c. R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5¼@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.
THE FRED W. MUTH CO.

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c. H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7½c; Florida honey, in barrels, 6@6½c.
BLAKE, SCOTT & LEE.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c; Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

CINCINNATI, Apr. 11.—Stock of comb honey here is larger than it ought to be at this time of the year, and this is why it is offered for very low figures. Water-white is sold at 14@14½c and hard to obtain; for extra fancy, 15c.

Extracted finds a steady sale, and amber is sold in barrel lots for 5@5½c; water-white alfalfa sells from 6@6½c, and white clover brings from 6½@7c. Beeswax scarce at 30c.
C. H. W. WEBER.

NEW YORK, Apr. 7.—Comb honey, last year's crop, practically cleaned up, but as we wrote a little while ago we had received new crop from Cuba, and are now receiving new crop from the South. Demand is fair at 14c for fancy white, 13c for No. 1, 12c for No. 2, and 10@11c for amber.

Extracted: The market is decidedly dull. Very little demand, with large stocks on hand, some of which no doubt will have to be carried over, and indications point to a further decline in prices. We quote: White, 6c; light amber, 5½c; amber, 5c; Southern, 5¼@5½c per gallon, according to quality. Even these prices are shaded in car lots. Beeswax, scarce and firm at 29@30c.
HILDRETH & SEIGELKEN.

BUFFALO, March 28.—Buffalo is very quiet on honey, except very low grades at very low prices. We quote extra fancy, 4c; No. 1, 12@13c; other grades, 8@10c. Extracted, 5@6c. Beeswax scarce; fancy, 28@30c; dark, 22@25c.
BATTERSON & Co.

SAN FRANCISCO, Apr. 9.—White comb, 10@12½ cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4½@—; amber, 4@—; Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Advices from the interior of this State indicate a big yield of honey this year and an early season. While quotable values remain in about the same position as last noted, the market cannot be termed firm. Buyers are operating lightly, anticipating easier values when new crop begins to arrive freely.

WANTED. EXTRACTED HONEY—either large or small lots; parties having same to offer, send samples, and best prices delivered at Cincinnati, Ohio. We pay cash on delivery. THE FRED W. MUTH CO., 104½ Front and Walnut Sts., CINCINNATI, O.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.

THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.

J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey-in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

Know What Your Dealer Pays

THIS BOOK CONTAINS
70,000 PRICES
17,000 PICTURES
1,000 PAGES

This book tells pretty nearly what your dealer pays for everything. It quotes wholesale prices on 70,000 articles, and shows pictures of 17,000 of them. It includes practically everything that anybody uses, wears or eats; and its prices are the lowest ever quoted. It will save the average family at least \$100 per year--some \$500. Two million people send for this book yearly as a buying guide, and we want you to have one too.

For 30 Years we have been selling merchandise by mail at about what dealers pay. Ours is the original catalogue business, and the greatest mail order house in the world. This enormous business has been gained and held by underselling everybody, treating customers fairly, and doing as we agree.

Two Million People are now numbered among our customers. We carry for them a stock valued at \$2,500,000. We employ 2,000 clerks to fill their orders. It requires 100 typewriters to write our letters to them.

You Need This Book because you can rely on it. Other catalogues are offered you, but this one is best. Our house is the oldest and largest, and our prices are always the lowest. Our guarantee is the fairest, and our record of a quarter century assures you of fair dealing. We keep our customers.

We Guarantee satisfaction and safe delivery. Every article in our catalogue is described exactly as it is. Not the slightest exaggeration is ever permitted. But if anything you get doesn't suit you in quality, or price, or fit, send it back and we will replace it. Or we will send your money back, and pay transportation both ways. We consider no expense or effort too great to avoid having one dissatisfied customer.

Two Thousand Stores in One

Two thousand average dealers together will not buy so much in a year as we. The makers who sell to us have no traveling expense, no credit risk, no losses, no salesmen to pay. They save the whole cost of selling the same goods to 2,000 separate stores, scattered everywhere. The fiercest competition in America centers in the effort to get our trade. The prices we pay are never

much above cost; and goods that we cannot buy low enough are made in factories of our own. Is it any wonder that we can sell for about what common dealers pay?

We get along with a fraction of the profit charged by stores. We have no salesmen--no selling expense save our catalogue. A dealer must make several times as much on each article to pay his expenses and live. Our expense is but a small percentage when spread over sales that amount to millions of dollars annually.

We simply combine the buying and selling of two thousand average stores. We save the wasteful methods that cost more than the merchandise, and we give the saving to you. This is the modern method of business, and the buying of the 20th century will be done more and more by mail. In this way we are now saving our customers from four to five million dollars annually. You will become one of those customers when you see this book.

Send Only 15 Cents If you want our catalogue, fill out carefully the slip to the left of this, and mail it to us today, enclosing 15 cents. This catalogue which we offer you costs us about 70 cents to print, even in million lots. The postage on it costs us 22 cents more. We ask you to send us but 15 cents (less than half the postage alone) just to show that you do not send from mere curiosity.

This book will save any average family at least \$100 per year. If you don't find that it will save you at least a hundred times what it costs you, simply write us, and we will cheerfully send you 15 cents back.

Please send today, before you forget it.

Cut this slip out and send it with 15 cents in stamps *Today*.

New York Anti-Bogus-Honey Law.

—Such a law has recently been enacted, and is a credit to that great State. It will be worth much to the whole country to have the adulteration of honey stopped in New York City. Chicago used to be headquarters for such work, but since the Pure Food Commission came into existence, there has been precious little adulterated honey put on the open market here, and most of that has been labeled so that the purchaser could see that he was not getting the pure article.

Here is a copy of the parts of the New York law as amended:

AN ACT to amend the agricultural law relative to prevention of disease among bees, and to add two new sections thereto relative to honey, to be known as sections eighty-a and eighty-b, and to read respectively as follows:

Section 2.—Said chapter, three hundred and thirty-eight, is hereby amended by inserting therein, after section eighty thereof, two new sections, to be known as sections eighty-a and eighty-b, and to read respectively as follows:

Section 80-a.—*Defining honey.*—The terms "honey," "liquid or extracted honey," "strained honey," or "pure honey," as used in this act, shall mean the nectar of flowers that has been transformed by, and is the natural product of the honey-bee, taken from the honey-comb and marketed in a liquid, candied, or granulated condition.

Section 80-b.—*Relative to selling a commodity in imitation or semblance of honey.*—No person or persons shall sell, keep for sale, expose or offer for sale, any article or product in imitation or semblance of honey branded as "honey," "liquid or extracted honey," "strained honey," or "pure honey," which is not pure honey. No person or persons, firm, association, company, or corporation shall manufacture, sell, expose, or offer for sale any compound or mixture branded or labeled as and for honey which shall be made up of honey mixed with any other substance or ingredient. There may be printed on the package containing such compound or mixture a statement giving the ingredients of which it is made; if honey is one of such ingredients, it shall be so stated in the same size type as are the other ingredients; but it shall not be sold, exposed for sale, or offered for sale as honey; nor shall such compound or mixture be branded or labeled with the word "honey" in any form other than as herein provided; nor shall any product in semblance of honey, whether a mixture or not, be sold, exposed, or offered for sale as honey, or branded or labeled with the word "honey," unless such article is pure honey.

ABSTRACT FROM THE AGRICULTURAL LAW RELATIVE TO PENALTIES.

Section 37.—Every person violating any of the provisions of the agricultural law shall forfeit to the people of the State of New York the sum of not less than fifty dollars, nor more

than one hundred dollars, for the first violation, and not less than one hundred dollars for the second and each subsequent violation. When such violation consists of the manufacture or production of any prohibited article, each day during which or any part of which such manufacture or production is carried on or continued, shall be deemed a separate violation of the provisions of this article. When the violation consists of the sale, or the offering or exposing for sale, or exchange of any prohibited article or substance, the sale of each one of several packages shall constitute a separate violation; and each day on which any article or substitute is offered or exposed for sale or exchange shall constitute a separate violation of this article. When the use of any such article or substance is prohibited, each day during which or any part of which said article or substance is so used or furnished for use, shall constitute a separate violation, and the furnishing of the same for use to each person to whom the same may be furnished shall constitute a separate violation.

Section 2.—This act shall take effect immediately.

We hope other States will copy the New York law, and thus get into line for pure honey. Nothing would so help the sale and table consumption of genuine honey as stringent laws against the sale of the adulterated article, and their rigid enforcement.

Honey at Fairs.—Mr. Smith reports in the Canadian Bee Journal that several years ago at the county fair he made a display of honey in sections and extracted, both clover and buckwheat, some clear, some candied, several hundred pounds altogether. He says:

Well, the result rather astonished me. I was overwhelmed with questions about honey. "How did I get it in the little boxes?" "How was it some was so light and clear, another kind so dark in color?" "What made it candy?" etc. People who had never seen or tasted honey before, stopped to admire and express a desire to purchase some; and the result was that we sold all our cell sections by cutting them into 5-cent pieces, that were eaten on the spot, instead of candy, and many who had once tasted honey purchased some to take home with them. I had a crowd around the exhibit the whole time. The honey was all sold, and orders were taken to be filled later.

This proved to be the best advertisement we ever had, and was the means of introducing honey into many homes where it was found to be so much more healthful and economical than many of the preserves in common use.

Bad Bees they have up in Canada. A lawsuit is reported in the Canadian Bee Journal, a Mr. Brock suing for damage done by Mr. Patterson's bees. Some who have kept bees close by their homes without any misapprehension may be surprised to read how very bad Mr. Patterson's bees were. Listen:

In stating his case Mr. Brock swore that he owned a house and a half-acre lot west of Mr. R. L. Patterson, who also owned a house and a half-acre lot, and kept about 120 colonies of bees. Mr. Patterson's bees had been very

troublesome to himself and family. His mother and sister were afraid to go outside of the house on account of them, and especially at swarming-time. He could not cultivate his lot, and had to give up fruit-raising, not only on account of their stinging the pickers, but through their sucking the juices of the fruit and destroying the berries. He believed that he could not sell the property if he wanted to on account of Mr. Patterson's bees. His horse had been stung, and injured through fear of the bees. The family washing could not be hung out to dry without being spotted by their excrement. The roof of his house was also deiled, and when the rains came this matter was washed off into the cistern, rendering the water filthy and unfit for use. His wood-pile, too, was affected; he could not get any one to saw his wood, and sometimes the bees would crawl on the pieces and be carried into the house, where they would sting and annoy.

Mr. Brock's mother and brother and sisters, and a number of others, mostly relatives, witnessed for the plaintiff. Mrs. Brock swore having had to wash the clothes three times. One of the sisters declared she had to leave home on account of the bees.

The strange thing is, that Mr. Brock should ask only \$60 for all that harm, and that the judge should be so hard-hearted as to find no cause for action.

Size of Honey-Cans.—The 60-pound tin can is a favorite size. But G. A. Deadman says in the Canadian Bee Journal:

It may surprise some when I say that I prefer a 10-pound slip-covered pail to any receptacle I have yet seen for honey after it is granulated. In the future, or until further notice, any honey I have no market in view for goes into 10-pound pails. If an order comes for a 60-pound tin I can send six of these with the assurance that the customer will be pleased rather than otherwise. They are so much nicer to handle, and more useful when empty. In sending these you will be doing a favor rather than otherwise. You can fill an order for 60-pound tins with 10-pound pails; but you can very seldom send a 60-pound tin in the place of six 10-pound pails. A 10-pound pail of honey almost any family can buy, although where honey is expensive I find 5-pound pails are in demand.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." Price, postpaid, 25 cents, or with the American Journal one year—both for \$1.10. Every bee-keeper ought to have a copy of this Report. We believe it is the finest ever gotten out for the Association.

FOUL BROOD—HOW TO GET RID OF IT.

"How shall we get rid of foul brood?"

Dr. Miller—Take the McEvoy treatment.

Mr. Clarke—Get a State inspector. In other words, get rid of foul brood.

Mr. Horstmann—There is only one way to get rid of foul brood—clean it out. I have had experience with foul brood for three years. I didn't know my bees had it until I got a report from Dr. Howard stating what it was. In the summer-time, during a good flow, drive the bees out on the starters of foundation—(that's the McEvoy plan). After the brood hatches out take the bees off the honey and save it, and cut the other combs out and burn frames and all. Scrape the hives out clean, and use them over again. That's the way I did, and I believe I have been successful.

Mr. Moore—Have you any foul brood now?

Mr. Horstmann—I cleaned out one hive, I think it was Saturday. There was foul brood. The first of September I noticed that there was some foul brood, and I took the bees and drove them right off on frames; and this is an experiment I am trying for next spring. The idea is to have the bees consume all the foul honey they have this winter.

Mr. Marvin—I suppose there are a great many here that knew my brother by reputation. He kept bees for a great many years, and his bees had foul brood.

Dr. Miller—That was James Marvin, whom we all looked up to as an authority along with Mr. Baldrige.

Mr. Marvin—He was an authority. I have bees myself, and I want to tell you all, for your benefit as well as those who are in hearing, if you have any foul brood, why, get rid of it. Don't try to monkey with it, but just burn it right up and get rid of it.

Mr. Moore—How many have used the McEvoy treatment and gotten clear out by that method?

Mr. Horstmann—How long a time will he allow? How much time are you going to give us to try the experiment, a year, or two years? You can hardly report on one year. I cleaned some out last year and I took them out again this year. I don't know whether it was the cause of the treatment or whether the disease was spread by robbing. I think it was caused this spring by robbing. I had a colony that was weak, and had the hive-entrance closed. It grew very cold and they knocked the entrance block off and the bees pounced in there and cleaned it out. I believe that is what spread my foul brood. I worked on the McEvoy plan but I won't be able to report on that until next fall.

Mr. Baldrige—The McEvoy plan will cure foul brood; there is no doubt about it. There is another plan, but I will not detail that. You need not expect, if you get rid of foul brood, that you will keep rid of it. There is too much in the neighborhood. I had it introduced in my yard several times from the bees robbing other people's bees. My bees have foul brood now. I can get rid of it, but it won't stay rid of it; but it will be introduced from other yards if it is not entirely eradicated from the section of the country.

Mr. Marvin—I believe, if you get rid of it—the trouble is you don't get rid of it. There is something about the hives, the honey, the comb and the bees. You don't get rid of it. Now I tell you, there is no other way but to burn it. My brother was a thorough-going bee-keeper. Dr. Miller knows something about it. You cannot get rid of foul brood unless you exterminate. You won't get rid of it from neighbors' bees. If you have it at home, get rid of it. My brother tried everything he heard of. He had 667 colonies of bees. He lost all but three.

Dr. Miller—Has he three left yet?

Mr. Marvin—About three, I think, or half a dozen, and that was down at St. Charles. They weren't up with his

others; if they had been, he wouldn't have any. Let some one who has cured foul brood, get up.

Mr. Moore—Have you cured foul brood, Mr. Clarke?

Mr. Clarke—I have not. My bees have had a touch of it every spring, and I have a neighbor next door who labored with it for about two years. Mr. Marvin spoke of 667 colonies. I can imagine how it would spread to every hive if the combs were burnt, and the work was not done properly, even in half a dozen hives. I think it an entirely wrong idea to burn up the combs, because, unless a person goes to work and covers up entirely—we tried it—and the fire will not, and cannot, consume the honey and wax, the honey will run down and you move away the ashes and find honey underneath, and when moved away the bees will get in there and take it off into all the hives. But when you say that you can keep clear of foul brood by cleaning it out of your own apiary when you have it within a mile of you, I would like to see the man that tells me he has it but can do it. I don't believe there is an apiary that has foul brood within a mile but what I can find it in the cells. It may not form this year. The honey that is ripened in the fall is in the cell; you don't get any from the pussy-willow, but the bees will naturally go to work for brood. Those cells may lie in the frames and they may not develop, but as sure as you have a month of May like last year, if your bees have foul brood, by the middle of June you will have it developed so that you will have to throw out the whole colony. If you have foul brood thoroughly developed there is no mistaking it, even a single cell of it. You can go to the hive and take everything out. If you go in the evening, shake all your bees off into the hive and bury the frames—put them down the same as you would in the bottom of a well—you need not be bothered with foul brood again, if you do it that way. Burning I am dead against. There is not one in fifty I have known to do that way that is without foul brood.

Dr. Miller—Will Mr. Clarke tell us what he would do?

Mr. Clarke—I would bury every frame. The amount of wax wouldn't be worth the trouble and the risk you run by the bees taking the honey. I am dead against burning.

Mr. Horstmann—I have burned the frames and I guarantee there wasn't a bit of wax left. I have carried it into the basement and was sure there wasn't a bee near, then I saved what wax I could and also honey. The honey was all right, and I have taken all the frames and put them into a furnace, and they make the nicest kind of fire, and saved coal for me. Take it out in the country where you can get lots of leaves, and I know you can burn up every bit of it—not a germ left. You can take the old wax and let it dry some place where the bees won't get it, and I know you can get rid of it by fire a great deal better than burying it. It may be dug up. I don't know but what the disease may spread three or four years afterwards. As to burning up the frames, bees and all, that is away behind the times. I think we have bee-keepers in this country that can exterminate foul brood without burning up the bees and all. I don't like the idea of burning bees, and I wouldn't do it. I think I have about as good a way as you can get.

Dr. Miller—Is there any city ordinance against combining the two, digging a pit deep enough to bury, and then burning it and burying the ashes? [Laughter].

Mr. Dadant—I have had no experience with foul brood. I never have seen a case even away from home, but I wish to say that I buy beeswax to make foundation, as you know, and in that way we certainly have many cases of foul brood; and our bees have access to the building in which we keep our crude material, and our bees get to all the beeswax that comes to us. If there is any honey about it they get it. And, remember, we have been doing that for 25 or 30 years, and I have never seen a case of foul brood. The scientists tell us that a temperature of 212 degrees will destroy any germ of life. Germs of foul brood, bacillus alvei, are living germs, and just boiling water will destroy them. Scientists tell us that, and I am satisfied that it is so. If it wasn't so I would have seen foul brood before this. As to the burning of bees, some of you say if you burn the hives you will destroy it, but perhaps some of the other hives will have it. Do you realize that foul brood is a disease? We had plagues—Asiatic cholera and small-pox—and there was a time when they put persons having either one of these diseases in the pesthouse and left them there to die. No one would go near them. Did that cure it? No. It was only when men devoted themselves to discovering a remedy, and in an assembly like this we don't want to advise burning it. Find a remedy. When we have a case of small-pox we vaccinate all who are around. You don't want to apply the treatment only to the one colony, apply it to every colony. When you have one, you don't know how many side by side may have the germs, just a small germ that may not develop for two or three months. If you treat not only the colony th

is diseased, then you can tell, as I have done, that you have cured it. But you tell us to destroy it by burning it. That is equal to the pesthouse. Did that cure it? Do you know how many cities were destroyed? Even to day when we are careless of the small-pox it spreads in our town. We vaccinate every one. We want to discover a cure, and not apply it to one but to every colony, and if you are careful even to the neighbor's bees, and if you find it will cure it, as you must sooner or later, then you have achieved something. Here is a gentleman that out of 667 colonies saved three. Might just as well burn them all at first, then.

Mr. Marvin—He was trying other experiments.

SHIPPING FOUL-BROODY COLONIES INTO ILLINOIS.

"Can a bee-keeper be prevented from bringing foul-broody colonies into Illinois?"

Mr. Moore—I think a great many things on this foul-brood question, but I don't suppose I can express them in a way that will be particularly interesting. About two years ago I found I had foul brood in my apiary. I had no experience with it whatever, but I began to read up on that question and I struggled along in my weak, imperfect way attempting to get rid of the disease. I studied up the McEvoy treatment and tried to carry it out. I failed in this. Last summer, in my apiary—I had about 30 colonies at that time—I repeatedly took all the bees off the honey and frames and gave them new frames, and gave them foundation, burning the whole thing up bodily, except the hive and bees. The result was I lost 20 colonies and out of the eleven I now have I am satisfied four or five are still diseased. I would have no objection to burning them up if I could get rid of it. I had any quantity of kindling, so that where I burnt up a pound of foul brood I had ten pounds of kindling to burn it with, and I got the fire good and burning, and I put it on and am satisfied that everything was burned up. Dig up the ashes and bury them in the ground about a foot, and you have clinched the thing. I think there is no way for the ordinary, every-day bee-keeper to get rid of it without burning it up. The McEvoy treatment may be all right for Dr. Miller, who can spend days and weeks at it, but for ordinary, everyday bee-keepers it is a failure. To burn up everything that comes in touch with it, even the hives, I am satisfied is the way to do it, excepting of the honey, brood and frames. Burn it up, then you have a fair, fighting chance. Mr. Marvin says you don't get foul brood from the outside, and you would better get rid of it in your own apiary when it is there. My experience is from 33 colonies down to 11, and nearly everything I have now is infected with foul brood, and I have been experimenting long with it. Perhaps if I had spent all my time at that, and quit my other business, I would have gotten rid of it, but in my own weak way I have tried to get rid of it and I have failed absolutely. The first thing, we ought to have a good, drastic law in this State. No use in going into details. You all have read about the laws other States have. Well, that covers the thing completely. A foul-brood inspector goes with them, and burns and destroys if necessary. I take it that there are 12 apiaries in this (Cook) county that are infected now with foul brood, and there is a chance to infect the whole State with foul brood.

Mr. Clarke—Can Mr. Moore tell us what time of the year it was when his colonies were infected?

Mr. Moore—It was mostly last spring, from April to July.

Mr. Clarke—Was it in April or May?

Mr. Moore—Probably May, June and July.

Mr. Clarke—You did your work in the worst possible time you could. This not only from my experience but from every bee-keeper's around, as there were very few days that you could open the hive and not have robbers come in, and you would get it into every other colony you had in the yard.

Mr. Moore—It is very easy to talk about what is the best thing to do. It is very easy to read McEvoy, but you know how hard it is to go home and carry out to the letter things that we believe are right to do. We won't do it. The moral is, to take the most drastic possible method with your case of foul brood. Do the thing you are absolutely certain the foul brood won't get away from, and I say there is nothing else but the consuming fire that will break up foul brood.

A Member—If this method is proceeded in, and a drastic law enacted by which all foul brood is destroyed beyond all recognition, where is there ever going to be any chance to experiment?

Mr. Marvin—I think we have had too much experimenting. When men can't get up here and tell us—among all the bee-keepers, and women, too—how to cure it, and cure it effectually, I think it about time to exterminate it, and I think that is the cheapest way. We don't want to spend money for nothing. Go right to work and exterminate it right at the

start when we find we have it, and then start in again buying new comb; I think this is the cheapest in the long run.

Mr. Clarke—I have tried the McEvoy treatment, and I have never known it to fail if it is done properly.

Mr. Moore—Your bees now have foul brood?

Mr. Moore—I am likely to have it in the spring because I have it around me. Directly you have foul brood in the colony it will show it.

Mr. Dadant—From the outside?

Mr. Clarke—From its work.

Mr. Horstmann—When I first noticed foul brood I had five colonies, and I have increased to 27. I had 1,700 pounds of honey the past season and cleaned out, I think, live or seven colonies. I worked on the McEvoy plan, and got over 90 pounds of honey from the colony I treated in June. If that doesn't show up well, I will give up.

Dr. Miller—There are some of us who haven't any foul brood in our apiaries. We will all take foul brood home with us. I move we change the subject.

"What is the best way to prevent foul brood, and keep it out?"

Mr. Dunn—That's what we all want to know.

Mr. Stanley—I have tried it. I think it can be done without burning the bees and destroying them. I will explain my way. It is to re-queen the colony, and about ten days afterwards shake the bees off the combs on the starters, and boil the combs up and use for wax, and the honey can be used after boiling. In 1884 we had over 200 colonies, and treated about 20 that way, and we had a barrel of honey and had no bad results.

Dr. Miller—That's the McEvoy treatment, but you had the additional—

Mr. Stanley—Then I re-queen the colony.

Mr. Horstmann—I would advise no one to handle foul-broody colonies unless there is a good honey-flow on. Then you will have no robbing; but be sure that there is a good honey-flow on.

A Member—Did anybody ever know foul brood to spread during a good season? It is during a poor season—that's when it spreads.

Mr. Walker—We don't have poor seasons here. There are several quite important particulars that he might tell us about. As to whether he handles them in broad daylight or was careful to handle them just at dark, and careful to see that no bees got into some adjoining colonies, as they are put off. I have had experience with foul brood for at least 20 years. I fancy Mr. Moore asking me why I am not rid of it now. I am rid of it now; and I will say that I have had more or less of it nearly every day from 20 years ago up to now, but it is because I have had to ship so many bees from different places. I have found out that foul brood, when you suppose you are rid of it you have to go at it again to get rid of it. It has been eternal vigilance in my case. McEvoy's treatment I have adopted, and it is all-sufficient. Some have tried a few cases, one season or two, and sit in judgment on Mr. McEvoy, to find out whether his treatment is proper or not. By way of suggestion, I think we get honey from all over creation, and then transport it all over, and expect to get rid of foul brood, and keep rid of it.

Pres. York—"Can a bee-keeper be prevented from bringing foul-broody colonies into Illinois?" Does any one know?

Dr. Miller—I don't believe there is a law to prevent it.

Pres. York—"Is the queen responsible for foul brood?" How many think she is—raise the hand. Two.

Pres. York—"With foul brood one-half to three-fourths of a mile from you, is it possible to keep from it in your own apiary?" How many think it is?"

Dr. Miller—It depends upon what kind of neighbors you have to keep bees.

A Member—Was foul brood ever known to exist in bees in a wild state?

Dr. Miller—Yes.

(To be continued.)

The Texas State Convention.

The 24th annual session of the Texas State Bee-Keepers Association was held in Greenville, April 2, 1902. Vice-President J. M. Hagood called the meeting to order, and prayer was offered by the chaplain. About 25 bee-men were present, representing nearly 3,000 colonies of bees, and an average of 20 pounds of honey per colony the past year, which year was the hardest on bee-culture in the experience of bee-keepers.

The convention was in session two days, and topics of great interest to all were discussed.

The venerable president, W. R. Graham, was too feeble to be present and preside, very much to the regret of all.

Messrs. Haggood, Morgan and Cooper were elected delegates to the Farmer's Congress to be held at College Station next July. W. R. Graham was re-elected president; J. M. Haggood, vice-president; and F. N. Hunter, secretary.

Don't Neglect the Bees—Other Good Advice.

BY MRS. L. C. AXTELL.

I BELIEVE the time is not far distant when the bees will do well again. We have had so many dry years here in the West, and the people are getting a good deal discouraged with trying to make bee-keeping pay, and so each year the poor bees are left more and more to live or die, just as it happens; and often they die for want of a little care.

Some of us will awaken one of these days to find a fine honey crop, and no bees, or but a few, to gather it.

"The platter kept right side up" should be our motto, and when the good honey season comes again, as it surely will—or everything else will dry up and all farming cease to pay—then, I say, when the good seasons come again, bees will increase and again fill their hives with honey as if by magic—if the bee-keeper has his bees in good condition. But if the bees have been neglected there will be no bees to gather honey, and all will be wasted, and the bee-keeper will take up the lamentation that "bees don't pay," when it will be his own fault, and not the fault of the bees.

BEE-KEEPING A SPECIALITY.

I am not sure but it pays to make bee-keeping a speciality. What is there we do make a success of if we do not make a speciality of it? I am sure it is not farming. Being merchants, or school-teachers, or any other business—we need to put our whole soul into any work we wish to make a success of, and push, and push, and push.

This is why some succeed and others fail. They simply play at work, and at every little failure will give it up and try something else. If one makes a speciality of his bee-work he will see to it that his bees are kept in good condition, so that they can take advantage of every honey-flow; he will see that there is no spraying of fruit-trees done in the neighborhood while the trees are in blossom, as spraying fruit-trees while in blossom will surely kill bees, and so depopulate the hives as to cause the colonies to be so weak that they cannot build up into strong colonies in time to gather a crop of honey when it does come, as it is strong colonies that gather a surplus of honey, and weak colonies get but little more than a living, and often not that.

BEEES A BENEFIT TO FRUIT MEN.

It seems a pity that there should be any friction between bee-keepers and horticulturists. If there is any difference it is the horticulturists that are more benefitted by bees than bee-keepers being benefitted by fruit. Bees do get a little honey from fruit-bloom, hence they may be poisoned when spraying is done, while the trees are in blossom; but most fruits are an injury to bees. It is almost universally acknowledged that the bees flitting from flower to flower carry the pollen, and thus cause the trees and bushes to have more and finer fruits.

Horticulturists and bee keepers should be firm friends, and thus help each other, and if losses do occur, to help each other bear the losses. If the bees seem to be hard on their neighbors' vineyard, let the bee-keeper be generous with his honey, and also the owner of the vineyard gather his grapes as soon as ripe and not leave them longer to crack open and thus tempt the bees, as bees never bother sound grapes. If both bee-keepers and horticulturists would vie with each other to make the injury light, and overlook what cannot be avoided, or do as they would wish to be done by, there would be no need of resorting to law. Honey is a wonderful sweetener!

BEE-KEEPING FOR INVALID LADIES.

There are many households where there are sick daughters that might be greatly benefitted if they would take more out-of-door exercise; and if they could be presented

with a colony of bees, or even given the profit from one or more colonies, it would give them new life. If once they could be induced to study the bee, they would find it so wonderful that many hours could be profitably passed in studying the mysteries of the hive and its wonderful inmates, and soon new life would come to the sick one in forgetting self, and in the prospect of earning a little fortune from the care of the busy bee. And when the bright, sunny hours of spring come, and the bees with their happy hum are flitting from flower to flower, the sick one would be induced to go out-of-doors and forget self and the many aches, as nothing is so conducive to health as to forget self and become intensely absorbed in something else, especially if one can see there is profit in it; and if one is so desirous of health that he or she will endure a little hardship in the way of working with bees, even if it does tire them some, and will grin and bear the stings, if they get any, as stings are a wonderful tonic—a summer thus passed may brown the face some and discolor the hands somewhat, but it cannot fail to bring more roses to the cheeks and a brightness to the eye, and give elasticity to the step, and an appetite that had before been a stranger to them. Never mind if the clothes do get somewhat soiled, it is "clean dirt;" and if you get too tired to walk, just lie down on the "soft side of a board" anywhere, if it is out-of-doors, or on the green grass, if the ground is warm and dry; and then look at the bees as they labor so earnestly to do their best, which they always do. I am sure, ere many weeks have passed the sick one will be on the highway to health, if not already there.

Foul Brood—Its Alarming Spread, Etc.

BY C. P. DADANT.

I have lately been reading reports of foul brood, and of the number of colonies treated in different States by a number of foul-brood inspectors. The last in my hands is the Colorado report, made to the Secretary of the State Association by a number of County inspectors, and published in the "Rocky Mountain Bee Journal" for January, 1902. These reports make me feel very much behind the times, for after some 33 years of active bee-keeping, and a good portion of the time on a large scale, I have yet to see the first case of foul brood, not only in our own yards, but also in any yard that I have visited from time to time. My father, whose experience goes back some 20 years farther, also says that he has never seen a case of foul brood. It is true that we have had, occasionally, especially in early spring, a case of dead brood, generally caused by spring-dwindling, or by the desertion of the bees, but this accidental dying of brood was easily ended by the prompt burying of the dead brood, which removed all danger.

But here is a report that astounds me. According to this report, in the State of Colorado, in 1900, out of 7952 colonies inspected 799, or a little over ten percent, were found diseased. In 1901, out of 13,131 colonies inspected, 804 were found diseased, or a little over six percent. Just think of it!

I take it for granted that not all the bees in those counties were examined, for that would be a terrible condition, if that percent of all the bees were infected with foul brood. But the report does not say anything about the probable number of colonies in the country, and we are led to infer that the number mentioned covers all the bees in that portion of the country. It seems to me that a more detailed statement ought to be published. For instance, the report ought to state in how many apiaries the disease is found, where they were located, how many apiaries were found immune; and, if any apiaries were not examined, how many of these, and the reason why they were not examined. The probable number of colonies in the State ought to be embodied in the foul-brood report, so that strangers reading such a report may not be led to believe that this contagious is spread all over the State.

The reason that prompts me to ask this, is that the plain report, as printed in the journal, will give foreigners a very bad idea of the condition of bee-culture in the States where such reports are printed.

It seems to me that it would be well, also, that the localities where the disease is raging with the greatest vehemence be mentioned in the report, so that bee-keepers should avoid buying bees, or honey for feeding, from those localities until the disease has been conquered.

A contagious disease should be treated as all contagions are—by a prompt and effective quarantine. This quarantine will be in the interest of the affected apiaries themselves,

because it is necessary that the disease should be confined in as small a space as possible.

This is very much like battling with small-pox. Our little town was invaded by that dread disease last November. Just as soon as it was detected, the facts were published by the Mayor; the houses of the sick were quarantined, and the public houses were closed. The town put itself under strict quarantine for some 40 days, and at the end of that time the disease had disappeared. In a neighboring city they kept the light under the bushel, for fear of losing trade, and the result was a much longer and much more extensive siege of the disease.

But while we are carefully guarding against foul brood, let us not be hasty in declaring the existence of foul brood at the first sight of a cell or two of dead brood. Foul brood is a special disease, which has been described often enough to make every body familiar with it, and when a case of dead brood is found, one ought to make absolutely sure that it is a case of malignant foul brood before resorting to the extreme measures which foul brood demands.

At two different times in my experience I have had samples of dead brood sent me by bee-keepers who thought they had the dread disease in their apiaries, and in both cases I had the pleasure of informing them that I did not believe the disease was the true contagion. In both cases the subsequent disappearance of the disease proved that this was correct.

But in the modern methods of rearing and shipping queens all over the country, there lies a great danger, and, for that reason, I believe that the State inspectors, after making absolutely sure of the existence of the disease in a locality, ought to publish the fact in their report. After the disease is cured, it would be their duty publicly to mention that fact also. Can we not hear from some foul-brood inspectors in regard to this matter? Hamilton Co., Ill.

[Any or all the official foul-brood inspectors are invited to express their opinions on this subject, in these columns.—EDITOR.]

No. 5.—Bee-Keeping for Women.

An Ideal Occupation for People Suffering from Nervous Troubles.

BY EMMA M. WILSON.

I HAVE received a letter from a lady in New York, asking a number of questions, seeking further information in regard to bee-keeping for women. As the answers to these questions may be of benefit to other readers of the American Bee Journal, I have concluded to give them here.

This lady is suffering from nervous prostration, and would like to know if I had any of her symptoms, and, if so, if I took much medicine, or simply trusted to the open air and suitable diet to cure me. I did not have nervous prostration, but I do not know how soon I might have had it if I had kept on teaching, as I needed a rest, both physically and mentally. It is not best to take any more medicine than can possibly be helped for nervous trouble, and I certainly would trust much to out-door air and suitable diet.

If you belong to the class of nervous people, bee-keeping is an ideal occupation for you, if a genuine interest in bees is once awakened. Why? Because it keeps you in the open air; gives you physical exercise of the right sort in that which deeply interests you; and because it takes your thoughts entirely away from yourself. That last is what you need more than anything else. You are obliged to give your whole attention to what you are doing while working in the apiary. Often and often people have stood for some time a few yards away from Dr. Miller and myself, watching us work, and neither of us knew they were there until they spoke, so intent were we on what we were doing. Not much time to think of your own aches and pains, you see. And nervous people can make themselves believe they have any disease under the sun if they only think about their own aches and pains long enough. Nervous people are poor sleepers, and that which will keep their thoughts off from themselves, and keep them in the open air, will induce sleep, if anything will. It must be dreadful not to sleep a wink for two or three nights in a week, and certainly anything that would help to counteract such a state of affairs would be a boon, even if there were no money in it.

This lady has been taking boarders. She says she would like to hire most of her housework done, and work

with her husband in the apiary. Let me advise you to give up all thoughts of boarders for the present, get as good a hired girl as you possibly can (for I think a poor one is worse than none), and give up all the care you can. No matter how good your help, the care of boarders would still be left upon you. It is not work that kills people so much as worry and fretting. A good, hearty laugh is worth more than a dose of medicine for nervous trouble.

The first thing to do is to get well. So please remember what I say: Give up the boarders as the first step. Try not to worry about anything, and keep in the open air as much as possible; then think about your bees instead of yourself, and I firmly believe you will soon be well.

To your further questions I answer as follows:

No, I do not run an apiary of my own. I work with Dr. Miller.

When we have a large enough crop of honey we ship it; if very small, we sell at home.

Yes, I wear gloves. I have described what kind in previous article. McHenry Co., Ill.

A Feeder for Feeding over the Frames.

BY H. DUPRET.

MR. TURNER BUSWELL, of Maine, desires me to describe the chimney feeder covered with glass, which I referred to on page 215.

In answer, I beg to say that the chimney feeder is a very simple affair. The principle involved is to allow as little warmth to escape from the cluster of bees as possible, and at the same time to give the bees free access to the feed, without compelling them to take more than they want. Any

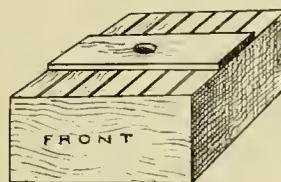

FIG 1.

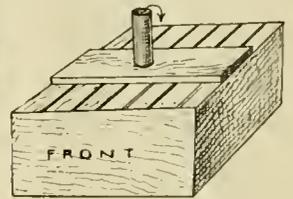

FIG 2.

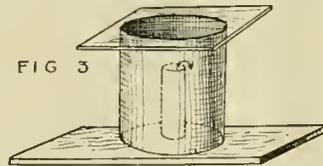

FIG 3

FIG. 1.—Communication Bridge with 1/4-inch space under it.
FIG. 2.—Chimney Feeder on top of the frames.
FIG. 3.—Feeder and Communication Bridge combined.

tin box or can will do. Punch a hole in the center, about one inch in diameter; solder a tube or chimney around this hole, taking care to make the chimney shorter than the walls of the box by 1/4 inch at least. Put in the feed (if liquid, cover it with bits of cork or wax to prevent the drowning of the bees), place the box in communication with the cluster of bees, on top of the frames, providing a stick as a ladder in the chimney for greater convenience of the bees. Then cover the feeder box with a glass, so that you can watch the actions of the bees whenever you wish. Cover also snugly the top of the frames with any warm material.

For greater convenience together with this feeder I use a Hill's device of my own. In fact, every hive is prepared for winter with such device, which serves as a communication bridge for the handy clustering of the bees during the cold season.

This communication-bridge, to be placed on top across the frames, and a 1/4 inch space for the free communication of the bees from one frame to another, and is provided with an auger-hole, which, when not in use, is covered with a bit of glass. Now any hive marked as light in stores in the fall will receive in the spring an early feeding through this auger-hole. Honey in sections can be given to the bees if the feeder be made of the right size.

In conclusion I must say that I found the principle of this feeder in the French paper, "L'Apiculteur," of Paris. Quebec, Canada.

The Part Bees and Other Insects Play in Fertilizing Fruit-Tree Bloom.

BY THADDEUS SMITH.

SINCE writing an article on this subject, published in the American Bee Journal of April, 1901, pages 262 and 279, we have had another season for observation and investigation; and as I made it my especial business to watch closely the fruit-bloom last May for insects, I propose to give some results of the investigation.

It is well known to be a fact beyond dispute that certain islands in Lake Erie, where there are no bees kept and bees never visit, produce an abundance of fine fruit. We see here, year after year, full and quite regular crops of fruit of various kinds, grown more uniformly, I believe, than in any other place in the state of Ohio, or of the same latitude. This completely settles the question with myself, and with others who have had personal evidence of the conditions that the bees are in no way necessary, nor of any advantage whatever, in producing a good crop of fruit—not on these islands, at any rate. If not necessary on these islands, why should they be anywhere?

This question being settled, the investigation I had to make last season was to try to find out what part, if any, other insects played in fertilizing fruit-bloom. To this end I gave my especial attention, not only here at home but upon other islands where I knew there were no bees. On May 15 I visited Middle Bass. I found the greatest profusion of bloom on many varieties of fruit trees and shrubs. They grow every variety of fruit and berries that can be grown in this latitude. They grow them successfully without bees. The friend with whom I stopped said to me:

"I have been watching the fruit-trees closely for bees and other insects. I have not seen a bee. The only insects seen were on the apricot trees which bloomed a week before the other fruit-trees. They were a peculiar kind of insect that I never saw before, and they soon disappeared. I have been among my trees daily since in bloom, and never saw anything more of this insect upon any other trees, and no other insect of any other kind."

Such was the testimony of Mr. George M. High. Mr. High is personally known to Prof. A. J. Cook, who will vouch for his intelligence and integrity, and he is known by many other men of prominence who have made his acquaintance in visiting the summer resorts of these islands, and through business. He is widely known as an intelligent and successful fruit-grower. In company with Mr. High we renewed the search in his orchards with the like results he described.

I watched very closely the bloom of fruit-trees and vines on my own place. Bees I found, for there are bee-keepers scattered all over the Island. My search was for the "other nectar-loving insects" that we are told do the work of fertilizing bloom with the bees or without them. I will not say that I did not see one single insect on any of the flowers besides the bees, but they were very scarce, and very small, much more so than I expected to find them. There were practically none worth taking into consideration in connection with carrying pollen from one flower to another. It would have been impossible that there were enough to visit one flower in 10,000. It was too early in the season, as has been observed heretofore by Mr. Hershiser, Mr. High, myself and others, for these nectar-loving or other kinds of insects to be out in any numbers to be of benefit in pollenizing the bloom.

In reviewing my former article upon this subject, our erudite friend of the "Afterthoughts," makes the very uncharitable intimation that I was not competent to see insects, and my evidence unreliable as to there being no nectar-loving insects found upon the fruit-bloom on these islands where there are no bees. Mr. Hasty dismisses our testimony with a sneer, saying: "It is quite possible that a skilled entomologist with *only half an eye*, would find nectar-loving insects *abnormally thick*." (Italics mine.) And again he says: "Apparently neither himself nor his friend are well-posted in insect lore." Perhaps not. But is it necessary to be "well-posted in insect lore" to see the insects when you look carefully for them as we did? The experience of over a quarter of a century engaged in fruit-culture, where we have to study and combat the many diseases and insects injurious to both trees and fruit, ought somewhat to qualify us to see insects of any kind on the trees, and should entitle our evidence to some respect. No, nectar-loving, nor other kind of insects, are *not* found thick here, "abnormally" or otherwise, as early in the season as the blooming of fruit-trees.

Mr. Hasty suggests that there should be a "chance for some friendly hand to show how much better results" could be obtained on these islands with bees. I believe that no intelligent person will claim that bees or other insects can possibly have any influence on the size and quality of fruit. It is only thought by some that bees have something to do with disseminating the pollen, thereby fructifying the stamens and giving a *better setting* of fruit, and a larger crop, than there would be without them. The most kinds of fruit on beelless islands *set too much fruit*, and it has to be picked off—thinned out—to keep it from being too small. Those that do not require thinning usually set as much as is wanted to give good size and quality. Now, what chance could there be to obtain better results with bees here when we get more fruit set than is wanted?

But that "friendly hand" has, incidentally, repeatedly tested that very thing by comparing the fruit crops grown on an island with bees, and that grown on a neighboring island without bees. Pelee Island, like its neighbors in this group of islands, is well adapted to fruit-growing, and many colonies of bees are kept upon it, but we know that the fruit crop is no more certain, no larger nor better than our neighbors' who are without bees. In fact, there are some incidents that would indicate to a superficial observer that the best crops are grown where there are no bees. For instance, last season I had 60 bearing peach-trees of a certain variety that bloomed profusely but did not set a peach. In visiting my neighbor in October I found that his peach-trees, of the same variety, had produced a good crop, and there were no bees. Now, if this had been the reverse—if the failure had been where there were no bees instead of where bees were plentiful—how quickly the incident would have been used as an argument to show the importance of our little friends in this matter. And this is just like all other arguments used to show that bees increase the fruit crop. The bees have nothing to do with it.

I would be pleased to have Mr. Hasty investigate to see if insects frequent the bloom here in May in "abnormal numbers;" and I hereby invite him to come over to Put-in-Bay next May. [This month.—Ed] and see for himself. There is a steamboat line from Toledo to Put-in-Bay, and it is only a short and pleasant ride. From the Bay he can visit other islands, and I shall be glad to have him visit me on Pelee Island, and I shall take pleasure in meeting him and entertaining him while on our Island, and will do what I can in assisting his investigation. I have no theory that I am wedded to, no "ax to grind," and only seek the truth. If he cannot come let him send some one else who is "well-posted in bee-lore." Not some one with "half an eye," or one eye, but with two good eyes assisted by glasses.

I have but little hopes of any accepting this invitation. They might learn what they do not wish to know. The old adage, "Convince a man against his will, he will be of the same opinion still," is quite true; and to convince one against his supposed pecuniary interest is still harder. The advocates of this bee-pollenizing theory seem to think that it is of great importance to bees and bee-keepers that its truth should be established, and therefore they are hard to convince otherwise, even when the facts are against them. There should be no antagonism between bee-keepers and fruit-growers. An experience of 40 years in both occupations has convinced me that neither is injured nor benefited by the other—not in my locality.

Ontario, Canada, Nov. 13, 1901.

[In the interest of fairness to both sides of this controversy we give place to the foregoing article. It should have appeared long ago, but perhaps now it will be just in time for those who so desire to make more careful investigation along the line indicated.—EDITOR.]

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

* **The Afterthought.** *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

BEES—RACES AND SPECIES—DEEP-TUBE FLOWERS.

Most species in Nature have few different races within the species, or none at all. *Apis mellifera* has distinct races, so many that it is doubtful if any other natural species can equal it in that respect. This is a hint for us. Prof. Cook thinks that we shall find the bee very responsive to intelligent breeding. In addition to the advantages of long-tubed flowers, which he mentions, there is another important one: They hold and keep a supply of nectar which lasts over and through the spells of weather in which none is secreted. I have seen dry hay in the mow in which the clover heads were decidedly sweet to chew. Page 183.

HONEY AND BEE STATISTICS.

It took lots of able, very able, guessing to get so far out of the old, inflated, and worthless estimates, and so nearly down to hard-pan, as are the Gleanings' estimates of honey-statistics on page 185. And this estimate makes the per capita over two pounds per person, which same might be a little hard to prove up. It would be ten pounds for each family of five; and so few families actually consume that, and such an immense number of them never eat an ounce of honey from one year's end to another, that a grain of doubt is still permissible. Were it not that bakers and other big operators take so large a share of the extracted, the grain of doubt would be something more than a grain.

Glad Uncle Sam has gotten around at last to have some bee-statistics. Of course, we are not to take them exactly as we take the multiplication-table and the Sermon on the Mount. We may safely draw a little on our own inner consciousness in digesting them. Manifestly the number of people keeping bees—707,261—is *not an exaggeration*. That's something to the good—and almost new. People are not very likely to report bees where there are none, that is, not when guessing colonies by the county-yields to actual enumeration. We may take also as safe on one side the total number of colonies—4,109,626—and the very modest valuation, which figures \$2.50 per colony. When it comes to the value of the product it's more of a guessing-match; but the tendency to exaggerate in guessing may be much more than balanced by individual census-takers, assuming that there are no bees in territory where such is not the fact. This last source of error we can know little or nothing about. The two are not for the same year, nevertheless it may be worth while to put the United States figures and the Gleanings' estimate side and side:

VALUE OF PRODUCT.	
United States.....	\$6,664,904
Gleanings' minimum.....	8,000,000
POUNDS OF HONEY.	
United States total.....	61,196,160
Gleanings' (comb only).....	50,000,000
Gleanings' total.....	175,000,000

As for the number of pounds, I'll guess that the truth lies between the two somewhere. Page 211.

HANDLING COMBS OF HONEY.

It seems to me that if Mr. Doolittle was an extracting fellow, and if he tossed heavy combs with the tips of his middle fingers for hours, the finger muscles would cry out, "We are sore, sir." Try the method, of course—then if you don't entirely like it try this: Grasp the comb at the corners with a grip like a vise. Imagine yourself about to pitch a base-ball with the center of the earth for home-plate. Pitch it. In other words, don't let the comb go down by its own weight and be jerked back, but jerk it both ways, being especially snappy on the down motion. But it won't do to try this on tender combs which are not built down to the bottom-bar. Page 185.

TOO MUCH RAIN AND GOOD HONEY-FLOWS.

Chili, down at latitude 40, appears to be a wet place. I figure 2,860 millimeters to be 9 feet 4 inches—more rain than we want sprinkled over us while we are trying to feed

up the bees—especially as we get the idea that there is no dry season there. Evenly distributed, it would give quite a heavy rain for every day of the year—one-third of an inch. Wonder if this too much rain bears some sort of relation to the very excellent honey-flows found just north of the rain-belt. Page 187.

FASTENING NO-DRIP STRIPS IN CASES.

Apparently S. D. Buell has a winning idea for getting the strips on the bottom of honey-cases. Slotted board three inches wide to hold them just where wanted, and nail them on the bottom-board before the rest of the case is put together. But T. F. Bingham thinks that first-rate paste will do instead of nails, and save possible leaks through nail-holes. Hardly know if the Buell method could come in when paper trays are to be added. Pages 189 and 219.

TEMPERATURE IN A WINTER BEE-REPOSITORY.

Wouldn't that corrected error on page 190 be a little more ideal if it were corrected some more? Get it up another 10 degrees, and say 45; 35 looks like hovering too close to the freezing-point. Pages 156 and 190.

* **Questions and Answers.** *

CONDUCTED BY

DR. O. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Building a Bee-House—Finding Queens.

I am very glad you called my attention to the question I should have asked above all others. But it is never to late to mend one's ways and profit by mistakes made. I will therefore collect a few of the many questions I would like to ask, and bother you once more. I will give you a pen description of the bee-house I have been thinking of making.

It is to be 10x12 feet, with an 8-foot studding 2x6 inches, and boarded up on both sides with matched lumber, and tarred paper between the boards: studding on both sides. That will keep the sawdust from leaking out in case there would be loose knots in the lumber.

I will put tarred paper on the outside, and then side the house up with good siding, and place one foot of saw-dust on the ceiling. To keep the house warm when it gets too cold, I will build a storm-shed in the same manner, and in the shed put a tank of water that has pipes running through the wall to the room with the bees in, so arranged that there will be a complete circulation of water. I will heat the water with a large lamp placed under the tank; this tank will have small tubes running from end to end, the same as a boiler with a tight-fitting hood on top, and a small pipe passing out of the roof. In this way there will be no fumes in the bee-house, and by turning the lamp high it will heat the water faster, and by letting it burn low it will keep the water just warm.

I have been thinking of using the house to keep bees in all summer, and in winter store a few more colonies that I might have in my yard. Now:

1. Would you advise me to build such a bee-house and operate it in that way?
2. When I took my 6 colonies out last week I found 5 of them had a good deal of brood, and one had none at all, nor any eggs, either; and the second day this one hive had no bees, either. Where did the bees go?
3. What made the 5 colonies rear so much brood while in the cellar? The temperature was all the way from 38 to 47 degrees all winter, and the bees very quiet?
4. I found 1 or 2 cells of brood sealed here and there in all parts of the frames. What does this indicate?
5. Will it injure the bees any to rear brood in the cellar? and will the chilly weather we have now (25 degrees above) harm the brood any if warmly packed on top?
6. I would like to do away with hunting up the queen, and have thought of placing the colony I wish to divide on top of a new hive with full sheets of foundation in the frames, and when I find eggs in the lower hive take the upper one off and set it by the side of the new one, and in

roduce a laying queen as soon as the time comes. Will that work all right? How long will it be before the queen comes down into the new hive? MINNESOTA.

ANSWERS.—1. No, I wouldn't advise it. I am very much afraid it would not come up to your expectations.

2. Very likely they swarmed out into one of the other hives.

3. I don't know; and yet it is nothing very unusual for brood to be present before bees are taken out of the cellar.

4. Nothing unusual.

5. They will probably come out all right.

6. How are you going to tell where the queen is? For when you find eggs in the lower story you are not at all sure the queen is there. I have had many colonies with two stories, and when the queen laid a quantity of eggs she would return to the upper story, and then kept going from one story to the other, so that I could never tell which story she was in without finding her. Possibly this plan may serve your desire of knowing in which of two hives the queen is without actually seeing her: Divide the colony, putting part of the combs with their bees in another hive. Two or three days later the part that has queen-cells started will be the queenless one. Of course that is on the supposition that no queen-cells were present at the time of making the division.

Dogwood and Honeysuckle—Bumble-Bees—Increase.

1. Does the enclosed flower yield honey? It grows on a tree called "dogwood," and the woods are full of it, hereabouts. Also, does "honeysuckle" yield honey?

2. Is the honey gathered from hops and bitterweed (wild chamomile) bitter in taste? I bought some colonies in Alabama lately, and the honey contained in the hives is very bitter, and tastes like a drugstore.

3. Do bumble-bees sting, or store honey? I notice about my well a great lot of rather small black bees that live in holes in the ground. To-day I noticed them balling a queen. Do you know anything of them?

4. If I take four frames containing some brood from a strong colony, and put it in a new hive, and move the old hive to a new stand, will I not stand a fair chance of getting two colonies? What is the objection to this means of increasing when one does not know enough about queen-rearing to increase *via* nuclei? MISSISSIPPI.

ANSWERS.—1. The dogwood (*cornus florida*) which you send does not, I think, yield honey, and the bees have not tongues long enough to reach into the deep flowers of the honeysuckle.

2. I don't know; I'm afraid it is.

3. Bumble-bees sting, as many a barefoot farmer's boy can testify; and they store honey, but never in any considerable quantity. I never found a nest with as much as a tablespoonful of honey in it. I have seen small black bees, but I am not acquainted with their habits.

4. Yes, you will stand a fair chance of having two colonies, and possibly three; for if the queen is taken to the new stand, and the queenless part left on the old stand, that queenless part, being strong, may send out a swarm when the first young queen emerges. An objection to the plan is that the queenless part will not have any increase from its new queen for nearly six weeks.

Drones—Rearing Queens—Transferring, Etc.

1. I have drones from a laying worker whose mother was a full-blood Italian queen; they are so yellow that you can tell them as far as you can see them. The drones in another full-blood Italian colony look like common black ones a little way off. Why is this? and which is right?

2. This is our main swarming-time, but on account of the cold spring they have not started but are killing off the drones like they do late in the summer. Why is this?

3. Will drones from one hive go into another hive?

4. Suppose I give a queenless colony young brood to rear, say to-day, and they start to rear a queen, how many days before they will have one sealed up?

5. Which will they use, an egg or one just hatched?

6. Which will be the most apt to try to rear a queen, one with laying workers or without? If there is any difference, which race will be the most likely to rear one, Italian, black or Carniolan?

7. Speaking of black, we have what a bee-keeper called a "brown gum" and "a little black fellow" that would try

to sting the "old boy" himself. Which is meant when bee-papers say "black?"

8. I have a large number of queenless colonies. Last summer and fall I think a large number superseded, and reared young queens. Do you suppose this has anything to do with the present large number of queenless ones? If so, how?

9. I know the comb comes off of the bees; where do they keep it, or rather, where does it come out?

10. Now, Dr. Miller, you know more about bees in 5 minutes than I do in a year, but I want to give a point or two. I read your answers to all our greenhorn questions; you advise several in answer to their question about transferring out of box-hives to do so in fruit-bloom time. I am sure that is all right up there, but in this part of the country, and may be in other parts, it is quite different. It is 2 or 3 weeks from fruit-bloom until our next honey-flow, and it is nearly always cold during fruit-bloom and for the next 3 or more weeks. Should one transfer then, and not feed, he would lose his bees, every time. The reason I call your attention to this is, because I believe that nearly all of us greenhorns that have bees in box-hives would never think of feeding, but would use an empty hive or dry combs. ALABAMA.

ANSWERS.—1. I don't know why it is, but there seems to be a great variation in appearance of drones, and either one may be pure stock.

2. Weather so cold that bees do not gather freely is sufficient reason in the eyes of the workers for disposing of their lazy brothers.

3. Yes, they seem to be free commoners.

4. In something like three or four days.

5. A larva perhaps two days old, or younger.

6. I don't know whether there is any difference; if there is, I should guess the Carniolan.

7. The subject is a little mixed, but usually the term "brown German" and the "black" mean the same thing. Tunisian bees are the blackest I ever had, and possibly the blackest that exist, and the ones I had were what my assistant called "vindictive little sinners."

8. It may, and it may not. The young queens may have been lost when taking their wedding-flight. As a rule, I think there is little loss of queens when bees do their own superseding.

9. Look sharp and you can see the little scales of wax between the rings on the under side of the abdomen, where they are secreted by the wax-glands.

10. No one realizes more fully than I the fact that there are a whole lot of things that I don't know about bees; and I feel a good deal like a humbug sometimes when I try to answer about things hundreds of miles away where I have never been, and I will be ever so much obliged if you good people in the South will straighten me out when I go wild in my answers. You probably are entirely right that fruit-bloom would be a bad time for you to transfer. More and more that time is going out of use, and the transferring is not done till 21 days after the issuing of the first swarm.

Stimulative Feeding.

Why is it that stimulative feeding of bees in the spring, in the hands of amateurs, is always spoken of as a dangerous business, and referred to as a two-edged sword, etc.?

NEW BRUNSWICK.

ANSWER.—Because feeding induces the bees to fly, and if the weather is such that they will be chilled and lost, there may not be a sufficient gain in brood to overbalance the loss.

Pollen Substitute and Robbing.

Will throwing out corn-meal, rye or Graham flour that has enticed bees from other apiaries cause robbing?

ILLINOIS.

ANSWER.—I do not believe that exposing any substitute for pollen will cause robbing.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

3-Frame Nuclei For Sale.

We have arranged with a bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei of bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 at \$2.75 each.

All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

BEES QUEENS

Smokers, Sections, Comb Foundation and all Apian Supplies cheap. Send for FREE Catalogue. E. T. FLANAGAN, Belleville, Ill.

I have a lot of 25 colonies of bees in fine condition, in hives holding frames 12x12 inches, the usual depth, that I will let go at the following rates, viz: One colony, \$5.00; 5 colonies at \$4.50 each; 10 colonies at \$4.00 each; or the entire lot to one party for \$75.00, cash with the order. These bees have a mixture of Carniolan blood in them, but are workers having averaged nearly double the amount of honey per colony that any of the pure stock did in the same apiary the past dry season. I guarantee safe delivery and freedom from disease. Act quick, for these bees are a bargain at the above price, and this advertisement will not appear again.

E. T. FLANAGAN, BELLEVILLE, ILL.

COMB FOUNDATION ADVANCED 3 CENTS A POUND.

Owing to the increased price of beeswax, until further notice, dealers handling the A. I. Root Company's goods are compelled to raise the price of Comb Foundation 3 cents per pound above the prices found in their price-lists and catalogs. Please take notice.—Adv.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

Selected, Warranted.....	\$1.00	\$5.00	\$9.50
Tested	1.50	8.00	15.00
Selected Tested	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Weekly Budget.

EMERSON T. ABBOTT,

The New General Manager of the National Bee-Keepers' Association.

Editor E. R. Root, of Gleanings in Bee-Culture, made this comment on Mr. Abbott, when announcing his election to the office of General Manager:

"One of Mr. Abbott's marked characteristics is his strenuous aggressiveness. Perhaps the fur may fly. If it does, it will be in the defense of the rights of bee-keepers."

And Editor Hutehinson, of the Bee-Keepers' Review, had this to say:

"Mr. Abbott is enthusiastic, progressive and aggressive, has modern ideas, always attends the conventions, is a good speaker—the best we have in our ranks—and I bespeak prosperity for the Association under his leadership."

MR. BOOMER AND HIS APIARY.—Through the courtesy of the Canadian Bee Journal, we are permitted to present to our readers the picture on the front page of this issue, and also the following, all taken from the April number of that paper:

A WATERLOO COUNTY APIARY.

We have pleasure in giving a picture of the apiary of Mr. A. Boomer, of Waterloo Co., Ont. Many of our readers are personally acquainted with this tall, old gentleman, here shown bending over his bee-hives, having met him in convention. We think that we are safe in saying that Mr. Boomer is the tallest of Ontario's bee-keepers, measuring 6 feet 4 1/2 inches, and although he has reached the full three-score years and ten, he is still straight as a reed, hale and hearty, and can run after a swarm like a boy. We wish that our good friend may be long spared to enjoy his pleasant and profitable "side line," as will be noted in the following:

"The photograph of my apiary was taken in August, 1901. I have been keeping bees for some 15 years with somewhat varied success. When I commenced I was, as I am still, a traveling agent, and as I was advancing in years I was looking for something that would give me some employment, and possibly some returns, when I became too old to travel; but long before I felt like giving up

the road I found myself with a yard of fully 100 colonies of bees. For a few years I found it more profitable to hire a man for some three months in the early summer than to give up my business; but last summer, although 70 years of age, I did the work myself (my partner, nearly as old as myself, helping me a little in the extracting-room), and I attended to the Division Court business of the township, of which Court I am the clerk; did considerable insurance business and conveying, as well as keeping up the sale of sewing machines and musical instruments. Not so bad for an old man, is it? especially as the crop of honey last season was somewhat large, running up to fully 10,000 pounds. I have only had one season of larger returns since keeping bees, and that was in 1899, when it ran up to fully 11,000 pounds, averaging about 120 pounds per colony. Last year the average would be about 110 pounds. My greatest average in any one year was 125 pounds per colony.

"I use the Richardson hive, mostly those made with beveled joints and sun caps, and don't have to keep the covers on with stones. My yard, as will be noticed, is rather contracted for such a large number of colonies, being only about 60x70 feet, the rest of the ground being taken up with buildings and garden. The small building to the right is the extracting-room, size 10x14.

"My bees are usually very cross, last year particularly so, and this, in the judgment of practical bee-keepers, was probably due to the congested state of the yard. This I intend to overcome by removing about one-fourth of them to an out-yard this season. It may be possible that if I were to devote my whole time to it I might make a greater success of it, but I find that my winter losses are not greater than of those who devote their whole time to them, and my average yield of honey per colony is about as good as that of the specialist.

"I might mention that at the time the photograph was taken I was in the yard taking out combs for extracting. A. BOOMER."

FARMERS' NATIONAL CONGRESS.—It is quite probable that farmers generally do not fully realize the scope and extent of the Farmers' National Congress, as otherwise they would take a much deeper interest in it. The topics discussed are more particularly those of a national or international character, quite different from what is generally on the program at farmers' institutes. The following is a copy of the program for the 1902 meeting:

1. Inter-oceanic canal.
2. National irrigation.
3. Reciprocity—how may it affect agricultural interests?
4. Effect of present insular possessions on the agriculture of the United States.
5. Preservation of forest and fruit trees and reforestation.
6. Injurious insects, insect pests and fungi.
7. What part of a man's farm does he sell when he sells the crop?
8. Postal reforms particularly affecting the farmer.
9. Mutual relations of Northern and Southern farmers.
10. Dairy interests of the United States as related to the markets of the world.
11. Farm products other than dairy products in the markets of the world.
12. The labor problem from the farmer's standpoint.
13. How can we best build up our merchant marine?

The Farmers' National Congress is made up of delegates and associate delegates appointed by the governors of each State. Every governor appoints as many delegates as the State has representatives in both houses of Congress, and as many associate delegates as he chooses.

The meeting will be held at Macon, Ga.,

We can furnish you with The A. I. Root Co's goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for beeswax. Send for our 1902 catalog. M. H. HUNT & SON, Bell Branch, Wayne Co., Mich

Oct. 7-10, and the people of that city will give a hearty welcome to all who attend.

The Southeastern Passenger Association has granted a rate of one fare for round trip; and there is a fair indication that the other passenger associations will make better than an excursion rate.

The men who will be invited to take part in the program will be the choicest that can be selected, and each one will be an acknowledged leader in his line. Isn't it about time the farmers took a practical hand in helping to solve the problems that pertain to their own affairs?

We hope to have at least 1000 delegates, associate delegates and visitors.

John M. Stahl, 4328 Langley Ave., Chicago, Ill., is secretary, and will gladly answer any correspondence for the Congress.

J. H. REYNOLDS, Treas.

Light Honey-Yield Expected.

Our rains came very early in this locality, and then a long, dry spell. Flowers started to bloom and then dried up. Then in March we had some good rains, which will insure good farm crops. But I fear Southern California is "not in it" for a honey crop. My judgment, based on 20 years' experience, makes me think the yield will be light.

DELOS WOOD.

Santa Barbara Co., Calif.

Rather Bad Spring for Bees.

The spring has been rather bad for bees; but to-day the thermometer has made a jump, and at noon it stands at 83 degrees in the shade. I did not suppose it had been warm enough to bring out dandelions, but they are out in considerable number to-day. Unless, however, we soon get rain all vegetation will suffer beyond repair.

I seem to be stealing some other man's thunder on page 245. All that is credited to Dr. Miller on the second half of the page should be credited to some one else.

C. C. MILLER.

McHenry Co., Ill., April 21.

[That seems to be an error of the shorthand reporter. It is impossible to correct it now.—EDITOR.]

Packing Bees for Winter.

On page 238, Mr. Turner Buswell, in referring to my statement as to how I winter my bees, asks:

"How many inches of planer-shavings are put next to the carpet? and why a layer of fine sawdust?"

In regard to the layer of shavings directly over the brood-nest, I was misunderstood, as I do not put any planer-shavings directly over the quilt covering the frames, but pack underneath and all around the hive up to within about 2 inches of the top of the hive, with the shavings, then I put on fine, dry sawdust, and extend about 2 inches above the hive; then put on 8 or more inches of the planer-shavings.

The reason I put the fine sawdust just over the brood-nest is for the same reason that one puts fine woolen blankets on the bed in winter, or the finest underwear next to the body, i. e., to retain the heat.

The planer-shavings are next applied in greater depth to keep out the extreme cold. Whether the sawdust alone would be just as good I can not say, but I do know that the shavings, which form numerous little dead-air spaces, are all right.

One year ago this winter the packing was given a good test when fully 75 percent of

the bees through this part of the country were lost, white mine came through with very little loss (and that was caused by starvation).

I have not examined all of my bees as yet this spring, but what I have examined are apparently in as good condition as when they were packed last fall. IRA D. BARTLETT, Charlevoix Co., Mich., April 14.

Another Frame-Spacer.

I send a gauge for spacing frames in the hive. A good many devices have been offered and used, but, having tried them all, there is no device that gave me such satisfaction as the gauge I am using, and have had for the last 20 years. Put a gauge at each end of the hive across the frames, and fasten a similar gauge in the center across the body of the hive, then when you fasten the cover and bottom-board with hooks to the hive, you may turn the hive whichever way you like, and none of the frames will become dislodged, and no bees hurt. As the gauges at the ends cover up the rabbet, the super closes better at the ends, and the bees have no chance to get out or in if the outside rim should warp.

If you want to take out or invert a frame, all you have to do is to take off the gauges, and you may move the frames to either side and take out or insert with the greatest ease, without fear of crushing any bees or scraping

WHEN ACCIDENTS HAPPEN

and you never know just when that will be—it's very convenient to have at hand a good, reliable, dependable remedy, like

Watkins' Vegetable Anodyne Liniment.

A burn, a bruise, a frost bite, a cut or a sprain, an attack of rheumatism, cholera morbus, cramps, diarrhoea, flux, sore throat, mumps or diphtheria do not admit of experimenting. You want something to help you, and you want it right away. Why not, then, keep on hand a really reliable remedy, so as to have it by you when you need it?

Watkins' Liniment, for internal and external use, for man and beast, has been for 40 years the best standard household remedy known to medical science. It has peculiar penetrating qualities, and gets at the root of the trouble as does no other liniment.

Watkins' Vegetable Anodyne Liniment is sold by our traveling salesmen through the country. If our agent has not called on you, send us your name and address at once, and we will see that you are promptly supplied. Price \$1.00 and your money back if it isn't the best liniment you ever used.

Watkins' Home Doctor and Cook Book free.

Gives home treatment for all common diseases of man and beast; contains numbers of valuable recipes, weather forecasts and an immense amount of interesting and useful information, for home and farm. Something for every member of the family, old or young. Send for copy free.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens
FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be **warranted** purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order for one queen for sending us the names and addresses of **two new subscribers** to the American Bee Journal and \$2.00; or for sending us **one new** subscription and 30 cents more (or \$1.30), we will mail you a queen; or send us \$1.60 and we will credit your own subscription for one year, and mail you a warranted queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

off the combs for the honey to run out and deaube the bees.

As you will notice, I use only 9 frames in my hives, but a gauge can be easily made to cover 10 frames.

I make my own staples, as I could not find any to serve the purpose, but I can make hundreds in an hour.

If any of my fellow bee-keepers will try this device they are welcome to do so, and I am sure that upon trial they will agree with me that the gauges are very handy.

CHAS. H. WIELE.

Vernon Co., Wis., April 1.

[The gauge used by Mr. Wiele is a wood strip 14 inches long, 5-16 inch thick, and 3/8 inch wide, having driven into it a row of 10 small wire staples 1/8 inch from one side, the staples being 1 1/2 inches apart.—EDITOR.]

Unfavorable Weather.

In this vicinity, as far as I know, the bees have come through the winter with very little loss, but so far the weather has been very unfavorable for the bees to work; however, everything looks quite promising when the weather warms up. Almost all of the bees are wintered on the summer stands here with the best success.

The honey crop in this vicinity was a little short last year. It was too hot and dry in July, just when clover was at its best, so it dried up. My bees were ready to swarm, when the weather got so hot that they just dwindled away, so by Aug. 1 the hives looked as if they had just come out of the cellar. One bee-keeper, about 4 miles from me, thought that

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Apr. 18.—The season in which comb honey sells prior to the new crop is now practically at an end; therefore prices are more or less irregular, as some sections in a case will be grained more or less and others free. The best lots of basswood and clover sell at 14@15c; other kinds of white at 10@13c; ambers are not in heavy supply and sell at 9@12c. Extracted is dull at 5@6½c for white, and 5@6c for amber, depending upon flavor and other qualities. Beeswax scarce at 32c. R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5¼@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c. THE FRED W. MUTH Co.

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c. H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7½c; Florida honey, in barrels, 6@6½c. BLAER, SCOTT & LEE.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

CINCINNATI, Apr. 11.—Stock of comb honey here is larger than it ought to be at this time of the year, and this is why it is offered for very low figures. Water-white is sold at 14@14½c and hard to obtain; for extra fancy, 15c.

Extracted finds a steady sale, and amber is sold in barrel lots for 5@5½c; water-white alfalfa sells from 6@6½c, and white clover brings from 6½@7c. Beeswax scarce at 30c. C. H. W. WEBER.

NEW YORK, Apr. 7.—Comb honey, last year's crop, practically cleaned up, but as we wrote a little while ago we had received new crop from Cuba, and are now receiving new crop from the South. Demand is fair at 14c for fancy white, 13c for No. 1, 12c for No. 2, and 10@11c for amber.

Extracted: The market is decidedly dull. Very little demand, with large stocks on hand, some of which no doubt will have to be carried over, and indications point to a further decline in prices. We quote: White, 6c; light amber, 5½c; amber, 5c; Southern, 5¼@5¾c per gallon, according to quality. Even these prices are shaded in car-lots. Beeswax, scarce and firm at 29@30c. HILDRETH & SGOLEEN.

BUFFALO, April 25.—Market is very quiet. Fancy comb, 14@15c; other grades, 9, 10 and 13c. Extracted, 5@6c; moderate demand. Beeswax, 25@33c. BATTERSON & Co.

SAN FRANCISCO, Apr. 16.—White comb, 10@12½ cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4¼@—; amber, 4@—; Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Demand is not very active, and market cannot be termed firm, although quotable values remain without important change. Considerable honey of last crop is now being offered, which up to a few weeks ago had been held off the market. New crop is expected to arrive in wholesale quantity in the very near future.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.

THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.

J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get grand bee-book for a very little money or work.

Number of Bees in a Swarm.—The number of bees going with a swarm, Editor Root guesses, may be 75 percent of the whole, leaving 25 percent in the old hive. Wonder if others would make the same guess?

Returning Bees to Cellar After a Flight.—This in early spring has been understood to be a thing not to be commended. Possibly it may, after all, be one of those things as to which traditions are not reliable. At least it looks a little that way, according to the following item from *Gleanings in Bee-Culture* for April 15:

The bees in our bee-cellars have wintered nicely. The larger portion, as will be remembered, were in our home cellar, comprising nearly 300 colonies, and these, many of them, two and three frame nuclei; and yet they came out bright and healthy. One or two nuclei succumbed, but they were very weak.

During the last days of March there was considerable roaring among the bees, and it seemed necessary to quiet them down. Mr. Wardell finally suggested taking them out on the first warm day and giving them a flight, and then returning them. This was done with the bees in both cellars, and the results were eminently satisfactory. In our first test, we took out 25 or 30 colonies that were quite uneasy. We gave them a flight, and put them back, and, presto! they were quiet, while those that had not had a flight were uneasy as before. These were put out, and they, too, became contented.

I believe it has been stated that it is a waste of time and labor to give indoor bees a flight during mid-winter or early spring; but our own experience does not seem to prove the statement.

When we put the bees out in the first place we numbered and marked their location, so that in a month hence, when they are put out again, they will go back in exactly the same places.

Whipping Up the Queen.—One of the things upon which the novice in bee-keeping seizes with especial eagerness is the idea that by some special measures he may secure more rapid laying on the part of the queen, and so have an extra number of laborers when the harvest is ready. One way in which he attempts this is by what is called stimulative feeding, or feeding a certain amount every day, or every other day, so as to imitate to a certain extent a natural flow. If this is done at a time when the weather is cold, wet, and windy, it will almost certainly result in loss, for it will start the bees to flying out. If done at a time when the weather is warm and bees are flying all day long, doing at least a little

at gathering natural stores, it can hardly make any increase in the queen's laying, for such times the queen is already laying freely. If at a time when the weather is continuously warm, yet no flowers yielding, the dearth continuing sufficiently long to stop the queen's laying, the feeding may be a good thing.

Another way by which increased laying is sought is by making such change in the position of the brood-combs as to bring an additional number of empty cells within the brood-nest, usually called brood-spreading. This matter is quite fully discussed by Mr. Doolittle on page 247. The fear is that the beginner will pay too little heed to the dangers mentioned.

Still another way advocated by some is to reverse the position of the hive and all its contents, making the front and back ends of the hive change places. The reasoning is that bees naturally prefer to have their brood close to the entrance and the honey at the back end, so when the hive is reversed the bees hasten to bring the brood again to the front. In this plan there seems little chance for doing harm.

The probability is that beginners have an exaggerated estimate in nine cases out of ten of the gain that can be made by any interference. Many seem to have an idea that brood-spreading and stimulative feeding will in all cases result in an increase of brood, whereas either one may have the opposite effect. Even in the hands of the most experienced it is not certain that gain can be made in every case. What possible gain can be made in a case in which a colony is carrying already all the brood it can cover? Before whipping up your queen make sure that she is not already doing her best.

Maeterlinck's Book seems to be judged quite differently by different minds, both in this country and abroad. By some it seems to be considered as rather a bad book, by others as of mixed quality, and by still others as of faultless beauty. This appears in the *American Bee-Keeper*:

There are one or two among us to whom the beauties of Maeterlinck's delightful book are overshadowed by the trifling inaccuracies which are but the imprint of humanity.

And this in the *British Bee Journal*:

I should say that the greater portion of his figures are open to criticism, and this is a circumstance the more to be regretted, inasmuch as the work is one that is evidently obtaining a wide general circulation. What, for instance, is to be said of statements that convey such ideas as the following?

1. That the common size of swarms is from 12 pounds to 14 pounds (page 38).
2. That bees on swarming commonly leave

behind them a compact mass of honey and pollen reaching about 1 cwt. (page 39).

3. That drones visit and sleep on the nearest flowers (page 287).

4. That the queen bears in her flanks close on two million lives (page 84), etc.

Such statements might be multiplied almost indefinitely, but I think the wildest flight of poetical license, or whatever it may be, is reached in the following, with which I conclude, although I can not pretend to be quite certain of the author's precise meaning:

".....immense fields of flowers that have been visited daily one or two thousand times" (page 293). Does M. Maeterlinck really mean to saddle our poor little servant with the task of a laborious journey during every half-minute of a long summer's day?

Sulphur Smoke and Black Brood.—

In European countries there are frequent reports of foul brood and kindred diseases being cured with drugs, but in this country little reliance is placed upon anything of the kind. It has been suggested that across the water bees are more nearly immune to the disease because it has existed there for a longer time, and so drugs that are not effective here may succeed there. In *Gleanings in Bee-Culture* T. F. Bingham reports what may be a possible cure with the fumes of sulphur. He says:

Mr. Ilesherington was at my place, and I wished to show him my first buckwheat colony. When opening it we found a non-laying queen and a few black, dead larvae scattered at intervals among the empty cells when, evidently, the brood had just matured. Mr. Ilesherington said there was no doubt that the dead brood was such as had made trouble in eastern New York. It filled the description given in the journals so far as we could decide. I told him I would try an experiment, and watch results. I gave them an unfertile queen five days old; and when darkness came I smoked the bees thoroughly at the entrance and at the top of the hive, and at the two joints between, with pure sulphur smoke. The following night I gave them the same treatment, but stopped the exits from the hive and compelled the bees to stay awhile. Just as the young queen had begun to lay, Mr. H. was again at my place, and, of course, we examined the first prime buckwheat swarm to see if the combs had still in them evidence of disease. Nothing could have been cleaner or in better order. The question, so far as cleaning out the few dead larvae was a factor, was complete. One factor, however, remained; viz., would the disorder develop again? I kept watch of the brood, and nothing could have been finer or more abundant. The queen laid abundantly till the flowers failed, and no signs of weakness or dead brood appeared.

The query will naturally arise, "Was the sulphur smoke the cause of the change?" The reason I have given this experiment publicity is because I am not likely to have an opportunity to test the experiment again; and while I do not like to say much, based on a single experiment, others may find it of value.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 277.)

It was decided that the secretary be authorized to send the necessary amount to the General Manager of the National Bee-Keepers' Association to pay the dues for all the members of the Chicago Bee-Keepers' Association.

THE ILLINOIS PURE FOOD COMMISSION.

Mr. Patterson—The bee-question is certainly a new subject to me. I remember when I was a boy on the farm I had a little experience I never forgot. The only bee-factory I have visited during my time in office was yesterday, at Mr. Wheeler's place, and he entertained me very well on the subject of bees. I heard a good deal of talk from him on foul brood and other matters pertaining to bees. It seems to me that the Pure Food Commission and the bee-people of Illinois should work hand in hand in all these matters. That is, there is no organization in my opinion that ought to be so thoroughly organized for the purity of goods as the bee-people, because if anybody is producing pure goods it is certainly the bee-people, and the only question that we had up before the commission was a car-load of extracted honey coming from the West, and we found it adulterated. It seems to me all the bee-people of Illinois would certainly be in favor of and willing that honey from other States should be tested, that in our own State not being adulterated, because adulteration would naturally decrease the production of honey. I want to say right now for the Pure Food Commission, that we would be very glad to come in contact with all of the bee-people. I intend to visit a few of the bee-keepers, but will not have much time now to do that, but I am so glad to see so many interested, I didn't have any idea there were so many bee-people in Illinois. As I said before, the only one I ran across was out at Plano.

Dr. Miller—There is another one besides those here! [Laughter.]

Mr. Patterson—It is certainly a great subject, and it is a great industry. Nobody likes honey, and pure honey, as well as I do, and I think if you all stand together as you are here, eventually honey will go up. I understand that honey is lower now in price than it has been for years and I don't see any other reason for it than the adulteration of honey. There has been a little mistake in the press upon the interview of our Commissioner about honey. You know as well as I do, that a reporter always endeavors to make a startling article on almost any subject of adulteration, and they say what they please. Some one said to me, "I saw a cartoon in one of the papers of one of the men out in the country adulterating comb honey." We can't stop those things. We are trying to bring about an honest condition, and that is surely your purpose. I will endeavor to have our chemist come and speak to you tonight. I assure you any question you ask the Commission will be welcomed, and we would be very glad to consult with you on any subject pertaining to honey.

Mr. Dunn—Can you, as an officer, visit the glucose factories?

Mr. Patterson—Yes, sir. That's another matter. There was some little honey in our last report that we found adulterated. One man I talked to had bees near the glucose factory, and he claimed they brought the glucose into the hives and thus naturally adulterated the honey. I don't know whether that is so or not, as I am not able to say. The law gives us the right to visit anything in the way of products, eatables or drink, in Illinois. I want each and every one of you who knows some one who is adulterating honey, and selling it as pure honey, to notify our Commission, and we will be glad to look into the matter thoroughly. We hope to have your co-operation in all this work. I thank you.

Mr. Dunn—Mr. Patterson, have you assistants to canvass this city thoroughly?

Mr. Patterson—We have only six inspectors for the entire State, and we have a chemist and his assistant, and a Commissioner, and his assistant.

Mr. Dunn—Have you force enough to be able to inspect this city thoroughly?

Mr. Patterson—Now, you know our six inspectors cover our entire State, and we have a good many complaints from different points, about different products, and when a complaint is filed we look it up. I am sorry we don't have more inspectors.

Mr. Dunn—What action can this organization take to give you the force required?

Mr. Patterson—Anything upon the line of this investigation, or to increase our force, would be a great help to us.

Mr. Dunn—Does that come from Congress?

Mr. Patterson—From the State.

Mr. Dunn—How many assistants would permit you to canvass it thoroughly?

Mr. Patterson—I think an inspector for every Congressional District would cover very thoroughly throughout Illinois. I know as we are now we are busy night and day with every inspector we have. We have so many complaints, and our chemists have so much to do, we can't possibly cover the ground.

Dr. Miller—I think we will always agree with the statement of Mr. Patterson that bee-keepers do not desire adulteration. There has been enough of it to injure us very, very seriously, and there is another thing which runs side by side with that, and that is, to get the public to believe that there is adulteration. It doesn't make any difference whether it is true or not, when you get the public to believe there is adulteration, you have injured the sale of our product to an extent that cannot be gotten over for a long time.

Pres. York—Are you talking about comb or extracted honey?

Dr. Miller—I don't care what it is, whether comb or extracted. Here is the condition that faces us right now. Here is a statement made in a reputable paper that one of the Pure Food Commissioners has said that there is scarcely any genuine comb honey; that it is nearly all adulterated, and that unless you see the brown coloring on the comb—what we bee-keepers call travel-stain—it is not pure! I am not bothering about what foundation they had for that, but I do know the result of what Prof. Wiley did years ago. I believe we have the impression now that the Commissioners are the ones that can do a great deal to help us as bee-keepers, and I believe that they will as gentlemen, do this, for if there has been anything said by them to give any foundation for the statement made in the papers, I believe they will, over their own signatures, in the same public manner in which the statement was made, say there is no foundation for it.

Mr. Patterson—I know positively we never made such a statement. The reporters, as a rule, use their own language and say a great many things that should not be said. Of course, this adulteration would come under the observation of our chemist, and that there was certainly some adulteration, especially in that one sample, and a reporter naturally takes that one and says all. You know the Commissioner, and no man of any sense, would say that honey was adulterated, or any other product, because he would be saying something that was not true. I would say that Commissioner Jones would be very glad to confer with you, or a committee, upon the subject. He said to me he never made such a statement, and he is particularly interested in the bee-interests, as he lives in a part of the country where there is a good deal of bee-raising. We are trying to bring about a condition that will meet with the approval of everybody that is honest and fair, and have put upon the market that which is labeled. If adulterated, mark it adulterated; if pure, mark it pure; and if they say it is pure let them invite inspection.

Dr. Miller—I believe Mr. Jones is a friend of the bee-keepers, and desires nothing but what is right. There is no need of any consultation of any committee. There is a statement made that is either true or not. Now, if it is not true, and there is no foundation for it, Mr. Jones, as our friend, will, over his signature, say that there is a slander, and we, I think, are entitled to just that much. If there was any foundation for it, that foundation was wrong. If anything was said that ought not to have been said I have confidence in Mr. Jones as a gentleman, to believe that he will withdraw whatever he may have said. We must remember that every man doesn't know as much about the business as you and I who have spent years at it; and a Food Commissioner might make a mistake. He may have said something that he wasn't authorized to say. As a gentleman he will withdraw that. That much I do believe we ought to ask. If some statement of that kind is not made I shall be disappointed in Mr. Jones. That should be said, and very plainly, and in as public a way as the statement was made in the papers. We are entitled to that much, and I believe we will get it.

Mr. Dunn—I move, as the sense of this convention, that Mr. Jones and his assistants be requested to state the facts, the truth, and nothing but the truth, for publication and correction. Mr. Jones can't take cognizance of anything that takes place in the newspapers, but we want an authentic report from him that those statements are incorrect so far as they go. He should give it currency all over this State. We only want him to give us the truth. Let him state what are the facts. Let him speak broadly what is pure honey. Give the public to understand what pure honey is. I move, as the sense of this meet, that we request Mr. Jones on behalf of the honest men interested in honey-production to state the broad facts for the information of the public.

Dr. Miller—Whilst I said what I did, I believe I am opposed to that motion, as I believe Mr. Jones is a gentleman, and I believe it isn't necessary. I believe we will get the right thing. Mr. Jones wants, I believe, to do what is right in this matter, if it were necessary to call his attention to it. He knows of it. The thing is fully known, and if he needs any instruction upon it, it is simply to tell him this: Here we have been for years offering premiums for the whitest and best honey that can be produced, and then you come in and tell us it is adulterated. I don't think it is necessary to pass that motion. I believe I would rather let him do something on his own hook.

Mr. Dunn—I want to give him some reason for it. We ask him as an organization, to state the facts for the public.

Mr. Moore—One thing mentioned in Mr. Patterson's address seems to me ought to be further taken up. This question of adulterating comb honey will not down. There is no such thing as artificial comb honey. It is impossible. It was put in this way, as to the question of glucose being carried into the combs by the bees. That I understand cannot be done. It is impossible and impracticable. Mr. Grabbe, one of the best known bee-keepers, said he was hired to make comb honey out of glucose and other materials, and he made other experiments on 300 colonies of bees, and the result was their entire death and destruction—poisoning by the glucose, lack of sweetness, or lack of food for the bees. I am satisfied myself that it cannot be made a success, whether it is made one way or the other, by the aid of the bee or not. I am perfectly clear, and I think the Pure Food Commissioners ought to know that artificial comb honey is out of the question altogether. Comb foundation is an article of industry: tons of it are made and sold by some of our best known bee-men. Some think if you can make comb foundation you can make the complete comb. It simply boiled down to this: It cannot be done; it isn't done. One man might go to work and make something that would be a sort of counterfeit, and that which is done and found in the market is altogether a farce.

Mr. Dunn—We are speaking for the State of Illinois and county of Cook, and we have a right to speak by the organization en masse, because they will require Mr. Jones to reply. I want something practical, and I want the response as coming at the call of this Association, that he shall put in black and white what is the truth.

Mr. Moore—At the time Mr. Jones was before our Association, a year or so ago, he was heartily in favor of all our work, and called upon us to co-operate with him, and it seems to me that this is a little in the light of "You don't know your business." I am afraid it won't be taken well.

Prof. Eaton—(Chemist of the Pure Food Commission)—It will only be about half a month before our report is out covering the work of the entire year in which every sample of honey we have taken in the market will be reported on, and full analysis given of pure and adulterated, and at that time I will probably give a resume of the work of both this year and previous years, and the work done for the Chicago Bee-Keepers' Association, or rather, the National Association. Most of you know that Mr. Jones will be only too willing to do anything in his power to correct the wrong idea that has gone out through the newspaper interview. These newspaper reports are not very accurate.

Pres. York—There are some reporters in the room, and they will please take notice of what is being said!

Prof. Eaton—It would be a hardship on anybody, to be held strictly responsible for everything a newspaper reporter says. To be called to task in this way would not be very pleasant, and I hardly think it is due Mr. Jones, particularly considering what he has done for the bee-keepers' association, and the interest he has always taken in pure honey. I have no doubt at all that if you go to him in an official capacity and present the matter to him that he will take every step he can to correct this matter.

Mr. Dunn—I trust that no gentleman in this audience will suppose that I want to reflect on the Commissioner. Mr. Jones has allowed this thing to go uncontradicted. It is the duty of

this Association to bring that to his notice. It is the duty of this organization to report, and they should appoint a committee to-day to answer that article also. Let it go forth from this Association also that no one wants to reflect on Mr. Jones. On the contrary, I feel friendly toward him. They must not be so thin-skinned as to take offense.

Mr. Horstmann—My idea was to go at Mr. Jones a little easy. I believe if we left it in the hands of Dr. Miller it would be settled. I have every confidence in Dr. Miller settling it to the entire satisfaction of us all.

It was moved and seconded that the whole matter be indefinitely postponed.

Pres. York—I have no doubt the representatives of the Commissioner who are here will report this all right. It may have the desired effect, anyway.

Mr. Dadant—I would like to speak to Prof. Eaton, the chemist. When there is any adulteration we want to prove it. We don't want our friends to hurt us in their names, when it is said here: "Commissioner Jones says it is comparatively easy for a purchaser to detect the imposition. 'Genuine honey,' he declared, 'has brown coloring around the cells. Glucose honey is perfectly white. The purchaser can detect the fraud by this simple rule.'" If he did say it, he certainly will correct it. We want to warn him of the mistake of Prof. Wiley, of the United States Chemistry Department, who did us the greatest harm in the invention of the story that people could make comb, put the honey in it, and seal it over. He called it "a scientific pleasantry." But it prevented the sale of pure honey. Since the story was invented and reported all over the United States, hundred of persons have come to our comb foundation factory and asked to see the honey put into cells and sealed over. Of course they go home very much disappointed. We make comb foundation and want to make it as near to the bee-comb as we can. I have told a great many people, something that has not come to the thought of many of you—an answer for you to give to those who say comb honey is manufactured. In this age of progress you don't know what they will invent to-morrow. There are no two leaves in the woods that are alike, and no two combs of honey are alike, but if man made comb they would be alike. You might have two or three different patterns, but they would be alike. Remember that, and tell it to your friends who say you can manufacture comb honey.

Mr. Dunn—I move you now as the sense of this meeting that we ask the Legislature, through our representatives all over the State, to furnish the additional help required by these gentlemen—one inspector for each congressional district.

Dr. Miller—I would like to ask, either Mr. Patterson or Prof. Eaton, whether that, in their judgment, is a desirable thing.

Prof. Eaton—Well, I don't know but what it might be a desirable thing if the other branches of the department were placed on an equality with the inspection. If you expect to keep as many inspectors as that busy, you will have to get more than one chemist.

Mr. Dunn—I move we amend the motion by adding additional chemists.

Dr. Miller—Then I would like to ask this question, in order that we move intelligently, because the Pure Food Commission understand this more fully than any of us. I would like to know whether Prof. Eaton can give us the view of the Commission as to the desirability of having these.

Prof. Eaton—I have not talked with Commissioner Jones upon the matter. You heard what Mr. Patterson had to say as assistant commissioner. I would say there is no State in the Union that has more inspectors than the State of Illinois. Minnesota has but six, Wisconsin but two or three, and one of those in the dairy department alone; New York has vinegar inspectors but not more than six all told. In fact, six inspectors is the largest number in the food commission to my knowledge in any State. Six inspectors, if they inspect nothing but food all the time, and doing nothing else but buying samples for analysis, could keep many more than that number of chemists busy, because it takes much less time to buy sample of food than it does to analyze them. Those are my own views. I can't speak for Commissioner Jones. Inspectors can do other things. They act as detectives. They can visit creameries and apiaries. It may be that more inspectors than six would be desirable.

Dr. Miller—That being the fact, and I suppose it is, that Illinois is up to all other States in their force?

Prof. Eaton—We haven't as many chemists, but we have as many inspectors as any other State.

Dr. Miller—There is then just this little danger in the matter. While it might be a very desirable thing to have

more, you know how the legislature is. If they asked, the request is not likely to be granted. Now you are asking what isn't done in any other State. Then we are only weakening our chances for getting something else we might ask them for. I don't know, possibly it may be all right, but unless we are pretty sure of having our request granted, we better not make any.

Mr. Dunn—I predicated the resolution on the statement he gave us. He said they could be used, that they didn't have force enough. The mere fact that other States are not doing their duty is no reason why Illinois should not. We all have our representatives. I don't see any objection to asking it, even if we are refused, even if we can't get so much more additional help.

Mr. Sylvester—Not that we say anything to the legislature, but labor with our representatives to ask for it. There could be no harm in that.

Dr. Miller—Let us understand which way it is.

Mr. Dunn—I want it both ways.

Dr. Miller—That this body as an organization should ask the legislature.

Mr. Dunn—And also that we see our individual representatives and get them to work for us.

The motion was then voted upon and carried.

(Continued next week.)

Length of the Bee's Tongue vs. Hustle.

BY "OLD GRIMES."

THIS discussion of late about improving the length of bees' tongues is not devoid of interest to "Old Grimes." And the boys and I have had several warm discussions over the matter. The boys, like all boys, are inclined to start out after new things. I have held them in on quite a number of things that have in time proved the Old Man's wisdom. But in this long-tongue business there is some danger that the whole crowd will stampede after it.

When I was a boy I was taught to have respect for David Crockett's maxim, "Be sure you are right, then go ahead." Now there are no indications in sight that the long-tongue fellows are right, and the indications are mighty slim for coming in sight for many years.

To me, the little bee seems to be a well-balanced insect, and it is, we might say, a little air-ship. Now, to increase one part without increasing the other parts, the bee loses its balance and more is lost than gained. Let us look into the matter a little.

There have been several articles recently in various bee-periodicals by Simpson, Getaz, and Miller of Rhode Island, all of whom are more or less versed in the science of breeding of animals, and none of these writers seem to be in haste to demonstrate that the long tongue is a fixed or desirable feature.

These gentlemen cite instances where in-breeding has produced variations, but every time it is at the expense of some other feature, and, if carried too far, results in diseased conditions. Witness the silk-worm and the dire financial results following from a too scientific breeding.

Our domestic animals and fowls show much variation from a wild to a domestic state. The hen in the wild state has more wings and less eggs, but by civilizing it gains in eggs and loses in wings.

The good, docile work-horse is a good-enough animal for most of us, but bred for racing he loses his sturdy qualities and becomes what we might call a "dude" in horse-flesh.

Examples might be multiplied, but these are enough to show without much scientific reasoning, that to breed for one good point many others are sacrificed.

In the bee the breeding for long tongues may result in the loss of wing-power, or some other greater weakness. And I find myself inquiring as to how far, and how many of the recent diseases of the bees can be traced to our modern methods of breeding.

It is a fact that when I was a boy my grandpa kept bees in the log-gum; they had their own sweet will about breeding, and there were no diseases in those days.

The modern diseases have come trooping along, one after

another, and the end is not yet, and all since the breeding of queens commenced. Has not the breeding for certain qualities, or the mixing of races, weakened the bee in certain qualities, or torn down its defense to diseases?

Our enthusiastic advocates of long tongues cite the gathering honey from red clover as an indication of their value, but there is no positive demonstration that such is the fact. I have seen black bees work quite freely upon red clover. This red-clover work is always done in hot weather and under conditions when honey is secreted rapidly. The nectar wells up in the flower-tube to an unusual height, and the hustling bee, either long or short tongued, soon finds it out.

There are a few points in relation to bees that can be demonstrated any day in the working season, and one of them is that the hustling colony is the one that gets the honey. And there are various ways to make them hustle without tampering with the queen. The moving of several colonies to a new location will give them this desirable feature, provided, of course, that there is honey to gather. All know that a natural swarm is a greater hustler than an artificial one, but still an artificial swarm can be made to hustle if it is given a large amount of brood.

It is the great army of bees that load the hive with honey, and here is where the most prolific queen is of the greatest service, for a queen that lays an abundance of eggs will surely preside over a hustling colony.

It is only a step from a hustling colony to a hustling apiary. Bees in an apiary of weak colonies do not go far for honey. I doubt if even a few strong colonies send their bees far afield. But a large and strong apiary—what an inspiring roar is borne to your ears upon the morning breeze! They will find honey if it is 4, 5 and even 7 miles away.

"Old Grimes" would not disparage experiments; they are legitimate in any line of work. But let us experiment until we demonstrate, then give it to the world.

Marconi came over quietly to Newfoundland and set up his tickers; when he recognized the ticks from across the ocean he had something to demonstrate.

The long tongues may just now have the innings on paper, but the hustlers are still on deck for profitable crops of honey.

Perhaps I will tell you some time how to get a big hustle into a small apiary.

[If "Old Grimes" is going to tell how to get that "hustle into a whole apiary," he'll have to "get a hustle on" himself soon, else it will be of no value this season. We are ready to furnish the paper on which to put it first!—Editor.]

The Use of Smoke in Controlling Bees.

BY T. F. BINGHAM.

I note this on page 123, "By all means avoid the use of smoke as much as possible."

The above remark was undoubtedly made from habit, not from any evidence demonstrating its reasonableness. It is of no consequence except as it conveys an answer to a query, and gives no reason for the answer. The fact of bees filling their sacks with honey and emptying them when they please does not imply that Nature has made a mistake in implanting in the hive-bee the instinct to fill said sacks when frightened, or from flowers. This instinct is all—yes, the only one on which modern or civilized bee-keeping is rendered possible.

Fright applies to all insects alike and in common. The rude log-cabin of the pioneer has its kettle of smoking chips to keep away the troublesome mosquitoes and other winged insects from its door; but to the hive-bees are given this special instinct to cluster, to huddle, to protect their home, and fill their honey-bags against a possible day of trouble.

I do not write about this subject because it is new, but because it is so oft-repeated without the shadow of evidence of proof. It seems handed down as superstitions usually are.

It has cost the lives of people and horses, and made the bee-keepers' union a necessity among superstitious bee-keepers.

The Creator made no mistake in fixing up the pale, hatching worker with all the instincts for its own and its colony's preservation without experience and choice of methods.

We say the reason why the bees do this and that—when no fact is so patent as the one that bees know as much when they gnaw open the cap that has protected in their

cells as they ever will, of what is of value to them individually or collectively.

Bee-keepers all over the land have smoked bees in and out of hives with all sorts of fuel—sulphur, tobacco, cotton-wood, puff-ball, etc.—and have never said that the bees were injured by any of these materials. Of course, every one will lift up the voice in holy horror at the sulphur smoke for bees, but sulphur smoke will not kill bees any more than tobacco; neither of them hurt bees if allowed a few hours exposure to fresh air. The fresh air restores them and smoke does them no enduring injury.

It will be well for all bee-keepers to bear in mind that statements are frequently made by bee-keepers more destitute of facts to prove them than much of the newspaper-talk we hear so much about. The fallacy of smoke consists in the lack of enough of it at all times. In an emergency a bee-keeper has no time to light matches.

In the handling of bees one may not at all times need to smoke them. But I would rather start out hunting without a gun than go among my bees without a cloud of smoke around, and within quick and easy reach.

If it was well understood by everybody that bees would not sting or proffer an attack away from their near-by home, or unless pinched, one senseless superstition would have disappeared, and happiness not common with inexperienced people would be realized.

Bees that are to be moved will fill their sacks without smoke just as if smoked. One has to consult his own convenience.

He will find smoke, reasonably used, will save the lives of individual bees and be of great convenience.

Men have shown their vanity and ego in words like this: "My bees never sting me; I can take them by the double handful. Bees are all right, they need to know their master." The safety of the community lies in knowing that the bees do not know anybody or anything, and that if proper care is taken of them, and you have no superstitious neighbors, you will also have no trouble.

Clare Co., Mich.

Rapid Increase of Colonies in the Spring.

BY G. M. DOOLITTLE.

THE past winter has been very serious with us, and from my correspondence I find it also has been so in some other parts of the country, so there has been quite a loss of bees. For this reason I am receiving enquiries regarding the feasibility of a rapid increase of the colonies remaining, in order that the combs from the lost colonies may be stocked with bees again, as quickly as possible. As it is quite a task to give a full answer to a score or more of people by private correspondence, I have told these that I would give an article in the American Bee Journal on the subject, and have referred them to this article, which I trust will appear in ample time for their use.

After trying everything I have ever heard of for a rapid increase of colonies, I prefer the nucleus-box plan to any other, for the purpose. To use this building-up process, all want one or more boxes similar to one of the shipping-cases used in sending section honey to market, only having wire-cloth sides in place of glass, and a hole in the top which will admit a funnel large enough to shake the bees from the frames down through, the same as is used in putting up bees by the pound. This large hole in the box should have something like a door to close it with easily, and one of the wire-cloth sides should be tacked to small wooden strips, like a slate frame, and thus made easily removable. All about how to make these "nucleus boxes" has been given by myself in back numbers of our bee-papers, but the above "brief" will enable any one to make it, if not able to turn readily to one of the former articles.

As early in the spring as you can do so without loss by cold spells, begin to stimulate the very strongest colonies you happen to have, by spreading the brood and feeding, as I have given on page 246, so that one or more of these colonies may swarm early, thus giving you queen-cells; or, what is still better, have these strong colonies build queen-cells by the plan given in my book, "Scientific Queen-Rearing," so that you can have plenty of queen-cells to use as you wish them, if you prefer to rear your queens to purchasing them. Having the queen-cells nearly mature, or having queens on hand by purchase or otherwise, go to any of your colonies that can spare bees without damaging their building up as fast as you desire, and take out two frames having to the amount of one-half pound of bees on

them, being sure the old queen is not on these combs. Set them down in an empty hive, or on the outside somewhere, and tap gently on them so as to cause the bees to fill themselves with honey; and as soon as they are filled shake them down through the funnel into the box, removing the funnel and closing the door or hole.

While the bees are filling themselves with honey, you can go to other colonies and take out the frames of bees from them, and thus keep things moving right along, instead of waiting as you would if there is only one colony in the apiary.

Having the bees in the box, return the combs of brood to their old place in the hive, marking the one having the most emerging brood, so you can get it in a moment when wanted. Now set the boxes of bees in a cool place, where there is little light that will come to them, and leave them till near night—just time enough so you can finish your work before it becomes so dark you cannot see.

At the right time—a little after sundown—go to the hive from which you took the bees, take the marked comb, shaking the bees which are on it in front of the entrance, and put a frame of comb from which the bees have died, in its place. Now take the comb of brood and a frame of honey, left from the dead colonies, and place them in a hive where you wish a colony to stand, putting in a division-board so as to make a small hive for the two combs. Now go to the hive having queen-cells, and, taking one of them fit it into the comb having brood, placing it near or at the upper edge of the brood, where it will be warmest; next close the entrance to the hive; get the box of bees, and put it with the funnel-hole next to the combs, then open the door over the hole, and if the box is within three-eighths of an inch of the brood, the bees will immediately run out of the box on the combs.

As soon as they begin to run out, close the hive, and the work is done till the next morning, when you will open an entrance large enough for three or four bees to pass at a time, on the opposite side from where the two combs stand. Then toward night of the same day you will take out the box and adjust the division-board, when you have a nice little swarm or nucleus started in that hive.

As soon as the young queen from the cell given gets to laying, you are ready to insert the combs from the dead colonies till the hive is filled, giving the combs, one or two at a time, as fast as the bees can occupy them.

In the above I have given the way of making one little colony, and you can make as many and as often as you have colonies that can spare the bees, and have queen-cells to give them, using about half a pound of bees for each colony made during the month of June, one pound during July, and two pounds during August. Where we have plenty of combs to use, there should be no trouble in making ten colonies from one old one in the spring, if said colony wintered through fairly well, as I have repeatedly proven.

If you prefer to purchase queens, instead of rearing them, then you will proceed the same as above given, but instead of doing anything about putting the bees in the hive at night, you will place the queen in a provisioned cage, go to the box of bees, and, by setting it down suddenly on the floor, drop all of the bees to the bottom, quickly open the door and hang in the caged queen so the bottom of the cage nearly touches the top of the box, when the bees are left till the next morning, the hive fixed as before, less the queen-cell; and, instead of opening the funnel-hole for the bees to run out of it, the movable side is taken off, and the bees hived like a swarm, releasing the queen from the cage so she can go in with them.

In this way I have made hundreds of little colonies and nuclei, and there is nothing that pleases me anywhere nearly so well for the purpose as this. But, if any one thinks otherwise, then let the colonies left after a bad winter, swarm as fast as they will, and six days after a swarm issues from any hive, divide the old colony into nuclei, using two combs with bees, brood and a queen-cell to start a separate colony, and build up these nuclei with the combs not occupied with bees, the same as by the first plan, after the young queen is laying. In this way I have succeeded in making from five to six good colonies by fall from one good colony in the spring, and in good seasons obtained quite a little surplus from the new swarm.

Onondaga Co., N. Y.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

Association Notes

By EMERSON T. ABBOTT, St. Joseph, Missouri,
Gen. Mgr. of the National Bee-Keepers' Association.

Extracts from Letters.—"The writer begs to extend congratulations and sincere well wishes."—H. E. HILL, Editor American Bee-Keeper.

"Permit me to offer my hearty congratulations on your election to the office of General Manager of the National Bee-Keepers' Association. Mr. John Froliger, who is a member of the advisory board of this company, joins me in the same. We know that the affairs of the Association are in the proper hands. We wish you a successful term. If I can be of any service to you in the affairs of the Association in this city, do not hesitate to command."—FRED W. MUTH, of Ohio.

"Accept congratulations for your successorship to General Manager Secor. May success lie in your pathway."—F. W. HALL, of Iowa.

"I am glad to see that the Association has an energetic manager, and hope you will have the time to spare to keep its affairs in proper order. I should like to know where I can get information in regard to keeping bees on the public highway in the State of Illinois."—C. F. BENDER, of Illinois. Who can answer this question?

"I hope you will receive all the support necessary from the members of the Association, to lessen the duties of the office now imposed upon you. Co-operation we must have to maintain the honor and usefulness of the Association."—JOHN W. LYLE, of Nevada.

"In the earliest days of the Association I was a member, and now desire to take it up again."—L. A. PENNOYER, of Minnesota.

"If necessary to make an assessment of one or two dollars to fight this spraying-of-the-open-blossom business, my assessment will be ready any time you want it. That man Williams ought to be pulled out of the hole without any regard to the cost."—RALPH B. DAILEY, of New York.

The Important Thing just now engaging the attention of the General Manager is the subject of spraying fruit when in bloom. He had mailed to him a circular letter issued by William Stahl, in which is advocated spraying when in bloom. This circular gives the testimony of 15 or 20 people who say they have tested the matter. The General Manager wrote a letter to each of these persons, asking him for further information, and requesting him to explain fully why he thought it a good thing to spray when in bloom. Up to this time only two have replied. One of them shows clearly by what he says that he has been spraying blindly. The General Manager will have more to say about this in future notes. We quote an extract from another letter which will explain itself:

"Replying to yours of the 19th, I will say that three years ago I sprayed my fruit while in bloom, and I did think at that time that it benefited the trees. However, that was the first time, and, also, the last time I sprayed my trees while in bloom. Now, I do not intend to do it any more. I can not say if I am quoted correctly in Mr. Stahl's circular, as I have not seen one. I wrote him something about it at the time, but do not remember just what I said. However, I will say to you that I am too fond of *bees* to do anything to kill them."—E. CHAPPELL, SR., of Michigan.

Membership Dues still continue to come in, but there is yet room for many thousands more. Have you sent in your dollar? If not, do it now.

The Sweet-Clover Bill, in Ohio, is probably safely pigeon-holed for good, writes Secretary Mason. We congratulate our Ohio friends on their successful campaign against this bill. All that is needed is energetic work on the part of the bee-keepers of the United States, and in a short time the busy bee will be recognized as having some rights in law, as well as elsewhere.

Sweet Clover Bulletin.—The General Manager is in receipt of a letter from Prof. Frank Benton, in which he says:

"Your letter of April 19 [to the Secretary of Agriculture], in reference to the growing of sweet clover, has just been referred to me for reply. I went immediately to the Agrostologist, and, not finding him there, consulted with his first assistant regarding the issuance of a bulletin on sweet clover. He seems to think the subject might warrant something of the kind. I think that a candid discussion of the subject, giving, so far as possible, all phases of the matter, would place it in its right light, and our interests, as well as the farming public in general, would be benefited thereby. I shall see the Agrostologist himself, and endeavor to bring the matter to a point as soon as possible, and then report to you further."

The General Manager is very glad indeed to have the co-operation of Prof. Benton, and he wrote him at once to urge him to look after the matter, and do what he could to secure a fair and candid discussion of the subject by some government official, who will give both sides of the question. Prof. Benton is in a position to aid the bee-keepers in many ways, and we are glad to have his co-operation.

E. T. ABBOTT, *General Manager.*

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

ROBBER-BEES STINGING OTHER BEES.

One competent observer, S. T. Pettit, of Ontario, reports on the robber-bees. They sometimes sting the bees they are trying to rob, but quite rarely. Page 191.

QUOTING THE HONEY MARKET.

Anent page 95, it is easy to see that the dealer who buys honey outright, and also deals on commission, and also furnishes quotations for the bee-papers, is *tempted* to quote a little too low, whether he yields to the temptation or not. Furthermore, it is easy to see that the rascal who deliberately intends to skin his consignors alive, is tempted (if that's a proper word for him and Satan) to quote prices a good deal too high.

Low quotation? Honest coon.
Scoundrel—prices to the moon.

EVERYBODY KEEPING BEES.

Yes, Mr. Wisconsin, we are not anxious to have our neighbors dip into keeping bees; but if we refuse to sell them any it will stimulate their determination to have some—as well as lower our own standing. Offer them swarms the next swarming season, they to send you the hives to put them in. Let the rates offered be reasonable. The chances are that they will not actually send the hives. Page 196.

PUTTING UP THIN HONEY.

I expect (but if you're a rogue, and want to do it, don't read this) that if thin honey be heated and put in air-tight condition before it begins to ferment, the fermentation will then be slight or lacking until the package is opened. But I don't believe a wooden barrel can be depended upon for any such results. Page 197.

CLIPPING THE WINGS OF QUEENS.

That's a good record, Miss Wilson, if with all the queens you have clipped in a large apiary for years you have never found a queen with 5½ legs as a sequel. Still, I'll supplement your warning a little. The queen being secured, let the beginner experiment a little before actually clipping. Notice when she is touched with the scissors how quick as a flash she will put a leg between the blades and take it out again. Do you soberly think your collocation of things is safe enough to clip and get away without danger? If yes, then go ahead. Page 197.

CURING FOUL BROOD WITH ROSEMARY.

Yes, the rosemary method of curing foul brood is an easy one (15 to 20 drops dropped into the hive from time to time), and if we only knew just *when* such little help would

be enough, and just when the conditions positively demanded something stronger, it might be a blessing. As it is, I fear ten will waste time, and let the blaze get unnecessarily big, for each one that will succeed in putting the blaze out. Page 198.

REMOVING BEES FROM THE CELLAR.

About removing bees from the cellar in the spring, I trust that readers will at least not fail to notice that Dr. Miller has no trouble at all, where many of the brethren have serious troubles indeed. This for many years. Must be some reason—and it's queer if his success cannot be duplicated. Serious nuisance to have to secure 10 or 12 good days to put out when one would suffice; and even then the first ones get on their robbing clothes and rob the last ones. I winter bees outdoors, and had no recent experience in putting out—and my surprise is that he insists on sunshine instead of a mildly cloudy, warm day. Of course, he's right rather than I who does not know anything about it. May it be that bees once out stay out until they feel dry, and that that time arrives very much quicker in sunshine? Page 200.

VARIOUS "AFTERTHOUGHTS."

A locality in New York where there are no Italian bees! Who'd a-thought it? Page 200.

S. E. Miller did well to extemporize a double-walled melter for \$1.90. Page 203.

Dried apples and water to keep the slender queen from getting through the zinc—worth more than the carrier-pigeon suggestion, Mr. Alpaugh. Make the pigeon eat the queen first; then she'll go all right. Page 204.

Too much divergence of the doctors about the maximum of dead bees from 100 colonies—4 quarts or 2 bushels. Page 206.

Yes, have several wise fellows measure tongues from the same colony and see how they tally. Page 206.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

A Reporter's Error.

Are you quoted correctly in the convention report on page 245, second paragraph, right hand column, where they made you say? "I built a cellar purposely to winter bees, 36x40 feet. I don't use it at all now." I supposed you always wintered your bees in the cellar.

PENNSYLVANIA.

ANSWER.—No, I don't know whether the reporter, the printer's devil, or some other person is to blame for the tangle, but the two paragraphs in that second column credited to me were spoken by some one else.

Getting Bees to Work in the Sections.

I would like to know the best method to follow to get bees to work in sections. CALIFORNIA.

ANSWER.—Usually there is no great trouble if conditions are favorable. The sections should, of course, be easy of access, preferably directly over the brood-nest, and as soon as there is any surplus to store the bees are likely to store it. Remember, however, that it is only the surplus that will be stored in the sections, and as long as there is plenty of room to store honey in the brood-chamber it cannot properly be called surplus.

There are, however, times—perhaps it would be better to say there are bees—which will continue to crowd honey into the brood-nest, when in all reason it ought to be putting it in the super. It will help very much to make them change their minds if you will give them a super filled with drawn-out comb. Even a single "bait"-section—that is, a section containing comb more or less drawn out, either with or without honey in the bait—will have the effect to hasten the work in nearly every case. In a season of failure I have

had many a case in which the bait was filled and sealed and not a drop of honey in another section in the super. In some cases a single bait may have the effect to start the bees so much sooner that it will make all the difference between swarming and not swarming. It would take a good deal of money to induce me to put on supers without having at least one bait in the first super given to each colony.

Another way recommended by some is to take a super or a section, bees and all, from a colony that is working well at storing, and give it to the balky colony.

Building a Bee-Cellar.

1. On account of heavy winter losses, caused by outdoor wintering of my bees, I have decided to build a cellar which I wish to hold 100 to 125 colonies without crowding. About what should be the length and width? The height will be 6½ to 7 feet. I shall probably use the Danzenbaker hive.

2. Which would you prefer to use for the walls, brick or stone? ILLINOIS.

ANSWERS.—1. A cellar 6½ feet high to hold 125 colonies should be about 14 feet square, inside measure, or 12x15, or 10x19.

2. I don't know. If there is no trouble about keeping it warm enough, perhaps the brick might be better, for brick being mere porous would allow more air to pass through the wall.

Changing Langstroth to Danzenbaker Hives.

1. I have had a few 10-frame Langstroth hives, and desire comb honey. As I think the 10-frame hive too large, I am thinking of cutting down the hives to about the size of the Danzenbaker, and using the Danzenbaker supers. Do you approve of the plan?

2. Will it pay to buy clover honey (extracted) and feed it to the bees in the month of August (when it is very hot and no honey coming in), thus turning it into comb honey for which I can get 16 cents per pound? I have to pay 8 cents for the extracted honey.

3. Candidly, what do you think of the Danzenbaker hive for comb honey? MINNESOTA.

ANSWERS.—1. Better go slow about changing from 10 to 8 frame hives until you know by some trial that 8 frames will be better for you. Moreover, are not your 10-frame Langstroths already the right size for Danzenbaker supers?

2. I don't believe it will. But you can decide by trying it with one colony.

3. The only experience I have is with two hives, and that did not decide me that I would gain anything by changing from dovetailed hives. The claims made for it by others are so strong that I may give it further trial.

Sweet Clover Honey—Other Questions.

1. Does not sweet clover honey taste very rank? A year ago last summer I got very little honey, as basswood was a failure, and there was considerable sweet clover around, the honey was very strong and I laid it to the sweet clover, but last year my honey was fine in flavor.

2. How old do bees have to be before they become field-workers? Do they act as nurses a while? Do certain bees stand guard, and do nothing more?

3. Which are the best comb-makers, young or old ones? 4. Is not the wax sweat through the bees after they gorge themselves with honey? They can't make wax when they can't get a surplus of honey, can they?

5. Why do some hives have small, black, shiny-looking bees in them sometimes, which the other bees kill? What is the cause? An old queen?

6. What is the best plan to keep the bees from swarming, and keep them up to the strongest working point? IOWA.

ANSWERS.—1. I don't know. I have made no little effort to overcome my ignorance with regard to sweet-clover honey, but I feel a good deal mixed about it. I have eaten honey that was supposed to be unmixed sweet-clover honey, and I didn't like it, nor did any of the family. I have had some that I supposed was a mixture of white clover and sweet clover, and we thought it better than any other honey we had ever tasted. Some say that if sweet-clover honey is not thoroughly ripened it will have a rank taste. I can

easily believe it, and it is possible that thorough ripening may remove the disagreeable quality.

2. Workers go afield when about 16 days old. Like good children, they all help "tend baby" during their first 16 days. There are sometimes bees that stand guard and do nothing more; but no bee ever spends its whole life standing guard.

3. I think comparatively young ones.

4. Roughly speaking, they might be said to sweat wax; that is, it is secreted by the wax-glands. They cannot make wax without having honey, but they can make it when they are not gathering any.

5. It may be bee-paralysis. The queen is probably not to blame, and it is hard to say what is to blame unless it be the presence of bacillus Gaytoni.

6. Oh my! my! my! Dynamite would answer the question, if you hadn't tacked on that last condition. Taking the whole question together, it may be answered in a tentative sort of way by saying to work for extracted honey, and when the honey-flow first begins raise the hive and put under it a story having foundation or empty combs, with an excluder between, and put the queen in the lower story.

Mineral Wool for Packing.

How would "mineral wool" do as a packing material in the spaces of a double-walled hive? It is said to be a non-conductor of heat, and insects will not stay in it. OHIO.

ANSWER.—I believe it is excellent.

Weekly Budget.

MR. W. J. PICKARD, of Richland Co., Wis., we regret to learn, is suffering from a continued attack of sciatic rheumatism.

DIRECTOR P. H. ELWOOD (Herkimer Co., N. Y.), of the National Bee-Keepers' Association, on receipt of the Buffalo Convention Report pamphlet, wrote thus approvingly:

"The proceedings are neatly gotten up, and with constitution and list of members is of added value. Bees wintered well."

MR. WM. A. SELSER, wife and daughter, stopped off in Chicago, for a few hours while passing through on their way East recently. They had been away from home for nearly three months, having been in Texas, California, Colorado, etc. Mr. Selser was representing the Government in its investigation of honey analyses, he going out to secure samples of various kinds of honey in different parts of the country. His report will likely be made in about a month to Prof. H. W. Wiley, at Washington.

Mr. Selser and family had a splendid trip, and all were looking well.

NO LIQUOR ADS. NEED APPLY.—In the Modern Farmer for April we find the following from Editor Emerson T. Abbott:

We had the pleasure last month, if pleasure it may be called, of returning a whiskey ad. which was written and sent in to us by an agent. The contract called for \$100, and it was signed by a firm with a good rating, but we refused to run the ad., and returned it to the party who sent it.

The Modern Farmer is not so rich that it can afford to throw away one-hundred-dollar contracts, neither are we in this business for revenue only. It remains, however, to be seen what appreciation the friends of a clean paper will show of our effort to keep it clean. If they will stand by us and give us their patronage, we will try to make a farm paper which will be clean in every department.

We are led to wonder, sometimes, how it is that those who claim to be in favor of cleanliness and purity in the home will take and pay for a farm paper which inserts liquor ads. We feel like saying to our readers, "Are you doing it?" If so, our advice is to order the paper stopped at once. You can not afford to take a whiskey drummer into your family circle, and, in addition, pay it for coming. There is surely temptation enough for the boys in this direction on the outside, without bringing it into your own home clothed in the fascinating form of so-called cheapness. Others may help on this kind of work if they choose to do so, but so far as we

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested.....	1.50	8.00	15.00
Selected Tested.....	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

COMB FOUNDATION ADVANCED 3 CENTS A POUND.

Owing to the increased price of beeswax, until further notice, dealers handling the A. I. Root Company's goods are compelled to raise the price of Comb Foundation 3 cents per pound above the prices found in their price-lists and catalogs. Please take notice.—Adv.

are concerned, we will have nothing to do with it; and should we fall in our attempt to make a clean paper, we will have the consciousness left that we have been true to our own convictions, and this, to us, at least, is worth more than the money.

Good for the Modern Farmer! We are entirely with Mr. Abbott in saying that if we can't succeed in publishing a clean paper we prefer to fail. But the agricultural press is quite free from whiskey and tobacco advertisements. It is the daily and weekly newspapers that seem to have a monopoly of such abominations. But bee-keepers, above all people, would not tolerate in their homes a bee-paper or farm-paper that would publish such advertisements. They think too much of their families, and have more self-respect than to do that.

A SONG OF TONGUES.

BY HARRY LATHROP.

Some months and weeks have passed along Since I've been heard in prose or song;
So on the "Journal's" shining page I'll speak of what is all the rage;
Fooling with what no profit brings— Time lost that might serve better things.
But here I close this introduction,
To pen the following short production:

Longer tongues for bees, indeed!
And longer tails for dogs;
And why not also try to breed
Some longer jumping frogs?

"Bees with longer tongues," they say,
"Would gather where others couldn't;"
But Doolittle said, the other day,
"Some gather where others wouldn't."

Better not idle away your time
With longer tongues or tails,
Or others will beyond you climb,
And the wind take out of your sails.

I'm satisfied with my bees' tongues;
I'm satisfied with their stings;
But give me the bee that has good lungs,
And the bee that honey brings.

The tongues of bees are long enough:
As well improve the lung;
This talk of tongues is only "stuff"—
The song will soon be sung.

Another fad they soon will start,
But what? Oh! who can tell?
Unless he act the prophet's part,
And act it very well.

Improvement now should comprehend
Improvement of bee-keepers;
For some for silly fads contend,
While some are only sleepers.

Green Co., Wis.

MR. W. C. GATHRIGHT'S APIARY is shown on the first page this week. He writes as follows concerning it:

I send a kodak picture of a corner of my apiary, also showing some cacti and amole plants in the background. This apiary consists of 250 colonies, and is run for both comb and extracted honey. I also have a large number of nuclei.

There is something like a dozen wild plants that yield honey in this locality, though the mesquite and alfalfa are the main source. The honey-flow is slow, but lasts, on the average, about 5 1/2 months. During all this time there is enough nectar in the flowers to keep the bees busy, and they never kill off the drones until late in the fall. This makes the ideal conditions for queen-rearing.

The picture was taken in winter, and shows the style of hive I prefer for comb honey. It consists of an upper and lower story, the upper one having frames 5 inches deep. The lower, or main brood-chamber, has 9 frames 7 3/4 inches deep. The upper story contains most of the winter stores, and is left on until time to put on sections. When the bees have

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you." Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30), I never found these bees to show the least indication of unrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

One of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chilly winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, Ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italian and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers **one ounce** of the seed for sending us **ONE NEW** subscriber to the American Bee Journal for a year with \$1.00; or will mail to any one an ounce of the seed and the American Bee Journal one year—both for \$1.20; or will mail an ounce of the seed alone for 30 cents.

begun storing in these shallow combs they are taken off and the sections are put on, and the bees enter and begin work at once. By this plan I have but little swarming. The shallow combs that contain brood are placed over weak colonies.

W. C. GATHRIGHT.

Dr. C. C. MILLER, of McHenry Co., Ill., writing us on April 29, had this to say about the Buffalo Convention Report and his bees:

I think I will be doing a favor to any new subscriber to advise him to send 25 cents to obtain a copy of the Report of the last convention of the National Bee-Keepers' Association. The time of the convention was almost entirely taken up with live discussions, and these are reported in an unusually correct manner. In such discussions thoughts are brought out that would not be obtained in any other manner; and the discussions in this report are exceedingly interesting. I am free to say this without being charged with blowing my own horn, for I was occupied so much of the time during the sessions at the directors' meetings, that I had comparatively small part in the discussions of the convention.

Bees are now having fair opportunities on dandelions and some other flowers, and fruit-bloom is just opening, seeming a little earlier than usual.

C. C. MILLER.

The Report referred to we mail for 25 cents, or with a year's subscription to the American Bee Journal—both for \$1.10. It contains 80 pages and cover; portraits of all the officers and directors of the National Bee-Keepers' Association, besides the two latest bee-keepers' songs, words and music. It is indeed a valuable Report also, as Dr. Miller says.

Bees Wintered Well.

The bees are in fine condition. They seem to come out better than usual. All of the colonies seem to be strong, and if we have the right kind of weather for the flowers to secrete nectar, we will have some honey.

ADA L. PICKARD.

Richland Co., Wis., April 29.

Bee-Keeping in Arkansas.

I am very much interested in bees and newspapers. I enjoy reading the reports from different bee-keepers very much. Although some of them sound pretty big compared with anything we can do here, I remember that we live in a big world, and pass on.

As no one else tells the readers of the American Bee Journal anything about the bee-keepers' luck here, I will try again to tell them about our hopes and disappointments. Of all the different kinds of work that people follow, either for a living or for pleasure, I believe that we bee-keepers have the most and bitterest disappointments.

As stated in my last, I have part of my bees in movable-frame hives and part in box-hives. They were put into winter quarters in fine shape, by feeding a few of the lightest ones. They were all in better shape than in the fall of 1900.

We have had one of the worst winters I have ever seen—cold and wet nearly all the time until the first of March, when we began to have a little warm weather. About this time the bees began to rear some brood. As a result of the cold winter and spring I have had no end of trouble, feeding to keep some of them from starving. As far as I know, 8 of the colonies in frame hives, and may be one or more in the box-hives, are queenless.

Two weeks ago we had a fine prospect for

— BEST —
Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey ❧

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey ❧

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

As this is a main branch, order from any catalog or quotations given from Medina.

Healthy ITALIAN BEES. Full colonies, 8 frames and queen, \$7.00. Wholesale rates on application.

1902, but we have had our part of bee-keeper's luck. Bee-keepers work hard, early and late, to be ready for the main honey-flow, and presto! just a week or 10 days' rain, or heat, or cold, and all their fond hopes are dead for another year. Just so here now. The last two weeks have been cold and cloudy very nearly all of the time.

Poplar is our main honey-flow. It blooms in April and lasts for about three weeks; sourwood comes next, in June; bitterweed in August. April is our main swarming-time, but up to the present time (April 14) I have not had a single swarm, and very little prospect of any. Unless the weather changes within a few days honey will be very short here this year.

I am still feeding some to keep them from starving.

I think this is one of the worst places for bees. We have only a good year about every 3, 4 or 5 years; 1889, 1892, 1895, and 1900, are the only good ones I remember.

There are several bee-keepers within 15 miles. They all use box-hives, and keep from 10 to 30 colonies. I have tried to get them to use the frame hives, and they keep saying they are going to, but they never get started.

I have asked them to take some bee-paper, but they say they are not able. They call a queen a king. I think some of them think the drones lay eggs, and some that they get comb off of the sweet-gum tree. They could not tell in a month whether the bees got honey from pine, oak or poplar.

Hale Co., Ala. J. S. PATTON.

Bees in Good Condition.

My bees are in grand condition, several hives having as much as eight frames of brood. I have encouraged their breeding to their full capacity, as this is the fruit year, and I wish to get a crop of apple-blossom honey.

ALLEN LATHAM.
 Norfolk Co., Mass., April 29.

Rearing Long-Lived Bees.

On page 105, F. Brown, of Florida, wishes to know why his best honey-gatherers live longer than the average bees. I have had much experience along this line for many years. First, I observed that some colonies, "never having more brood than others," were twice as strong. Why was this? Queens were exchanged with results the same. Strong colonies pass the winter better, build up more rapidly in spring, and have greater force to gather honey when the flow comes. These

Standard Belgian Hare Book!

BY M. D. CAPPS.

THIS book of 175 pages presents a clear and concise treatment of the Belgian Hare industry; its growth, origin and kinds; the sanitation and construction of the rabbitry; selection of breeding stock; care of the young, feeding, diseases and their cures, scoring, marketing, shipping, &c. First edition of 50,000 copies was sold in advance of publication.

Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apizry, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

Good Second-Hand Hives —FOR SALE—

10-frame Simplicity-Langstroth, standard in every way. When I kept bees I would have been glad to pay \$1.00 each for such hives. Write for particulars. **MRS. B. J. LIVINGSTON,**
19A21 CENTER CHAIN, MARTIN CO., MINN.

workers living longer was the only cause of their gathering more honey than others. By changing queens I proved the longevity of their workers.

Next I found I could rear queens from my poorest queens that produce long-lived workers, while queens could be reared from my best queens whose workers were very short-lived.

This proves to my satisfaction that long-lived bees gather more honey, and are in the lead in every respect.

It is just as easy to rear queens that will maintain strong colonies during the honey season as to rear those that produce only weak colonies, if you know how.

I find it is not so much the mother as it is in the manner her daughters are reared.

Geo. W. Riker.

Lucas Co., Iowa, April 14.

All Wintered Well.

My bees are working nicely, carrying in lots of pollen when we get a day that is warm enough. The spring is very cold and backward here. I put 11 colonies into the cellar last fall, and they all came out in good shape. I have wintered bees three winters, and have never lost a colony. **C. M. LAWRENCE,**
Blackhawk Co., Iowa, April 29.

No Foul Brood in Bee-Trees.

I noticed the article on page 253, and the Editor's remarks, and I will say we do not find foul brood in bee-trees. Foul brood and black brood have the same origin, only under different conditions of the atmosphere, and can be eradicated by the same remedy or process.

Bees came through the winter stronger than ever, flew 25 days, from March 1 to April 1, brought in honey and pollen March 20; last year April 8. It has been so dry during April they have not made much advance.

D. H. METCALF.

Calhoun Co., Mich., April 19.

Last Three Seasons Poor.

I have been in the bee-business for a good many years, and the last three were poor ones in this section. I keep my bees in chaff hives; 12 died the past winter, and the rest are very light.

DAVID LIVINGSTON.

Somerset Co., Pa., April 16.

Bees All Right this Spring.

I have unpacked my bees and found them all right—plenty of honey and pollen, and plenty of young bees. I wintered them on the summer stands, with chaff cushions in the super and old hay packed around the hives. I had eight colonies last spring, increased two, and the ants killed one colony. I got 139 pounds of comb honey last season, and plenty to winter on. I wintered nine colonies.

MRS. BEN FERGUSON.

Ford Co., Kans., April 21.

Results of Last Season.

I began last season with 21 colonies, and got 1900 pounds of honey, about one-third comb. I sold it all at home at an average of 10 cents a pound. I have 28 colonies now in good shape for the summer.

C. H. BENSON.

Calhoun Co., Mich., April 23.

Blind for Five Years.

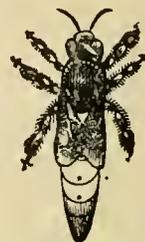

I used to write a few years ago about my bees and my blunders. Since I became blind, about five years ago, I have kept pretty still. My bees keep still, too; neglect has caused their silence. Neglect has a different effect on me.

They lived along at a "poor, dying rate" until the past winter, when a damp, poorly ventilated cellar finished them. A year ago the mice tried to do so, but spring came too soon, so a few were left.

I remember one of your correspondents, a

"What Happened to Ted?"

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 $\frac{3}{4}$ inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,

227 EAST OHIO STREET, CHICAGO, ILL.

Please mention Bee Journal when writing

few years ago, wrote about being sick. While lying on his couch where he could overlook his bee-yard, he saw swarms after swarms depart, and no way to help himself. I remember I shed tears of sympathy; I was very happy then with my bees. Ten of the happiest years of my life was the 10 years with the bees. Then came five years of heartache. But I have many blessings left, when I can remember them. **Mrs. B. J. LIVINGSTON.**
Martin Co., Minn., April 30.

Bee-Keeping in Florida.

The past winter here in western Florida has been a cool one, though there was no severe freezing. The spring is rather late.

I look out upon an orange tree in its garb of shining leaves, and the air is fragrant with the odor of orange blossoms. Some orange trees lost their leaves, while others did not. Pomegranates are now in bloom, and magnolias are opening.

The past winter being cool, the bees were slow in building up strong, and few swarms have issued. Many persons still use the tall box-hives, which are made of pine. To-day I saw two Langstroth hives with many bees clustered in their porticoes. All the bees I have seen are the small, black ones.

At West Bay—an arm of St. Andrews Bay—I was told that white comb honey sold for 5 cents per pound; it was chunk honey, not in frames. I have purchased good extracted honey, produced at Wewahitcha (commonly called the Dead Lake) for 25 cents per quart.

Mrs. L. HARRISON.

Washington Co., Fla., April 23.

Honey Prospects Poor.

Last season was a very poor one for honey. I now find white clover scarce, and a poor prospect for this season. I have 23 colonies in good condition. **CONRAD JON.**

Putnam Co., Ind., April 22.

Feeding to Tide Over—Alley Trap.

I have 48 colonies of bees, one having died, and since taking them out I found another colony queenless, to which I gave a couple frames of brood. I have fed some sugar, and expect to feed two or three sacks before white clover comes. I think it pays. I fed 25 colonies two sacks last year, and it paid well. I had my bees strong as soon as the honey-flow started. We have white and yellow sweet clover; I never saw the yellow until about two years ago, then I saw a few sprigs of it near the depot. I suppose it came in some way on the cars. It is spreading some; most people in town oppose it, and cut it down on the streets, as it grows so rank, though not as rank as the white.

I think the Alley drone-catcher is a fine swarm-catcher. When you expect a swarm put on the catcher, and when the swarm issues you will find the queen in the catcher. Remove the old colony, put a new live in its place, and when the bees return let out the queen, and they will all go in like a flock of sheep.

WM. CLEARY.

Kossuth Co., Iowa, April 22.

CONVENTION NOTICE.

Illinois.—The Eastern part of the Northern Illinois Bee-Keepers' Association will hold their spring meeting at the residence of O. J. Cummings, 2½ miles northeast of Rockford, Ill., Tuesday, May 20, 1902. All interested in bees are invited to attend. **B. KENNEDY, Sec.**

SHEEP MONEY IS GOOD MONEY and easy to make if you work for us. We will start you in business and furnish the capital. Work light and easy. Send 10 cents for full line of samples and particulars. **DRAPER PUBLISHING CO., Chicago, Ills.**

3-Frame Nuclei For Sale.

We have arranged with a bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei of bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 or more at \$2.75 each.

All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Apr. 18.—The season in which comb honey sells prior to the new crop is now practically at an end; therefore prices are more or less irregular, as some sections in a case will be grained more or less and others free. The best lots of basswood and clover sell at 14@15c; other kinds of white at 10@13c; ambers are not in heavy supply and sell at 9@12c. Extracted is dull at 5@6½c for white, and 5@6c for amber, depending upon flavor and other qualities. Beeswax scarce at 32c. **R. A. BURNETT & Co.**

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5¼@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.
THE FRED W. MUTH Co.

ALBANY, N.Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14@15c. Extracted, 6@6½c. Beeswax, good demand, 30@31c.
H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases, about one cent less. Extracted, California light amber, 7@7½c; Florida honey, in barrels, 6@6½c.
BLAKE, SCOTT & LEE.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6¼@7c; dark and amber, 5@6c. Beeswax, 29@30c. **M. H. HUNT & SON.**

CINCINNATI, Apr. 11.—Stock of comb honey here is larger than it ought to be at this time of the year, and this is why it is offered for very low figures. Water-white is sold at 14@14½c and hard to obtain; for extra fancy, 15c.

Extracted finds a steady sale, and amber is sold in barrel lots for 5@5½c; water-white alfalfa sells from 6@6½c, and white clover brings from 6½@7c. Beeswax scarce at 30c.
C. H. W. WEBER.

NEW YORK, Apr. 7.—Comb honey, last year's crop, practically cleaned up, but as we wrote a little while ago we had received new crop from Cuba, and are now receiving new crop from the South. Demand is fair at 14c for fancy white, 13c for No. 1, 12c for No. 2, and 10@11c for amber.

Extracted: The market is decidedly dull. Very little demand, with large stocks on hand, some of which no doubt will have to be carried over, and indications point to a further decline in prices. We quote: White, 6c; light amber, 5½c; amber, 5c; Southern, 52½@58c per gallon, according to quality. Even these prices are shaded in car lots. Beeswax, scarce and firm at 29@30c.
HILDRETH & SEGLKEN.

SAN FRANCISCO, Apr. 16.—White comb, 10@12½ cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4¼@—; amber, 4@—; Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Demand is not very active, and market cannot be termed firm, although quotable values remain without important change. Considerable honey of last crop is now being offered, which up to a few weeks ago had been held off the market. New crop is expected to arrive in wholesale quantity in the very near future.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.
THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market. J. B. MASON, Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

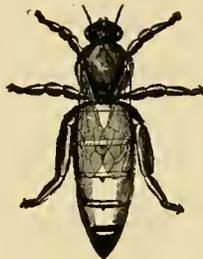

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be **warranted** purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order as follows:

No. 1.—For sending us the names and addresses of **two new subscribers** to the American Bee Journal and \$2.00, we will mail you **one** of these queens free.

No. 2.—Or, for sending us **one new** subscription at \$1.00, and 30 cents more (\$1.30), we will mail you a queen, and the Bee Journal for one year to the new subscriber.

No. 3.—Or, send us \$1.60 and we will send to you the Bee Journal for one year, and also a queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

ESTABLISHED IN 1861

AMERICAN

THE OLDEST BEE-PAPER IN AMERICA

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., MAY 15, 1902.

No. 20.

Editorial.

The Jamaica Bee-Keepers' Association is not a bee-keepers' association in the usual sense of the term. This office is in receipt of a circular "setting forth the object and methods of the Jamaica Bee-Keepers' Association more clearly," from which it appears to be a good deal like a company united to dispose of honey on commission, charging patrons $2\frac{1}{2}$ percent commission and 1 percent brokerage. At present their market is to be London and Bristol, the honey to be shipped in barrels in preference to tin.

Weather for Handling Bees.—Some have said that less stings will be received when handling bees in cool, cloudy weather. Possibly there may be something in that with some bees, especially black bees, if the air is so cool that they are inclined to be stupid. But beginners should understand that even if the bees will permit it, the brood-nest should never be disturbed when it is too cool for bees to fly freely. Moreover, it is true in general that the hotter the day the better-natured the bees. If you want to have a big fight on your hands, just open a hive of Italians when it is so cool that none of the bees are flying. Even in pretty good weather it will be found that as the temperature becomes cool toward evening the temper of the bees changes with it. When it is too hot for you to stand coat or vest, if bees are gathering at all, you will find them on their best behavior.

Apropos of this subject, Bulletin de la Meuse says: "To open a hive in cold and windy weather is as imprudent as to take a baby from its warm cradle and expose it to a current of air in its chemise."

Don't Crowd the Bees.—One of the factors that plays an important part in causing bees to swarm is the lack of room. Indeed, it may be the greatest factor, for with very large hives and abundant super-room some report that not more than two to five colonies in a hundred swarm. As it is quite generally admitted nowadays that swarming militates against the greatest yield of surplus, the effort should be to give all the room needed. For after preparations for swarming are started, no amount of additional room will dissuade the bees from their purpose. The old rule to give supers as soon as bits of white wax are seen along the top-bars is an excellent rule in all respects except as to its bearing on swarming. The likelihood is, that

when these bits of new wax are found deposited where they are not needed it is because there is some feeling on the part of the bees that they are getting into cramped quarters—a feeling that ought not to be allowed to obtain if it is desired to keep down all thoughts of swarming.

Do not wait for any inside indications of the need of supers, but take your cue from the outside. If you are in a white clover region, watch for the very first clover blossom that appears, and put on supers at once. They will not be heeded by the bees for ten days, because a stray blossom will be seen here and there before the clover harvest begins, but if supers are on in advance the bees will begin promptly in them when the harvest begins, and in many cases they will become so interested in storing that they will not stop to discuss whether they should swarm.

The little harm done by having needless room to keep warm will be richly repaid by the great advantage of having full attention given to storing with no distraction in the way of swarming.

Value of Old Combs.—In the Australasian Bee-Keeper is a symposium upon extracting wax from old combs. Among others G. Colbourne gives his plan, but closes by saying:

But I would like to ask, Why melt up those old combs? I have yet to see the comb that was too old to use. I would never think of melting a comb because it was too old; those combs are as good as a little gold mine to me. How I can make the extractor hum, in throwing out thick honey from them, whereas, if I had a new comb I must go slow, no matter how well it is wired. No, my friends, don't melt up your old combs. If you want to get good wax melt the new, and keep the old ones to extract from.

Keeping Breeding-Queens in Nuclei.

—This question is raised by a correspondent who seems not fully determined in his own mind that best results in queen-rearing can be obtained if the queen whose eggs are used for queen-rearing be kept in a nucleus. He says:

"As a queen thus confined and kept back in her egg-laying duties is surely not in a normal condition, the thought came to me that it might possibly have a detrimental effect on her progeny. It might be very slight at first, but if kept up for several generations it might be more noticeable. Isn't it agreed that better queens can be reared when 'all hands' are busy and the queens are laying 'full speed' than at any other time? I don't know that there is the least ground for my suspicions, but I thought it might be well to look the matter up a little."

It is not likely that there is anything wrong in the general impression that better queens are reared when bees are gathering freely, and the temperature in the brood-nest is such that

there is never any danger of the slightest chilling of brood. For at such times there is every facility and every inducement on the part of the nurse-bees to feed the royal larva bountifully. A royal larva in a full colony is not likely to be well fed at a time nothing is doing, and consequently a limited amount of the proper food prepared; and no doubt the case is still worse in a nucleus. Observation on the part of many confirms this belief.

How is it if the mother-queen is in a nucleus? If the proper proportion of nurse-bees are present, may they not be as active as in a full colony? And having a limited amount of brood to feed, may they not feed the queen as lavishly as she would be fed in a strong colony? Being well fed, and having little laying to do, if it is true that laying is exhaustive, ought she not to be in a greater vigor, if possible, than in a strong colony? and as a consequence ought not her eggs to be of the best quality? Then during the very short time that the young larva are fed before being taken—a time not exceeding perhaps 24 or 36 hours—why should they not be fed as well as in a strong colony? The case might be different if queens were reared in cold weather, when proper heat can not be kept up in a nucleus; but queens are reared at a time when the bees have to work to keep down the temperature rather than to raise it.

If there is anything wrong in the foregoing view it is very desirable that it should be pointed out, for in a matter on which so much depends it is important that no wrong view should prevail.

Prolonging Life of the Queen.

When one has a queen that is especially valuable for breeding purposes, it may be desirable to have her live as long as possible. A practice more or less common is to keep such a queen in a nucleus. The question may be raised whether there is any evidence that a queen kept in a nucleus will live any longer than if she were kept in a strong colony. It is well known that workers live much longer when doing little or nothing than when working hard. As laying eggs is the work of the queen, there seems some reason for believing that heavy laying will shorten the life of a queen, just as hard work shortens the life of a worker. It would be a satisfaction if those who have had much experience in the matter would report upon it, and say how the length of life of queens in nuclei has compared with that of queens in strong colonies.

The idea of keeping a queen in a nucleus will result in greater longevity of offspring has been scouted as ridiculous, but it may be questioned whether any one has ever seriously advocated such a thing.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 294.)

A WAX-PRESS IN A SOLAR WAX-EXTRACTOR.

"Has there ever been a wax-press on the inside of the solar wax-extractor?"

Mr. Blunk—That's a question of mine. I have seen a good deal about the German wax-press. Why cannot we press it right in the solar extractor? That's why I ask if there has been one, and, if a success, I would like to have one. If not, I am going to make one.

Mr. Dadant—While I can't exactly answer the question, we have used solar extractors both for combs and residue of hundreds or thousands of pounds of beeswax. The first principle is to have the sun strike the beeswax. Put a press in there, and the sun doesn't strike the beeswax.

Mr. Blunk—You wouldn't be pressing all the time.

Mr. Dadant—Take what is in your solar extractor, and put it in the press while hot.

Mr. Blunk—Press right through at the time. When you get enough in there, press it by screwing.

Mr. Dadant—You must remember the thing must be all in the sun, and it must be scattered. When scattered there will be very little of it. If you put two combs, one on top of the other, the under comb will not melt. If you have only one-comb thickness there will be so little to press that it will stick. One thing we have done, and that is to take it out on a hot day, in the heat of the July sun, and press it right through, and get little of it; but it isn't worth it.

INTRODUCING QUEENS TO A LAYING-WORKER COLONY.

"When a colony loses its queen and develops a laying worker, can a fertile queen be introduced successfully?"

Dr. Miller—Find that laying worker, take it away and put another queen in. The only trouble is that when there is one laying worker there, there may be 50 or 100 or 1,000 of them. The notion that there was only one laying worker in a hive is exploded, and it is often that there are many engaged in it; and while it is difficult, it is not utterly impossible; yet you can manage to have the queen introduced.

"What would you do with a laying-worker colony?"

Dr. Miller—I would break it up, because you don't have laying workers until they have been a long time queenless and nothing but old bees. I would break it up and distribute the bees to other colonies.

Mr. Riker—Sometimes we have colonies of young bees that become queenless and they have laying workers. My method of subsiding that is to introduce a fertile queen in a cage for ten, twelve or fifteen days in that colony, and then liberate her, and everything is all right.

Mr. Whitney—Mr. Riker's experience has been mine. I found a colony with laying workers; I introduced a queen and inside of 48 hours everything was all right.

Mr. Blunk—Was she caged?

Mr. Whitney—I introduced her just as I would introduce a queen to any colony. I had some misgivings, as I expected they would kill her, but they didn't.

Mr. Dadant—I would suggest, if you have a valuable queen, not to introduce her to a queenless colony. If you have a queen to spare, and she is good, introduce her to a colony where the colony is not very valuable; and if you have a queen and you don't care whether she is killed or not, introduce her into the colony with drone-laying workers; by introducing her you will succeed half of the time, and if you lose her, well, there is nothing much lost.

Mr. Whitney—That's just what I think. Change the queen, take out a poor one, and put in a good one.

Mr. Hintz—In my experience, I had two about two or three years ago that were queenless, and the most successful way I found was to take away the hatching brood and the laying workers will disappear. Six times out of a dozen you won't succeed, but you take a frame of workers or hatching brood

and they almost always will, as soon as hatched out, accept a queen within 48 hours.

Mr. Green—I had a little experience last spring, different from anything I have run across in the bee-books. In consequence I got a good colony. The colony lost its queen. I went through the colony, clipped the queen just before swarming, and I think I clipped a virgin queen. I introduced a frame of brood and they started queen-cells, and I selected a good one, and soon after that I found laying workers and eggs scattered all over. I read so much about layer workers—that you couldn't do anything with a colony of that sort. The queen had hatched, and I concluded they had destroyed that queen and consequently broke up the colony and distributed, and after going too far in that process I found a good queen in that colony. They had gone right on and reared their young queen from brood, and all that time they had laying workers laying as fast as they could lay.

Mr. Swift—I would like to know whether, when you break up the colonies and introduce them into their hives, you will introduce the laying workers in those hives?

Mr. Hintz—In that one colony of mine I put eggs and larvae, and they wouldn't start a queen-cell; but as the young bees were hatching, they accepted a queen in 48 hours.

Dr. Miller—Answering the question asked, I think you will find that if you distribute to other colonies the bees that have laying workers, that you will distribute the laying workers, but they will go into another colony with a good queen; their occupation is gone.

SEVERAL QUESTIONS AND ANSWERS.

"When should a queen begin laying in order to have colony in shape for the honey-flow by June 10?"

Dr. Miller—Whenever good weather comes.

"Will a queen that has been a good one through the season, but commenced laying drone-eggs in worker-cells, be all right next spring?"

Dr. Miller—No.

RIPENING HONEY.

"Should all comb honey be ripened after taking from hive?"

Dr. Miller—No.

"How long before putting in cases would you consider the proper time for the same?"

Dr. Miller—That depends. All comb honey should not be ripened, because if ripe enough it doesn't need any ripening, and if it isn't, as to the time, depends on the time needed. As a general rule, when honey is sealed it is ripened, but not always. There is no law you can put down to it.

Mr. Hodge—How am I to know when I take it off that it is ripe? I had some experience the past summer with comb honey. I found some of my honey, after four weeks taken off, that was dripping—looked like sweat. I thought the honey looked as if it was perfectly sealed.

Dr. Miller—Take the ripest honey you can get, the best honey in the world, all perfectly sealed, put in a place where it has a chance to attract moisture and leave it there long enough, and it will leak through the combs.

Mr. Hodge—There was other honey right with it that didn't do it.

Dr. Miller—The probability is some of the honey was less ripe than the other. Allow me to step just to one side of the question a little. None of it ought to have been allowed to become thin. The place was unfavorable to evaporation, and it was favorable to the attraction of moisture. The best honey that was there was probably hurt a little by being there, but the thinnest of it would weep through the cells. Although honey may be taken from the hives so ripe that it doesn't need any more ripening, I should, if possible, put it in a place where it would ripen more, and if you put it in a warm, dry place it will be constantly getting a little thicker and better.

Mr. Dean—We used to have some difficulty with our comb honey in Pennsylvania when we kept the Italian bees. We had some Italians and blacks. The honey from the Italians was sealed directly on the honey. The honey would swell a trifle, seem to sweat, and there would be a bubble of water on it, while honey from the blacks, in the same place, wouldn't do that. We discarded the Italians entirely. I think that was the trouble perhaps with this gentleman's honey. When the bees cap it directly on the honey it has no chance to expand, and the consequence is it seems to force water.

Dr. Miller—It is true, there is a difference, as has been suggested in that fact. I have had Italians that would do that very thing. They fill up the honey too close to the capping. The blacks I had were a great deal worse than any Italians I ever had. As a rule the blacks will produce better looking honey.

Mr. Dean—I wouldn't be sure but what I got those Italians from Dr. Miller!

Mr. Hogge—It was my fault, and not the fault of the bees. I had some honey that came off of the very same hive, and it did not act that way.

SWEET CLOVER HONEY.

Pres. York—"How many have found that people are prejudiced against sweet clover honey?"

Six raised the hand.

"Is there any way to remedy such flavor?"

Mr. Hintz—Does that mean comb or extracted? If comb, it wasn't well ripened. I never had that trouble.

Mr. Chapman—I asked that question, and I never extracted any honey that wasn't sealed. I took it the second week in September when it was perfectly ripe, and any that lacked sealing I put down for the bees, and I have still had people object; I myself object to the sweet clover as being rank.

Mr. Hintz—My experience is that if sweet clover honey is entirely sealed over, and a long time in the hive, it doesn't taste rank.

Mr. Mooney—My honey in the early part of the season doesn't taste like what I get later. The early-flow honey taken away doesn't have the chance to ripen as it should, and I know that mine was strictly sweet clover honey in the fall.

Mr. Chapman—The honey wasn't taken until the first or second week in September, and I ripened it. I have since moved my location, and have honey from asters and I have none of that trouble.

Mr. Hintz—Mine has never given me any trouble when properly ripened.

Mr. Whitney—Was that honey, when you extracted it, thick or thin?

Mr. Chapman—Good, thick honey; five gallons will weigh 60 pounds. I call that thick honey.

Mr. Purple—In my locality I get nothing but straight sweet clover honey, mixed in August with burdock, and I notice that the honey we get first after blossoming is our best honey. Just the time the sweet clover is in blossom is the best. As the season advances it gets stronger. I extracted July 14, but I never extract until it is all sealed over, and the first extracting is always the whiter.

Mr. Chapman—Isn't that mixed with white clover? When the honey is thus mixed—in my present location I get it that way—it is the finest. When I had the pure sweet clover nearly every one objected to the flavor.

Mr. Purple—The latter part of July the white clover is all gone, even burdock. Then it comes in nearly white, and it is as nice a honey as I get during the season in the middle of the flow.

Mr. Chapman—Ever have any objection to it?

Mr. Purple—I have customers who don't ask for any better honey than that honey. They will go to the market and buy samples of honey, and it is good honey, but still they would rather have the sweet clover honey than have that.

HONEY TAKING COLOR FROM DARK COMBS.

"Is honey darkened by putting into dark combs by the bees?"

Mr. Riker—That is one thing that I have seen and read considerable about, and I have tested it in every possible way, and find that it will take color from the comb. Water put in such comb will pick up the dark color, but honey will not. I never have been able to discover that the honey would take any coloring of the dark comb. One time, at the State Fair of Iowa, a gentleman made a remark that dark comb made dark-colored honey. I told him that was opposite to my experience. I never noticed anything of that kind. It is the fact, he said. I looked about. He had some bees there in a little glass box, and comb, and I discovered that the comb was black, but there was a little white honey around the edge and it appeared to me that that was white honey. I asked him if he would permit me to take some of the honey out of the blackest comb and a little honey out of the whitest comb, to compare with each other. He took the dark comb and put a sample of the honey on a piece of paper, while I took the whitest and put it on a piece of paper, and put it by the side of the dark. We then presented it to the crowd standing by for them to judge. Every person decided that the honey I took out of the black comb was the whitest. I took a little advantage of the old gentleman when I took the honey out, as I spread it *thin* on the white paper. When he took it out of his comb and put it on he left it perhaps twice the thickness of the paper. After they had all decided mine was the whitest I told them it was the same honey. Then I showed them and the old gentleman how I had taken advantage of him, that the honey

that I put on I spread out more than he did his; but when I came to spread his down to the same depth as mine, they couldn't tell which was which. I have tested it. I have tried every which way, to see if black comb will color the honey. It will color water but not honey.

Dr. Miller—I wouldn't like to take either side of that, for I want to get out of this crowd alive. There are different views. There are some who say that black comb will yield honey just exactly the same as that in virgin comb, and yet there is this that is difficult to answer. Mr. Rieker knows black comb will be colored, and most of you who have had combs out in the rain, and left them out all night, when shaken out will notice it looks like ink. I saw an explanation of that the other day. I can't recall where I did see it. I am not sure but what it was at the Buffalo convention. Some one said honey is not watery, it is oily; that, therefore, the black coloring-matter cannot come into the honey because of its oiliness. We know pretty well, at least in my locality, that water is not oily, and honey and water will mingle together. There are those who make a business of exhibiting very fine, white honey, taking it from virgin comb, and they claim they had whiter honey by doing that.

Mr. Chapman—I made an engagement with a man who produces a great deal of honey to meet and determine that question. There was over a ton of honey produced in brood-combs, which had never been used for other purposes than breeding, and the first extracting was very slightly discolored, but the subsequent extracting was just as good as that in the new combs. We tried the experiment of filling the combs with rain-water, and found that the cocoons absorbed the water and allowed the material deposited to come through into the water, and into the cell, but honey didn't soak into the cocoon, and the first that was extracted was slightly discolored. You would have to have a great quantity in order to notice the coloring at all.

No. 6.—Bee-Keeping for Women.

Things Learned Only by Experience—Robber-Bees.

BY EMMA M. WILSON.

THERE are some things in bee-keeping that can be fully learned only by experience. Among these is the danger from robber-bees. No matter how much the beginner may be told about the danger, she will go on in blissful freedom from anxiety until she has one serious case of robbing, and then she will know what robbing is as no book or bee-paper can tell her; and after that she will always be on the alert.

During the time of a good honey-flow there is little danger in that direction. Honey may be left standing exposed for some time without causing any trouble; the bees pay no attention to it. They can get all the nectar they want from the field. But in early spring, or at any time during the season when there is not abundant nectar coming in, look out for robbers. There is danger. My, what a commotion a bit of honey carelessly dropped at such a time will cause! It would seem as if the bees had gone crazy. The apiary that a little time before seemed all peace and quietude is suddenly changed into a howling mob of angry, stinging bees. It would seem as if the entire apiary were engaged in the uproar, when in reality there may be only one or two colonies engaged in robbing. But it affects the whole apiary, for when that bit of honey is gone the robbers set out in quest of more spoils, and every hive in the apiary is likely to be tried. Every colony is alert and on the defensive. If any are weak or poorly protected look out for them. If the robbers seem to be getting the better of them, stop up all cracks where a bee can get through, and close the entrance, leaving only room for one or two bees to pass at a time. Then throw an armful of hay or straw over the entrance and soak thoroughly with water. That will dampen the ardor of the robbers, as they do not like to crawl through the wet hay, and they will most likely give up the fight. Under no

consideration open any hive at such a time, for the robbers will be ready to pounce in if you do.

You can very easily start robbing working with the bees without leaving any honey exposed, when there is a dearth of honey. If you are inexperienced they can get quite a start before you realize that they are robbers. If on opening a hive you see some bees flying with quick, darting motions, trying to get in; or if you see a bee alight on a comb, and it is promptly seized by one or more of the bees of the colony, you may be sure they are not honest bees; and if at the same time the bees of the colony you are working at are angry and excited, stinging without apparent provocation, you may be sure robbers are at work, and you would better close up operations, no matter how anxious you are to work. The only safe way to work at such a time is under a tent, where no outside bee can get in its work. Sometimes, by leaving the apiary undisturbed for a few hours, things will quiet down and you can go to work again. But you must be on the alert, and at the first sign of robbers you must be ready to close up promptly.

If a frame of brood or any honey has been left exposed, and the bees have got started on it, do not take it away from them and leave nothing in its place. If you do they will probably pounce upon the nearest hive and there will be a royal battle. You can take it away and put a comb without any honey in its place, or one that has a very little in it. That will satisfy them.

Dr. Miller often tells me that I am not as afraid of robber-bees as I should be. We have never had a very bad case of robbing, at least none that ended very seriously. The most we have suffered from robbing is having weak colonies robbed out in the spring. But they have got started enough a number of times to show what they might have done if we had not been able to control them.

A year or two ago Dr. Miller was called up in the middle of the night, and asked if he would not come and straighten up a man's bees. The man lived some six miles away. It was his hired man that came for Dr. Miller. He said that several hives had been knocked over, and the man had been so badly stung that he had had to go to bed, and send for the doctor, and there was no one else that could touch the bees. Dr. Miller told him that he could not do anything until daylight, but that he would come early in the morning.

I assure you it was a scene of desolation that we looked upon when we reached that apiary the next morning. He had quite a little apiary, had kept bees for years, but I imagine he had never had such an experience before. He had tied a young calf, with a rope long enough to reach the bees, to an apple-tree near the apiary. The bees stung the calf, and the calf commenced a mad race among the hives, as far as the rope would allow him to go, overturning hive after hive. In some cases the combs had been thrown entirely out of the hives, and it looked as if the calf, in its mad career, had run over them several times. Broken brood-combs filled with nice brood, combs of honey, bees and sections, were in a sad mix-up, and the bees were fast waking up to the fact that there was plunder to be had.

We straightened things up as best we could; got the hives back on their stands, and whenever it was possible we tied the brood or honey into the frames that were left whole; put the bees back into the hives where we thought they belonged, etc. Fortunately there was not much honey in the sections, so that simplified that part of it somewhat, but it was a little the worst wreck I had ever had anything to do with.

I think that man has had his lesson. I do not believe he will ever tie any animal near his apiary again. But it was expensive.

Bleaching Combs to Make the Honey White—Bees Don't Hear.

BY C. P. DADANT.

ON page 52, a Mr. Krause proposes to bleach the combs of the extracting-cases in order to secure white honey, and suggests a weak solution of sulphuric acid for that purpose.

In the first place, I am not fully satisfied that the dark combs always give a color to the honey. We have been in the habit of extracting our honey for some 32 years, and the readers all know that we have been the champions of the special system of extracting all the honey. Yet we have harvested just as white honey as any one else ever did, when the nectar in the fields was white. We have used old combs. In fact we are still using combs which were built by bees in 1870, and we much prefer these to others, because the bees

seem to have strengthened them season after season by rebuilding the damaged cells. Yet I wouldn't like to set myself up against the numerous testimonials which say that honey is colored by being stored in old combs, but I hold that this coloring is exceedingly slight, and that in the instances where people claim that its color has been very perceptibly deeper the fault has lain more with an inaccurate examination. The bees do not separate their different grades of honey when harvested at the same time; but some colonies do get lighter honey than some other colonies, probably because their fields are different. For instance, I have seen some colonies harvest honey-dew when colonies adjoining them did not get a drop of this, their labors taking them to other crops.

Now, taking for granted that this coloring of the honey is a fact, and we have tried to remedy it, the most active agent in this change of color would be the yellow coloring matter which the bees seem to gather so plentifully when harvesting yellow pollen in the fall. This, in my opinion, is caused by the deeply colored pollen, and is so powerful as a dye that it is difficult to get rid of it. Wax-bleachers are well acquainted with it, and say that this is one of the most obstinate colors they have met. It seems to stay with the beeswax, and often will not allow it to bleach, but will remain in it. Acids have no effect upon it. This we know by our own experience, and we find that the red beeswax, which is produced in countries where these fall blossoms are found, still remains a deep yellow after purifying. Sun-bleaching changes this deep yellow to a paler shade, which never becomes quite white. If this is the coloring-matter which darkens the honey, it is useless to expect to get rid of it except by melting up the combs.

Now to come to the proposed process of soaking the combs in a solution. Even if we were to expect a decided change in the color of these combs by the use of a solution, it would be unadvisable to use it because it would be sure to leave a smell that would be objectionable to the bees, and very probably also a taste which would damage the honey more than the slight amount of coloring-matter which it was sought to remove.

Now as to combs blackened by brood-rearing. The only way in which these combs could color the honey would be if the latter was so thin that its presence in the cells would liquefy or dilute the hard substances which have gone towards making this dark color. Otherwise there is no possibility of a change in color. If the soaking of the combs in a solution of sulphuric acid were resorted to, the result would be a dissolving, by the action of the acid, of all the cast-skins of the bee-larvæ, and of all the refuse that colors these combs; but, as this exists in large quantities in old combs, there would be a very large amount of residue, and unless the cells could be washed clean afterwards, by repeated drenching, it seems to me that there would still be enough coloring-matter remaining to stain the honey. It is out of the question to make a dark comb white, short of melting it up in the rendering kettle.

If the extracting-combs are removed shortly after the crop, and put away till the following season, and if they are put upon the hives only a few days before they will be needed for storing the crop, there seems very little chance of their getting much stain. Of course they will get some color; this is unavoidable. But what percent of extracted honey is produced in new combs? Undoubtedly a very small quantity. And if there is any very light-colored honey produced with the extractor, it is evident to me that in many instances, at least, old combs have been used without injury to the color of the honey.

BEEES DO NOT HEAR.

On page 62, A. H. Homersham (a quotation from British Bee Journal) says that he has proven to his own satisfaction that bees cannot hear. Well, we have all made those tests ourselves. There is probably hardly a bee-keeper who has not tried shouting when next to a hive of bees. But on these questions Cheshire says:

"Should some alien being watch humanity during a thunder-storm, he might quite similarly decide that thunder was to us inaudible. Clap might follow clap without securing any external sign of recognition; yet let a little child with tiny voice but shriek for help, and all would at once be awakened to activity."

We might add also that as the bees emit different sounds at different times, there is very likely some response to these. The only thing that we can knowingly assert is that there is no response to whatever noise we may make, whenever this noise does not act as a disturbing element. Thus, as far as we are concerned, the bees do not hear.

Does Getting Bees Started in the Brood-Nest Seriously Interfere with Storing in the Supers?

BY G. M. DOOLITTLE.

A venerable tradition has come down to us, that allowing bees to get started storing in the brood-nest seriously interferes with their storing in supers. I have bowed to that idol long enough, and now stand up to say I don't believe there's a word of truth in it. So there, now!—Dr. C. C. MILLER.

I am half inclined to think the Doctor is right. If there is a supporter of that "venerable tradition," let him speak out.—E. R. ROOT.

By the time the surplus season begins (10th to 15th of June in this locality), the brood-combs will usually be exhausted of stores, or nearly so, and no work can be expected in the sections until these are filled to their utmost capacity; and the amount of the choicest honey of the season required for this purpose would be an important item if secured in the sections.—H. R. BOARDMAN.

But the persistence with which they (the bees) continue to store in the brood-combs at this time, is often disappointing.—H. R. BOARDMAN.

The above are some items which appeared in print some time ago, and I have been waiting ever since to see if some one was not going to say something further in the matter, but so far this is all that has come to my notice as especially bearing on the subject. It would have been very interesting, indeed, to have had Dr. Miller give us the reasons he had for saying that he did not believe there was a word of truth in the doctrine as taught during the past, that if bees once got thoroughly started at storing honey in the brood-nest it would seriously interfere with their storing in sections. But I have not seen a single reason given by him in support of his disbelief.

And it would have been equally interesting had Mr. Root told us what he had run across in his bee-keeping experience which led him to be half inclined to think the Doctor was right in making such a sweeping exclamation against something which hundreds of bee-keepers believe they had proven true. But Mr. Root does not give us even a little bit of experience in support of his half think.

Mr. Boardman, on the contrary, tells us something which hundreds and thousands of bee-keepers have noticed, doing the same without even hinting at the unbelief of Dr. Miller, or the skepticism of Mr. Root, and probably wrote what he did without a thought that he was running counter to what those gentlemen believe. Were I asked which of the three was right, I should have to decide with Mr. Boardman, for all of my experience of over 30 years arrays itself on his side, and I cannot doubt my own experience.

When I commenced to keep bees I adopted the 12-frame Gallup hive, and thought that hardly large enough, as the colonies of bees that lived through at that time, year after year, were always the ones in very large box-hives, the colonies in the smaller box-hives being lost in winter more frequently than otherwise. Everything worked well so long as it was increase I desired more than surplus honey, but with the desire for surplus honey came the fact that I had the most of it stored in three or four combs occupying each end of the hive, these eight combs often containing from 40 to 50 pounds of the very choicest of honey, just as Mr. Boardman says is the case with him. Then, after these eight combs were nearly or quite filled with honey, the bees instead of entering the sections, would, as Mr. Boardman says, persistently continue to store in the other four brood-combs, instead of taking to the sections, until, at the end of the honey harvest, if it continues long enough, the colonies in such hives would be very small in numbers, the combs crowded with honey, and very little in the sections for Doolittle.

As soon as I saw where the real trouble lay, I reduced all of these 12-frame to those holding 9 frames, then worked these hives so that each of the nine frames were solid with brood when the honey harvest commenced, upon which the bees would immediately enter into the sections with their honey (as they had nowhere else to put it), when I had something which gave me from double to three times the yield of nice, salable honey that I had ever had before. Yes, and I used dummies in a part of these hives, too, for any colonies that did not give a prospect of filling the nine frames full of brood by the time the honey harvest was on, were confined to the number of combs that would be fully occupied with brood, even through that number was as few as five or six. The older readers of the American Bee Journal will remember my writing several articles on "those six-frame hives," telling how they were worked, and how, in 1877, I secured the unparalleled average yield of 166½ pounds per colony from the whole apiary, nearly all of which was nice, marketable honey.

And then to have Dr. Miller stand up and say that he

doesn't believe there is a word of truth in it (not in the yield of honey, but in the plan), seems strange to me. Will he kindly tell the readers of the American Bee Journal the reasons he has for his unbelief, or give them a better plan, if he has one. I am very anxious to learn, and if there is a better way than the one I have been following I would gladly follow it. And if it is better, the giving of it will be a blessing to the giver, and also a blessing to the bee-keeping world. Onondaga Co., N. Y.

Fertilization of Fruit-Bloom by Bees.

BY DR. C. C. MILLER.

ON page 280, Mr. Thaddeus Smith makes an assertion that is entitled to consideration, to the effect that he thinks bees are not needed on certain islands to fertilize fruit-blossoms, and then asks: "If not necessary on these islands, why should they be anywhere?"

Mr. Smith found a small number of "nectar-loving insects" present, and it is possible that they could do all the fertilizing that was needed, while in other places the number of such insects may have been less, so that there would not be enough of them to do such fertilizing without the aid of the bees.

The testimony of Mr. Smith should be given all the weight to which it is entitled, but he should remember that testimony has been given on the other side that is equally entitled to consideration. That testimony has been given by many—some of them experts with no possible bias in favor of the bees, men of ability on both sides of the ocean—and however honest in his opinion, he should hardly ask us to throw to the winds the testimony of a number of men supposed to be competent and trustworthy, just because the testimony of one man is different.

The following item appeared in the American Agriculturist of Feb. 15, as a reply from the extensive greenhouse man, W. W. Rawson:

How many colonies of bees do you keep in your house 300 by 40 feet when cucumbers are fruiting? "Usually four colonies are required for a single house, and they are put in just before the blossoms begin to open, so that they are ready for work as soon as the flowers are ready to receive them. Early in April the old colonies are taken out and new ones put in. We contract for our bees at \$5.00 per colony and use about 50 colonies each season. We usually lose about one-half the colonies, even after the most careful attention is given them. Many of them get out of the house through the ventilators, and are unable to return. Many others lose their lives in the house and various places; but we find it absolutely necessary to keep the house well stocked to insure fertilization and thus good fruit."

It will be seen that it costs at least \$125 a year to have these bees as fertilizers. Does Mr. Smith think it at all likely that this expense would be endured each year if the bees were not needed as fertilizers? McHenry Co., Ill.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

NO PROGRAM FOR BEE-FEVER PEOPLE.

Very true, very true; two men afflicted with bee-fever do not need any program when they meet, and couldn't possibly be made to follow one if somebody should make it. Same of a live convention, I suspect. But when Dr. Miller swung on the ball the next time he didn't do quite so well. Went out on a "fly," as it were, seeing he couldn't go out on a bee. To the conundrum "What's the best honey?" he just said, "The bees' honey." The correct answer is "The bridegroom's." Page 213.—[Of course it's none of our business, but we'd like to know how Mr. Hasty knows. We believe he has never "dared" to be a bridegroom.—EDITOR.]

SWEET CLOVER HONEY.

Sweet clover 12; white clover 8; alfalfa 3; orange 2; basswood 1; California sage 1; buckwheat 0; sweet clover mixtures 3. The commanding lead of sweet clover honey at the Chicago convention surprises me. I had supposed the apicultural world was settling down into the belief that sweet clover honey had a bad flavor. Can well accept the

correction that extracted too soon, and not properly ripened, is the real trouble—that is, for the most part. Perhaps I can add one more important consideration. Almost any nectar which has a decided flavor is liable to be dreadfully over-flavored *when the yield is very scant*. Nature seems to pour in her little spoonful of flavoring extract without much regard to whether she is pouring into a gill or into a barrel; and in the former case she made a bad mess of it. Apple honey has a reputation for being bitter from this cause. Sweet clover in many regions is rather more liable to scant yield than are most of the flowers we look to for honey. Page 213.

THAT "STEAM BOTTOM-BOARD."

It occurred to me that Mr. Dupret failed to indicate to us where the steam should be turned on to run all these little parts and items of his steam bottom-board. But then critics are liable to get over-critical a great many times. Page 214.

GETTING EXCITED BEES OUT OF A CELLAR.

The experience of C. Davenport in getting an awful stack of excited bees out of a too contracted cellar makes an instructive anti-climax to the experiences of Dr. Miller. Surely circumstances alter cases. Perhaps some who never had any such troubles think they could have weathered the situation all right. Old maid thinks she could have made an angel out of the "enfant terrible." Every one could have managed the bad wife save the poor fellow that had her. Editors could always succeed at farming, and farmers always succeed at editing. But don't ask me to succeed at Mr. Davenport's job. My advice to the young brethren is: Don't get into any such a scrape in the first place. Pages 215-217.

BEES PERISHING WHILE "CLEANING HOUSE."

So two bee-brothers came to an agreement that quite a lot of bees perish by "cleaning house" while in the cellar. It stands to reason that the bee which tumbles to the floor with a dead bee it is dragging off is not likely to get back again. Outdoors they frequently fly off with the dead; but I don't think they would try that in the darkness of a cellar. A fence half an inch high terminating the exposed edges of the bottom-board would make it impracticable to drag the dead any further. And the fences could be made of strips of tin, or even of stiff paper. But, let me see, bees even at two dollars a pound would be 22 for a cent; and I am not sure you could not save enough to earn wages while erecting your fences. Page 221.

EXPOSED BROOD AND ROBBING.

As to page 222, I have my doubts whether setting out a frame of brood for a few minutes would incite robbing any worse than setting out an adjoining frame from the same hive with no brood in it. If, in mending combs or transferring, you scatter small chunks of mangled brood on the ground and leave them there, the consequences may make you *think* that brood is specially "bad medicine" for robbing.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Fumigating Brood-Combs.

The past winter was a hard one on bees. I am 10 colonies short, all last year's swarms, and I have 80 frames of nice, white comb, and want to keep them from the moth. I have had lots of trouble in keeping them clean.

I now have a nice house, 12 by 18 feet, for a honey-house and a workshop, full 8-foot story, with floor above and room to store odd stuff. Now I have some 1-inch square pieces, 18 feet long; if I were to nail these to the under side of the upper joists and hang the frames up there, could I fumigate them with brimstone, or something that would kill moths, eggs and all?

I have a little honey on hand, all in tight shipping-

cases. Would that be hurt by the fumigating? Tell me all you know on this line.

The rest of my bees seem strong and in good shape. Last summer I ran out of hives, and put 7 swarms in cracker-boxes, with frames and starters; then I sent for 5 hives, and in the latter part of the season I lifted out the bees, frames and all, and put them in the new hives, all in good shape. The 2 left in the cracker-boxes came through all right. The boxes were on bricks facing the south, and covered nearly all over with snow for some time. The box is only $\frac{3}{8}$ inch thick, with $1\frac{1}{2}$ inch space at each end, and covered over bees, with $\frac{1}{2}$ inch space above the frames.

ILLINOIS.

ANSWER.—Brimstone will do no good whatever in killing the eggs of the moths. It will only kill the larvæ, and will not make the very best work at that after the larvæ have attained full size. If you put the frames in a small space, and brimstone them very heavily, you might succeed in killing the larvæ, but it would take another fumigation after all the eggs were hatched. In so large a room as you have you would hardly make a complete job of it with the frames hanging at the top of the room. No harm, however, would come to the honey in the cases.

You will do better with bisulphide of carbon. That will kill eggs and all. Read up about it in back numbers of this journal, especially in the report of the Buffalo convention. Make two piles of your combs, putting them in hive-bodies, five in a pile; set an empty hive-body on top, and set in it a saucer containing bisulphide of carbon; cover up tight, and leave covered 24 hours. But don't bring a light near it to blow you up.

Perhaps it may be as well, or better, to let the bees attend to the job. Put a hiveful of the combs under a strong colony, and you may feel sure the bees will clean them out and keep them clean.

Making Increase by Dividing.

Is it time for me to jog your memory (as you suggested) so that you would give me a plan for making increase by dividing, or artificial swarming, in the American Bee Journal?

Will there be time enough if I get a queen in June, to make some nuclei and give them cells from the new queen? How shall I go to work to do it?

I wish I lived near some one that made it a business to keep bees, but as a rule my neighbors know less than I do. One old farmer told me the drone-bees laid the eggs for the swarms. Did you ever see such ignorance?

We are having a cold April—a great deal of rain—but hope soon for spring weather. CONNECTICUT.

ANSWER.—Let me answer your questions without taking them in their exact order. Although too early yet in your locality to take any active steps toward artificial increase, it is none too early to study up plans with regard to it.

If you get a queen in June, there will be plenty of time for you to make colonies queened by her royal progeny. There are different ways of proceeding. I'll give one that I think appropriate for those with only a few colonies:

The first thing is to get your new queen in a strong colony. If the colony is not very strong when she is first introduced (and it is usually a little easier to introduce into a colony not too strong), you can strengthen it by drawing from others. A frame of brood, as nearly as possible all sealed, will in a short time add considerably to the strength of the colony. Indeed, a comb may be so well filled with brood that four of them, when the brood has all hatched out, will make 20,000 bees—not a bad colony. Be sure never to give more brood than the bees can cover; that would be a waste. You may, however, give more than the bees can cover, if, with the brood, you take the adhering bees. But if you put in too large a proportion of strange bees there is danger that the queen may be attacked. If there are three frames of brood already well covered by bees in the hive, there is probably no danger in introducing a fourth frame with bees from another colony. But it might not be safe to introduce two frames from another colony, for that would make too strong a proportion of strange bees. If you add more than one frame of bees, it is safer to take them from different colonies. If you use bees that have been queenless 48 hours or more, you may have little anxiety about adding any number. These remarks apply to strengthening either nuclei or full colonies by taking brood or bees, or both, from other colonies. Remember that it is safer to use queenless

bees when convenient, although there is little danger in taking from colonies with queens if you do not take too large a proportion from any one colony. The safer way, if not to slow, is to take brood without bees. I may say, however, that in my own practice it is rarely the case that I take brood without bees, and the few exceptions are generally because I cannot find the queen in the colony from which I take the brood. Of course, the queen must always be found if the bees are taken, otherwise she might be taken with the bees.

If you have the material to spare in other colonies, you may make the colony with your choice queen so strong that it may require two or three stories to hold the frames, or you may do with only one story. The colony will now be made queenless, but at least six days must elapse after giving the last brood to the colony, else you may have queens reared of the wrong stock. Take two frames with the queen and adhering bees, put them in an empty hive and set on a new stand. Nine days after you have made the colony queenless you will form your nuclei. Into each hive put two frames of brood with adhering bees from the queenless colony. There will be some honey in the frames you use, and it will be an additional advantage if you can give each nucleus another frame containing some honey. The bees, being queenless, will not be much inclined to desert their new localities, but you can help matters by plugging up the entrance with green leaves. A day or so later you may open the entrances, and if you happen to forget it no great harm will come, for the green leaves will dry and shrivel so that the bees themselves will open a passage.

If you use up all the material of the queenless colony, as probably you will, there will be nothing left on the old stand. Take the hive that now contains the queen, put it on the old stand (of course you will fill the hive with combs or foundation), and put in its place one of the nuclei.

Nothing has been said about queen-cells. They will be on different parts of the combs, some of them where you want them, but mostly where you do not want them. Cut them out, where wrongly placed, and see that each nucleus has at least one good cell—better have two or more in each nucleus—the cells being between the combs and centrally located, so there is no danger that they will get chilled. You may fasten each cell in place by pinning it on with a slender wire nail or a pin $1\frac{1}{2}$ inches long; and it is still better to fasten it on by means of a staple an inch wide, or wider, making sure that in no case the cavity of the cell shall be punctured.

In two weeks examine each nucleus for young brood or eggs, and if you find none a mature queen-cell may be given, provision for such queen-cells having of course been made in advance. Whenever the young queen is laying, you may build up the nucleus to a full colony in the manner already given.

Comb Honey Wanted Instead of Increase—Buying Hybrid Bees—Foundation in Sections.

I have 17 colonies of bees, 11 of which I think contain 3 or 4 frames of brood now, the remaining 6 being weaker.

I have intended following the plan Mr. Doolittle outlined in his book on "Scientific Queen-Rearing," of stimulating brood-rearing by reversing the brood and supplying them with honey inside the brood-nest. My object is to secure as much comb honey this summer as possible, instead of making an increase.

1. When would you advise me to begin active operations here, where our main honey-flow is from sweet clover, although we have some white clover?

2. Would it be possible for me to build up all of these colonies by equalizing the brood in the manner you described in the last number of the American Bee Journal, or would it be good to follow Mr. Doolittle's plan of uniting the weak colonies, by which I understand that I would have 3 less colonies for the production of surplus, 3 of them forming nuclei.

3. Under these circumstances, if I should buy bees, would it be best to buy full colonies, or nuclei? That is, would I be able to build up nuclei purchased now, so that they would produce surplus this season?

4. I notice an advertisement in the Bee Journal of hybrid bees for sale. Would it be well to purchase such bees, or would they be objectionable for some reason?

5. Will you please tell me what amount of foundation you use in section-boxes? It should not extend entirely from the top to the bottom of the box, should it?

ILLINOIS.

ANSWERS.—1. So far as the season of the year is con-

cerned, there is little danger that you will begin too soon, but there is danger that you may begin before the bees are strong enough to be meddled with. Take a colony that has no more bees than just enough to keep warm what brood it has, put a frame of honey between two of its frames of brood, and you will have a lot of chilled brood. So don't begin until you have so strong a force of bees that they can take care of more brood than they are already covering. In many cases that will mean not to begin at all, for an ambitious queen under favorable circumstances may keep all the cells supplied with eggs that the bees can care for.

2. I don't know, for I am not sure from what you say how strong yours are. You say your strongest colonies contain three or four frames of brood. If by that you mean there is brood in three or four frames, that's a very uncertain quantity. For it sometimes happens that when there is brood in four frames, the two central frames will each have a patch three to six inches in diameter, while in each outside frame there will be a patch much smaller, the brood in all four not being as much as one frame would easily contain. If, however, you have three or four frames well filled with brood, say three-fourths full each, then there ought to be no trouble in bringing all up to full strength for the sweet clover, and perhaps for the white clover. At any rate, if you follow the instructions on page 266, you will do nothing with the weakest till all the others are strong; and if you find that crowds too hard on the time of harvest you need not do anything at strengthening the weakest.

3. I don't know. It depends on the strength of your colonies, and the strength and number of the nuclei bought. If honey is your object, perhaps you will do as well with what you have.

4. Hybrid bees are often objectionable on account of their tempers. But they may be good workers, and it is not hard to change them to Italians; at least you need not increase from them, and then you will not be getting any more on your hands.

5. The top starter is $3\frac{3}{8}$ inches wide and $3\frac{1}{4}$ inches deep. The bottom starter is $3\frac{3}{8}$ wide and $\frac{3}{8}$ deep. That makes the starter extend clear to the bottom, of course, but there is a space of something like $\frac{1}{4}$ inch between the two starters. About the first thing the bees do in the section is to fasten the two starters together.

Introducing Queens.

As I have received queen-bees from a large number of different queen-breeders in the last 15 years, also this spring, I should like to ask in regard to one I received a few days ago. When the queen was shipped he also dropped a card requesting me to kill all escort bees.

1. Why would he advise me to kill the bees? Do you think he has any bee-disease in his apiary?

2. If removing the bees is any advantage, at what time should they be removed? When you put the cage in the hive, or when you remove the plug in the cage?

WISCONSIN.

ANSWERS.—1. It is not likely that he instructed you to kill the escort bees because they were diseased. A man dishonest enough to send diseased bees would be dishonest enough to keep quiet about it. The probability is that he believed that the presence of strange worker-bees would hinder the cordial reception of the queen; and it is quite possible his belief is correct. The department of the queen herself has something to do with her reception, and she may not be so ready to make friends with strange bees so long as some of her own daughters are at her side. Besides, the bees of the queenless colony might have some animosity to the strange workers, which would make them less friendly to the queen. In most cases, however, the queen will be received kindly without her escort being killed.

2. If the escort is to be killed, it should be done before the cage is put in the hive at all.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

WISCONSIN BEE-KEEPING is the title of Bulletin No. 2, just issued by N. E. France, State Inspector of Apiaries. It contains about 80 pages, and is fully illustrated with pictures of bee-fixtures, Wisconsin apiaries, etc. It is really a pamphlet on practical bee-keeping, by a practical apiarist. This Bulletin is not for sale, but for free distribution among Wisconsin bee-keepers only, of whom there are reported to be over 10,000. For a copy, address Mr. France, Platteville, Wis., who will see that a copy is mailed you—if you live in Wisconsin.

FRANCOIS HUBER—A BLIND DISCOVERER.—One of the most beautiful stories in the world is that of a blind man, his devoted wife, and his faithful servant, who lived in Switzerland in the middle of the eighteenth century. The name of Francois Huber is known to every naturalist; but greater than his work was the man himself, and his life story is worth reading by every young man or woman who to-day wants to make the best out of life.

It did not seem as if Francois Huber could make anything out of life, for, though his father was a scientist, and the boy had the best of teachers, he became practically blind at the age of fifteen. The same disease which

FRANCOIS HUBER.

caused the blindness of Milton attacked him, brought on by much study at night in insufficient light, and by intense application to his books when his health was not equal to the strain. His father, in alarm, took the lad to Paris, where Tronchin, the famous physician, ordered him at once to give up all study and try life on a farm. So Francois Huber went to work like a peasant lad, following the plow. In a short time his health was completely restored; but, alas! his eyesight was not a whit improved, but rather the worse for the experiment. The highest authorities now pronounced the disease incurable, and darkness day by day closed in upon him.

Although so young, Francois had yet a sweetheart, Marie Aimee Lullin, the daughter of a prominent Swiss official. The boy and girl had loved each other from their earliest school days, and, though the father vigorously objected to his daughter's betrothal to a blind man, Marie never faltered in her devotion to Francois. Her father forbade all communication between them, and she obeyed; but, when she came of age, her first act was to marry the man she loved, and the marriage proved ideally happy. The blindness of Francois only drew out the ex-

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gaudy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested.....	1.50	8.00	15.00
Selected Tested.....	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Quirin the Queen-Breeder,

PARKERTOWN, OHIO.

[Parkertown is a P. O. Money Order office.]

512 MASS. AVE. INDIANAPOLIS, IND.

quisite devotion and tenderness of his wife's unselfish nature, and when, after 40 years of perfect companionship, she was taken from him, he summed up his loss in one pathetic sentence: "It is only now that I realize that I am blind." She was his reader, his secretary, his helper, and neither the cares of her household nor her children were ever allowed to interfere with her untiring service to his every need.

With her help, Huber began his life work—the study of bees. When we consider what powers of close observation are demanded for this sort of work, we can not at first understand how a man, totally blind, could follow the minutest habits of insects, and make discoveries which the most patient investigators before him had failed in making. But, besides his wife, Huber had a servant, a peasant named Burnens, whom he soon found to be "born with the talent of an observer." With infinite patience, by asking a thousand questions, and repeating each observation over and over again, Huber trained this uneducated man into an accurate investigator, upon whom he could rely. Burnens was deeply attached to his master, and willing to take any trouble to please him.

"It is impossible," Huber says, in his preface to his great book upon the bee, published in 1792, "to form a just idea of the patience and skill with which Burnens has carried out the experiments I am about to describe. He has counted pain and fatigue nothing. If there be any merit in our discoveries, I must share this honor with him; and I have great satisfaction in rendering him this act of public justice."

Huber had other interests outside of his bees. Like them, he was ever at work. He invented a sort of printing machine, by means of which he could write to his absent friends—and no man had more friends, or loved them more loyally. He was passionately fond of music, and could compose as well as execute. He loved to walk in the open air, and had knotted cords stretched beside the rural paths near his house, so that he could walk without troubling any one to lead him. As we read his life, we find it not a darkened one, but one full of light, and affection, and sweet compensation. It was a long one, too, for he died in 1832, at 82, full of years and honors, leaving behind him the memory of a noble and victorious fight against a great affliction, under which most men would have given up hope of achieving anything. His work was great; but the greatest thing about Francois Huber was his character, of which indeed it might be said that it had that

"Equal temper of heroic hearts
Made weak by time and fate, but strong in
will
To strive, to seek, to find, and not to yield."
—PRISCILLA LEONARD, in Forward.

Mr. F. GREINER, of Ontario Co., N. Y., wrote us on May 3:

"Our bees have wintered well, although the spring has not been favorable so far."

THE ATTIC APIARY OF REV. W. S. SLY, in his beautiful residence, appears on the first page of this issue. He writes us as follows about it:

Four years ago I built a house, located within 2½ blocks of the Capitol building. Other houses are built on all sides of me. There seemed no way of keeping bees unless I carried out a long-cherished plan of having an attic apiary when I became my own landlord. The high attic—full size of upright and rear wing—is floored, lathed and plastered. A stationary hive was built in a south gable to begin with. An entrance and alighting-board were made of one piece, with side-pieces and wire-screens cover reaching from the hive-entrance through the clapboards.

Purchasing a strong colony in May of the same year, half of the frames with brood and clinging bees were transferred to the new hive, leaving the queen in the old hive, which

The Business End of the NEW RUMELY SEPARATOR

Like all the "Rumely Goods" this is simply perfection. When coupled to our New Rumely Rear Geared Traction Engine they constitute a threshing outfit that not only makes big money for the thresher, but saves grain and money for the farmer. They are durable beyond comparison and when you buy them you are done buying for years to come. Take a little time to think about how it would pay you to own such an outfit, then write us for free catalog.

Going for the Doctor

through the storm and darkness while the suffering one at home is in danger, perhaps of death, is a terrible trip. Why not have a good, sure family remedy in the house? One that has proven a life saver in thousands of cases during the last forty years.

Watkins' Vegetable Anodyne Liniment.

Think what a world of terror and anxiety was saved this man.

DISPENSES WITH DOCTORS.

Middle Grove, Illinois, June 4, 1901.
We have used Watkins' Vegetable Anodyne Liniment in several cases of flatulent colic: have employed veterinary surgeons before, but rely entirely on Watkins' Liniment now, for family use as well as for stock.

WALTER DIKEMAN.

Watkins' Liniment is not only a great thing in cases of serious injury through accident, but is always helpful in cases of Cold, Colic, Diarrhoea, Dysentery, Indigestion, Cuts, Burns, etc. It is equally good for man or beast. If by any chance we have no agent in your vicinity, write to us, and we will see that you are supplied.

A TREAT FOR ALL.

Our new Cook Book and Home Doctor, containing a hundred pages of valuable information in cooking, gardening etc. is out for '02. We mail it free to anyone sending his name and address on a postal card. Write at once and address

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

was placed in another gable. The empty spaces in both hives were filled with new frames with starters.

The hive containing the old queen was worked for honey, and to test her longevity. It was done by giving large storage-room in early spring. She died the past season, having become infertile, aged over 5½ years, the colony having given over 60 pounds of comb honey each year after the first.

The other half of the original colony was worked for increase, and last spring showed 10 strong colonies, which, by autumn, had increased to 24—all but 2 by natural swarming—and over 600 pounds of choice honey for the season, half in pound sections, 113 pounds of which was from a single colony, and sold for 15 cents per pound, wholesale.

Most of the hives have each a glass end and side; so have the section-holders and extracting supers, heavy curtains excluding the light.

The bees have not disturbed any one, as they fly so high; when they swarm, passers—like the priest and levite—"go by on the other side" until the bees cluster on a tree or shrub on the lawn, or in the garden at the rear of the house.

No change is made in the condition or covering of the hives, summer or winter, save to put on or take off section-holders and extracting supers.

The bees have no chance to disturb the operator nor rob open hives. When a few get out into the room they dash for the window-screens and pass out through the bee-escapes.

The plan is an unqualified success. The average profit on each colony the past season was \$7.00, not counting the increase.

WINFIELD SCOTT SLY.

Colonies Strong for the Season.

Bees are in fine condition and strong for the season. The western hot wave has not reached this part of the world.

HENRY ALLEY.

Essex Co., Mass., April 23.

Shade for Hives.

I saw it recommended to plant artichokes for hive-shade. I do not think I should want my hives in an artichoke patch. I want the hives where I can see them, and when there is a breeze they can get the benefit of it.

For shade I put a stone on top of the hive, and then mow grass, weeds and artichokes, and put them on top. Mow in the evening or morning, and put it on green or wet. It will surprise you to see what a good shade you will have. Do not put the stone on top of the grass, for, if you do, when it rains it will run down under the stone and keep the top of the hive wet. By putting the grass on top of the stone, green or wet, when it dries you have a fine shade that will shed rain and keep the hive cool. The stone on the hive leaves an air-space under the grass.

Winnebago Co., Iowa. L. C. GREEN.

A Word for the Cyprian Bees.

On page 232, Mr. E. E. Hasty, in his "Afterthought," makes some assertions which I think, to many, will convey ideas which he did not intend.

Mr. Hasty does not say what races he designated as the longest and shortest tongued, but from all recent measurements we are led to think he refers to Cyprians as the longest, and blacks as the shortest. This has been the result of measurements made by Profs. Gillette, Benton, and many others.

Mr. Hasty says, in his article, that the short-tongued race beats the long-tongued race in storing section honey. Whoever heard of Cyprians being recommended for work in sections? Evidently Mr. Hasty implies that blacks gather more honey and cap

it better. I grant the latter, as they do not fill their cells as full before capping, thus giving their combs a better appearance; but as to their surpassing Cyprinus in gathering power, even the most prejudiced have admitted that Cyprinus are the greatest honey-gatherers. Even Mr. Doolittle says they have excellent storing qualities.

For extracted honey the Cyprinus are most certainly far superior. They fill a place in American apiculture that no other race can occupy.

There seems to be much prejudice against these Eastern bees, but in spite of all opposition they are steadily gaining in popularity, which, though not exactly in accordance with Mr. Hasty's statement, that they have been universally abandoned, is an actual fact.

I grant that tongues "are not all;" yet when long tongues urged on by such ambition as is universally accredited the Cyprinus, the results must be obvious to all unprejudiced bee-keepers. Doubtless Mr. Hasty's views are due to his "new and unreliable glasses."

I do not sell bees or queens of this race or any other, but wish for facts rather than individual prejudice. B. E. GOODENOUGH, Orleans Co., Vt., April 17.

A Bee-Keeping Woman's Dress.

I read recently an interesting article on "Bee-Keeping for Women," by Emma M. Wilson. I wish to suggest to her, and to other bee-women, the wearing of bloomers instead of an underskirt for bee-work. They will find them much lighter than an underskirt, and, besides, more protection from the bees. Bloomers are best made of blue drill or denim. I also wear leggings of the same material; that is so I can wear low shoes. I like a duck skirt and a gingham apron, as the gingham washes much more easily than denim. I wear gloves made of white duck, if I get into a hive that is inclined to be cross. I keep them in my pocket, handy, or else near by on a hive. I wear a black tarletan veil. MRS. N. O. PENNY.

Brevard Co., Fla.

Artichokes for Hive Shade.

Bees are working now, having wintered in fine condition. Wild and tame plums are blooming, also early cherries, and artichokes are up, too.

I wish to offer thanks to Mr. Hasty, and will also say that there will not be very many hot days before artichokes will furnish shade. The strange thing about artichokes is, if the blossom is picked off the stalk, the tubers die a natural death. You see how easy they are kept from spreading. Asparagus, grapes, and rhubarb, are a whole season behind artichokes for shade.

I wanted to have sunflowers a few years ago, so I planted some on my place for poultry feed, but the neighbors gave me "a big talk," and I therefore gave it up. Five miles north of here there is a 160-acre farm not in cultivation for two seasons, and if I saw sunflowers it was on that place.

Kansas is called the "Sunflower State," but those farmers who live in a sunflower neighborhood hate them worse than cockleburrs.

ALBERT WILTZ.

Atchinson Co., Kans., April 20.

Cause of Low Prices of Honey.

I think our bee-keepers are to blame for the low price offered by the commission men early in the season. Take the year 1897, for example: There was about 10 days of the best honey-flow from clover that I ever saw, and immediately the bee-keepers began writing of honey "just rolling in." Well, that was all the surplus we got in this section, and some of our bees starved, but the commission men started in with low prices, and people sold. For did not the bee-papers report a great honey-flow? And it has taken a long time to convince the people that there is not a great deal of honey in the country.

I do not believe one could find 10 pounds of white honey in this locality to-day.

I wonder if the bee-keepers can not be in-

COMB FOUNDATION ADVANCED 3 CENTS A POUND.

Owing to the increased price of beeswax, until further notice, dealers handling the A. I. Root Company's goods are compelled to raise the price of Comb Foundation 3 cents per pound above the prices found in their price-lists and catalogs. Please take notice.—Adv.

structed to wait until the chickens are hatched before counting them.

When the dwindling ceased last spring I had only 10 colonies out of 25, and there were only two of those that I considered of any value. But I fed them up and they did wonders, increasing to 15 colonies, and giving me something over 400 pounds of honey in sections. I sold it to the home trade at 12 and 15 cents per pound. Mrs. C. A. BALL, Oneida Co., N. Y., April 9.

Does Noise Disturb Bees?

There has been some discussion lately in regard to bees hearing. "Does noise disturb bees, etc." I tried 5 colonies the past winter in a new cellar, which I built last summer. This cellar is directly under the kitchen floor. Now, I have a family of boys and girls that like to romp and play as well as the average family of children does; furthermore, some of those colonies were directly under the kitchen wood-box. I have been in the bee-room when the boys would bring in their wood and drop it into the wood-box, and it actually seemed as if the wood-box and all were coming down through the floor into the cellar, yet it did not seem to disturb the bees in the least. This occurred every day, and yet after a confinement of five months and three days they were placed on the summer stands strong and in fine condition. GEO. W. STONEMAN, Door Co., Wis.

An Advantage of Clipped Queens.

What is probably new to many is thus given by G. M. Doolittle, in Gleanings in Bee-Culture:

I do not believe in not having hives all in readiness for swarms when they come; but in case of emergency, if the queen is clipped, you can hold a swarm out on a limb while you make a dozen hives, or all summer if you wish. If you ever wish to do this, as soon as you have the queen in the cage attach a short piece of wire to the cage; and as soon as the bees begin to alight, bend this piece of wire over the limb, so the caged queen will hang where the cluster will naturally be, when the swarm will alight and cluster the same as they would had the queen not been clipped. You can now go about anything you may wish to, making hives or anything else, resting assured that you will find the bees there when you are ready to take care of them. If they should go off they will come back to the limb as soon as they find their queen is not with them, and cluster there again, as I have had them do when conducting experiments along this line, I even holding them thus until they had started several combs, evidently concluding to make their future home on this limb. I at first thought, when they started off so, that they would return to the parent hive on coming back, instead of seeking out the limb; but the queen is of all-absorbing consequence to any swarm, and so they come back to her every time.

The Food Value of Honey.

You ask for an article on "Food Value of Honey as Compared with Meat, Cheese, Butter, etc." This is hard to give. All kinds of food are necessary to health, and the best condition of our bodies. The proteids—meat, cheese, white of egg—we positively must have to live at all. We call food containing much of these "hearty." If we have too little we are poorly nourished and crave them. The carbohydrates—starch and sugars, including honey—if not so absolutely necessary to life, are surely requisite to health and strength. We have a great sugar-factory in our bodies—the liver—so that we may have this necessary food even though we do not take it in our daily regimen.

Fats and oils are likewise necessary to the

3-Frame Nuclei For Sale.

We have arranged with a bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei of bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 or more at \$2.75 each.

All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

best condition of our bodies. We could live on proteids alone, but not in best health, and such diet is very expensive when it alone ministers to our bodily needs. The liver can manufacture sugar when we eat only proteids, but it works much easier and more effectively when we eat liberally of the carbohydrates. Nearly all sugar and all starch must be digested before it can pass to the blood. Not so honey. The bees digest this for us. Thus we may well believe that of all the carbohydrates, honey is the best.

Thus we can say that honey is doubtless the very best food of its kind, and that such food is absolutely necessary to health and strength, and greatly conserves the more expensive and absolutely requisite proteids. The child voices his need of such food in his longing for candy. We act wisely when we give him all he desires in the best of sweets—honey—which should be served most liberally at every meal-time. This will check the desire which leads to the pernicious habit of taking candy at all times and on all occasions.—**PROF. A. J. COOK, in Canadian Bee Journal.**

Is there Danger in the Cell-Cup Plan?

Arthur C. Miller thinks there is. In an article in Gleanings in Bee-Culture, he says among other things:

Under natural conditions a queen lays an egg in a cell. For three days the embryo in this egg grows, the nourishment for the forming larva being the vitellus, or yolk. On hatching, it receives a food prepared in the stomach of the nurse-bee, consisting of honey and pollen acted on by the digestive secretions of her body. If the larva is destined to become a worker it receives such food for approximately three days, after which a gradual change takes place. According to Dr. A. de Planta's analysis, the solids in the food of the worker-larva, before the fourth day, consist of albumen 53.38; fatty substances 8.38; sugar 18.09 percent. After that time the proportions of the same elements are respectively 27.87, 3.69, and 44.93 percent—a very decided change. According to the same tables a larva destined for queen receives of albumen 45.14; fatty substances 13.55; sugar 20.39. These figures are taken from Mr. Cowan's book, "The Honey-Bee," page 123. Mr. Cowan also quotes Dr. de Planta as saying that, for the first three days, the food of queen-larva is the same as of the worker-larva for the same period (page 122), and that "queen-larva were fed the same food during the whole term of their existence." There is a discrepancy here which needs investigating.

What I desire to impress on the mind of the reader is that, with each varying stage of the development of the embryo—that is, from the commencement of the incubation of the egg until the larva spins its cocoon, there takes place a change in the proportions of the elements of the food. It is of vital importance that these changes occur at the proper time, if the embryo is to develop normally. It should be borne in mind that the larval bee is as truly a developing embryo as is an unborn mammal.

Size of Hives.

"Is a larger hive than an 8-frame Langstroth desirable?"

Mr. Hall—For what purpose? I have equal to the 8-frame Langstroth hive, and I have equal to the 11-frame, and for extracted honey I want the large one, and for comb honey I don't trouble which one it is.

Mr. Holmes—Answer it both ways.

Mr. Hall—For comb honey the smaller one. In the location where you have a fall flow the smaller one, every time. In locations where you have nothing but white honey, where it shuts off July 22, the large one every time.

Mr. McEvoy—Wouldn't the man have something to do with it?

Mr. Hall—The man has something to do with all these things. He is the smallest portion of it. The field is first, the man is next, the hive is next.

Mr. Fixter—As far as my little experience is concerned, I have no use whatever for the large hive.

Mr. Hall—But you have no fall flow.

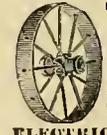

Mr. Fixter—No. We have had the 8-frame

Wanted Gomb and Ex-tracted Honey!

State price, kind and quantity. **R. A. BURNETT & CO., 199 S. Water St., CHICAGO 33A1f** Please mention the Bee Journal.

Langstroth, and a hive 15x15x20, and a hive 14x15x12; we have the Heddon hive; the 8-frame Langstroth hive can knock them all out. That is a three years' test.

Mr. Hall—Mine had 25 years' test.
Mr. Holtermann—I might just say that the company I am with are beginning, and after weighing it all carefully we have come to the conclusion, at least I have, that we are going to have 250 hives made, and that they are going to be 12-frame Langstroths.

Mr. Hall—Mine is equal to a 13-frame Langstroth.

Mr. Holtermann—I agree with Mr. Hall entirely. Mr. Hall says he wants the large hive for extracted honey, and for comb honey he does not care which he has. I don't want to run two kinds of hives if it can be avoided. If you are beginning two sizes of hives, and you can make both do for comb or extracted, I don't just see the objection that Mr. Hall has if you have the fall flow.

Mr. Hall—The objection is this: I tell you what I do at home. I take every ounce of white honey I can get from the top, and I either fill them up with foundation or put two together and run them down to the fall flow. They work together, and they give me 50 or 60 pounds of a fall flow.

Mr. Holtermann—You can contract through the light flow, and then give them more room for the dark.

Mr. Hall—I would rather keep them in the small hive so that they would not have any surplus honey down-stairs, and then give them a good chance to fill up with the fall flow.

Mr. Holtermann—You would contract to about 8 for winter?

Mr. Hall—If I am not lazy I would contract to 4. Four will hold 35 pounds.

Mr. Gemmill—I have some on 4 solid sealed combs now; that is all they have. I would like to endorse what Mr. Hall says. It is not so much the hive, it is the location and management. If I had Jones' hives I would use them; if I had smaller hives I would utilize them in such a way that I could make them big if I wanted to.

Mr. McEvoy—I think Mr. Gemmill set it right when he said it was the management; but I would want that management conducted with the 8-frame Langstroth.

Mr. Gemmill—In regard to wintering, do you mean?

Mr. McEvoy—No; in wintering, the big frame is nowhere. I would want the smaller hive then, every time.

Mr. Gemmill—Do like Mr. Hall, contract it if you want to. I want the big hive for summer.—Canadian Bee Journal.

CONVENTION NOTICE.

Illinois.—The Eastern part of the Northern Illinois Bee-Keepers' Association will hold their spring meeting at the residence of O. J. Cummings, 2½ miles northeast of Rockford, Ill., Tuesday, May 20, 1902. All interested in bees are invited to attend. B. KENNEDY, Sec.

400 Boxes 2d-Hand Cans.

We have on hand 400 BOXES of 60-lb. Tin Honey-Cans (2 cans in a box.) Many of them were emptied of honey by ourselves, and all have been carefully inspected. If we had occasion to do so, we would use them again ourselves. We need the room they occupy, and offer them at a low price to close out, as follows, f.o.b. Chicago: 5 boxes at 50 cts. each; 10 boxes, 40 cts. each; 20 boxes, 35 cts. each, 50 or more boxes, 30 cts. each. NEW boxes of cans are worth 75 cts. a box of 2 cans. So these 2d-hand cans are a bargain. Better speak quickly if you want any of them.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, May 8.—The trade in honey of all kinds is light, especially is this true of comb, the little trade that exists is for the best grades. Basswood ranges from 14@15c; that having more or less basswood, willow or other white nectar, 13c; off grades of white, 10@12c; amber, 8@9c. Extracted, white, 5½@6c; amber, 5@5½c; some lots of new extracted offered, but no sales have been made. Beeswax scarce at 32c.

R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.

THE FRED W. MUTH CO.

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and seasons practically over. Some comb honey is selling at 14@15c. Extracted, 6@6½c. Beeswax, good demand, 30@31c.

H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7½c; Florida honey, in barrels, 6@6½c.

BLAKE, SCOTT & LEBB.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c.

M. H. HUNT & SON.

CINCINNATI, May 8.—As the warm weather set in, the demand for comb honey is as good as over. There are no settled prices; for whatever is left, prices are made to force sales. Extracted honey is in fair demand and finds steady sales. Amber is sold in barrel lots for 5@5½c; water-white alfalfa, sells from 6@6½c, and white clover brings from 6½@7c. Beeswax scarce and brings 30@31c.

C. H. W. WEBER.

NEW YORK, Apr. 7.—Comb honey, last year's crop, practically cleaned up, but as we wrote a little while ago we had received new crop from Cuba, and are now receiving new crop from the South. Demand is fair at 14c for fancy white, 13c for No. 1, 12c for No. 2, and 10@11c for amber.

Extracted: The market is decidedly dull. Very little demand, with large stocks on hand, some of which no doubt will have to be carried over, and indications point to a further decline in prices. We quote: White, 6c; light amber, 5½c; amber, 5c; Southern, 5½@5¾c per gallon, according to quality. Even these prices are shaded in car lots. Beeswax, scarce and firm at 29@30c.

HILDRETH & SEGLEEN.

SAN FRANCISCO, Apr. 16.—White comb, 10@12½ cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4½@—; amber, 4@—, Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Demand is not very active, and market cannot be termed firm, although quotable values remain without important change. Considerable honey of last crop is now being offered, which up to a few weeks ago had been held off the market. New crop is expected to arrive in wholesale quantity in the very near future.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.
THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.
J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order as follows:

No. 1.—For sending us the names and addresses of **two new subscribers** to the American Bee Journal and \$2.00, we will mail you **one** of these queens free.

No. 2.—Or, for sending us **one new** subscription at \$1.00, and 30 cents more (\$1.30), we will mail you a queen, and the Bee Journal for one year to the new subscriber.

No. 3.—Or, send us \$1.60 and we will send to you the Bee Journal for one year, and also a queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.,

* Editorial. *

Answering Comb Honey Lies.—This should be done in the very same papers that publish the lies. We are very glad to have our readers send us clippings from newspapers showing what is being said on the honey question, but please don't ask us to answer them all in the American Bee Journal. So few of the people who read those lies in the daily press take this journal, that it is hardly worth while for us to devote much time or space to them.

The thing to do, is for the readers who subscribe for and read the newspapers that are guilty of publishing untruths about honey, to write to the editors of such newspapers, placing the truth before them in a courteous manner, and requesting its publication.

Not even the editor of a newspaper can possibly know everything, and if he is only half-witted he will be glad to publish a correction of misrepresentations that have unintentionally appeared in his paper. But it is useless to publish such corrections in a paper not read by the same people who read the misrepresentations in the first place. Something like a paper that for a time tried to correct the errors found in other papers, when its own circulation was only a fraction of the papers it was correcting. It seemed to be almost a flat failure.

Alfalfa and Irrigation.—Editor Root having expressed the opinion that alfalfa does not yield nectar except on irrigated lands, Carl F. Buck replies in *Gleanings in Bee-Culture* he does not know what they would do in Kansas if it were not for alfalfa. He says:

Alfalfa does not seem to do much good in Missouri, Illinois, and other eastern States; but in Nebraska, Kansas, Oklahoma, and Indian Territory, alfalfa on the bottom lands does yield honey, in some quantity at least, and in many localities it yields it in abundance—but, of course, not like the irrigated districts of Colorado and other western States.

Honey-Questions in Newspapers.—Several of these have appeared recently in a certain Chicago daily newspaper, having been referred to one of its special writers for reply. Here is a sample:

"Please inform me if pure honey will turn to sugar. I have been told it does. If so, what can I do to get it back to a liquid?"

"L. H."

Our readers will enjoy the indication of the quantity of information on the characteristics of honey possessed by the one who answered the question, when they read this:

"Pure honey should last for years without candying if kept in a close jar or bottle. Nothing will bring it back to a liquid state after it has candied, unless you adulterate it with water and boil it."

Think of mixing water with granulated honey, and then boiling it, in order to re-liquify it! What a big free advertisement that is of the amount of ignorance concerning honey the one answering has in storage. How much better it would have been to have quoted from Dr. Miller's large stock of "I don't know's."

Well, here is another that is pretty good:

"Do you agree with Dr. Kellogg, of Battle Creek, in his statement that honey should be partaken of very sparingly and as a relish only, for the reason that the bee injects a small quantity of poison into each cell just before capping the same for the purpose of preserving the honey? I believe this poison is called formic acid."

And this is the answer given to the foregoing question:

"The idea is novel to me—and startling. However opinions may vary as to the cause, honey is certainly extremely unwholesome when eaten in large quantities. Some people can not eat it at all. I have supposed this to be in consequence of the clogging and congesting effect of the wax upon the alimentary organs. The suggestion of formic acid is an unpleasant complication."

Surely, it is a novel idea that the bee "injects a small quantity of poison into each cell just before capping" it.

And so it is extremely unwholesome to eat large quantities of honey? It might be just as unwholesome to take "large quantities" of water, or large doses of anything else that is good. But who eats honey like a hog eats corn or potatoes? It isn't necessary to make a whole meal of honey alone, any more than one would eat all butter or all pie at one meal. A person ought to use a little sense in eating, that is, if he has any.

Yes, we have seen people who couldn't eat honey. The trouble was, we found, they had been trying to eat glucose with a piece of honey-comb in it. As soon as they got hold of *honey* they were all right. Now, we can eat perhaps a half section of honey at one meal, if we feel like it, but that, of course, is almost bordering on the swinish idea, we must confess. Perhaps a quarter of a section of honey would be sufficient. But we never stop to count the cells and estimate how much bee-poison we are eating. That would be ridiculous.

When it comes to extracted honey, we like to have at every meal about two full teaspoonfuls in a little side-dish. We like to

clean it all up at each meal. Then it "tastes like more." But if we were to be a little piggish, and try to put down a half-pound at one meal, we would likely not care for any more at the next meal, or for several days. A little and often we believe is a good practice when it comes to eating honey.

But to return to the poison the bees put in the honey. Dr. Kellogg ought to get a few bees and watch them inject the poison into each cell. Unless he *knows* such to be a *fact*, he should not give utterance to the idea. Some people are so easily influenced by what they read that they might be induced to deprive themselves of so luscious a viand as honey, and all because they had read somewhere that a certain doctor "said so." We have no doubt some people will actually stir some water with granulated honey, and then boil it, in order to ungranulate it.

But we wonder why the daily papers don't refer their bee and honey questions to people who are supposed to know something about such things. Dr. Miller and many other beekeepers would gladly help to get the truth about bees and honey before the people.

◆

The Denver Convention promises to be fully equal to the Chicago conventions of the National Association, and that is saying a good deal. Of course, there is a possibility of the Denver one being greater in many ways. We hope it will be such. The following has been received from Pres. Hutcheson:

THE COMING CONVENTION AT DENVER.

Of course, we naturally expected, if the National convention went out to Denver, that those Western people would do the handsome thing, but the present indications are that they are going away ahead of anything that any of us have *dreamed of*. Some things have come to me in private letters, giving hints of what may be expected, but all of their plans are not yet sufficiently completed to be given to the public; however, I have a letter from Secretary Working, that I have permission to publish, and here it is:

DENVER, COLO., April 26, 1902.

Mr. W. Z. Hutcheson.—

Dear Sir:—We have put both feet into it! Yesterday and the day before our Executive Committee (Harris, Gill, Raubfuss, and Working) made the preliminary arrangements for the big meeting in September. Following are the chief points decided upon:

The Colorado Association will meet on Tuesday morning, Sept. 2, and devote the day to business, and in the evening and the following days take part in the general sessions of the National Association. Our program committee will work with yours.

We will give a complimentary banquet to members of the National Association coming from other States than Colorado, and a "Seeing Denver" trolley ride to all the attractive places in the city to the same people. Our members, and those of your Association who have the good fortune to live in Colorado,

will have the pleasure of sharing in these pleasures for a fixed price—to be fixed later.

We will plan for special excursions at low rates to places of interest in various parts of the State.

We gave our committee on exhibits \$50, and the authority to beg a thousand, for the purpose of making a great exhibition.

We decided to "spread" ourselves in such a way as to make the visiting bee-keepers forever proud of having attended the Denver meeting, and those who don't come everlastingly ashamed of themselves. And we have persuaded the Mayor of the city, and the Governor of the State, to do their utmost to make the occasion memorable; and the men who hold the purse-strings of the city, are interested. Promises later. Then, too, the Secretary of the Denver Chamber of Commerce, who is past-master in such matters, has become an enthusiastic member of our banquet committee—a committee that is not too big to do things.

That ought to be enough to tell you now. You are to tell us when we may give the banquet. You are to name us three men, including yourself, who will respond briefly and *thankfully* to addresses of welcome by President Harris, Governor Orman, and Mayor Wright. As for the banquet, you are to prepare for it and nothing more—to be in good humor, in good appetite, and in large numbers.

As for our people? With the kind co-operation of the railroads, we'll bring them to Denver in crowds. There'll be as many of our folks as of yours, if you dare! And before we are done with you, you'll be ours and we'll be yours.

Scatter the news! Tell it in Gath and Askelon. We'll tell it wherever Denver papers circulate. Yours truly,

D. W. WORKING,

Secretary Colorado State Association.

It is very evident to me that the man who misses the coming convention at Denver will miss the treat of his lifetime. I expect to see it outstrip its predecessors in every possible manner—and that is saying a great deal. But look at the conditions: In the heart of the great West, and for the *first time*. Bee-keepers of both high and low degree, all over the West, will flock to it. The local arrangements, upon which the success of a convention is so largely dependent, are in the hands of very capable men. The rates of the railroads will be low. It is at the right time of the year—before cold weather, and after the work and heat of the season are over. The sights to be seen in and around Denver are equal to any on earth. Go to Denver, meet the boys, have one grand holiday, and go home loaded with enthusiasm and new ideas—the two things upon which all successes have been builded.

W. Z. HUTCHINSON, Pres.

Now, we submit that if the whole of the above doesn't sound about as windy as the windiest thing that ever came from this notorious "Windy City" (Chicago), we are no lover of honey. But if there are any who doubt the ability of those Denverites to carry out their big plans and schemes, the best way to see them fail (or succeed) is to go to the convention.

Just think of that banquet—with meat and other eatables soaring aloft in price! And the trolley ride! Yes, and the Governor and Mayor! And there's that hustling Secretary Working them all!

Well, it looks to us as if it is going to be a regular hallelujah time. We hope to be able to "take it all in" when the time comes. But our capacity may not be equal to it, even if we should be "Aikin" ever so hard to do so.

Let's all abscond to Denver, and swarm down on the bee brethren and sisters there in regular apiarian style.

Hurrah for Denver! And the convention!

Weekly Budget.

RED CLOVER QUEENS.—The breeder who rears and mails the red clover queens we have been offering, writes us that he expects to be able to begin to mail our orders June 10 to June 15. If the weather is favorable, he intends to have all our present queen orders filled by July 1st.

A postal card will be mailed a day or two in advance of sending the queen, to each person entitled to receive a queen from us.

This will answer a number of readers who are getting somewhat anxious about the red clover queens they are to have.

CACTI AND ALFALFA IN ARIZONA.—Editor E. R. Root, of *Gleanings in Bee-Culture*, as will be remembered, made a trip through the South and West last year, and afterward described his journeys with pencil and picture. This week, through the courtesy of *Gleanings*,

THE CELEBRATED FOREST OF GIANT CACTI ON THE ROAD LEADING FROM TEMPE TO PHOENIX, ARIZONA.

we give two of the illustrations that will be of interest to our readers, and the following part of the write-up which accompanied them:

We had planned to drive to Phoenix, and in doing so we had to pass by a cactus forest, perhaps the most remarkable in the world, on the main road leading from Tempe to Phoenix. As we came up alongside of these magnificent specimens of tree cacti, monarchs of their kind, I could not help thinking of my old boyhood days at school, when I was studying geography, how I used to look at the pictures of these giant cacti, or what seemed to me to be very funny trees then, and whether or not I should ever see the real thing. I asked Mr. Chambers to drive up near some of them while I, with my little pocket kodak, would take in a more permanent reminder of them, and here are some of the "shots."

On the top of these cacti will be seen small objects. They are nothing more nor less than beautiful blossoms that yield copiously a rich, thick nectar. Quite a little swarm of bees will hover around them (they were thick

around them when the photos were taken; but on account of their small size, of course they do not show), for all a bee has to do is dip down into one of the great, big cups and drink and drink to its fill. Then it flutters off, scarcely able to fly, while the others are gorging themselves only to go back home in a lazy, uncertain flight.

In the picture shown we have a general view of the whole forest of tree cacti. Over in the distance will be seen the mountains near which orange-growing, I was told, was possible. The broad expanse of country shown in the general view, is a perfect desert. Nothing will thrive there but these cacti; a peculiar kind of thistle, or what seemed to be such to me, and the ever-present sage-brush; and yet, on the *other side* of the road were beautiful market gardens and fields of alfalfa. Why this difference? you ask. The one can be irrigated, and the other can not; and I hope it never can, because this desert has some attraction just as Nature left it, and man should not be allowed to desecrate it.

This forest is probably the largest, both in the number of trees and in its general size, of any in the world. There seems to be no apparent effort to preserve these magnificent specimens. They are mutilated by curiosity-seekers tearing off a piece of the bark. Then, as if the work of civilized man was not enough, the Indians mutilate them with their bad aim, throwing stones to knock down the fruit that develops from the flowers, of which the bees are so fond. Indeed, there is no way

by which this fruit can be gotten out by pelting it down. Taking it all in all, it seems too bad that the general government is not taking more active measures to preserve such magnificent specimens of cacti—specimens that take years to grow, and that landscape gardeners in the Eastern cities would pay thousands of dollars for if they could only cultivate them.

Speaking about the fruit of the tree, cactus reminds me that no one but an Indian can eat it. It affects white men very seriously, and some have been known to die from it; for it has a beautiful flavor, and therein lies the danger. Before civilization had encroached on either side of this magnificent forest of cacti, the Indians were in the habit of getting water from them. There is a trick about it that they alone understand; and although the water, I am told, is somewhat brackish, yet to one almost dying of thirst, I suppose it has all the freshness of the delightful cool springs that we knew in our childhood days.

After I had snapped the kodak right and left, I got into the buggy again; but as I did

BY A SHORTHAND REPORTER.

(Continued from page 309.)

HIVE BOTTOM-BOARDS.

"How many are satisfied with the Danz. bottom-board?"
Five voted favorably.

"How many are not satisfied with it?"

About the same number voted unfavorably.

Mr. Swift—Why not?

Dr. Miller—Because I do not think it is as good as the Miller bottom-board, after which it patterns. The Danz. is simply an imitation, and it isn't as solid. The original Miller bottom-board was made to be reversible, but I think it is better not to be reversible. In the first place, I think the Danz. is not strong enough. I would rather have it made of good, strong lumber. In the second place, I would rather have it made not to reverse. Another point, the Danz. is not deep enough. It is $\frac{1}{2}$ and $\frac{3}{4}$. I want it two inches one side and nothing on the other side; and I want that depth of two inches to be filled up in the summer-time with a false bottom thrust in, and I can pull it out again with a great deal less labor than I can reverse it: so that I much prefer the bottom-board to stay with the hive winter and summer, in the same way, and when I want a deep bottom I pull it out.

Mr. Horstmann—My objection is like Dr. Miller's. His idea of having the big entrance would be all right for any one wintering the bees inside, unless he has some advantage in it with the bees during the honey-flow: but otherwise I think the common bottom-board, the same as he uses, the every day bottom-board, is the best.

Dr. Miller—Did I understand Mr. Horsemann to say that there is no advantage in the deep bottom-board?

Mr. Horstmann—The way I winter my bees in the cellar I raise the hives up and put a lath across the front and rear; that gives that width all around the hives. There is no possibility of a mouse getting into the repository, and it is usually warm enough; that is, the bees are warm enough to get at them if there is a hole gnawed through. I don't see the advantage of the big entrance, because I think the rats or mice will get in and have a good time, because the repository is apt to get cold as well as the hive, unless underground, and by and by, having them higher, unless there is some kind of a guard over it, I think it is a disadvantage.

Dr. Miller—There is no law against having a guard at that entrance, and that's just what I want. I want that two inches under the hive in the winter-time more than any other time. I need it more for the cellar than any other place, because then I don't need to separate it from the bottom-board. The bottom-board is fastened to the hive with staples, and when it comes time to take the bees into the cellar the false bottom is taken out, and there is a deep place for the bees to fall down in, and much more easy for you to clean out a space two inches deep than one one-half inch or one inch deep. And when the hives are taken into the cellar a piece of wire-cloth, three meshes to the inch, can be put at the front and there is no possibility of any rat or mouse getting in there then. It is much less work than raising by a lath or anything else. I follow that because it saves me all the labor. All in the world I have to do is to take out that false bottom and put in the wire cloth at the entrance, then it is ready for the whole winter.

Mr. Horstmann—I believe I will have to take it back. I believe Dr. Miller's method is the best, since he has explained it.

Mr. Mooney—Is that a reversible bottom-board?

Dr. Miller—As made in the first place it would be a reversible bottom-board, because in the first place I used it with old hives that had an entrance cut in the hive in front, and they stood on the flat bottom, but with the dovetailed it wouldn't work unless I nailed strips around; but I wouldn't have it to reverse, for the reason I would rather have the deep space there summer and winter.

Mr. Blunk—How far back will that extend?

Dr. Miller—Within one-half inch of the back of the hive—enough so that the bees will not glue it to the hive.

Mr. Mooney—Is that false-bottom supposed to be drawn out any time in the winter to take out any dead bees that may lie there, or is it substantially stationary?

Dr. Miller—It is made of thin material—a shallow box with one end opened—and when I first made it I intended to have it put in.

Mr. Mooney—As a draw?

Dr. Miller—Yes; but I concluded afterwards it was less trouble to draw it out and scrape. I believe I would rather have it taken out entirely.

COMB HONEY SAID TO BE BOGUS.

Pres. York—Prof. Eaton has with him a sample of comb honey from Springfield, Ill., which he has analyzed, and I would like him to explain it.

Prof. Eaton—The public in general have rather queer ideas of the adulteration of food products, and I don't know that there is any one product that they have more misleading ideas about than the adulteration of, and the price of, the pure article of honey. A lady came to me with a sample of honey which was granulated. It was reported that it looked as if it was adulterated. It was rather white in appearance; being solid she was sure that it must be adulterated. I had hard work to make her understand that, if anything, the granulation was a sign of purity rather than of adulteration. Of course, all granulated honey is not pure, but glucose does not granulate. A great many people have the idea that honey must be adulterated if it solidifies, and the newspapers have lately given the public the idea that all white comb honey must be adulterated. You know that is a fallacy. That false statement has brought us a number of samples. This sample is vouchered for as being artificial by one of the State officials of Springfield, and, consequently, I made a more than usually careful examination of it, as it was sent up to me with almost an affidavit that it was manufactured, comb and all. I telephoned for Mr. York and had him examine the honey. I knew he was an expert along that line, and he said it showed every appearance of being manufactured by the bees. I have examined quite a number of samples of comb honey, but I have never yet found a sample in which I did not have every evidence to lead me to believe that it was made at least in part by the honey-bee. This sample is granulated in part and is quite white, but under the microscope I find evidence of pollen, which of course indicates its natural origin; and you will notice many other indications which would lead one to believe that it is made entirely or partly by the honey-bee. It apparently has comb foundation in it, which I suppose a great deal of the honey put on the market nowadays has. I examined the honey extracted from it, and find it to be pure honey; the comb has also been examined, and up to the present time I have found nothing in the examination of the comb that would lead me to believe that it is anything else but pure beeswax. There is one little anomaly in the composition. It doesn't have the same composition as some beeswax.

Mr. Dadant—Was the comb cut, or open, or sealed?

Prof. Eaton—Just as it is now. It came as you see it here, with something on the top and bottom.

Dr. Miller—The capping is there now.

Prof. Eaton—Knowing both the honey in the inside to be pure honey, and the comb to be what I believe is pure beeswax (although I have not definitely decided that yet), and as I find evidences of pollen, I cannot help but conclude that that sample is pure honey, in which conclusion I am aided by Mr. York, who says that it has every external evidence of being pure honey. If any of you can see anything to the contrary from the examination of the sample I wish you would tell me. I don't want to make a mistake.

Mr. Dunn—It was sent as a bogus article?

Prof. Eaton—Yes, sir. The statement was made that there is a lot of adulterated comb honey sold at Springfield.

Mr. Purple—In that sample, what percent of foreign substance did you find? (Referring to a sample of adulterated extracted honey.)

Prof. Eaton—I wouldn't like to state the exact amount of adulteration of any sample of honey. I don't know the composition of the original honey, nor the glucose, because they vary. As Mr. Dadant says, every bee manufactures a different product. If I knew the composition of the original honey and glucose in a given mixture, I could tell the exact proportions.

Mr. Dadant—I think that I must have said that the different blossoms give different results; because I don't think that the bees would make very much difference in the result.

Prof. Eaton—Perhaps that was what you intended, and

said. At any rate, I think it is true, where you have individual bees working, the bee will work on different flowers and perhaps create a different flavor.

Mr. Dadant—If it was what I said in regard to leaves in the woods, what I meant to say was this: That in a section of honey the cells are not all filled up—you will find an empty cell here, two or three there, one over here; then the undulation of the comb. There is another one here, and there are no two alike. I didn't mean to say that the bees made it different; I meant to say that they built it as the leaves of the trees grow differently. I don't care if you take combs or sections of honey, put them side by side, the formation is entirely different. If man—granted that he could, for the sake of argument—build that comb, make the honey and seal it, whenever he sealed them over he would seal them all alike, unless he had two or three, or half a dozen, samples; but take a carload, and one section is just as much unlike the other as two trees. I am conceding the possibility of sealing combs. Prof. Eaton, excuse me for interrupting you so long. You can use the same argument as we do. Grant it that people say that honey is manufactured and put in the comb and sealed. They stated or claimed that the chemist said that the genuine bees' honey has a brown coloring around the cells, and that glucose honey is perfectly white. Take three out of half a dozen sections, you can show him they are not alike—one empty cell here, and there, and that they are never in the same places. How is a human going to begin to do that? You make artificial leaves—you know when they are artificial. Anybody can tell an artificial leaf from a natural leaf. Take all the leaves in one timber, and you can't find two alike.

Prof. Eaton—I accept your correction. I think you can apply the same reasoning to the honey itself. I say the grade, the quality of glucose and cane sugar, would differ; but the saliva of the bee, I take it to be about the same, and that's all she puts into it.

Mr. Dunn—Will glucose granulate?

Prof. Eaton—Not commercial glucose.

Mr. Dunn—Has that been in a cold place? (Referring to the piece of comb honey.)

Prof. Eaton—No, sir.

Dr. Miller—Is there grape-sugar in honey?

Prof. Eaton—There is grape-sugar. There is dextrose (grape-sugar) and levulose forming inert sugar. The commercial glucose contains dextrose. There is dextrin and dextrose in honey but no commercial glucose in honey, and there is not, in a chemical sense, any glucose in honey. Glucose refers to a group of sugars in a chemical sense. It does not refer to any one product.

Dr. Miller—I have watched with exceeding interest the very careful manner of the chemist in making his statements. It occurs to me that if all the statements that go from the Pure Food Commission to the public are made as carefully we bee-keepers will not suffer.

INJURIOUS NEWSPAPER STATEMENTS.

"What can we do to counteract the injurious statements in the newspapers concerning honey?"

Mr. Dunn—I move you, sir, that in view of the statements that have appeared in the Chicago Tribune, it is the duty of this body to set that matter straight. We represent the honey-men of the United States, and inasmuch as that statement has gone forth, it behooves us to answer it on behalf of this organization. I move that Dr. Miller, Pres. York, and Mr. Dadant, be appointed a committee to reply to that article in the Tribune, because they are the best competent to do it. The motion was seconded and carried.

Prof. Eaton—One other thing I think you can do, or at least I will try to do it for you, and that is, to have incorporated in the report of the State Food Commission, a statement similar to what you gentlemen have said in my hearing here, that it is impossible to adulterate comb honey, and quote the fact of the reward for any adulterated comb honey found, and make the statement that there never has been a sample of adulterated comb honey found.

Mr. Moore—One of the reporters here suggests that this motion in regard to the article in the Tribune should say "the newspapers," whereas, if we mention the Tribune, it will not be taken any notice of by the other papers.

Mr. Dunn—I believe in taking the bull by the horns. We have a right here, as an organization, as well as ordinary common-sense individuals, to put the blame where it belongs. Why blame the Chicago press? If they refuse to publish the resolutions of our meeting—

Mr. Dadant—Mr. Dunn is right. We as bee-keepers meet, and they say these lies about us and we stand and say nothing, and that means they are true. They can say these folks met

and passed a resolution as to that. Here is a cartoon showing me putting the honey into the cells!

Pres. York—Yes, that's you. The man in the picture has whiskers, and so have you. [Laughter.]

Mr. Dadant—He is right, let us protest.

Dr. Miller—I don't know whether we are all understanding this thing alike. Now, if one paper makes a false accusation, that paper ought to make a retraction. The next question is, is it not desirable—

Mr. Dunn—You bet they will all take it.

Mr. Miller—Then let us go before all of them.

Mr. Moore—This reporter suggested merely a technicality. If we mention the Tribune the other papers won't pay any attention to it. But if it is stated "in the newspapers," then the City Press Association puts it in, and sends it to all the papers and they report it.

Mr. Dunn—The Tribune can very well say that they were misinformed. We are going to state positive facts here. We are going to challenge the statement that has been made.

Mr. Moore—This reporter represents every paper in Chicago—his report will be sent broadcast. If we refer to a particular paper, there is no attention paid to it. Substitute in place of Tribune, "in Chicago papers."

Mr. Dunn—These gentlemen have common-sense; they won't insult anyone.

Dr. Miller—Allow me to remark, that is capable of two interpretations. One is, they must answer in the Tribune the article in it. It is the article in the Tribune that is wanted to be answered. I don't know what I can do with the other two stubborn heads, but I suppose the committee will do what might be best for the bee-keepers!

Pres. York—We have a pure food show at the Coliseum, and one of the circulars to be distributed at that show has on it the following:

"A REWARD OF \$1,000

for the discovery and presentation of A SINGLE POUND of manufactured comb honey has been standing as an offer for about 20 years, and is still untaken. Why? Simply because there is no such thing as manufactured comb honey, and there never was a pound of comb honey that the bees didn't store themselves.

"A U. S. Government chemist started the story, or lie, about this matter, and when pressed for a reason for his libelous statement, said he did it as a scientific pleasantry. And there are thousands of people who believe that lie about comb honey being manufactured. He said the comb was made of paraffine and then filled with glucose, sealing the cells afterward with a hot iron, or by some equally impossible manner.

"What a pity that so honest and honorable an industry as honey-production should have to suffer so greatly, and so unjustly, just because of the foolish utterance of an otherwise sensible man. Nothing that he can ever say or do toward undoing the awful wrong he did to bee-keeping will atone for the mischief his first statement did. It doesn't pay to try to be funny, particularly when one must tell a downright lie in order to amuse."

The convention then adjourned until 7 o'clock p. m.

(To be continued.)

Experiments in Rendering Comb into Wax.

BY C. DAVENPORT.

DURING the last 8 or 9 years I have used quite a number of divisible brood-chamber box-hives. But, for reasons I will not now take space to explain, I decided last season to quit using this style of box-hive, or at least such large number of them. This decision gave me a large amount of combs to render by some means into wax. I also overhauled the brood-chambers of about 150 colonies in frame hives and cut out all the drone and old, crooked combs and replaced the same with foundation. The old comb I, of course, also wished to convert into as much wax as possible. Now all of this comb is not rendered into wax yet, and some of it never will be, for the moth-worms "got away" with quite an amount of it last season.

I wish to say, before going farther, that I do not believe any man, living or dead, ever did more experimenting in regard to rendering wax than I have, or spent more money for different machines and appliances to be used in this work. I do not say this because I consider there is any credit or honor about the matter; far from it, for all the wax there

was in the large amount of refuse comb I had would be worth but a very small part of the money I have paid out, to say nothing about the time and work. With this, as with many other things in regard to our pursuit, an irresistible impulse has seemed to draw and lure me on.

Previously I had rendered comb into wax by the kettle-and-sack plan, but having heard the Ferris steam wax-press very highly spoken of, I secured one of the latest improved. I next made a steam machine, or rather, had one made, on something of the same plan as the Ferris; it was made very strong, and so constructed that the refuse could be subjected to enormous pressure under boiling water; the baskets were long and narrow, and there were two powerful screws, one at each end of the basket. This machine cost me \$21, and I sold it for \$4.50.

I next had a machine made on a different principle; with this one the wax was rendered with boiling water, and the refuse or slumgum subjected to great pressure under boiling water. I will briefly describe how this machine was made:

It was about the shape, only a trifle larger, of a common, No. 9 wash-boiler. This outer part was made from heavy galvanized iron to fit the inside of this, and leave a space of about 2 inches. Between the two was a basket in which the combs were to be placed, this basket also being held up from the bottom about two inches by means of a heavy, iron spider, which was riveted and soldered to the bottom and sides of the boiler. The method of using this machine was to set it over a fire, put in three or four pails of water, and, as soon as it began to boil, put in as much old comb as the basket would hold. After it had boiled a short time a follower that just fits the inside of the basket was placed on and pressed down by means of a powerful screw at each end. These screws were attached on something of the same plan as those on the Ferris machine, but instead of being small ones, they were made from two medium-sized jack-screws. After the follower had been pressed down the wax would of course rise to the top of the water and was dipped off. This machine cost me \$29.00, and I sold it for \$7.00. I regret now that I did not keep this machine, for it may be that it is as good a machine as I will be able to devise.

The Root-German steam wax-press (one of which I purchased) could be made with but little change so that the refuse could be treated to pressure under boiling water, if desired; and the Root machine has a large and very powerful screw.

I next decided to make a machine on the Hatch-Gemmill principle, that is, boil the comb and press the refuse in a separate machine, for the inventor and one of the users of this style of press told what a large amount of wax could be secured from old comb when this method was practiced.

I sent to Chicago for a powerful screw, with which I at first used a 4-foot lever or handle to turn it, but this did not give power enough to press out all the wax from the slumgum. I next put on a 6-foot handle, but still the power was insufficient. I then put two men on the lever, and broke the screw. I do not believe it would be practical to apply power enough to secure all the wax from slumgum treated on this plan. I could take up a handful of the refuse that had been subjected to pressure by this method and squeeze out wax from it with my hand. I do not mean the wax would drip out of it, but there was wax enough in the refuse so that it could be plainly seen by squeezing a small quantity in one's hand. Of course, a good deal of wax can be secured from the refuse when treated to strong pressure in this way, but by no means all of it.

The readers, if there are any who have followed me this far, may wonder why I bought and made so many different machines. I was not fully satisfied with any of them, and it seemed as if I could improve or make the next one a success.

I also made three or four other machines; one of these treated the refuse to pressure by passing it through rollers. I had great hopes of this principle, but I have given it up as impracticable. Another principle that I have tried, though, leads me to believe that we have been making a mistake by endeavoring to secure all the wax from the refuse by great pressure, for with moderate pressure combined with agitation I secured a considerable amount of wax from refuse that had been subjected to great pressure under the Hatch-Gemmill process.

A far greater percent of wax can be pressed out of the slumgum if the pressure is done under boiling water, but contrary to what some seem to infer, all the good the water does in this case is to keep the refuse or slumgum boiling-

hot while the pressure lasts. After only moderate pressure has been applied no water can penetrate the mass.

When the refuse is dipped out into a separate press the wax, or at least a part of it, gets below the boiling-point at once, and the colder it gets the greater pressure it requires to press the wax from the slumgum. When it gets too cold I do not believe any force it would be practical or possible for us to use in this manner would separate the two.

In pressing refuse or slumgum, whether it has been rendered in water or by steam, or if it is pressed under water or in a separate press, a great deal more wax can be secured if the screw just fits down loose on the follower than can be had if the screw fits in a socket rigid so that the follower has to go down even. Especially is this so when a cloth is used to hold the refuse. Why this is so I am unable to explain. Of course, with any of the machines I have mentioned, what refuse comb I had could soon have been rendered into wax, but I kept the comb on hand because I wanted plenty of material with which to test my new or different machines. But this pastime or holiday work must soon cease, for a while at least, for the time draws near when my real work of producing comb honey will begin for the season.

Southern Minnesota, April 7.

Tongue Length and Glossometer—Co-operation.

BY PROF. A. J. COOK.

I WAS surprised at our good friend Hasty's suggestion of criticism of my statement, that the tongue length of bees as ascertained with the glossometer must agree with the measured length as indicated by the microscope. Why, bless your heart, Mr. Hasty, both tell the truth, and truth never wars or quarrels with truth. The old-time hog had an infinite nose. He was a rooter. With such a hog a plowed meadow only required propinquity. The hog present, and the meadow must be rooted.

The microscope told of the long Syrian-bee tongues—told that all had long tongues, or that their tongues were surprisingly uniform, and all of great relative length. The same instrument spoke of equal uniformity and the same relative brevity of the tongues of black bees.

Mr. Hasty, all bee-keepers know that all bees will push hard for nectar. If the glossometer is put into the hive they will reach to the utmost for the coveted sweet. The Syrians having the longest tongues, they must clean the glass farther than the equally eager black bees. If I had said they must gather more or whiter honey, it would be different. They usually will gather more because of their longer tongues, as they can reach the nectar in flower-tubes which is inaccessible to bees with shorter tongues. They will also be able to reach deeper into long, tubular flowers, and thus get more. They might have other characteristics that would prove a greater hindrance than would be the advantage gained in the longer tongues, when, of course, they would really secure less nectar. In many cases, too, as in the case of such flowers as linden, sage and figwort, the honey is so exposed, and so easy of access, that any tongues can reach it in its entirety; and here the short tongue would serve as well as the long.

We cannot have bees with too long tongues, but with these we also must have in the perfect bee all the other advantages, like early habits, maximum activity, eagerness to defend the hive, etc.

In a letter from Prof. Gillette, he objects to my method of obtaining the tongues. I cut off the heads of the bees, and then dissect out the tongues. Prof. Gillette threw the bees into hot water. His objection to my method is that the tongue will move. Of course we must wait until the muscles die, which requires many hours, often a full day. I have known a headless wasp to inflict a painful sting more than 12 hours after it had lost its head. Of course the muscles were not all dead yet, and the sting will be thrust out as long as the muscles are alive. Might not the hot water set the muscles? If we stretch the tongue by pressure on the mentum as soon as the muscles are dead and inactive, and before regor mortis has set in, I believe we have the conditions best suited to give the most correct results. I have reason to think so from the uniformity of results in the measurements of bees from the same colony.

CO-OPERATION AMONG HONEY-PRODUCERS.

We have great reason to hope from the temper and spirit of our late and last convention, that we should very soon have a honey exchange that would rival in excellence and advantage to its members the Citrus Fruit Exchange of

Southern California. That organization saved the citrus industry. I now markets 60 percent of the citrus fruits, and with the present rate of growth it will soon handle nearly or quite all. The great advantages arising from buying supplies cheaper; packing better, cheaper and more uniformly; distributing more wisely in the market; developing more and better markets; of keeping informed most thoroughly as to the state of the markets, throughout the entire country; and of keeping all the profits to the grower, are simply stupendous. It is co-operation on a large scale, and is blessed in performance.

The bee-keepers desire to enter an exchange, but at the same time wish to keep the right to sell their own honey if they will so to do. Of course no such exchange could live. It must know its supplies as to quantity, quality and whereabouts, else it cannot command the market. In case any bee-keeper learns of a good market at a high price the exchange will be glad to know of it, and give the bee-keepers the advantage of it. But, of course, the organization must handle the honey, and, unless this is permitted, the organization would be like a rope of sand.

There are two things that stand in the way of the rapid realization of such organizations. People are slow to trust them, and quite as slow to pay salaries that will secure the ablest management. A bee-keeper or fruit-grower who works hard the entire year, and counts his income possibly with three figures, finds it hard to see why the manager of an exchange should receive a four-figured income, with the fourth figure probably a large one. It is simply this: In doing business, as does the Citrus Fruit Exchange, that reaches up into the millions, a shrewd business sense will often, in a single deal, save many times the salary of the manager. He must be far-sighted, alert, cautious, experienced. The railroads, and all large, successful corporations, are all the time looking for such men; once found, and they will have and keep them at any price. The exchange must be the same.

The Southern California Citrus Fruit Exchange pays its manager \$8,000. I am free to say that she is wise, and would far better add to this large sum, if such addition were necessary to keep him. This organization does business away up in the millions of dollars, and yet, for several years, has met no losses at all, in the way of bad sales; does the business for 3 percent of sales; has the full confidence of the trade; and is developing a constantly larger and better market. All our rural industries must and will wheel into line. Let us all urge that it be soon.

Los Angeles Co., Calif.

Something on Honey-Flavors, Marketing, Etc.

BY THOS. CHANTRY.

IN reading the report of the Chicago convention, on page 213, I could hardly keep my seat. I wanted to add a little of my own experience to the question, "What is the best honey?" I see that the bee-keepers there like sweet clover, principally, but want a little aster or goldenrod or something in with it to modify it a little. How many have tried, as I have for years, to carry a glass or sample of 5 or 6 different kinds around from house to house, and exhibit at fairs, and always insist on everybody, who likes honey at all, to sample all kinds with pocket-knife, table-fork, or toothpicks, and note how different people are in regard to taste, even among members of the same household?

Most think honey is honey, and the notable difference in taste between sweet clover, alfalfa, white clover, basswood, goldenrod and buckwheat, for instance, will give rise to many questions of how they can be gotten separately, and give good opportunity to explain the use of the extractor, and why extracted honey can be profitably produced at a lower price than comb honey; and, in time, you will learn to tell when asked "Which is the best honey?" (before tasting the samples). They are all good honeys, and as to food value one is as good as the other, but I can't tell by looking at you which you like best.

Now, since you like your sweet clover a little mixed with some other, I would say if you have pure basswood honey put in $\frac{1}{3}$ alfalfa, and people who like basswood honey will like it better; also to your pure buckwheat put in $\frac{2}{3}$ alfalfa and it is so mild it is not noticeable to the taste, only makes the buckwheat flavor less rank, and improves the whole; and you will be surprised to see how many will like it better than any other and order it. Also California sage should be diluted with alfalfa. I say alfalfa because it is so mild and of such good body.

Dr. Miller expresses the idea about too much flavor, and I find it pays to teach people the difference, and label each kind always true to name.

One store sold over 500 Mason jars of honey this season, nearly all candied, because it is cleaner to handle; clerks like to handle it better, and people can take it home safer and eat it candied, or melt it, as they please. The result is all because I took special pains to give every man, woman, and child in the small town, who was fond of honey, a taste of the various flavors, and explained how we kept the various kinds separate, etc. I told them that I would put my honey in the store, always labeled true to name, advised them to remember which kind they like best, and, to call for it at the store. If they ever found I have deceived them, to take it back and get their money. So well has this experiment of thorough canvass succeeded that if I only had the time to go to every town in the United States and do likewise, I could use almost an unlimited supply. I have added two more towns to my list of thoroughly canvassed—educated somewhat in regard to honey. I gave them an opportunity to educate themselves about flavors, and already the stores are asking for more honey. One small town has used over 1,000 pounds, while two towns four times its size, on either side, have used 120 pounds, all because of a little time in educating people as to what extracted honey is, how much difference in flower-flavor, how to melt when candied, etc.

Now, in mixing various honeys, heat from 130 to 160 degrees, stir thoroughly, let it stand an hour and skim what foam rises, then draw off into jars properly labeled true to name, and put in the store and let it candy when it may; the label will explain that.

When I say mixed-flavored honey, I don't mean adulterated with glucose or syrups—no, no, but mixed one flavor of pure bees' honey (perhaps of strong flavor) with another pure bees' honey of a milder flavor.

Naturally, we would generally get buckwheat honey with some of the last of clover or basswood, and then with some goldenrod, heartsease, or aster, but principally buckwheat; also sweet clover in our country here will get mixed more or less with other clovers, and shoestring, snowdrop, etc.

Oh, for a honey exchange that would see to it that our good honey was properly put on the market, in a standard but otherwise useful package, properly labeled true to name. One man cannot do it. The creamery men see to it that their fancy butter gets to the consumer in good order, and not mixed with oleo; then why shouldn't the bee-keepers do the same, and not throw it on the general market, and let it be mixed with glucose before reaching the consumer, and perhaps labeled "Red Top Clover Honey," or "California White Clover Honey," or, as I saw in Sioux City this winter, "King-Bee Honey?" Such stuff, along with poorly ripened, strongly flavored honey, tends to disgust the public with extracted honey. In fact, all my remarks refer to clear or extracted honey.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

HAVANA LITTLE GIRLS AND HONEY-DEW.

As for the nice frontispiece for April 10, I can't make very much connection between bees and the little girls of Havana having a procession in the street, teachers alongside—but I'm glad to see the little girls all the same. If it's true that without love the world wouldn't go round, it's still more true that without little girls, there wouldn't be any world to go round—and then the great big question whether honey-dew is ever actually dew couldn't be "argued." You see, I'm a little disposed to open the chest where we keep last century's chestnuts, because at my apiary I recently had a case where bees in such enormous numbers were at the dew on the grass and herbage that it hardly looked possible that water only was what they were after. Still, perhaps it was—each one getting a drink for herself, and then promenading and sunning herself awhile before going home.

THE POST CHECK.

In other words, the Post check is a dollar bill (or other denomination) with room and lines to write on it. When it is once written on it is no good until redeemed, and therefore not desirable to steal in transit. But and if the thieves in making a haul take it along, and finally destroy it—well, I haven't found out yet where the remedy comes in. Nevertheless, let's have the Post check. Say, have a coupon on one end to be cut off, or not to be cut off, as the sender chooses, and to be payable after six months if the body of the note is not presented. Page 237.

WINTERING BEES IN A FURNACE-ROOM.

Seemingly preposterous experiments with bees are quite apt to turn out all right. C. B. Howard contributes one by wintering bees in the furnace-room of his cellar. That experiment should be repeated; it may contain the germ of something valuable. I'll venture the guess that it will usually turn out well, so far as the bees are concerned, but that sometimes flying bees will be a nuisance to the one who tends the furnace. Page 238.

WAX-WORMS ON BASSWOOD.

And now comes a man who sees wax-worms prey on the basswood and let the pine alone—just the opposite of the report sent in a bit ago. The man is Mr. A. Ziegler. So merrily we swing around the circles, and get more facts than we can find pigeon-holes for. Page 238.

PERHAPS A JOKING MINISTER.

A. E. Taylor may not be such a bad minister, after all. He was joking; and presumably said what he did with the verdancy of a child. Didn't think (or never heard) what immense mischief has been done by just such jokes, and the statements not jokes which they give rise to. Neither did he realize how sore bee-folks are on that spot—nor what a lot of them feel ready to trade a kick for a joke. Page 243.

SWEET CLOVER HAY.

I was decidedly surprised that the call for a man who had a whole load of sweet clover hay in his barn should so nearly fail of response—after all these years of agitation and publication in the matter. What shall we do about it? Vociferate a little louder, and tear the strips of our raiments a little longer, or give the whole thing up? Mr. Baldridge was able to certify some extensive use of it for hay in the South. They can cure it there—and are also in most distressing need of something to make hay of. I suspect the great hindrance in the North is that suitable hay-weather mostly does not come so soon as sweet clover needs cutting. Page 228.

MR. AIKIN'S WAX-SEPARATOR.

In the cut of Aikin's wax-separator, on page 234, there is a funny source of error. We think we see two galvanized iron pails. Mentally estimating them at ten inches high, or such a matter, we see the device standing up as tall as a man's shoulders, and big in proportion. When we read it is seven inches high and two inches wide on the bottom, we are rather taken back.

Good style of straining. McIntyre, of California, was one early practitioner of the gravity method of straining, if I remember rightly.

EXTRACTING WHEN THE WEATHER IS COLD.

To extract honey successfully 20 degrees below freezing would be quite a triumph, surely; but he didn't mean exactly that. He meant when the *weather* was that many degrees to the bad. The process of warming up can be helped along materially by bringing the combs into an ordinary room, which stands at 40 or 50, a day or two beforehand. Page 236.

RIPENING CUBAN HONEY.

Rambler told us Cuban comb honey was ripe, but he did not tell us why Cuban extracted honey could not be well ripened, too. One would think that with an honest son overhead, and an honest son beneath, the feat would be possible. Page 236.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, *Marengo, Ill.*

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Increasing by Dividing.

I wish to increase my bees when the time comes, and I want to do it artificially. If I put a new hive on an old stand with starters, and queen clipped, with almost the entire swarm, and then put the old hive on top of the new one with the rear end in front, entrance closed, and put a tube at the rear end for the hatching bees to escape, how long must I leave the tube on? Should I put moisture or water in the old hive? How long should I wait before I give the old colony a ripe queen-cell? COLORADO.

ANSWER.—I have had no experience with the plan you mention, and I doubt the advisability of trying it. If, however, there are those who have tried the plan and approve it, I will gladly give them the floor to answer you. In late numbers you will find some plans for artificial increase that may suit you.

Early Drone-Killing and No Swarming.

Why do some colonies make such cleaning out of the drones, and so early in the spring? I have 2 hives now that have a large quantity of dead and some live drones ejected. I had 10 colonies last year; the spring was late and cold, like this spring, and quite a number of colonies emptied their hives of drones, and I had but one new swarm. I got from the 9 colonies a little over 250 pounds of surplus honey last year, and it looks as if the bees have started to do the same thing this year. All the colonies are working well on fruit-blossoms now. Let me know the cause of early drone-killing, and no swarming. WASHINGTON.

ANSWER.—Bees may vote down drones at any time when stores appear to be getting scarce. They may also vote that they have no immediate use for drones when the old queen has been superseded and a new one has commenced laying, even if the superseding comes early.

Honey, Not Increase, Wanted—Italianizing—Managing Swarms.

1. I have several colonies of bees in 2-story 8-frame dove-tailed hives. I wish to manage them for comb honey and no increase. Our main honey-flow is white clover, beginning about June 10. What plan would you advise?

2. My bees are blacks and hybrids. I wish to introduce pure Italians. At what time of the year would you introduce them? And would you get laying or untested queens?

3. Would it be better to buy queens reared in this latitude? And is there a liability of introducing "foul brood" with a queen?

4. Under all conditions would you give full sheets of comb foundation in frames and in sections, to a swarm? If not, what would be the exception? When would you add the super? ILLINOIS.

ANSWERS.—1. It is just possible that by allowing them to continue in the two stories (if by that you mean that there are two stories in the brood-chamber), there may be no swarming. One way is to have the queen clipped, destroy the queen when a swarm issues, and when the young queen pipes, a week or more later, destroy all queen-cells.

2. You can introduce queens almost any time, but the introduction is less risky when bees are gathering, and it is easier to get queens after the June flow begins. Untested queens are always supposed to be laying queens, only they have been laying so short a time that their worker progeny have not yet hatched out. If you want to be entirely sure of what you get, it will be well to get tested queens; but it will cost less to take some risk and get untested ones.

3. I don't know as it makes much difference about the latitude. No honest man would send you foul brood, but to

make matters safe you can kill all the escort bees without fear as to conveying the disease.

4. If I wanted to be very saving in outlay, I would give a swarm four or five frames with starters, and when these frames were filled out I would give the remaining frames filled with foundation. I do not think of any other condition except that of the necessity of economy that would make it desirable to do other than to give full frames of foundation to fill the whole hive. The super may be given to the swarm as soon as it is hived if a queen-excluder is used, otherwise there should be a delay of perhaps two days to avoid the danger of having the queen go up in the super.

Introducing Queens.

If I take an Alley queen-trap and trap the first queen, can I introduce a new queen without using an introducing-cage, if I don't catch the swarm? WISCONSIN.

ANSWER.—If you have an Alley trap at the entrance, the queen will be caught in the trap and the swarm will return; and I suppose your idea then is to remove the queen that is in the trap and give another queen in its place. The chances are that the new queen will be killed. Even if caged, the plan would not be a success, unless you wish the bees to swarm with the new queen.

Putting on Supers—Placing Hives.

1. My bees work from about 7 a.m. till the sun goes down when it is a nice day, and they have something on the hind legs as they go into the hive. Can you tell me what it is? It looks like honey.

2. When do you prefer to put on supers.

3. Will bees do as well to have their hives all in a row about 12 inches apart, or is it better to have them further? IOWA.

ANSWERS.—1. Bees never carry honey on their legs. Usually the load carried on their legs is pollen, but pollen does not look like honey. Sometimes propolis or bee-glue is carried on the bee's hind legs, and looks somewhat like very thick honey.

2. As soon as the first white-clover blossoms.

3. They are better not to be placed regularly quite so close together, but you can manage to have all right without occupying any more ground. Leave the hives with the odd numbers, 1, 3, 5, etc.; right where they are, and then move No. 2 close up to No. 1, No. 4 close to No. 3, No. 6 close to No. 5, and so on.

Increase Wanted—Extracting Honey.

1. I put 9 colonies into the cellar to winter, one of them being a nucleus colony that I started about September 15. You remember I wrote you during the winter the particulars about this colony. I put them out April 5. Well, all of the 9 colonies are in good shape, as far as I can see, and I thought I would divide them instead of letting them swarm. I have 3 extra hives on hand. Do you think I would better divide, or let them swarm once? I want to increase, but not too fast.

2. Can I, or rather would it be practical to extract from the brood-chamber the frames of honey used during the winter or spring?

3. What is the best plan to arrange the hive for extracting? Should I use a double hive, or just the brood-chamber of one hive?

4. Is the Cowan extractor as good as any?

5. Would you advise me to get a 2-frame extractor? I intend to keep bees always, and want to keep 40 or 50 colonies, so you can judge from this. As I never saw an extractor at work, I do not know much or anything about it.

NEBRASKA.

ANSWERS.—1. If you have not much experience in the matter, perhaps it will be as well to let each colony swarm once.

2. If warm enough, and if the honey is not granulated, it can be extracted. But it will almost surely be better to leave it in the brood-nest. You will find that up to the time of the beginning of the main honey-flow the bees will consume a large amount of honey, and if you extract all out of the brood-chamber you will compel the bees to fill up the space you have made vacant before they do anything in the super. It is not at all likely that there is any more honey in the brood-chamber now than there should be.

3. It is not considered a good plan to disturb the brood-

chamber at all by extracting the honey from any of the combs in it. Put a queen-excluder over the brood-chamber, and over this put a second story to contain the extracting-combs.

4. Yes, it is an excellent extractor.

5. Unless you expect to run above one or two hundred colonies, the 2-frame will be all right. Some say it is all right for 200 or more.

Painting Hives—Foul Brood—Wax-Extractors.

1. Will it hurt bees to paint the hives they are in?
2. Is there any danger of getting foul brood by introducing queens bought of queen-breeders?
3. How can I make a good solar wax-extractor?

VERMONT.

1. No, except that with ordinary paint there may be a little trouble in having their feet daubed with it while it is very fresh. It will help the matter to use a drier in the paint and to do the painting in the evening.

2. It is pretty generally agreed that a queen will not carry the disease, but the workers might if taken from a diseased colony. So it is safe to kill the escort. Answering your question on general principles, it might be said that the danger of getting foul brood through buying queens is very small; for an honest man would not sell queens if he had foul brood in his apiary, and the number who would be so dishonest as to send out the disease is probably very small.

3. That depends a good deal on what you mean by "a solar wax-extractor." You can put a pane of glass over a box, and have in the box a sheet of tin with small perforations, placing on this the scraps to be melted, with a receptacle underneath to catch the melted wax, and it will do a good bit of work. If you mean a solar wax-extractor as good as one you can buy, it will not pay you to undertake it, and it would not be worth while to give a description, for you can buy one cheaper than you can make it. If you want something still better than a solar wax-extractor, get a steam wax-press.

Spraying with White Hellebore.

If gooseberries and currants are sprayed with white hellebore, will it do any harm? Will it kill the bees?

OHIO.

ANSWER.—That depends upon when the spraying is done. When the plants are not in blossom, the spraying will do no harm. Spraying when the plants are in blossom will be a damage to the bees and also to the fruit crop.

A Beginner's Questions.

1. Does the old queen come out with the first swarm? If so, how old is the virgin queen at that time?
2. How many days old is she before she makes her bridal trip?
3. Do they ever mate while swarming?
4. After the young queen hatches, how long will the two stay in the hive without swarming or killing one of them?
5. I hived a good swarm April 20. Will they be apt to swarm this year if I give them plenty of room? I gave them three frames of drawn comb and five with brood-foundation starters.
6. How soon shall I put on a super?

SOUTHERN ILLINOIS.

ANSWERS.—1. The old queen comes out with the first swarms generally about the time the first queen-cell is sealed, or about a week before the young queen leaves her cell.

2. Somewhere from five to ten days old.

3. Sometimes.

4. The old queen leaves before the young one leaves her cell.

5. Likely not; but they may.

6. Just a little before the main flow begins. In your location it is likely white clover is the first thing from which surplus is stored, and you should put on the supers as soon as you see the first white-clover blossoms.

I am sorry you didn't ask the question, "Should I get a text-book?" Of course it might not do for me to answer the question you have not asked, but if you had asked a question of that kind I should have said that it would probably be big money in your pocket to pay \$5.00 for a text book, and then study it carefully.

400 Boxes 2d-Hand Cans.

We have on hand 400 BOXES of 60-lb. Tin Honey-Cans (2 cans in a box.) Many of them were emptied of honey by ourselves, and all have been carefully inspected. If we had occasion to do so, we would use them again ourselves. We need the room they occupy, and offer them at a low price to close out, as follows, f.o.b. Chicago: 5 boxes at 50 cts. each; 10 boxes, 40 cts. each; 20 boxes, 35 cts. each, 50 or more boxes, 30 cts. each. NEW boxes of cans are worth 75 cts. a box of 2 cans. So these 2d-hand cans are a bargain. Better speak quickly if you want any of them.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

GENERAL ITEMS

Encouraging Outlook for Honey.

All things considered, the outlook for a good honey-flow in Utah is encouraging this season. There is plenty of water for irrigation nearly all over the State.

There have been some winter losses in some localities, but, as a rule, the bees have wintered fairly well, and barring the danger of grasshoppers, in two or three places, good crops and a good honey-flow are confidently looked for. It is to be hoped that the tremendously heavy rains the past month may have rotted the eggs. Where there was a partial failure last year the principal cause was drouth and grasshoppers; these causes being wholly or partly removed, we know of no reason why our farmers and bee-keepers should not succeed this season.

Smelter-smoke is still the principal cause of trouble in Salt Lake County.

E. S. LOVESY.

Salt Lake Co., Utah, April 26.

Hard Winter on Bees.

It was a very hard winter on bees around here, fully 75 percent having died. They were housed up two months without any flight. The prospects are good for a good crop of honey. All kinds of fruit are beginning to blossom, clover is looking fine, and we are having plenty of rain.

My bees were bringing in pollen in March, which I do not remember ever seeing before.

IRA D. HYDE.

Washtenaw Co., Mich., May 6.

Never Wintered Better.

Bees never wintered better than they did the past winter. The hives are full of bees and brood, and if we can have plenty of rain I think the clover will come on all right, and we will have a good season.

We will hope for the best, and get the bees ready for the crop when it does come.

Grant Co., Wis., May 3. M. M. RICE.

Rearing Long-Lived Worker-Bees.

A subscriber desires me to explain what is meant when I say, on page 302, "Next I found I could rear queens from my poorest queens that produce long-lived workers."

I mean when I say "poorest queens," that such queens are below the average in every respect, less prolific, and whose workers are short-lived so their colonies are always weak.

It is the manner in which the queens are reared that causes long or short lived workers. I was a long time studying how this was done. I have lost hundreds of dollars since 1868, in experimenting with bees, as to just how to rear queens whose workers are always long-lived. All queen-breeders know there is a great difference in queens and the longevity of their workers, but do not know why.

Lucas Co., Iowa. GEO. W. RIKER.

Is it a New Bee-Disease?

I have 21 colonies of bees here, and all seem to be in good health but one. They have been dragging out dead and helpless bees for the last month, but the weather has been too cool and changeable to open the hives, so I left them alone until yesterday, when I concluded to take off the cover and look in, and on doing so I noticed a few of the affected bees at the top of the frames. I took out over one-half of the combs and found the queen, which appeared all right. The colony seemed quite strong with bees, and combs well filled with eggs and brood. There was no foul odor from the hive, and the brood in all stages looked healthy, so far as I could see, but it

To make cows pay, use Sharples Cream Separators. Book Business Dairying & Cat. 2123 Free. W. Chester, Pa.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested.....	1.50	8.00	15.00
Selected Tested.....	2.00	10.50	
Extra Selected Tested, the best that money can buy... 4.00			

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

WALTER S. POUDER.
512 MASS. AVE. INDIANAPOLIS, IND.

commenced raining before I had finished, so there were three or four frames in the hive that I did not take out.

The bees affected turn black from head to coupling, and the point of the tail end also black; in the last stages they are black all over, and look more like large-winged ants than like bees, having a slick, oiled appearance. They seem smaller, or more slender, than the healthy ones. They are Italians, the queen very yellow, and only one year old, being one that I reared myself last season.

There has not been any contagious disease among bees in this section that I know of. I would like to hear from some of the old professionals—Dr. Miller, Doolittle, or any one else who may have had bees affected like mine are.

I have just re-read the discussion on black brood at the Buffalo convention, but I can't find anything in that that covers my case. If this is something new to older heads than myself, I will watch the colony's progress a few weeks longer, and make another report.

I have kept bees here for seven years, and they have always seemed healthy.

S. A. WILSON.

Siskiyou Co., Calif., April 30.

[It would be well to keep close watch of the colony, also mail a sample of the bees to Wm. McEvoy, Woodburn, Ont., Canada, telling him about them, and getting his opinion. —EDITOR.]

Discouraging Spring.

For two days it looked as if spring was here. It was the coldest, windiest spring I can remember. I had a loss of 8 colonies out of 40 since I took them from the cellar. The cold, windy, sunshiny days dwindled them to nothing. Soft maple buds drop off by cold, and willow for the last few days for pollen makes a more hopeful prospect. But my bees were old ones.

It was so dry last summer that there was no brood after July. The white clover will be very scarce, and all other clovers the same.

N. A. KLICK.

Stephenson Co., Ill., May 2.

A Bridegroom at Buffalo.

The report of the Buffalo convention is just received in pamphlet form, and I assure you it is highly appreciated, being a handy reference-book, and a fine history of that memorable occasion. I suppose I appreciate it more as it was my first attendance, and I was then on my wedding-trip, and neglected the Pan-American to attend every session of the convention. Pretty good for a bridegroom, eh?

My bees are building up strong this spring, having wintered well, and although the spring is cold I expect them to be in fine condition for clover.

E. B. TYRRELL.

Genesee Co., Mich., May 1.

Another Bee-Sting Remedy.

On page 218, a bee-sting remedy is asked for. For single stings press firmly over the site of the puncture a coin, say a half-dollar, for five minutes. The pressure causes the absorption of the poison into the general circulation, and the local irritation is prevented. I often used this remedy when a boy, in the case of hornet or wasp stings.

GEO. WENTZ.

[We will have to try this the next time we are stung—if we can raise the half-dollar! If there are any banker bee-keepers, they can use twenty-dollar gold pieces, we suppose. —EDITOR.]

The Chaff Hive.

Some one asks, "How is it we do not hear much about chaff hives?" I use them (150), and have for 20 years. Many started with bees in common hives about the time I commenced, and have gone "where the woodbine twineth." Others I know have chaff hives and still have their bees. My loss this spring

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

Thousands of Hives, Millions of Sections, ready for Prompt Shipment.

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

An Italian Queen Free!

We would like to have our regular subscribers (who best know the value of the American Bee Journal) to work for us in getting NEW subscribers. We do not ask them to work for us for nothing, but wish to say that we will mail ONE FINE UNTESTED ITALIAN QUEEN for sending us ONE NEW subscriber for a year, with \$1.00; or 2 Queens for sending 2 new subscribers, etc. Remember, this offer is made *only* to those who are now getting the Bee Journal regularly, and whose subscriptions are fully paid up.

In case you cannot secure the new subscribers, we will mail one of these Queens for 75 cts., or 3 or more at 70 cts. each; or the Bee Journal one year and a Queen for \$1.50. We expect to be able to send them almost by return mail.

(Please do not get these offers mixed up with our Red Clover Queen offers on another page.)

We can furnish you with The A. I. Root Co's goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for beeswax. Send for our 1902 catalog. M. H. HUNT & SON, Bell Branch, Wayne Co., Mich

Our Choice for honey-gatherers is a cross between the Italian and Carniolan. A limited number of Nuclei and full colonies for sale. Healthy, vigorous, and excellent workers. Address: 20A4t E. S. ROE, CLARISSA, TODD CO., MINN.

\$5 TO START YOU IN BUSINESS

We will present you with the first \$5 you take in to start you in a good paying business. Send 10 cents for full line of samples and directions how to begin. DRAPER PUBLISHING CO., Chicago, Ills.

3-Frame Nuclei For Sale.

We have arranged with a bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei of bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 or more at \$2.75 each.

All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

GEORGE W. YORK & CO.,
144 & 146 Erie St., - CHICAGO, ILL.

was one queenless colony. I never have had a bad loss in winter but once (30 percent), and that was caused by late feeding of sugar syrup. To-day my bees average six frames of brood, and but few days that they could get out for pollen. J. C. STEWART.
Nodaway Co., Mo., May 3.

Swarms All Around.

There are swarms of bees in every direction all over the valley. One boy across the street has picked up 15 swarms the past week. Mr. Sutton has picked up 6 within 10 days. My youngest boy, 12 years old, went down First street two miles, on Saturday, and came home with one swarm in a box and one in a grain-sack. Three swarms went over my house to-day. Dr. E. GALLUP.

Orange Co., Calif., April 30.

Pickled Brood—Nature and Character.

1. Has pickled brood absolutely no perceptible odor?

2. Will there be absolutely no ropy matter adhere to a toothpick when withdrawn from a dead larva having had the disease known as pickled brood?

3. Will a comb that has been rotten with foul brood during June become filled with healthy larva afterward? Or will a foul-brood cell produce healthy larva at times and diseased ones at other times?

R. C. HUGENTOBLE.

[1. Pickled brood has no odor like foul brood, nor has it a foul smell—in fact, no smell at all, as a general thing. If any odor is present at all it is slightly acid, or sour, and hence the name, pickled brood. In the advanced stages there will be a white mold over the surface of the comb; and this, in fact, is the best evidence that it is pickled brood.

2. Pickled brood is slightly ropy at times, but it never draws or ropes out more than an eighth of an inch, and, unlike foul brood, does not have a stringy character.

3. Cells that have contained foul brood may be cleaned out by the bees, and afterward healthy brood be reared in them; but the probabilities are that those same cells containing the spores of the disease will again give the disease to our healthy larva. Yes, cells that have been foul-broody at one time may be apparently healthy at another.—ED.]
—Gleanings in Bee-Culture.

Robbing—An Unusual Occurrence.

I had a case of robbing after extracting this week. I covered the hive being robbed with a cloth. After awhile bees belonging to that hive and the robbing bees united and clustered on the cloth. In the course of two hours the cluster dispersed and entered a weak nucleus containing a laying, clipped queen. The bees balled the queen for awhile, but finally released her and settled to work like a regular swarm, and are doing well. What will bees do next?—J. F. M., in Australasian Bee-Keeper.

Giving Cellared Bees a Flight.

One of the things fully settled long ago was that it is a bad thing to put bees out of cellar for a flight and then return them. Having tasted the pleasure of the free air they would not again be content to be imprisoned. Now, Mr. Editor, you've gone and unsettled the whole business again. Please tell us minutely as to the final result. Also tell us when you took out, returned, and took out for good. There have been times when I felt I'd like to give the bees a flight, and then return them to the cellar; but I had too strong respect for traditions.—[I think we have proven, to our own satisfaction at least,

COMB FOUNDATION ADVANCED 3 CENTS A POUND.

Owing to the increased price of beeswax, until further notice, dealers handling the A. I. Root Company's goods are compelled to raise the price of Comb Foundation 3 cents per pound above the prices found in their price-lists and catalogs. Please take notice.—Adv.

that the old idea that indoor-wintered bees should not be given a flight on some warm day in midwinter, is not good practice for Medina. In a normal state of health bees are compelled to void their excreta at certain regular intervals. We know that they do retain them during the winter; and we know that, just as soon as they are set out, the first thing they do is to spot everything in the neighborhood. This goes to show that Nature has been peut up for a long time, and seeks relief. To give the bees a cleansing flight during winter is not only rational but humane. We manage to keep our bees quiet till about the latter part of March. Then we set them out and let them have a cleansing flight, and put them back again, and then they are perfectly contented—no doubt about that.—EDITOR.—Stray Straw in Gleanings in Bee-Culture.

Stimulative Feeding.

I have been, and am still, experimenting with stimulating food for bees, but I am already satisfied that here, at least, feeding in the spring is done at a loss. Cane-sugar syrup has to be "inverted" by the bees, and that process calls for an expenditure of vitality that old bees, after a winter's confinement, can illly meet. Under normal conditions—during the natural flow of nectar—there are an abundance of young bees to do such work, and it is believed that they do much, if not the greater part, of it. But in the early spring, when stimulative feeding must be done if to be of any use, there are but very few young bees, and so the labor falls upon the old ones. If we could afford to feed honey, or honey and water, at such times, would not such evils be avoided? it may be asked. Not entirely. I can not discover that colonies stimulated with honey and water are in one whit better condition for the harvest than are colonies left entirely alone, but having plenty of honey (and pollen) left from their winter supply. On the contrary, even with such skill as I have acquired in the past 20 and odd years, spring-stimulated colonies are more often behind the others than ahead of them. Other things being equal, I believe bees winter better when they have a super-

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

abundance of stores than they do if they have barely enough to carry them through.

It may not be considered as economical management to give colonies much more honey for winter than will suffice them till fruit-bloom. Perhaps it is not in some places, but it certainly is the best plan here, and colonies so supplied are ready for the supers first, and produce as fine a grade of white comb honey as can be desired. The dark honey, which may be in the combs below, never seems to be carried into the supers, so that feature is no bugbear.—ARTHUR C. MILLER, in the American Bee-Keeper.

Swarms With Clipped Queens.

G. M. Doolittle directs, in Gleanings in Bee-Culture, to let the queen when found run up into a cage, then let 20 to 50 of the bees enter the cage with her as they rush out of the hive, and then continues:

"As soon as you have secured the queen, lay the cage down in front of the hive, when you will move the old hive back, and put in its place the one which the swarm is to occupy, when the cage with the queen is to be laid near the entrance. Place the old hive where you wish it to stand, or move it up beside the new one at right angles, *a la* Heddon, as you prefer. Have, in a convenient place, two sheets, one of which is to be placed on each of the hives on either side nearest the one now awaiting the swarm, so that they can be spread over them should the swarm attempt to enter these hives upon returning, which they very rarely will do if only one swarm is in the air at once, and if the caged queen and the bees with her is left at the entrance of the new hive. When about two-thirds of the bees have returned and entered the new hive, pull the stopper out from the cage, which liberates the queen, when all run into the hive, the whole swarm will sometimes take wing again, and this is the reason that we wait about giving her her liberty till at least two-thirds are settled in the hive. If several swarms come out together, more sheets are needed, so that, if more than the right proportion of bees draw toward one of the new hives placed on the old stands, a sheet can be thrown over for a little until the bees are drawing about alike to all."

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you."—Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30) I never found these bees to show the least indication of unrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

Out of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chills winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italians and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, May 8.—The trade in honey of all kinds is light, especially is this true of comb, the little trade that exists is for the best grades. Basswood ranges from 14@15c; that having more or less basswood, willow or other white nectar, 13c; off grades of white, 10@12c; amber, 8@9c. Extracted, white, 5 1/2@6c; amber, 5@5 1/2c; some lots of new extracted offered, but no sales have been made. Beeswax scarce at 32c.
R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5 1/2@6 1/2c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.
THE FRED W. MUTH Co.

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14@15c. Extracted, 6@6 1/2c. Beeswax, good demand, 30@31c.
H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7 1/2c; Florida honey, in barrels, 6@6 1/2c.
BLAKE, SCOTT & LEE.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6 1/2@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

CINCINNATI, May 8.—As the warm weather set in, the demand for comb honey is as good as over. There are no settled prices; for whatever is left, prices are made for force sales. Extracted honey is in fair demand and finds steady sales. Amber is sold in barrel lots for 5@5 1/2c; water-white alfalfa, sells from 6@6 1/2c, and white clover brings from 6 1/2@7c. Beeswax scarce and brings 30@31c. C. H. W. WEBER.

NEW YORK, Apr. 7.—Comb honey, last year's crop, practically cleaned up, but as we wrote a little while ago we had received new crop from Cuba, and are now receiving new crop from the South. Demand is fair at 14c for fancy white, 13c for No. 1, 12c for No. 2, and 10@11c for amber. Extracted: The market is decidedly dull. Very little demand, with large stocks on hand, some of which no doubt will have to be carried over, and indications point to a further decline in prices. We quote: White, 6c; light amber, 5 1/2c; amber, 5c; Southern, 5 1/2@5 3/4c per gallon, according to quality. Even these prices are shaded in car lots. Beeswax, scarce and firm at 29@30c. HILDRETH & SEIGLEN.

SAN FRANCISCO, May 7.—White comb, 10@12 1/2 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4@—; amber, 4@—; Beeswax, good to choice, light, 26@28c; dark, 24@25c.

The market presents an easy tone, but there are no reductions in quotations. Holders of last crop honey are desirous of effecting a clean-up, and buyers are operating in same only to cover most immediate needs. The new crop will soon be on market, and whether it proves large or small, the fact of it being near at hand is unfavorably affecting the situation for spot stocks.

(Continued from page 324.)

so I turned back lingering eyes, thinking that perhaps it might be many a year (and possibly never) before I should see the remarkable sight again.

GROWING ALFALFA.

To me, one of the most interesting developments throughout the arid regions of the West, was the growing of alfalfa. Almost no other hay will grow in those hot irrigated districts, and yet this thrives wonderfully. A hot, dry climate and moist roots give us a fodder that, for fattening cattle, and making them grow sleek and handsome, beats anything else I ever saw. For work-horses it is not quite the equal of timothy or oats; but as nothing else is to be had, except at considerable expense, farm-horses are able to do a big day's work on it, so I was told.

When Mr. Chambers and I were driving by one of his apiaries we came across a field of alfalfa that had reached its perfection of growth. It was in the height of bloom, and the beautiful violet blossoms, and the hum of the bees, made a combination alike pleasant to sight and hearing. I attempted to take a photo of it, but the result was very disappointing. However, I will show it to you as it is. If you were standing out in the field the tips would reach very nearly up to your chest; for alfalfa grows in Arizona, especially in that section, as it does nowhere else.

But one of the novelties to me was the mode of harvesting this crop. It is cut with mowers as we cut hay in the East; but instead of being put into barns it is always put up outdoors in stacks, giant in size as compared with the little mounds of hay in the rain-belt. Some of these great masses of alfalfa hay, I should judge, were 60 feet long and 25 wide. Instead of pitching the hay from a wagon with a pitchfork on to the stack in the good old-fashioned way, it is carried up by a simple piece of mechanism.

The climate in Arizona is so dry and warm, and there is so little rainfall, barns are not needed. (This is true of all the alfalfa-growing regions in the West that I visited.) It is, therefore, not necessary, or not so much so, to make the stack shed water as with us in the East. The alfalfa is piled up until it reaches the height of 15 or 20 feet, and then is left to stand till used. The hay, when stacked, is of a beautiful light-green color, and remains so for a year or more, or until it is used, except the portion that is exposed to the direct rays of the sun, which bleaches it somewhat. Stacks such as we have in the East would be altogether too small; and, besides, the hay would be bleached too much. These large mounds economize room, and at the same time keep the hay in much better condition for stock when it is needed.

Advance in Prices of Foundation...

We quote an advance of **THREE CENTS PER POUND—WHOLESALE AND RETAIL**—in Comb Foundation.

We are much in need of Beeswax, and pay the **HIGHEST PRICES**. Send us all you have to spare, either for cash or trade.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.
THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. Hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.
J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

WEEKLY

APIARY OF CHAS. SCHWEINHAGEN, OF HENRY CO., OHIO.
(See page 340.)

This is our Famous Catalogue. It can be found in over two million homes of thinking people. Is it in yours?

Why Not Start Now?

Spring is at hand and you will need supplies of all kinds. If you are a progressive, up-to-date buyer, go slow and place your order where you will get biggest returns for your dollar.

HAVE YOU EVER TRIED MONTGOMERY WARD & CO. of Chicago? Perhaps you have long intended to, but never knew how to begin. Why not start now? Our Catalogue No. 70, revised for Spring and Summer, is just out, our building is piled from basement to roof with good things—the very best our active buyer could gather in the best markets; every employe in our big establishment is ready and waiting to serve you to the best of his or her ability—just as though you were shopping over our counters. We've been preparing for this event all winter, and believe that there never was a better opportunity for shrewd, active buyers to start purchasing on our wholesale prices—no middlemen—one profit plan. The Spring and Summer edition of

CATALOGUE NO. 70 IS NOW READY. Over 1000 pages packed with the good things of life—everything you use—gathered by our buyers from the markets of the world. Page after page of high grade merchandise, all illustrated and honestly described.

SEEMS TO US THAT YOU OUGHT TO HAVE A COPY. We want you to have one—so much so that we will furnish the book free and pay one-half the postage if you will pay the rest, fifteen cents. There are so many people in this country bubbling over with curiosity, or trying to get something for nothing, that we are compelled to make this trivial charge. It is only fifteen cents but it assures us that you are acting in good faith and are interested in our business. Why not ask for it today, before you forget it?

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

Please mention Bee Journal when writing advertisers.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be **warranted** purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order as follows:

No. 1.—For sending us the names and addresses of **two new subscribers** to the American Bee Journal and \$2.00, we will mail you **ONE** of these queens free.

No. 2.—Or, for sending us *one new* subscription at \$1.00, and 30 cents more (\$1.30), we will mail you a queen, and the Bee Journal for one year to the new subscriber.

No. 3.—Or, send us \$1.60 and we will send to you the Bee Journal for one year, and also a queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.,

* Editorial. *

The Denver Convention.—Don't decide on the route to take east of Denver until you see the announcement we expect to make soon in these columns. We think we are going to be able to tell you the cheapest as well as the quickest way to go, especially for all who are going east of Omaha. So please wait a bit until you have seen our announcement.

The Illinois Food Commissioner. Hon. A. H. Jones, has just recently sent out his Second Annual Report. It is a pamphlet of 260 pages, and can be had by addressing Mr. Jones at 1623 Manhattan Building, 315 Dearborn St., Chicago, Ill. The matter of greatest interest to bee-keepers is the part of the report prepared by Prof. E. N. Eaton, the State Analyst. In this issue we begin the republication of it, and will complete it next week. It is interesting reading, we think. Prof. Eaton surely has a desire to help the producers of pure honey, as well as those who put out pure goods in any other line.

Sealed vs. Porous Covers.—A subscriber says that in the catalog of the A. I. Root Co., the advice is given to use a burlap covering with chaff for outdoor wintering, while in *Gleanings in Bee-Culture* the editor says enameled quilts or sealed covers are better; and he wants to know whether the catalog or *Gleanings* is the better authority. Both may in general be considered good authority, but in the present case one or the other must have the preference. Possibly the obliging editor of *Gleanings* may offer some middle ground so that both may be followed.

Honey in Old Oil-Cans.—We have recently had some experience with some Western honey that was put into oil-cans. It makes us feel like publishing the names of the bee-keepers who put it up. They deserve just such notoriety as that. We shipped some of this honey to a customer in Massachusetts, and here is his report on it:

MY DEAR MR. YORK:—The honey arrived in a reasonably short time, and in good shape. I opened one lot, and had soon filled jars with that from six cans. I liked the honey the more I ate of it, and was more than pleased with it, declaring that I should sell no other as long as I could get that. Last Saturday I went to bottle the other lot of honey. The first can that I opened I of course tasted. Ugh, but what a taste! I threw aside the

knife, wondering how it happened to get near the lamp or the oil-can. I tried the honey with a spoon, and I got the same taste of oil. I washed the spoon thoroughly, hoping still that the bad taste was not in the honey itself. But no amount of washing did any good. That can of honey and its mate, also the cans from another case, are contaminated with some kind of vile, oily taste. Other people may be able to eat the honey, and it is possible that a few may call it good—one can never account for tastes—but the honey is spoiled for me.

It seems very unlikely that you could know the condition of these two cases, though you may possibly have known of other cases which had thus been injured. I suppose that the producer of the honey made use of second-hand cans which had had oil in them, and failed to get them clean. It is surely a fearful mistake to put good honey into such cans. In my own case, I hesitate to allow any of this contaminated honey to go out to my customers for fear that it may do me untold injury. At present I hold the reputation of putting up the best honey that is found in the markets about here. Where will the reputation be when my customers' tongues meet that oily flavor?

Except for the two cases of the second lot of honey it was the equal of the first lot.

I should like to hear from you in regard to the matter. Perhaps there is some way in which I can eradicate that evil flavor. At the worst, you can look over your lot of honey and see that no more oily cans go out. And you can put some thunder into the American Bee Journal against the folly of using oil-cans for honey.

I say again that the uncontaminated honey is fine; that I never ate extracted honey which so pleased me.

Yours very truly,

No, we don't know how to remove kerosene-oil taste from honey once it has become tainted with it.

But we can't understand how any bee-keeper can be so short-sighted as to use second-hand oil-cans in which to put honey. He should know that only one sale of such stuff can be made in the same place. We are out something like \$5.00 on our deal in freight charges alone. We have heard that the school of experience is very valuable, but the tuition rates are high. Yea, verily.

We hope that no reader of the American Bee Journal will be such a scamp as to put honey into oil-cans, and then mix it in among a lot of good honey in good cans, and thus work it off.

Improvement of Stock is a subject that has been so much discussed of late that it is likely some may think it should have a rest. If it were a matter for the consideration of a few leaders to whom the mass are looking for improvement, there might be no sufficient excuse for this present word. But so long as every bee-keeper can do something himself for the improvement of his stock aside from trying to get better stock from outside, and

so long as the probability is that not one in ten, if indeed one in a hundred, is doing anything in the line of improvement, there is abundant excuse for insisting upon attention to the subject, even if nothing can be said that has not already been well said. To every beginner it should be said, "If you have only two colonies, you can do something—perhaps much—toward improvement of your stock."

For the chance is very small that the two colonies are exactly alike. If, with equal opportunities, one of them gives a larger surplus than the other, there will be a gain to have all your increase from the better colony. Left to themselves, the probability is that if you do not have the same amount of increase from each, the larger increase will be from the poorer colony, because it is likely to be the case that the colony most given to swarming is the one least given to storing. It is not a hard thing to reverse the case, and indeed to go so far that you will have all the increase from the better colony. Give the better colony brood from the poorer, so as to make it so strong as to swarm first. Then when it swarms, set the swarm in its place, putting the old colony in place of the poor one, and putting the poor one in a new place. The field-bees that leave the poorer colony for the next day or two will all go back from the field to their old location, and a week or so later another swarm will issue with a queen of the better stock, while the poor colony will be so weakened that it will not be likely to swarm till later, if at all.

It is possible that the beginner may think that it is not worth while to pay attention to the matter until the number of colonies is considerable. Exactly while the number is small is the time to give the matter attention, for with only two or three colonies it is less trouble than with a hundred, and the little pains taken now will tell upon the whole hundred when they come. And if year after year constant care be taken to breed from the best, the difference made in the total income will be no slight matter. Even if your colonies are numbered by the score or hundred, if you have heretofore given no attention to breeding from the best, begin now.

Tiering Up Supers of Sections is a thing that puzzles beginners, and unfortunately the most experienced must do more or less guessing about it. Suppose the first super to be given about ten days before the full flow, the question is, What rule shall guide as to giving additional room? No definite rule can be given, but some general principles may be given to help in the guessing.

If there is too much delay in giving room,

the crowding may mean a loss in storing, and what may be in many a case still worse, it may bring on swarming. If too much room is given—or what is the same thing in practice, if room is given too rapidly—there is waste of heat in keeping warm the unnecessary room, and there is danger of having a lot of sections partly filled or filled and not completed.

On the whole, it is perhaps better to err on the side of giving too much rather than too little room. Only one super should be given at first, and usually a second may be given when the first is half filled. If the colony is weak, or if the flow is such that the work goes very slowly, it may be better to give the second super not till the first is more nearly filled. On the other hand, if the colony is strong, the flow heavy, and there is every expectation that a second super will be filled, it may be given before the first is half filled; in some cases when there is only a slight beginning made in the first. For if there are bees enough to fill promptly the two supers, they may be the better for the room.

When there is apparent waning of the flow, then one must be more chary about giving room. When the close of the harvest comes, whether that close be two weeks or two months after the beginning, it is better that there be a little crowding rather than too much room. The chief reason for this lies in the fact that when the bees have too much super-room they are slow about sealing up the last cells of a section.

As already hinted, it is a case of guessing, at best, because it can never be told in advance just what the flow will be.

Statistics of the Honey Crop seem hard to get, and even when they seem to be reliable it is hard to compare one region with another, because when it is a good season in one part it may be poor in another. The following figures are given in *Gleanings in Bee-Culture*:

Texas produces 18 pounds of honey per square mile, according to the census report for 1899; California 31 pounds, according to Rambler's estimate for 1901; Cuba 114 pounds, according to exports for 1901; and by the same authority, Jamaica 358 pounds.

Tiering Under or Over.—In tiering up supers of sections on the hives there is not entire uniformity of practice. There are some reasons why each added super should be put under those already given, and some reasons why they should be put over. If they are put under, the bees will be more prompt about beginning work in them, and there is less danger that sections will be darkened by being on too long if they are some distance above the brood-nest than if they are directly over it. If the additional supers be placed over, the filled supers under them will be more promptly finished, and there will be a smaller number of unfinished sections at the close of the harvest.

Perhaps the best plan is that followed by many of the veterans, to put each additional super under if there is a fair degree of certainty that it will be filled, and when it is a matter of doubt to put it over.

Weekly Budget.

MR. EDWIN BEVINS AND APIARY, of Decatur Co., Iowa, are shown in the illustration herewith. The hives had just had the winter-cases set up around them when the photograph was taken.

Mr. Bevins sent us, several months ago, some rhythmical stanzas that were written before the great Chicago Fire, in 1871, when he lived within about a block of where our office is now located on Erie Street. The lines were addressed to the woman whom he afterward married, being written when Mr. Bevins supposed he was on his death-bed. He did not send them to us for publication, but we think he will not object to seeing them in print. He did not place a title above the

beginning with July 1, for three months we will close our office and bee-supply store at 1 p. m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open a month later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

CHAS. SCHWEINHAGEN AND APIARY are shown on the front page of this issue. When sending us the photograph, Mr. S. wrote thus:

I send a picture of my apiary and myself. It is hard to get a good picture of the apiary, for I have too many shade-trees in the yard.

By looking at the picture people may think I am a "darky," and the only darky bee-keeper in the State of Ohio. But I am not a darky. I am standing under a little cherry-tree, with an umbrella placed over my head in the tree to keep the sun out of my face.

Looking at the picture you look to the north. The hives all face to the south, but a few at the left in the picture are facing the

APIARY OF EDWIN BEVINS, DECATUR CO., IOWA.

stanzas, but we have taken the liberty to name it—

LIFE'S FAREWELL.

My sands of life are flowing fast,
The end of earth seems nigh,
But words of welcome, low and sweet,
From a distant church-yard fly—
A gift of holy cheer to bring
To loved one near to die.

Those words of welcome, low and sweet,
Withheld from me so long,
Come to me now mine ear to soothe.
With cadences of song;
Those cadences shall go with me
E'en to the gates of doom,
And be prolonged when thee I greet
Beyond the dreaded tomb.

There shall our souls united sing
To Him who saves from sin,
Glad that His love has bought for us
The right to enter in;
And may the souls assembled 'round
Join to enhance seraphic sound.

Through tribulation great is reached
The rest for which we sigh;
Through agony of soul is wrought
Its fitness for the sky;
And they who wear a crown of gold
A crown of thorns must try.

EDWIN BEVINS.

CLOSE SATURDAYS AT 1 P. M.—Our customers and friends will kindly remember that

east. All hives facing the south are in sheds, with the back of the sheds open during the summer. By looking closely you will see three rows of hives with a shed over each row, with the back of the shed open, which I close up in the fall to keep the cold winds off. I also put clover chaff back of and between the hives, and wheat chaff in the upper story. I have never had a great loss by packing this way.

Bees in this locality are wintered on the summer stands. I put 110 colonies into winter quarters last fall, and have wintered 105, which are in good condition at present. I use the Hoffman frame, and make my own hives, with loose bottom-boards.

I had 6000 pounds of honey last year, comb and extracted, as I run for both.

The main honey crop in this locality is from alsike and basswood, no buckwheat being raised to amount to anything.

CHAS. SCHWEINHAGEN.

MR. B. S. K. BENNETT, of Los Angeles Co., Calif., referring to the Denver convention to be held in September, wrote us May 6:

"I believe we will bring a big part of California bee-keepers with us."

Now, look here, Mr. Bennett, you'd better notify those Denver people to make ample preparations if you're going to swarm on them with "a big part of California bee-keepers" next September. They may not be able to take good care of "late swarms," without having due notice.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 326.)

SECURING A FOUL-BROOD LAW FOR ILLINOIS.

"What can we do as an association towards securing a foul-brood law and inspector for the State of Illinois?"

Dr. Miller—I should think that a resolution making a request might have a little influence, possibly as much as anything that we could do; and then by privately making application urging the matter, the legislators might do something. As an association, I think all we could do would be to pass a resolution asking that such action be taken.

Pres. York—Is there to be a session of the legislature this winter?

Dr. Miller—No, there is not.

Pres. York—Then there is no use of discussing this question now—if there is to be no session this winter.

Mr. Dadant—In regard to this matter of getting the legislature interested in bee-culture, I would say that I was intimately acquainted with J. M. Hambaugh, who was one of the State representatives at one time, and I took advantage of it to urge him to help the bee-keepers along. I had experience in what was required in order to succeed in getting a law passed in which the general public has no particular interest, and yet no decided opposition. It must have the support and be helped and sustained by those who want to see it passed. Mr. Hambaugh was a nice man (he is yet), and he did get an appropriation of \$500 for the bee-keepers for two years, and, of course, after that it was dropped. He had me go four or five times to Springfield, to appear before their committee, to state what I knew in the interest of bee-culture, and asked me to write to the representative from our district, and I wrote to a dozen of the representatives to help. Then we had one or two members in the Senate that worked for us, and by that means we got part of what we wanted done; but it takes a great deal of work on the part of the bee-keepers, and somebody there who will work and take the matter to heart and push it before the Committee in the house and in the Senate, and prevent opposition. Things that are in the interest of the agriculturist are not hard to pass, for generally the legislature wants to favor the farmer; they know he is behind the whole thing. There are no such questions at stake as when you touch the transportation matters; then they are ready to fight, if you touch the railroads. The farmer does not fight; he stays at home, and if he writes to his representatives he probably does not know how to spell very well, and he has to have some voice behind him before he can be heard; on the other hand, if once he is heard, they will not be likely to oppose him. What we need, and want, to get a law passed, is to get somebody well interested—then each and every one of us must influence all the men whom we are acquainted with in the legislature. Personally, I have no politics in me; I have never been able to follow politics, and I would have done nothing if it had not been that I was personally acquainted with the man who was a member of the legislature.

BEES STARVING IN WINTER.

"Is it possible for bees to starve in winter, with a few drops of honey in the center of the cluster?"

Mr. Hintz—Yes, I say it is possible, but it is very probable they will not starve as long as there is honey that they can get. They will not starve provided it is liquid; but if it is candied, of course they will.

Dr. Miller—I think the bees are very accommodating to one another—if there is any honey in the center of the cluster, they would pass it from one to another, and those in the center of the cluster would not keep it to themselves. I have some little doubts whether they might possibly starve with candied honey in the center, if they had first gotten

out of the liquid part. There is one way in which there might be liquid honey there and yet not taken. I would like to know how many of you have ever had bees robbing, and had some comb honey laid out before them where they were robbed, and have them leave that comb honey.

A Member—Sealed comb, do you mean?

Dr. Miller—I mean sealed comb honey. There is just one way in which it may be that bees will not take it. If you will take a comb of honey and have it sealed over, and then move the combs apart in such a way that the bees will commence building again on that sealing, and fill in some more honey on top of that, they will never get through the capping that contains that inside honey; at least I never knew them to do it; I don't believe they will; they seem not to know enough to know they can go through the capping. I have seen that in a number of cases, and never have seen cases in which they knew enough to dig through.

Mr. Dadant—I think they could get it from the other side.

Dr. Miller—I suppose it must be that the other fellow on the other side is getting that. In that way they might have honey—liquid honey—in the middle of the cluster and starve. I don't understand French, Mr. Dadant, so there are some things I can't get at. He has been told that, in French, and he has got it!

(Continued next week.)

Report of the Utah Bee-Keepers' Convention.

The convention was called to order by Pres. E. S. Lovesy, and in the absence of Secretary J. B. Fagg, Assistant Secretary Belliston reported the proceedings.

The first general discussion was on the purchasing of supplies, the marketing of bee-products, and as to the advisability of Utah bee-keepers exhibiting their productions at the St. Louis World's Fair. These subjects were discussed by many of the members, and while many thought the reputation of Utah honey was pretty well known, the State would not lose anything by sending an exhibit to the Fair.

General management and the best method of protection, and the most successful way to enlighten the people as to the benefit to be derived from the general use of pure honey as food were considered. It was shown that people enjoy a higher degree of health by a moderate use of Nature's sweet—honey.

The next was a discussion as to the advisability of forming an exchange for the disposal of bee-products, and a letter was read from the Pacific Honey-Producers' Association. A committee was appointed to confer with them as to the best general method for forming a union of interest for the Northwestern States.

ELECTION OF OFFICERS.

President, E. S. Lovesy; 1st Vice-President, R. T. Rhees; 2d Vice-President, Andrew Nelson; Secretary and Treasurer, J. B. Fagg, of East Mill Creek; Assistant Secretary, Wilford Belliston.

COUNTY VICE-PRESIDENTS.

Salt Lake County, Geo. Wilding; Utah, Geo. Hone; Wasatch, J. A. Smith; Davis, J. F. Stevenson; Box Elder, J. Hansen; Weber, C. O. Folkman; Juab, Thos. Belliston; Cache, Henry Bullock; Morgan, T. R. G. Welch; Uintah, C. C. Bartlett; Emery, Chris. Otteson; Wayne, P. M. Grigg; Sevier, R. A. Lowe; Carbon, Ulrick Braynor; Washington, A. N. Winson; Tooele, B. Barrows; and Kane, W. F. C. McAllister.

As a rule, the presidents of county associations are the county vice-presidents of the State Association.

Secretary J. B. Fagg made a few remarks in regard to the industry in Salt Lake County. He said that in his locality the greater portion of the bees had died from the effects of the smelter-smoke.

Mr. Warren said he had come over 300 miles to attend this convention. He gave a very interesting account of the industry in Washington County, in the southwest corner of the State: they had a good honey-flow last year, and the indications for irrigation water and for fruit, honey, and other crops, were flattering for the present season. He said they had had a very good market for their honey from the adjacent mining camps.

George Wilding, an old pioneer bee-keeper of Salt Lake County, gave a very interesting sketch of the early bee-keepers of the State, at a time when bees were worth \$50 a colony, and honey was worth 50 cents a pound.

Mr. Miller, of Cache County, and Thos. Neilson, of Sevier County, gave good reports of their respective counties; they also reported that the present honey-crop indications were flattering.

J. N. Elliott, an old Iowa bee-keeper, gave an interesting sketch of the industry in that State. He said the bee-prospects there were not very bright; that honey often sold for 20 cents or more a pound. He praised the Utah honey as being the finest in quality that he had seen. He thought we should exhibit at the St. Louis Fair.

Marketing Honey.

Very few bee-men are able to market their honey successfully, but many can produce it. There are certain qualifications necessary to be able to put it in shape to get the best results. It should be put in shape first to supply the local market, which is always the best; and, next, that it be in proper shape and condition to ship to any market.

All packages should be scrupulously clean and attractive. The packages should be uniform, and the contents exactly as represented. Under these circumstances the market will hunt the honey instead of the honey having to hunt the market, and command prices that will be remunerative.

Bee-men can be the best judges of the package, according to the locality and prospects in marketing conditions; they vary with localities. If you want the top price for your product see that it is in the very best shape and condition.

T. R. G. WELCH.

President's Address.

I take pleasure in greeting so many of you at this time. While we meet, and greet many new faces we still have many of the old true and tried friends with us. And while all of our bee-keepers, as a rule, are kind, generous and true in their sympathies for each other personally, many of them lack interest in a unity of purpose necessary to the building up of the bee-industry; while many express a hope and a willingness that the bee industry may be built up and become a grand success, they wait for others to do the building, and the great trouble has been that there have been too many in the waiting column.

We should form a co-operative exchange for the benefit of all concerned. In union is strength, and if we would succeed we should form a strong bond of union.

I have received a number of letters of late from several bee-keepers in different parts of the State favoring the adoption of an exchange for the general benefit of our bee-keepers, and we hope to see it pushed to a successful issue. A strong organization should be formed, and the best possible plan or method should be adopted for the purchase of supplies, and for the disposal of all bee-products. We find that organization for general protection is the order of the day among all orders and classes, and why should not bee-keepers? It needs but little argument to prove that when each is striving alone to push his product on the market, the result will be a demoralized market and low prices. Thus the best way to avoid these difficulties is to ship all products collectively to the market where it is required.

I have in view the publishing of a treatise in the interest of the industry as soon as our financial condition will allow us, on the general management, the protection of bees, etc.; and also as to the benefit to the health of the people in the general use of honey.

I find some very crude ideas exist in regard to honey, some believing that nearly all honey is adulterated, even the very purest and the best white alfalfa, which is said to be the peer of all honeys. Even this peerless honey, in its granulated condition, which is a general test of its purity, some claim is adulterated. These mistakes need correcting. We do not believe there is a bee-keeper in the State that is guilty of adulterating, and Utah honey has a name which it justly deserves, of being par excellence.

Shall Utah bee-keepers exhibit at the fairs? We cannot afford to miss the great World's Fair at St. Louis. Utah honey has carried off the honors on all occasions where it has been properly exhibited, and if we send a good exhibit to St. Louis we need have no fears for the result.

From present indications over the greater portion of the State the outlook for a good honey-flow is encouraging, and thus if the results of the season prove satisfactory it will be beneficial from every standpoint to put in a good exhibit at our own State Fair this fall.

Our bee-keepers should take pains to protect their bees from ants, wasps, and other bee-enemies, and also from disease. If there should be any trouble of this nature in any

part of the State, steps should be taken to get the law enforced, and thus try to eradicate the disease.

No. 1.—Longevity of Bees—Rearing Short-Lived Ones.

BY DR. E. GALLUP.

WHEN I read in the report of the Chicago Convention Mr. Riker's account of longevity of bees, I felt like hurrahing for him. He has struck the right key. I have been watching the discussion about long tongues.

Allow me to tell how to rear short-lived queens, and short-lived workers, so that the merest novice can run an apiary for profit in two seasons, and never make a mistake. Understand that I have been "through the mill"—it is no guess-work or theory with me. Now we are ready to commence.

Take a small box, say 6 inches square, fit in some comb containing a few eggs and larvæ just hatched. Now get a small quantity of bees and place them in the box with the comb; place them in a dark room or cellar, and in about three days set them out and let them go to work, and if they succeed in rearing a queen you will have a short-lived one, and she will rear short-lived workers. Don't bother your head about whether your nucleus contains old workers or nurse-bees, it won't make so much difference only the fewer nurse-bees the nearer you come to starving the embryo queen.

I obtained my first Italian queen from W. W. Cary, of Massachusetts. Queens were then selling from \$5 to \$20 each, and I was going into a fortune at once (in theory), and it was "just as easy as rolling off a log." But in practice it was a failure. I did not sell any queens, but I was learning, all the same.

When I went to the first Cincinnati convention I roomed with Adam Grimm and we discussed the queen-breeding theory thoroughly, and when I bade him good-by, he said, "Gallup, next summer I will send you a queen that is a queen." And he did. She was one of the very best queens I ever owned—prolific, long-lived, and reared long-lived workers. She lived to be 6 years old. Those bees were extra honey-gatherers. When I got my first large hive, whose colony produced 600 pounds in 30 days, I hived a large prime swarm on the 10th of May from my Grimm stock. As soon as they commenced to build droue-comb I filled out the balance of the hive with ready-made worker-comb—48 combs, all on the ground floor, and the queen spread herself grandly.

I made other large hives containing 36 combs each. None of my large colonies cast a swarm the second season, so I thought I had a non-swarving hive. But the third season my large colonies all swarmed, some 8 to 10 days earlier than those in standard hives, because they had superseded and reared new queens to suit the capacity of the hive. Those swarms were so large when they came out that it took three standard hives, one on the other, to contain them. The queens all lived 3 or 4 years, and one lived 5 years, whereas many queens reared on the small nucleus plan die of old age the first season, and all are worthless the second season. Bees hived in cracker-boxes, nail-legs and small boxes for a series of seasons soon get so they rear queens to suit the size or capacity of the hive or box.

Now allow me to tell how to rear long-lived queens and bees. My 14-year-old son takes quite an interest in bees, and he has made two 9-frame Langstroth hives all under the same roof, side by side, so that all can be turned into one hive. Now when all are full, and if the two queens do not fill to suit with brood, we will fill with hatching brood from other hives, so as to have an immense quantity of nursing bees, and bees of all ages. Now in a hive of that capacity, and filled in that manner, we expect to rear long-lived queens and long-lived workers, and we shall not be disappointed. I know positively, by actual experience, that the lifetime of the bees from queens reared under the best possible conditions is fully three times as long as those reared under the opposite extreme.

Now, Mr. Riker, let us shake, as you and I are both on the same side of the fence. San Diego Co., Calif.

How to Introduce a Queen Successfully.

BY EMMA M. WILSON.

TO introduce a queen successfully is not a very difficult feat for a veteran, but it is an entirely different thing with those who have had no experience whatever in that line, and scarcely know a queen from a worker. With them the introduction of a queen is an undertaking attended with a good deal of nervousness, and the success or failure of the venture means so much more to them than it does to one who has had years of experience.

I well remember the first queen I introduced all by my lone self. Dr. Miller was away from home, to be gone several days, and the very first day after he left a valuable imported queen arrived. How my heart sank. I sat down and looked at her, and just about made up my mind to leave her in the cage until he came home. Still I was afraid she might die if left in the cage so long, and I finally concluded she must be taken care of. But not a bee would I risk with her valuable ladyship. I had helped Dr. Miller introduce an imported queen that had come unexpectedly some time before, and I concluded to try the same plan.

I put a piece of wire-cloth on top of a strong colony, placed an empty hive on it, then went to two or three strong colonies, and selected several frames of sealed brood from which the bees were just hatching, and placed them in this empty hive, being very careful that not a single bee was left on them. I was afraid they might need water, so I soaked a cloth with water and put it in the hive. Lastly, with fear and trembling, I put in the queen (killing the attendants for fear of foul brood), and covered her up snug and tight so that not a single bee could get in, and left her to her fate.

I wanted so much to look for her the next morning to see if she was all right, but concluded to leave her until evening. When evening came I could wait no longer, so I opened up the hive, and was delighted to find her all right with quite a cluster of baby bees, and more hatching, so I concluded they would do to put on a stand by themselves, as the weather was warm, which I proceeded to do, taking the precaution to close the entrance so that only a few bees could get out at a time. By the time Dr. Miller got back there was quite a little colony.

Dr. Miller said it would have been better if I had left them on top of the other hive for four or five days. In this case I don't think it did any harm, as the weather was so warm. If it had turned around cool some of the brood might have chilled.

If I had a very valuable queen to introduce I would rather take the plan I have described than any other I know of, for it is perfectly safe.

In ordinary cases the introducing-cage is a boon, especially at the out-apiaries. You often want to remove a queen, or kill a worthless one, and you don't want the colony to go queenless until the next time you visit the apiary. All you have to do is to remove or kill your queen, fasten a queen in a Miller introducing-cage on one of the frames with a wire-nail pushed through the cage into the comb. By the time the bees have gnawed through the paper and eaten their way through the candy they are ready to accept the new queen without any trouble. That is, they very rarely make any trouble. Once in a great while you find the queen missing. Perhaps they gnaw their way through too quickly, and reach the queen before properly making her acquaintance. Sometimes, however, when a queen is not kindly received it is because there is something in the hive which the bees regard as a queen.

I remember one colony that I thought was hopelessly queenless. There were no eggs nor any unsealed brood in the colony, and I looked the frames over carefully and could find no young queen, so I gave them a queen in an introducing-cage, and the next time I looked she was gone. I gave them another, and she shared the same fate. Then I thought I would try them once more, and gave them another, taking care that everything was all right about the cage. When I opened the colony the next time I found that she also had disappeared. Then I concluded that they must have some sort of a worthless queen. I looked very carefully but could not find the least trace of one. Then I gave them a frame of young brood. In a day or two I looked again and they had not started any queen-cells. So I began my search for a queen again.

I went over the frames carefully several times and no queen could I find. Just as I was about to close up the hive

I caught sight of a little black queen with one bad wing, not much if any bigger than a worker. That was what had been making all the trouble. I tell you, her head came off pretty quick, and the next queen was accepted all right.

If nectar is coming in freely, and robber-bees are not causing any trouble, and we know that a colony is queenless, all that we do is to drop a queen on a comb among the bees and she is generally accepted all right. In a case of this kind it is a little safer to introduce her in the evening.

Management for the Production of Comb Honey.

BY G. W. STEPHENSON.

IN writing on the production of comb honey I suppose the proper thing to do would be to begin in the fall, tell how to prepare the bees for winter and build them up in the spring ready for the honey-flow. But as that would take up too much valuable space I shall assume that they have come through the winter and early spring to the time of fruit-bloom, which occurs about the last of April or the fore part of May, in this locality. At this time each colony should be examined carefully, clip all queens that are not already clipped, and note especially the very weak and very strong colonies, for these are the ones with which we have to do at present.

I believe some bee-keepers advise taking brood from the medium-strong colonies to build up weaker ones. I prefer to go to the very strongest colonies. I have been thinking it is better to use up one or two strong colonies to build up several weak ones than to weaken the medium colonies—to make the weak ones only medium. Take one or two frames of hatching brood (be sure and have the bees just emerging from the cells), place these frames in the center of the brood-nest, and your colony is strengthened at once. As fast as the young bees emerge the queen will lay in the empty cells and the eggs will be right where they can be kept warm.

The queen will also extend the brood-nest on each side, as there are now plenty of young bees to take care of the brood. There is nothing like lots of young bees to encourage a weak colony. By continuing this method, always replacing the frames of brood taken from the strong colony with empty combs, we will soon have all the colonies in a flourishing condition and ready for the harvest.

We come now to the time of swarming and putting on the supers, but before we put on the supers I wish to call your attention to the one I have used for the last three or four years, which is arranged in this manner: It is what is known as the T super, the size to fit a 10-frame hive, and will hold twenty-eight $4\frac{1}{4} \times 4\frac{1}{4}$ bee-way sections; but instead of putting in 28 sections I put in only 24, with a follower at each side, leaving a bee-space of about $\frac{1}{2}$ inch between the inside of the super and follower. It is to the importance of this bee-space that I wish to call your attention. I find the bees will build out and finish the outside sections much quicker and better than without it; it also acts as a ventilator, giving the bees a chance to ripen up the honey very fast. There should also be a space of at least $\frac{3}{8}$ inch between supers, and between the cover of the hive and super, for if we expect to have the sections of honey built out and sealed to the top and bottom we must have room for enough bees to cluster to keep up the heat. In such a super there is a living blanket of bees from $\frac{3}{8}$ to $\frac{1}{2}$ inch thick all over the top and around the sides, and they are bound to produce a first-class article.

Having the supers all ready with sections filled with full sheets of foundation, and a few bait-sections in the first ones put on, we are ready for the harvest; and as the honey begins to come in we are likely to have some swarms: but to prevent this as much as possible I raise up the hives on $\frac{1}{2}$ -inch blocks at each corner, and give plenty of super-room. But, do all we may, we will have some swarms, which I should manage in this way, (and this management is for a long, continuous honey-flow, and admits of very little increase):

I use a 10-frame hive. Provide a hive with 5 frames containing full sheets of foundation or empty combs, putting them all together in the center of the hive. When the first colony swarms set the old hive to one side, place the new one in its place and fill up with two frames of honey and three of brood from the old hive, being sure to destroy all queen-cells. Take the brood that will not emerge for four or five days, put on the super at once, and the bees will go right to work. Fill up the old hive with full sheets of foundation or empty combs; in from five to seven days shake

off most of the bees in front of the new hive, and use the old one for the next swarm, putting it on the stand of the next colony that swarms, leaving that hive at the side of the stand for seven days, then placing it on a stand of its own, beginning again with a new hive as with the first swarm. In this way we increase only one-third, and our colonies are almost as strong as if they had not swarmed.

By this method the strength of the colony increases from the day it is hived, instead of decreasing for three weeks before there are any young to take the place of the old ones that are wearing themselves out every day.

As soon as the first super is well started, raise it up and put an empty one underneath, and so continue, taking off the full ones as soon as finished. But at any time when the flow begins to slacken, place the empty super on top, which will in a great measure prevent having so many partly-filled sections, as the bees will usually finish the lower ones before going above, especially during a light honey-flow.

Cook Co., Ill.

Difference in Localities—A New Wintering Scheme.

BY F. GREINER.

AS favorable as the past winter was relative to wintering our beloved little bee, it may be noticed by the observing that location plays a most important part in wintering bees. From what has come under my observation during a period of more than 25 years, I am convinced that natural protection is of greater importance than double walls, chaff-packing, tarred-paper covering, and what other auxiliaries we may have, and employ, to give protection to bees. In an exposed place, where a dog couldn't keep his hair, the bees will go, no matter how well they are protected. Such a location will probably prove unsatisfactory even during the summer season.

We also know, however, that there are many sections where bees may be kept with profit if the wintering problem could be solved. A suitable cellar could be used in such a locality with advantage. However, I wish to bring out a scheme that, I believe, is practicable with the professional, and has certain advantages for such as are situated to put it in operation.

It seems singular that natural protection in our climate should be worth more than the skill of the professional, but it really does seem that way many a time. I have known of small after-swarms, which had built but little comb in one corner of a thin-wall soap-box, to come through the winter unharmed and built up and make good colonies ready for the harvest, simply on account of this natural protection. Sometimes the apiarist need not go very many miles from his own place to find the sheltered spot, where bees could be safely wintered.

There may exist a great difference as to wintering bees even in the different parts of the same yard. Mr. W. F. Marks says, for instance, the bees at one end of his home yard nearly always suffer badly, while those in the other part come through in good shape, usually. He attributes it to the exposure to the winds in that part of his yard, trees and buildings giving shelter to the others.

From what has been said it would seem, then, that we should winter our bees in one of the favorite spots, and that, indeed, is part of the scheme. The proposition is this: To stock up such a place—or more of them, if we can find them—with say 50 colonies of bees each. We need not even be very particular as to the kind of hives they are in. Box-hives, nail kegs and the like will answer as well as any. We allow our bees to swarm, and hive the young swarms in improved hives of some kind, preferably shallow brood-chambers. Very early and large swarms may even be "boxed," and thus give us a little surplus honey; but, on the whole, I would run the yard for increase only. It will take a lot of hives, of course; but swarms are just what I would want that first year. Small swarms are to be doubled up. One hundred young swarms could thus be obtained from the 50 old colonies. They should receive a large brood-chamber, in order to enable them to build up into large, populous colonies, and to store an abundance of honey for winter. It would not require a skillful hand to attend such a lot of bees. Any ordinary man, if not afraid of bees, could see to the hiving.

Every year this 50-colony apiary could be drawn on for 100 swarms, to be converted into comb honey the following season, when they would have to be moved to other quarters and run for all they are worth. They should be given small brood-chambers, and, after a while, they may be doubled down, and again doubled down, till finally we have little

left but honey, combs and hives. The specialist will know how to do this, and will reap a bountiful harvest in honey and wax. The best and perfect combs may be saved, all inferior combs melted up and made into wax during the season.

This method would be a slow way of getting anything out of the original 50 colonies, but they have not cost much, and the income would be pretty certain. The profits from wax would be no small item. We are neglecting the production of wax by far too much. This method will give us at least a fair yield of this desirable article.

To do justice to the originator of the above ideas, I want to say they developed in the brains of our friend, Mr. E. H. Perry.

Ontario Co., N. Y.

On Woman's Dress for Bee-Work.

BY MRS. F. S. A. SNYDER.

SEEING an article by Miss Wilson, on how women should dress for bee-work, I should like to say a few words, first on the subject of wearing woolen skirts, and second on gloves.

In advising woolen skirts we lose sight of the fact that the honey-bee has implements on the three little claws of its hind legs shaped like a hoe, a trowel and a rake, and these delicate little implements catch on the wool and cause no end of unnecessary annoyance to the bees. I know if I wore woolen skirts in the apiary the back, though "the apron covers the front," would be full of struggling, stinging little prisoners, caught on the fuzzy material. Nothing annoys me so much as to see somebody enter my apiary with a felt hat on. I always keep two or three straw hats and suggest an immediate change, with an extra veil.

Clean, starched clothes, and why not duck, short skirt with bloomers, no matter what color, so they are clean? I wear black cotton shirt-waists (because light colors fade and white soils so quickly), and clean cotton skirt. I rarely ever get a sting. I became so conceited about my method of handling bees that I rolled up my sleeves and went at a three-story hive with about 40,000 bees in it, and I got three or four stings. I reasoned it out and came to the conclusion that the arms and hands perspire more or less when warm, and the little bees in constant contact with the exquisite perfume from the flowers quickly discern that it is living flesh, and sting immediately.

So I tried this experiment:

I got an old pair of kid gloves, 3 or 4 buttons, and a size too large for me, so they will come well up on the wrist. Then I cut the finger-tips off to the second joint, and warmed beeswax and rubbed it well in, and then placed them in a warm oven so it would soak and permeate the gloves thoroughly. I have worn these gloves for three years, and rarely ever get a sting. They never sting the gloves, and I can wash my hands, as the wax protects the kid.

Yesterday I handled and looked over three 3-story hives, and thoroughly cleaned the bottom-boards, for I believe that strict attention to cleanliness prevents foul-brood, though I have never experienced a case here. Each of these hives contained, on an average, 40,000 bees. I extracted about 5 gallons of honey, besides hiving swarms. I never increase, but cut out all queen-cells and return a swarm to the hive from which it issued, on empty combs and comb foundation. I received only one sting during my stay in the yard.

The reason I cut off the finger-tips is, I cannot understand anybody handling the delicate little bees without being sensitive to every little creature that flutters on the hand; I should smash dozens, and could not work with despatch.

Sonoma Co., Calif.

Honey and Beeswax—Considered by the Illinois Food Commission.

BY PROF. E. N. EATON, STATE ANALYST.

Recently a report has been quite widely circulated and credited which has affected, injuriously, the reputation and sale of honey. This report pretended to give:

First.—The appearance of honey when pure.

Second.—The extent of adulteration on the market.

Third.—A description of the manufacture of comb honey (carton) and prevalence of this product on the market.

Knowing the report to be unwarranted, the Chicago Bee-Keepers' Association, at one of their semi-annual meetings, asked me to give the facts in this connection to the public.

Extracted honey varies in color according to the flower upon which the bee feeds. Alfalfa and basswood honeys are nearly white, goldenrod and buckwheat dark; the latter sometimes almost black. The clovers, orange flower, etc., occupy an intermediate position as regards color of honey produced from them.

Honey-combs produced from such plants are as white or whiter than the honey enclosed. Pure honey is usually a viscid liquid, but may be entirely solidified. All honey granulates in time, and this is rather a badge of purity than impurity. Granulated honey is not, however, of necessity pure.

Adulterated honey has had a long and prosperous reign in Illinois, but the "Dynasty" is tottering on its throne. The National Bee-Keepers' Association commenced war on adulterated extracted honey in Chicago in 1898, and I, as the expert chemist, found over 50 percent of samples taken adulterated. However, owing to loose food laws, nothing could be done with parties arrested. The creation of the Illinois Food Commission, however, had a wholesome effect on the honey market, and but eight of 22 samples analyzed were found adulterated in the preliminary work of the commission.

Since that time 30 samples have been collected and examined, with a view to selecting adulterated or suspicious goods, and but six, or 20 percent, were found adulterated.

While the adulteration of extracted honey has not been wiped out (indeed, never will be so long as there is a profit in adulteration, and a chance to escape detection), yet the market is in a more satisfactory condition than it has ever been, as gladly testified to by bee-keepers, and emphasized by the result of our work.

Many years ago Dr. Wiley described, in pleasantry, a process of manufacturing comb honey. Since that time comb honey has striven in vain to live down the aspersions cast upon its character. No doubt they have been fostered by the manufacture and common use of artificial comb foundation, and also the re-using of old comb after extraction of honey by centrifuge. In the course of my analytical career I have examined many samples of comb honey, usually those suspected of adulteration, the last just before going to press, and I have never yet discovered a sample which was not, in my opinion, supported by the chemical evidence, made in whole or in part by the bee. Nor have I seen, in any literature on the subject, a record of such fabricated goods.

However, I have seen and have analyzed adulterated comb honey. I will refer to this later on in a portion of this article on honey adulteration. Before discussing that part of the subject it were well to define accurately the article as understood by me, and describe its properties.

A comprehensive definition of honey must include the saccharine liquid food secreted by the honey-bee, *Apis mellifera*, the bumble-bee, *Bombus pennsylvanicus*, or other hymenopterous insect. Wiley (1891) defines honey as the transformed nectar of flowers. Cook (1893) would modify this definition to conform to our more extensive knowledge of the food of bees and our limited knowledge of honey by defining honey as simply transformed nectar. This definition, to be sure, would include aphid or louse honey, but would not include honey obtained by feeding bees cane-sugar, etc., a form of honey sometimes met with and very difficult to distinguish from flower honey.

Several States forbid the selling of honey obtained by feeding bees cane-sugar, and in view of the fact that the flavor of honey is the one important property that gives it its individuality and establishes its reputation as a delicacy, which flavor is wholly obtained from flowers; and also considering that the composition of such honey is oftentimes so greatly changed as to destroy its character as honey, I believe it to be just to adopt the following definition for honey as a marketable commodity:

Commercial honey is the nectar of flowers, transformed, and stored in a comb by the honey-bee.

It is true that this definition will rule out some honeys admitted by the comprehensive definition previously given, but not to the disadvantage of the producer, the tradesman or the consumer.

As stated by Cook, honey-dew (aphis) is so unattractive in appearance and flavor as to be rarely found on the market. Honey produced by other insects than the honey-bee is not made in sufficient quantity to give it commercial standing. Honey produced by artificial feeding is an adulteration in fact, and, although concocted with the bee as an accomplice, is a fraud and a cheat. The physical properties of honey depend somewhat upon the variety of bee, but much more upon the food. As previously stated, the color depends wholly upon the plant visited, as also does the flavor, this flavor and color being in part due to pollen carried by the bee from blossom to hive, and intended as a food for young.

The viscosity of honey varies from a solid sugar to a limpid syrup. The amount of water present will depend somewhat upon the variety of bee producing the honey, the time of ripening and the length of time kept in the hive. All honey will "candy," and some, more particularly alfalfa, will "candy" in the comb, and on short notice sometimes. Usually honey "candies" evenly, and a honey half liquid and half solid is suspicious. Honey should not contain over 23 percent of water.

It is the custom of bee-keepers to set a sheet of comb foundation in the center of a honey-box, that the bees may build regular cells and fill out the corners of the comb. The comb foundation is embossed on both sides with the form of the cell-bases, and is made from bees-wax. Other waxes, fats and paraffin have been tried, and found wanting. Even with this starter the cells are seldom, if ever, perfectly hexagonal, nor even level, and each section, like each leaf of the forest, possesses an individuality of its own. And the same is true, to a lesser extent, of the honey contained therein, as no two samples have exactly the same composition.

Chemically considered, honey is a water solution of invert sugar (sucro-dextrose and sucro-levulose). It also contains a small amount

of sucrose (cane-sugar), mannite (a sugar) and dextrin (a gum). Still smaller quantities of formic acid (?) and other organic and mineral substances are invariably present.

Genuine honey always turns a ray of polarized light to the left from 0 to 25 degrees; gives a slightly increased rotation on inversion; usually contains but 2 or 3 percent of sucrose, rarely $7\frac{1}{2}$ to 9 percent. The high percentage probably signifies unripened honey. Dextrin should be present in small amount only.

The statement is often made that honey normally contains glucose in greater or less proportion. Such is a mistake. Glucose, in a commercial sense, can not be incorporated in comb honey. Glucose, in a chemical sense, signifies a group of sugars having common characteristics, and includes almost two dozen varieties, the most common of which are dextrose and levulose. Honey, therefore, contains glucoses, but no "glucose." "Glucose" also contains glucoses, dextrose being common to both products.

The physiological process of converting nectar and sugar into honey is very little understood. The constitution of nectar can only be approximated, as it is obtainable in such very small quantity. Yet it certainly contains a much larger proportion of sucrose and dextrin than is found in honey. Watts affirms that the sugar is converted into glucose by a ferment in the honey. Cook, with more reason, thinks that the large compound racemose glands in the head and thorax of bees furnish the ferment which induces the change. In view of the fact that the inversion of cane-sugar is seldom complete, Mr. Doolittle thinks that the young bees work over the honey and more thoroughly digest it.

ADULTERATION OF HONEY.

In 1887 the United States Department of Agriculture caused an examination of honey to be made in various sections of the United States. It was found that the percentage of adulteration ranged as follows:

Seventy-six percent in Nebraska.
Eighteen percent in California.
Twenty-six percent in Kentucky.
Twelve percent in Massachusetts.
Thirty-four percent in New Orleans.
Fifty-eight percent in Pennsylvania.
Forty percent in Ohio.
Forty-eight percent in New York.

In calculating the percentage of adulteration all honey suspected of being adulterated with invert sugar, but not susceptible of positive proof, were classed as pure honey. It will be observed that this investigation, although extensive, was mainly conducted along coast lines. Nebraska is the only representative of the great corn and glucose producing territory between Ohio and California, and it was in Nebraska that the highest percentage of adulterated honey was found.

Bee-keepers seem to have been the last to recognize such a commodity as adulterated honey. Yet honey was adulterated extensively with cane-sugar as far back as 1865.

The manufacture of glucose gave an increased impetus to adulteration, as it had advantages not possessed by cane-sugar or other adulterants. Within the last few years honey, especially extracted honey, has been sold so cheap that it was not thought profitable to adulterate it. The American Bee Journal of July, 1888, says: "Adulteration of honey is now a thing of the past." Owing to the immense yield in California, honey is to-day cheaper than ever. But glucose and cane-sugar have also decreased in value. The work of the United States Department of Agriculture, in 1891, and my own work on honey, offered for sale in Minnesota in 1893, in Illinois in 1897 and to date, show that there is still balm for a seared conscience, and sufficient inducement in the sophistication of extracted honey to hazard detection and punishment.

(Concluded next week.)

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

FINE SAWDUST FOR WINTER PACKING.

At the Chicago convention Mr. Coggshall brought out one excellent minor trait of fine, dry sawdust used as winter-packing. When mice try to burrow in it the roof of their working immediately falls in, and they have to give up. And of course it does not, like chaff, offer premiums in the shape of an occasional eatable grain. Page 245.

PLANER-SHAVINGS FOR PACKING.

Dr. Miller's contribution to the wintering question ought to be passed around till all have had a chance at least to think about it. Put in six inches of planer-shavings and the top gets wet and keeps wet. Put in two inches and the whole keeps dry—and so presumably is better for the bees. Does damp packing, on the top of dry, really do much harm? And how about those who still stick to enamel

cloth for covering next the bees? Probably they would find a dry top on six inches. Page 245.

CHAFF HIVES FOR WINTERING.

Still debating, whether the chaff hive is a dandy or a dolt! 'Spects Mr. Dadant had the right of it. All depends on the weather and the style of winter. Severe winter with long mild spells in it and they are excellent. Severe winter with single warm days in it and colonies in chaff hives don't get half the benefit they ought—takes more than one day to warm the walls through. Presumably chaff hives ought to be best where a long, severe winter has no let up at all. At my apiary, and at present writing (May 13) nearly every chaff hive has shown surplus bees at the door; and not one of the other hives has so done. But then, I remember no other time in 23 years when the big hives have very markedly shown superiority. Unfortunately my tests are not between chaff hives and single-walls. Instead of single-walls I have 10-frame hives narrowed down to 7 frames by dummies and things inside—much better than absolute single walls, I think. Page 245.

DISCUSSING BEE-BREEDING QUESTIONS.

On page 246 Adrian Getaz shows remarkable valor in "massacreing" men of straw. Say, Mr. G., they tell us the Kentucky colonels say "watah" instead of water; who knows, but that's "nigger-milk" working out? Leastwise, in working at deep and elusive problems it is dangerous to go in with such a spirit as that shown by the following quotation: "To the one possessing even an elementary knowledge of physiology the error will appear at once." Had that spirit been always victorious where would the doctrine of parthenogenesis now be? Sometimes the elementary things themselves have to be torn up.

TOTAL EGGS OF A GOOD QUEEN.

Doolittle's estimate of the total eggs of a good queen—700,000 to 800,000. Page 247.

INCUBATION OF BACTERIA.

I was interested in A. W. Smyth's article on bacteria, page 253. Period of incubation in bacterial diseases a number of days. Bacteria reproduce to the extent of many generations in one day. Yet (apparently) no poison is secreted by any of them until about the time the victim begins to feel sick. If this is true so far it looks as if there might be more valuable truths lying around in the same vicinity. *What makes the earlier members of the new colony of minute pests refrain from secreting poison? What determines the time when poison secretion shall begin? Do they all go at it, or only a part of them? The doctrine that bacteria secrete poisons, and kill themselves and the patient also, for the benefit of the bacterial species—well, it seems to me as if that doctrine would bear some more looking at. Appears a little like sawing off the limb they sit on.*

PROPER NAMES OF SWARMS.

Yes, our literature is badly at sea about the proper names of the different kinds of swarms. It is partly because we try to get along with too few names. The term "first swarm" is objectionable because it sometimes is not the actual first but third. Then when an actual first has a virgin queen, things differ materially from what they would have been with a laying queen; and such a swarm deserves a separate name. I say "prime," "virgin prime," and "repeater prime," for these three kinds of swarms. But I also say "repeater prime" in the quite different and much more common case where the same bees fill a hive with brood and then start out again bag and baggage—and that's a weak point in my nomenclature. First kind have plenty of young bees; last kind are apt to be all old bees. Perhaps the term "old-fool repeaters" would about fit the latter case. Then, to extend if not complete the list, we have "seconds," and "thirds," and "fourths," and "repeater seconds," and also "hungry swarms," and "absconders" not hungry swarms, and "fool swarms." The latter are those which in early spring might evidently have lived and done well had they not become so desperately excited that they had to swarm. Page 229.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Honey More Than Increase Wanted.

1. Not wishing any increase except one swarm from each colony, would the swarms issue earlier were no supers put on?
2. Would it be wise to put no supers on until after swarming? I wish honey more than increase.
3. Would it not be better to have smaller swarms earlier than larger ones later? ILLINOIS.

ANSWERS.—1. Yes, at least in some cases.

2. I think it would be unwise, unless your chief dependence is a late flow.

3. I don't think you would gain anything in honey by having smaller swarms early. Besides that, so long as honey is your desire, if you put on supers early enough, and give abundant ventilation, some colonies will not swarm at all, and you will be ahead on honey if an early flow, such as white clover, is your chief dependence. If you depend mainly on a late flow, then it might be better to have early swarms.

Cost of Bee-Books.

On page 330, "Southern Illinois" is told that it would be money in his pocket to pay \$5.00 for a text-book. Are there no cheaper bee-books that are good?

"CHEAP SKATE."

ANSWER.—It was very careless in me to give an answer that might be so misunderstood. You can get any one of the best text-books for one-fourth that amount; but it would pay you well to give the \$5.00 if you could not get one for less.

Hiving Swarms on Extracting-Combs Containing Pollen.

Will you please tell me whether extracting-combs with bee-bread or pollen in them will be all right to hive new swarms on? MAINE.

ANSWER.—Yes, unless there is too large an amount of pollen that is soured, moldy, or badly dried.

Management of Swarms—Transferring—Increase—Keeping Comb Honey.

1. In hiving a small swarm it is best to contract the space in the hive down to what they can fill? What I mean is, on just the frames that they are on or can hang on. We will say we have a swarm of a quart of bees, now shall I give them 3 frames, or shall I give them the whole hive and contract the entrance?

2. Having done transferring this spring by the Heddon method, they staid in the hive 13 days then they swarmed out. I hived them on starters. What caused them to leave?

3. I am running for increase. I let them swarm twice, then I wished to stop them. I put on the extracting super and raised 2 or 3 of the frames. Will that stop them? If not, what is the best way besides cutting the queen-cells out? That will do when a man has but a dozen or two colonies, I think.

4. How can I keep comb honey until along in the fall without the moth getting into it? I find it hard to have a moth-proof house. Will it be safe to fumigate with bisulphide of carbon? CALIFORNIA.

ANSWERS.—1. There is hardly any need to contract either hive or entrance, unless it be that you want to give them starters for the first four or five frames, and then full frames of foundation after the first are filled. That will save foundation, but you are not so sure of having all

worker-comb as you will be if you give nothing but full sheets of foundation.

2. I don't know enough to answer. Will any one help us out?

3. I doubt that raising two or three frames into the supers will stop them in many cases, although cutting out cells would. Perhaps a better plan would be this: When the second swarm issues, hive it and set its hive in place of the hive from which the swarm has just issued, setting the old hive in a new place. That will strengthen your second swarm, and will so weaken the mother colony that it will not be likely to swarm again.

4. The bisulphide of carbon is the thing.

Queens Direct from Italy.

Who is a reliable person in Italy to whom I could send for Italian queens? And what would they cost me?

INDIANA.

ANSWER.—I am sorry to say that I cannot answer your question.—[We would be pleased to publish an advertisement of a reliable queen-breeder in Italy. But gilt-edged references would have to be furnished.—ED.]

Proper Temperature for Opening Hives, Etc.

1. What is the lowest temperature at which it is safe to open hives and handle frames without danger of chilling brood, in the spring of the year?

2. When working on alsike clover, buckwheat and goldenrod, do you believe that Italian bees would gather a greater surplus of honey than pure black or German bees?

NEW BRUNSWICK.

ANSWERS.—1. It is not possible to answer that question by giving a single number. Sunshine and wind must be considered as well as the thermometer; and also the length of time the brood is out of the hive. At one time you may kill brood when the thermometer stands at 65 degrees, and another time you may do no harm to have it out at 55 degrees. It is better not to open hives when the thermometer is below 70 degrees if you can avoid it, but if the air is still and sun is shining there is no great danger at 65 degrees. If you must open a hive at a lower point than 65 degrees, keep the brood out as short a time as possible. A tolerably safe rule is to say that brood should not be taken out when bees are not flying freely.

2. I think they would.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well if they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 348.

Please mention Bee Journal when writing advertisers.

California Prospects for 1902.

Never since I came to California, in 1894, have the indications been so favorable for a most successful year. The rains have not only been generous, but they have been so timed and moderated that all has been utilized and most effective. A large grain-grower said to me yesterday that the crop of hay and grain was better than it had been for seven years.

With rain and vegetation at full vigor, California is sure to give a goodly crop of honey. I think that every indication points to a first-class honey crop this year. The bees have been at work for weeks on the black sage, and now are swarming on the tall flower-stalks of the white sage, which is just coming into bloom. California is a region of most beautiful flowers, and the bees realize and appreciate what this wealth of bloom means to them. They will be heard from this season, I am sure. A. J. COOK.

Los Angeles Co., Calif., May 7.

Made a Fine Start this Spring.

My apiary consists of only 8 colonies, but they have made a fine start this spring. I had only 4 colonies a year ago, having lost 4 colonies during the winter before. They were short of honey, owing to the dry weather in the fall. I had an attack of pneumonia in the winter, and when I became able to take care of and feed them the 4 colonies were dead. I saw then that I should have to feed them in the fall, but I thought at that time they had honey enough to winter on.

LEVI J. WHITEHEAD.

New Haven Co., Conn., May 12.

Colonies Strong Early.

Our bees are in fine condition, and are lying out some now.

I did not get to attend our State convention last fall, and I feel that I lost quite a feast.

I like the American Bee Journal very much, and am always glad to get it.

CHAS. BURCHAM.

Sangamon Co., Ill., May 14.

A Pleased Member—Bee-Prospects.

The proceedings of the Buffalo convention of the National Bee-Keepers' Association is just received. I can say it is a very neat piece of work, and must congratulate you on having put before the bee-fraternity in condensed form as nice a piece of literature as they will

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested.....	1.50	8.00	15.00
Selected Tested.....	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Quirin the Queen-Breeder,

PARKERTOWN, OHIO.

300 Boxes 2d-Hand Cans.

We have on hand 300 BOXES of 60-lb. Tin Honey-Cans (2 cans in a box.) Many of them were emptied of honey by ourselves, and all have been carefully inspected. If we had occasion to do so, we would use them again ourselves. We need the room they occupy, and offer them at a low price to close out, as follows, f.o.b. Chicago: 5 boxes at 50 cts. each; 10 boxes, 40 cts. each; 20 boxes, 35 cts. each, 50 or more boxes, 30 cts. each. NEW boxes of cans are worth 75 cts. a box of 2 cans. So these 2d-hand cans are a bargain. Better speak quickly if you want any of them.

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

be able to obtain for thrice the money. Enclosed find 25 cents for another copy. Such energy needs encouragement.

Bees in this section have wintered fairly well, as far as heard from. My 100 colonies came through with no loss, and are booming now on fruit-blossom and dandelions. I am pretty busy trying to keep back the swarming fever, but I fear results unless storm or frost come to help me out. At any rate, I shall be with them and try to keep them busy guessing whether to swarm or not.

J. NO. W. LYELL.

Washoe Co., Nev., May 19.

Bees in Fine Condition.

Bees are doing fine here. Never before have they come through in better shape.

FRANK COLE.

Mecosta Co., Mich., May 12.

Succeeding With Bees.

I have succeeded quite well my first year with bees, as I just went into the business last year, and did not know anything about bees. But by the help of the Bee Journal, "A B C of Bee-Culture," and advice of some kind bee-men, I got along nicely, although it was a poor year.

I kept my bees from swarming, and had good, strong colonies for the late flow. I got over 500 pounds of honey from 9 colonies, while our neighbors' bees swarmed, and some went away, and while the others did not have enough stores to carry them through.

MISS B. L. HACKWORTH.

St. Clair Co., Mo., May 13.

Fine Season So Far.

We are having a fine season here so far, and between trying to farm, nail up and paint hives and supers, and hiving swarms, I am having a merry time, but one that suits better than last season. We are having plenty of rain, and everything is growing fine. The prospects for good crops and lots of honey are good.

F. W. VAN DE MARK.

Payne Co., Okla. Ter., May 10.

Bush Clover.

Enclosed please find a sample of a "weed" that grows in the timber and along the roadsides of the woods, but not on the prairie at all. It grows about one foot high, and has from one to 15 branches, and a pink or purple blossom, spike-shaped like cleome, but smaller. It is a very fine honey-plant.

CHARLES M. DARROW.

Vernon Co., Mo., April 28.

[The enclosed plant is one of the bush-clover species, but the exact identification is rather difficult to determine, owing to the immature condition of the specimen. In common with other members of the same family, it is undoubtedly a good honey-producing plant.—C. L. WALTON.]

Worst of All Springs for Bees.

I thought we had had some very hard springs for the bees, but this is the worst one I ever knew, during the 33 years in which I have been a bee-keeper. We have had just one good, warm day, but before morning the mercury had dropped from 80 of the afternoon before to 28. Wind, snow, rain, cold and clouds was the order of the day up to Thursday morning, May 8, when we had more or less snow during the forenoon. Toward night it cleared with a gale from the north, and on the morning of the 9th, after the sun had been shining two hours, the mercury stood at 22, with the wind still on. Ice formed fully one inch thick, and all of our fruit was spoiled, unless, perhaps, as we hope, apples may have survived on the later-blooming trees, which were still in the bud form. Then it froze nearly as hard on the night of

To make cows pay, use Sharples Cream Separators. Book Business Dairying & Cat. 212, Free, W. Chester, Pa.

An Italian Queen Free!

We would like to have our regular subscribers (who best know the value of the American Bee Journal) to work for us in getting NEW subscribers. We do not ask them to work for us for nothing, but wish to say that we

will mail ONE FINE UNTESTED ITALIAN QUEEN for sending us ONE NEW subscriber for a year, with \$1.00; or 2 Queens for sending 2 new subscribers, etc. Remember, this offer is made *only* to those who are now getting the Bee Journal regularly, and whose subscriptions are fully paid up.

In case you cannot secure the new subscribers, we will mail one of these Queens for 75 cts., or 3 or more at 70 cts. each; or the Bee Journal one year and a Queen for \$1.50. We expect to be able to send them almost by return mail.

(Please do not get these offers mixed up with our Red Clover Queen offers on another page.)

We will present you with the first \$5 you take in to start you in a good paying business. Send 10 cents for full line of samples and directions how to begin. **DRAPER PUBLISHING CO., Chicago, Ills.**

3-Frame Nuclei For Sale.

We have arranged with a bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei of bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 or more at \$2.75 each.

All are f. o. b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

GEORGE W. YORK & CO.,
144 & 146 Erie St., - CHICAGO, ILL.

the 10th, and we had a white frost on the morning of the 12th. It rained a little on Monday night, but Tuesday, the 13th, it turned cold again, and Wednesday morning we had ice 3/4 of an inch thick, and the ice was 3/16 thick this morning. The bees have secured nothing but pollen so far this year, and a close inspection of the basswood reveals that the embryo blossoms, at the base of the incipient leaves, have assumed a brownish color, which would denote that they are all killed. If this is so, the bees will have a hard time, and this section will cut no figure in the white honey market during the fall of 1902.

G. M. DOOLITTLE.

Onondaga Co., N. Y., May 15.

Ready for the Honey-Flow.

Bees are in good shape for the honey-flow when it comes. It has been cold and windy until the last few days. We have had rain and snow in the mountains of late, so we will have water for irrigation, and I think we will have a fair crop of honey.

This county will be represented in Denver, in September. **G. W. VANGUNDY.**
Utah Co., Utah, May 6.

Stone for Bee-Cellar Wall.

On page 297, "Illinois" asks the question, "Which would you prefer to use for the walls of a bee-cellar, brick or stone?" to which Dr. Miller replies as follows:

"I don't know. If there is no trouble about keeping it warm enough, perhaps brick might be better, for brick being more porous would allow more air to pass through the wall."

I may say that I prefer stone to brick for a cellar wall; because a stone wall may be so built that it will be practically air-tight; then the ventilation can be controlled to suit the weather conditions, which can not be done with a porous wall. I would even provide against the air coming in through under the wall.

Then there is another thing, the air that passes through a porous wall of a bee-cellar will be made impure by the impurities with which said wall will be saturated from cellar air. With a properly built stone wall it is always sweet.

When I built my cellar wall I paid the men by the day, and I had a definite bargain with them that I should have the privilege to stand right by them when the wall was being built and boss the job, and I did, and all went along pleasantly and well; but the building cost more than the ordinary way would have done, but it gives good satisfaction, and that is a valuable consideration to me.

I ask the Doctor's pardon, but may be he will agree with me, after all.
Ontario, Canada. **S. T. PETTIT.**

QUEENS—Try Our Stock.

DAVENPORT, IOWA, Dec. 31, 1901.
Your queens are fully up to standard. The honey queen that you sent my brother takes the lead. She had a rousing colony when put up for winter. The goldens can be handled without smoke or veil.

Very truly yours, **JOHN THOEMING.**

"What Happened to Ted"

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 3/4 inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,
277 EAST OHIO STREET, CHICAGO, ILL.

Please mention Bee Journal when writing Advertisers.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO. Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

An Enthusiastic Queen-Clipper.

After an experience of 30 years, G. M. Doolittle has the following to say in Gleanings in Bee-Culture:

I am so well pleased with the plan of natural swarming with queens' wings clipped, after trying all other plans used in such natural swarming, that I would as soon think of going back to the box-hives as to return to the old way of letting the queens have their wings as nature made them.

Larvæ or Worms.

L. Stachelhausen evidently thinks that it might not be a safe thing if every one should take Mr. Hasty as authority, and consider it his inalienable right to use names to suit himself. In the Lone Star Apiarist he gives an interview between himself and his storekeeping friend, W. Here is part of the conversation:

"Friend W.," I said, "you know that some people, not acquainted with bee-keeping, will very often use incorrect expressions, and you have laughed when you told me of such occasions; so it is with all branches of trade and science. The better a man is educated the less wrong expressions he will use. As we can not know everything, we all blame him for ignorance. For instance, if a bee-keeper calls the queen a king-bee, etc. If I make a mistake of this kind in some branches of science I am not familiar with, I am always glad if another man, better educated in this branch of science, will correct me, as I do not like to expose my own ignorance if I can avoid it. So I think Hasty is entirely wrong in this respect."

"O, no!" our storekeeper fell in, with a smiling face; "I go with Hasty, whom I do not know, as I am no bee-keeper, but I can see at once the advantage of his opinion. If I fix up a glucose mixture and call it honey, or if I call some margarin the finest country butter, and sell it that way, it is one of my inalienable rights, and you have to give me a premium if I do not sell you axle-grease for butter. Ha! ha! do you see the point?"

"That will not do," said W.; "this is against the pure-food law."

"If it is against my personal liberty, if somebody wants me to call these things by the correct name, as Hasty says it is, then the whole pure-food law is against this inalienable right, and consequently against the constitution."

The Wind and Wintering.

The wind is a factor in wintering that is not sufficiently considered. Some speak as if an increase of latitude must make an increase in the severity of the winter. The isothermal lines do not by any means keep company with the parallels of latitude. The wind may cut more figure than either. Where I live the wind thinks nothing of keeping up a lively gait 24 hours at a stretch, with the mercury not far from zero. I can easily imagine a place 500 miles further north, and a good many degrees colder, where it will be easier on outdoor bees than in this windy locality.— [It is not much wonder to me that Dr. Miller has never been able to make a success of outdoor wintering in his locality. A lively gale of wind for 24 hours on a stretch, with a zero temperature, is something we do not have in Medina, for perhaps more than one day in the winter, although we may have several days of high wind when the temperature is 20 above; but these are liable to be followed by a warm spell, and it is not an unusual thing during the winter for bees to have a flight. Notwithstanding, however, we have made a great success with outdoor wintering at Medina, I am coming to the conclusion that

the indoor method, even here, will be more economical in the consumption of stores, and give us stronger colonies for the honey-flow. I may change my mind; but that is the way the straws round about Medina blow just now. —EDITOR.]—Stray Straw in Gleanings in Bee-Culture.

Box-Hives.

These are ruled out by all advanced bee-keepers in this country. But it must not be forgotten that the advantage of movable-comb hives is all on the side of the bee-keeper, and if no advantage is to be taken of the movable feature—in other words, if the movable combs are never to be moved, then it may be the better plan to use box-hives. Writing in the American Bee-keeper upon the subject of spring dwindling, W. W. McNeal says:

The movable-comb bee-hive, while it greatly facilitates work in the apiary, compromises in a large measure the natural protection of the box-hive to the bees. This must be conceded, since bees in box-hives nearly always pass this critical season of the year more successfully than do those in frame hives.

You may say it is because colonies in the larger box-hives usually have more and better stores; that by reason of the good, ripe sealed honey the bees winter better, and they are stronger than if compelled to feed upon honey that was gathered late in the fall. This is all very true, and one of the essentials in the prevention of spring dwindling. But the natural advantages of the box-hive is seen further in the fact of the combs being attached to the cover-board, thus dividing the spaces between the combs into so many little rooms. The bees are enabled to regulate the heat of the cluster earlier in the season, for it is held right where it is needed. And by the time the bees can fly actively in the spring, there are a large number of young bees ready for duty.

In frame hives the air circulates freely all around the combs, and unless the hive has abundant protection from the cold, the actual comb-space within the clusters that is sufficiently warm for brood-rearing is so small that the colony barely holds its own till the arrival of settled warm weather. The old bees wear themselves out from exposure in a vain attempt to carry on brood-rearing. With the air circulating freely throughout every part of the hive, and a loose cover-board permitting the escape of warm air, the conditions are about as adverse as they could be.

Calahan, General Agent, 111 Adams Street, Chicago. Phone Central 2057. 7—22A1

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, May 19.—The market is without special change from that prevailing early in the month, with perhaps less doing than was noticed at that time. White comb honey sells in a small way at 14@15c for fancy, if white clover and basswood; other kinds at 12@13c; ambers of all grades and flavors are dull at 8@10c. Extracted unusually quiet with white ranging from 5½@6½c; ambers, 5@5½c; dark, 4@5c. Beeswax still active at 32c.

R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings 7 from 5½@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.

THE FRED W. MUTH Co.

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14@15c. Extracted, 6@6½c. Beeswax, good demand, 30@31c.

H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7½c; Florida honey, in barrels, 6@6½c.

BLAIR, SCOTT & LEE.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

CINCINNATI, May 8.—As the warm weather set in, the demand for comb honey is as good as over. There are no settled prices; for whatever is left, prices are made to force sales. Extracted honey is in fair demand and finds steady sales. Amber is sold in barrel lots for 5@5½c; water-white alfalfa, sells from 6@6½c, and white clover brings from 6½@7c. Beeswax scarce and brings 30@31c. C. H. W. WEBER.

NEW YORK, May 19.—There is a limited demand for comb honey and prices range as follows: Fancy white, 14c; No. 1, white, 13c; amber, 11@12c; no backwheat or dark on the market and no more demand for any. Market on extracted remains very inactive. Plenty of supply with only fair demand. We quote: white, 5½@5¾c; light amber, 5@5½c; southern, in barrels, 50@55c gallon. Beeswax firm at from 30@32c pound, according to quality.

HILDRETH & SGOELEN.

SAN FRANCISCO, May 14.—White comb, 10@12½ cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4½@—; amber, 4@—. Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Spot stocks are not of heavy volume, but there is more offering than can be accommodated with prompt custom at full current rates. Business now doing is mostly of a light jobbing character on local account.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.

THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.

J. B. MASON, Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

Red Clover Queens

FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen.)

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order as follows:

No. 1.—For sending us the names and addresses of two new subscribers to the American Bee Journal and \$2.00, we will mail you one of these queens free.

No. 2.—Or, for sending us one new subscription at \$1.00, and 30 cents more (\$1.30), we will mail you a queen, and the Bee Journal for one year to the new subscriber.

No. 3.—Or, send us \$1.00 and we will send to you the Bee Journal for one year, and also a queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.,

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER
IN AMERICA

42d YEAR.

CHICAGO, ILL., JUNE 5, 1902.

No. 23.

* Editorial. *

Ho, for Denver!—There seems to be much enthusiasm among Western bee-keepers with regard to the convention to be held September in Denver. They have had excellent local conventions in that region, and with the addition of others from outside it is likely to be one of the most notable National conventions ever held.

Honey by Mail.—It seems a little strange to us Americans to see in the British Bee Journal mention made of improved boxes for sending sections of honey by mail. We couldn't afford it in this country, but, with all our boasting, Johnny Bull is away ahead of us with his "parcels post" to send things cheaply by mail.

Pear-Blight and Bees.—The Pacific Rural Press contains a report from Charles Downing, who covered trees with netting to note the result. He seems to conclude that the bees are responsible for much of the damage, if not all, estimating his loss on his crop of Bartlett pears last season, due to blight, at \$10,000, and his loss this season up to the time of the report, at not less than 1000 tons of fruit on 9000 trees. Just how the discrepancy between his view and the views of others can be accounted for remains to be seen.

Sweet Clover in Ohio.—A bill was introduced in the Ohio legislature intended to kill sweet clover in that State. Instead of sweet clover being killed, it seems that the bill itself was killed, according to the following item from *Gleanings in Bee-Culture*:

The iniquitous sweet-clover bill that was introduced in the Ohio legislature has been killed, and killed so dead that I hope no succeeding legislature will try to pass another measure like it. This only illustrates that bee-keepers, when they are united, and write to the members of their legislature, can exert a powerful influence. If it had not been for the bee-keepers of New York the new anti-adulteration honey law would not have been passed.

Bees Not Carrying Pollen into a hive when other bees are carrying in large loads is generally considered a sign of queenlessness, and that is probably all right; but the converse is by no means always true, that when bees are carrying in pollen they have a laying queen. Most bee-keepers have probably noticed that a queenless colony has an unusual amount of pollen in its combs. That would

not be the case if the bees would stop carrying pollen as soon as queenless. Possibly the truth is something like this:

Bees have some discrimination in the matter of collecting pollen, and if there is an over-supply in the hive they will let up on the gathering, no matter whether they have a queen or not. When a colony loses its queen, the workers keep right on gathering pollen just the same, but when the combs begin to be well supplied with pollen then they desist from gathering. So when a colony is carrying in no pollen, it shows that it has been queenless for some time.

Using Starters, Full Sheets, and Combs for Swarms.—Not infrequently the question is asked how to mix these when hiving upon them a swarm. G. M. Doolittle says in *Gleanings in Bee-Culture*:

"My advice to all is, and has been ever since comb foundation came into use, to use only starters in the frames in living swarms, or else fill all frames with foundation, or give all frames filled with comb."

Italians and Red Clover.—Discussing the question of getting honey from red clover, M. Leger says in *Le Rucher Belge*:

"October, 1899, we received an Italian queen, but she was small, dark, and insignificant to such a degree that it was hard to distinguish her from the workers. However, in the summer of 1900 she built up an enormous population, which, however, gave no more surplus than the blacks. The last harvest came at the beginning of August, and this Italian colony, which had hung out during the excessive heat, received a super of frames simply furnished with starters. Fifteen days later, upon the visit of a friend, we opened this super; it was completely filled. So in two weeks this colony had built 10 extracting combs 13x6 $\frac{1}{2}$, had filled them with honey, and sealed them. The combs were beautiful, of an immaculate whiteness, almost transparent. Other colonies with black bees had at the most one or two pounds of honey in their supers."

Circumstances were such as to warrant him in thinking that the great advantage of this one colony was in its working on red clover.

Are Long Tongues of Value?—With the passing of time it ought to be possible to get an unprejudiced answer to this question. One thing that seems to be settled is that there is a decided difference in the length of different tongues. As to the importance of extra length, opinions have varied from thinking that bees should be valued in exact proportion to the length of tongue, to thinking that length of tongue is not worth considering at all. Probably neither extreme is correct. The thing that is desired is to have the largest possible crop of honey; and if it

should happen that a colony with short tongues should get the larger crop, why not prefer the colony with shorter tongues?

At the same time it looks reasonable to suppose that wherever there is any plant like red clover with corollas too deep for ordinary tongues—and it is possible that such plants may be found quite generally—extra length of tongue must mean extra storing of honey.

However great may be the value of tongue-length, it may be that it will be wiser to measure the crop stored rather than the tongues that stored it.

Labeling Honey with the producer's name and address is the proper thing if the producer retails it himself. If he sells his crop to a dealer, then he should omit his name and address unless the dealer gives him permission to label it.

Retail Packages for Honey.—In the discussion in the Ontario convention reported in the *Canadian Bee Journal*, the thought seemed to prevail that in the country it was not necessary to have less than from 20 to 60 pounds in a package, while in the cities half-pound packages were needed. J. B. Hall put the matter tersely by saying, "The larger the city the smaller the package."

Extracted Honey—Which is Right?—In the *Progressive Bee-Keeper*, Editor Doolittle quotes some withering accusations against bee-keepers, in which they are charged with putting on the market extracted honey so vile in character that it hurts the market more than the adulteration with glucose, and says:

"Bee-keepers, as far as I know, take every precaution to put nothing but the best before the public at the present time."

The difference in these two views is very extreme; both can not be right. Do bee-keepers themselves put on the market that which is unfit to eat, or is there nothing but extracted honey of the best quality to be found?

Low Price for Extracted Honey, according to "X-Rays" in the *Rocky Mountain Bee Journal*, is not so much due to adulterating foes as it is to the bad practices of bee-keepers themselves. He says:

Of course, the presence of large quantities of glucose mixture labeled "honey," and offered cheap, has a depressing effect on the price of pure honey, especially if the mixture and pure honey bear any resemblance in quality and taste. There is so little difference between glucose honey and thin, unripe pure honey (and that is the character of much of the extracted honey found in the city mar-

kets) that the consumer can not detect it. Both are so vile that the consumer is soon disgusted and quits trying to eat it, and thus is the demand lessened and the market spoiled for really good honey. Here is the root of the apparent over-production.

The remedy is to put only first-class goods on the market, in which case he thinks it will be difficult to meet the demand.

Relative Size of Bees.—Locoppe Arnold, in *Le Rucher Belge*, takes comfort in the thought that workers are the smallest members of a colony of bees. Suppose the order were reversed, and the drones were smallest and workers largest, what use could be made of excluder-zinc?

APIARY OF T. S. APKER, OF LYCOMING CO., PA.

Weekly Budget.

THE BUFFALO CONVENTION REPORT in pamphlet form was mailed to the membership of the Association, as shown by the published list of names. But it seems that some have not read the Report carefully, and so are sending us 25 cents for the copy we mailed them, when it says on pages 11 and 12 of the Report that the Association voted to have the Buffalo convention proceedings put in booklet form for the members. The Association pays for it, so the members need not pay again for the Report.

THE CANADIAN EXPERIMENTAL APIARY is shown on the first page. We are permitted to present it to our readers, through the kindness of Prof. James Fletcher, Entomologist and Botanist of the Dominion Experimental Farms, who wrote us as follows:

In the autumn of 1893, in response to many representations made to the Honorable Minister of Agriculture, arrangements were made for the institution of an apiary at the Central Experimental Farm at Ottawa, in the extreme west of the Province of Ontario. This work was placed under the supervision of the Entomologist and Botanist; but the practical management of the work was entrusted to Mr. John Fixter, the Farm Foreman, who has had considerable experience as an apiarist, and who has carried out all the experiments which have been tried from the beginning of this work until the present time, and which have been reported upon year by year in the report of the Division of Entomology, which forms part of the general report of the Experimental Farms.

A suitable space was chosen near Mr. Fixter's house, where the colonies could be conveniently watched and attended to. About 50 colonies has been the average capacity of this apiary, and some interesting experiments have been tried. Among these may be mentioned the testing of various comb foundations as to quality, and when milled at different temperatures, heavy and light sheets made with different mills; the wintering of bees—in a cellar, in a pit dug in hill-side, in a house-apiary, in a root-house, and out-of-doors, with various protections; experiments with different degrees of artificial heat in the cellar, with a careful record of the temperatures and the results; the feeding of sugar syrup for winter stores; experiments with the house-apiary against the open apiary in summer; and also experiments to decide whether bees could puncture sound fruit of various kinds.

Records have been taken of the weights of colonies daily during the summer, and also of the various plants in bloom which were particularly attractive to bees, not only of the

more commonly cultivated plants, but of many others in the extensive collection of native and introduced plants grown on the grounds of the Central Experimental Farm.

A large number of farmers and fruit-growers visit the apiary every year, and every facility is given them to examine the work and to avail themselves of the information at the disposal of the apiarist. Mr. Fixter is an enthusiast, who is thought by Canadians to be the right man in the right place, and is well known to many of the fraternity in the United States, who have met him at the annual conventions. JAMES FLETCHER.

We may say further that we have had the pleasure of meeting Mr. Fixter at several of our National conventions. He certainly has a very neat apiary. We think bee-keepers, both in Canada and in the United States, would be glad to hear from Mr. Fixter.

CLOSE SATURDAYS at 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we will close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

THE APIARY OF T. S. APKER, of Lycoming Co., Pa., is presented herewith, through the kindness of Mr. W. H. Heim, who visited it, and sent us the following concerning it:

About 21 miles north of Williamsport, in a small town, is located the apiary of Mr. T. S. Apker, who is an extensive bee-keeper. When a little boy he took great pleasure in his father's apiary, by helping his father what he could until at the age of 16 years, when he began to have bees of his own, and has been a successful bee-keeper for 22 years. However, in the year 1891, misfortune came to him, as it does to nearly every bee-keeper. At that time Mr. Apker lost 45 colonies with that dreadful disease—dysentery. This did not discourage him in the least, for he made a new start, and has now an apiary of 125 colonies in good condition.

The apiary is located in an orchard with grape-vines as shade. A better location could hardly be found for basswood honey, which is his main crop. He works his apiary mostly for comb honey, and a little extracted, but finds good sale for all the comb honey in his neighborhood and in Williamsport.

The hives that Mr. Apker uses are of his own make, and are somewhat on the same principle as the Langstroth. The supers are made the same as the T-super, using the 4-opening sections with wood separators. The finest comb honey I saw last season was produced at this apiary, and was of the finest quality, being the best filled sections and of nice basswood flavor.

In the picture will be noticed in the background the hills where there are plenty of basswood, also on the west side of his apiary are hills of the same, surrounded with good pasturage of basswood, where nectar is gathered by his strain of bees, which are mostly blacks and Italians.

Now a word about Miss Nellie, daughter of Mr. Apker, who is also taking a great interest in bees. I am sorry that in the photo the readers are not able to see the colony of bees which she owned at the time I was there, it being on the south side of the apiary, and, therefore, not shown in the picture. This was a runaway swarm which she lived herself, being stung some. But this did not discourage her in the least. She is quite a help in her father's apiary, and takes a great interest in the busy bees.

Through the effort of Mr. Apker and two other men, who helped him during the last flood in December, his apiary was saved. Near the apiary flows the Lycoming creek, which overflowed its banks, endangering the apiary from being flooded or washed away. There was 16 inches of water in it, which made it necessary to move the bees to a higher location. Some bee-keepers lost their entire apiaries during this flood, and some lost from 40 to 50 colonies, which was quite a loss to many in this section. This was also true of Loysock creek, which overflowed, and caused bee-keepers to lose their apiaries. Mr. F. A. Hayes lost 50 colonies during the flood. He is also an extensive bee-keeper in this county. I am sorry to say that many bee-keepers lost their apiaries in that flood.

W. H. HEIM.

Rearing Our Own Queens.

W. H. Bridgen, although a well known queen-breeder, seems to think it well for bee-keepers largely to rear their own queens. In an article in *Gleanings in Bee-Culture* he says:

The tendency on the part of honey-producers is, to a greater extent than ever before, to rear their own—not only because a larger proportion of those reared at home give better results than those transmitted through the mails, all else being equal, but because the essential conditions for the production of the highest type are more generally understood.

Bees are no longer regarded as bees without considering their qualities; but each progressive bee-keeper is continually on the lookout for superior honey-gatherers and other desirable traits shown by individual colonies.

The ability to rear our queens from the best mothers, and control their mating to some extent by weeding out and preventing the production of objectionable drones, and thus, step by step, make permanent improvements in the working qualities of our bees, not only increases our profits, but lends enchantment to pleasure.

Next Week we will be able to announce something definite about rates and accommodations for the Denver convention in September.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 341.)

THE PRODUCER'S NAME ON COMB HONEY.

"Should the producer put his name on the sections and cases of the honey he sends to markets?"

Pres. York—Mr. Burnett, you are one of the men who control this market—so Mr. Dunn said—what do you think about it?

Mr. Burnett—I don't think that was really established—that I am a market controller. Well, I don't know, where people are sending honey to a large market, whether or not it is any advantage for the names of the producers to be put on the shipping-cases. As a matter of fact, my experience has been that it is a disadvantage, as a whole. I presume it would be conceded by most of you that the best honey is the honey that a person likes. It is immaterial what the name of it is, or where it was gathered. When the people can see the name of John Jones, of Colorado Springs, Colo., on the honey, they might say, "Oh, I have seen that place out there; that honey is all gathered from wild stuff; I guess it is not very good; I would rather have some clover honey." On the contrary, if he wants some of that honey, if you don't happen to have any of it, and you let him taste something else, why he says, "Yes, that is what I am looking for." He will give it a name, and tell you what honey it is, which may be quite the contrary to the fact, but he is entirely satisfied that that is the honey he wants. I have, as a matter of fact, lost sales of honey from the fact that the producer's address was on the cases. For years we used to scrape the names off the cases, so that people would buy on their judgment, and not on their prejudices. The question was up this afternoon, while I was here, with regard to sweet clover honey, as to the taste of it, and its tasting strong. There is a gentleman of means in this town, who perhaps for years has bought a case of honey of us nearly every autumn, and has happened to get something that suited him, so a year ago he came; he is a man about 60 years old, and in business, a man of more than ordinary intelligence. He bought a case of honey, and in two or three days he came back. I happened to see him when he came in. He went up to the cashier's window and asked for a bill for the case of honey he had bought at such and such a time. He got it, and after he had the bill receipted, having paid it, he came over to where I was sitting, and said: "I bought a case of honey here the other day, and it has got to be like everything else, you can't get any honey that is pure and fit to eat; I want to send that case of honey back." "Well," I said, "all right, sir." So he got his money back, having returned the honey. As soon as I saw it, I knew, of course, what the trouble was—he got a nice-looking case of sweet clover honey, but he didn't know anything about sweet clover honey, only that it tasted wrong. People have heard that honey from certain sections of the country is not good; others have heard that the honey from that same section is very good, but if they have an opportunity of judging what the article is, for themselves, and not by the printed matter that is on it, so that their prejudice will prevent there buying something that they really want, it often results in sales; otherwise it might be a loss. This is from an experience running over 25 years, and when people really ask me, honestly, whether their names ought to be put on, I tell them, as a matter of fact, for sale in this market, it ought not to be. But in nearly all cases we are misunderstood; they say we want to sell something on which we are making a greater profit, therefore we don't want their names; also that people will want to buy this honey and won't take any other, and so on. Now that isn't fair; we want to sell all the honey we can; we at the same time want to satisfy the people who buy it. Why, if there was no one to buy the honey we couldn't sell it, so we are as anxious to please the party who has honey to sell as we are

to please those who want to buy honey. A gentleman comes in to see me occasionally, and twits me with what Dr. Miller here will enjoy very much, as it is a joke on me. He was in one day, and wanted to know if we could sell honey at a high price. "Oh, yes," I said, "we have the reputation here for selling honey at a high price." There was a gentleman standing right beside me who wanted to buy some honey. I turned to him and said, "Do you want to buy some honey?" He said, "Yes, but I want to buy it cheap." "Certainly," I said, "we sell cheap." He said to me, "I just heard you tell that man that you sold for a high price." There is just this about it: The man who has goods to sell wants to sell dear, and the other man wants to buy cheap. It is a little difficult to please both of them, but we try to strike a happy medium.

Mr. Dunn—I want to take exception to Mr. Burnett on this question. It is the duty of every man who produces honey to brand it; if it is a good article, he can afford to stand on that; if it is a poor article, he will soon find it out, and know what the market for it is. I brand all my honey—all my cases—and I stand on my record and guaranty, and there is no trouble about it. I would recommend every bee-keeper to brand his honey; that is what gives it a standard. Make a reputation for yourself by sending proper goods to the market, and proper weights, and there will be no trouble about selling your honey.

Mr. Horstmann—I think we have to satisfy the people we are buying honey from. I don't believe it is necessary to stamp honey, if we are selling it to commission men who are going to sell it again. In my own neighborhood I would put my stamp on. They would notice that stamp. But in sending it to a commission firm, I would not do so. After I have sold the honey to them, it doesn't belong to me any more, and I don't think it is right to put my name on it, unless they want it on. It all depends on the party who is buying the honey; if he wants it, all right; if not, it should be left off. If I had a lot of honey to sell in that way, I would ask, "Do you want the stamp left on or off?" and if I was told to leave it off, it would be left off.

Mr. Riker—If I were to buy honey from commission men, I would much rather the name of the producer would be on the case of honey; then I would not be afraid that the honey had been tampered with in any manner.

Mr. President—This is comb honey, Mr. Riker.

Mr. Ricker—I would have the producer's name on it, if I were going to buy honey of a commission man, as that would be a guaranty that it was good honey. That is the way I would look at it; I think other people would do as I would do in that respect.

Mr. Burnett—Does a fact of a name being on a section of honey guarantee that it is good?

Mr. Riker—Not necessarily.

Mr. Burnett—Then that doesn't amount to anything.

Mr. Riker—If the producer puts an article in the hands of commission men with his name on it—the man who buys it would expect that the producer was honest, or he would not want his name on it.

Dr. Miller—Like most questions, this one has two sides to it, and I think it may have three sides. If I have comb honey, and am supplying the market, if I am known even a little bit as an honest man, people get to know the honey that I sell, and I put my name on it. Say where one of you live, you have the reputation there of being honest; people will buy your honey and would rather buy it than any other, and in that case it is well to have the name on it, if you are the producer. Your groceryman will prefer it, providing that you produce good honey. Here is another case, in which a man has a trade. Suppose that I were selling honey in Chicago, and going around and delivering it. I must buy from you producers; now I would rather not have the name on, because I have a trade of my own that I am building up. If one of you should say to me, "I am willing to supply you that honey, but I want my name on it," I would say, "No, I have built up my trade, and have taken pains to get customers, and I am entitled to get credit for the work I have done. I want to sell my honey that simply goes as my own, and I don't want any name on it; and if you don't like that, you don't need to sell the honey to me." If a man were doing a large enough business, so as to produce an amount to supply largely any one of the large markets, it might be possible that he would prefer to have his name on it, because it would be handled largely, and his name on it would have its advantages, and the dealers might want it on. The same as I have in mind now—the Atwood Clothing people handle the Rogers, Peet & Co.'s ready-made clothing, and the Atwood people want that name on those goods, because they are supplying those par-

ticular goods to the trade. There might be such a case in handling honey, where both sides would want it: the same thing applies to the Diston saw; any dealer in hardware would be glad to have the stamp of "Diston" on their saw goods, because they will sell better for it. It is a matter of mutual understanding. I think it must be conceded, that if any man wants his name on his goods, it ought to be on, and if any one does not want to handle it, he doesn't need to do it. I have some doubt about the propriety of having commission men, or any dealer, scratch off the name from the cases; I very much doubt the rightfulness of that. Then there is that matter of prejudice which has been spoken of here. It is a poor rule that won't work both ways. The very fact that people are prejudiced might work good for the producer as well as it might work harm. A person is prejudiced in favor of a certain kind of honey, so he buys it. It works both ways, but I very much doubt whether you will settle the question here; people will do as they please, and every one of you who produce honey, if you want your name on it, you have a right to put it on.

Mr. Moore—There is one thing that occurred to me. I am actually spending five cents a pound in expenses and advertising, to put honey on the market; that entitles me to have my name printed on every pound of honey I sell. My customer wants uniformity. If I give him, this time, honey that Mr. Baldrige produces, the next time Dr. Miller's, then honey that Mr. York or Mr. Dadant produces, there is a lack of uniformity, and he will think right off: "If this man gets his honey from Dadant, and Baldrige, and York, and some one else another time, I don't want it;" whereas, if it all comes with Moore's name on it, the uniformity will strike him and help sell the honey.

Dr. Miller—If Mr. Moore has a customer, and he sells to that customer some honey that he likes very well, and it has my brand on it, the person may find out that he likes my honey best, and he will buy his honey from me, or whoever produces it; Mr. Moore will lose his sale. There is a question whether I would gain in that instance. He is working and spending five cents a pound to make his market—ought he not to get the benefit of it rather than I? We must look at both sides. Looking at it from my side, I might say, "I don't care; I want to get the credit for it;" but if I want to be entirely honest, he ought to have some reward, if he is expending money to build up his trade.

Mr. Horstmann—If I sell my honey to Mr. Moore, Mr. Moore will sell that as Moore's honey. He is responsible to his customers for that honey, and I am not responsible to his customers, only to Mr. Moore; so I think it is perfectly right, if the buyer wants the name left off, he should have it left off. If any man buys honey from me, I don't care whether my name is on or not; if he doesn't want it on, I won't put it on. If you insist on putting your name on it, it will lose you lots of customers. If I were buying honey, I could get all I wanted without any name on it; and if some one selling me honey wanted to have his name on it, and insisted on its being on, I would buy from somebody else.

Dr. Miller—I move that we allow every bee-keeper to do as he pleases.

Mr. Stowe—I believe as Dr. Miller does on several points. I sat in the grocery-store last evening, and a man came in and said: "Have you any of Stowe's honey on hand?" I was standing there, but he did not recognize me. The grocer said: "Yes, I have it; it has his name on it." Then the man said, "I want some; I know it is pure; I bought some in Chicago a few days ago, and my folks didn't like it at all, so I want some of Stowe's—some that is pure." My name on that honey was a recommendation for it; but if I were going to ship honey to Mr. Burnett, I would leave off the name.

Pres. York—I should like to know what right Mr. Stowe has to put *his* name on it, when his *wife* is the bee-keeper!

Mr. Stowe—It is an old stamp—it didn't have "Mrs." on it. [Laughter.]

(To be continued.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Does Getting Bees Started in the Brood-Nest Seriously Interfere with Starting in Supers.

BY DR. C. C. MILLER.

ON page 311, Mr. Doolittle asks me to tell the reasons for my unbelief in the statement "that allowing bees to get started storing in the brood-nest seriously interferes with their storing in supers." I am very glad to reply to the man to whom I owe not a little for some of the things I have learned about bee-keeping.

I do not see that the first quotation from Mr. Boardman conflicts in the least with my belief. I think that no bee-keeper of any experience ever expected his bees to begin storing in supers while there is plenty of vacant space below. I should be glad to understand how that conflicts with what I believe to be the fact that starting to store in the brood nest does not seriously interfere with their storing in supers.

The second quotation from Mr. Boardman is given without saying where it is to be found, and, taken from its setting as it is, I do not know its full bearing—do not know what time is "this time," nor the conditions involved—so I cannot say whether it conflicts with my belief or not.

If I am not mistaken, storing in any and every case, in accordance with the first quotation from Mr. Boardman, begins in the brood-nest—possibly, to be more exact, in the brood-chamber or brood-combs—which, however, does not materially alter the case. The bees first store in the brood-chamber till it is filled. Moreover, a writer for whose opinions I have much respect is very positive in the opinion based on very careful observations that no bee coming from the fields ever goes straight to the super to deposit its load, but leaves it always in the brood-nest. Afterwards, it is carried by younger bees into the super, providing there is not room for it in the brood-chamber. If, however, there is room for it in the brood-chamber, in the brood-chamber it will be left, no matter how strong may have grown the habit of storing in supers.

One year, a good many years ago, I thought I might prevent swarming by giving additional room in the brood-chamber for the queen to occupy. I put one, two or three empty combs in the middle of the brood-nest. If three combs were given, the bees promptly filled them with honey, in spite of the previous habit of storing in supers, and only when the queen was ready to use those combs were they emptied out for her.

When I used 10-frame hives, there was more honey stored in the brood-nest than I find in 8-frame hives, and if the harvest began with empty combs in the brood-chamber those empty combs had to be filled before work was done in the super, and I would rather have that white honey in the super; but when the brood-chamber was filled I could not see but the bees went to work in the super just as willingly as if they had earlier formed the habit of storing in the super. Perhaps that does not exactly express the thought. Bees are creatures of habit, and after storing in a certain place, other things being equal, they will go on in that place more readily than they will commence in a new place. But always the desire to have their stores near the brood-nest is stronger than the habit of storing away from it, and they will store elsewhere only when compelled for want of room in the brood-chamber. What I mean is, that after filling up two or more combs in the brood-chamber they will then as readily form the habit of storing in the super as they would have done in the first place if they had not had those two or more combs to fill.

I think I have seen stated in forcible language by the same writer whom I have mentioned, that when the old queen is succeeded by a virgin queen the bees during her virginity devote their energies to filling the brood-chamber with honey, and then when the young queen begins laying the honey is rushed above and the supers filled with marvelous rapidity; that, in spite of the fact that the bees have been fixing the habit of storing in the brood-chamber. Does Mr. Doolittle think he would get any more honey if, during the time that the young queen has not yet commenced to lay he would fill the brood-chamber with dummies so as to force the bees to continue the habit of storing in the super?

Give a colony an extracting-super, and keep it restricted to that one story, emptying it often enough to give them room, and after having the habit of storing in that one story continued during three weeks time, give them a second story without emptying the first, and see if they will not as promptly enter the second super as if it had been given two weeks sooner.

It is probably the truth that habit has its bearing, but not enough to be a serious hindrance; that bees always prefer to have their stores as near as possible to the brood-nest, and store away from it only when compelled to do so; that after having continued the habit of storing in the supers no matter how long a time they will always change to storing in the brood-chamber if room there is given; that they *always* begin storing in the brood-chamber before storing in sections; and that the length of time they continue storing in the brood-chamber has no special bearing upon their hesitancy to begin in the supers.

Mr. Doolittle wants me to give a better plan if I have one. As no plan has been mentioned I do not understand to what he refers. If he will say to what plan he refers I will be delighted to give him a better one—if I have one. But I have not been aware that we have differed in any plan that might be affected by a difference of belief as to the things that are herein mentioned. McHenry Co., Ill.

Question, "Do Robber-Bees Sting?"—Answered

BY W. W. M'NEAL.

ON page 115, in an editorial under the heading, "Do Robber-Bees Sting." A suspicion is ventured that robbers do not sting the defenders of the hive they are trying to rob. Moreover, the Editor asks for something positive upon the subject, and here it is: Robber-bees do sting at such times, and with terrible effect, too. If this were not so, how is it they are so successful in over-running at times a good, normal colony? Surely, the bees of the attacked colony are not intimidated by any superior force of numbers, and retreat before the robbers in their rush for the stores! This is not in the nature of the honey-bee when she feels that her home is worth fighting for. When such a colony submits to the plundering of its combs, you may know that its fighting force has been swept away by the fierce onslaughts of those frenzied desperadoes.

There is something peculiar about the apparent ease with which robber-bees will, in so many cases, get the better of a bee that opposes it in an endeavor to enter the hive. The robber is worked up to the very highest pitch of excitement and abandonment to an evil habit; the poison-glands pour forth their fiery fluids more bountifully; and, the honey-sac being almost perfectly in a state of depletion, it will be seen that she is in the very best possible fighting condition. But a robber-bee will not use its sting for the mere pleasure of killing—that characterizes a villain in human form. There is a risk to run which she is not willing to take in any such way. I mean the risk of losing her sting. The danger of having it torn away is not so great when thrust into the body of another bee; but when the sting has penetrated sufficiently to kill outright, the bee can not withdraw it easily, and I have often seen them crawling about upon the ground in front of the hive dragging the dead bee thereby.

Robbers will often bite and sting just a little a bee that has surrendered, in an effort to make her give up the last mite of honey, which may cause the bee to die in a short time. This, to me, is more plausible than that the captives, so to speak, join the victors in their own hive. When a robber has been seized by a fighting bee, and the two are buzzing so rapidly on the alighting-board or ground in front of the hive that the eye can not determine what is actually being done at the time, the fact that one, and quite often both, of them have their mandibles fastened upon each other at the close, convinces me that both were fighting. Sometimes they cease buzzing, and wrestle on the ground for the advantage. The mandibles hold a death-grip while the two hindmost legs of each are dextrously used in an effort to prevent the other from getting into position to use its sting. The bee whose abdomen is distended the least of the two that are fighting, usually succeeds in this and destroys the other. So soon as the fatal thrust of the sting has been effected, the victorious bee will usually make an effort to break away; but the other will often cling by the mandibles till she is too weak to do this.

As the editorial in question suggests, evidence of a very conclusive nature may be had in cases where the conten-

tion is between a colony of Italian and black bees. The untrained eye then can easily separate the robbers from the regular inmates of the hive. But the experienced observer will not often be deceived by the maneuvers of robber-bees. The sweet melody in the hum of a bee engaged in honest pursuits is so different from the loud, shrill notes of robbers that the ear alone may detect them. The bright, cheery color of honesty is soon swept away, being replaced by a dirty, glassy, greased appearance in a short time, when a bee resigns itself to this evil habit. All Italian bees will, when they become aged, assume a darker color than they had when in younger life; but this shade of blackness that comes with waning vitality—vitality spent in honest toil—contrasts largely with the other, though the novice may be wholly unable to determine a robber by its color.

Upon approaching a hive—and I might say any hive—even its own—a robber-bee will hover over the entrance just out of the reach of the guards, very much as a sparrow-hawk will flutter above a certain spot in some grassy, weedy field when watching for a mouse.

There is anything but pleasantness in an apiary where the bees have acquired the habit of robbing. On behalf of the little honey-bee, and the good graces of every reader of this Journal who has the care of bees, I beseech you to use great care not to provoke them to rob. Their mission is a noble one, and they should not be tempted to pursue an ignoble one through the careless exposure of sweets.

I would be pleased to hear from others upon the subject of robber-bees. Scioto Co., Ohio.

Italianizing Bees at the Time of Swarming, Etc.

BY G. M. DOOLITTLE.

QUESTION—I see that you sometimes answer questions in the American Bee Journal, so I send along a couple. Wishing to Italianize my bees I have thought that it might be done by changing queens during the time of swarming. What I mean is this: If I have my queens' wings clipped, and hive the new swarm on the returning plan, can I pick up the old queen while the swarm is out, put an Italian queen in a cage, put the new hive on the old stand, and when the swarm returns let the Italian queen run in with the bees into this new hive, the same as would the old queen did I not change them? Would it be safe to let a strange queen go in with the swarm?

ANSWER.—From an experience of 30 years I have found that the changing of queens, upon the hiving of any swarm of bees, in any place, is liable to "raise a rumpus," and especially is this the case where the swarm is hived upon a new stand; for in this case the least disturbance or dissatisfaction will start the swarm running out and all over the hive, resulting in the larger part of the bees going back home. And the chances of failure are too great for all practical purposes with a single swarm hived in a new location. Where two or more swarms cluster together, if the new queen is placed in a large cage made wholly of wire-cloth except the stopper, so that the bees can get near the queen in large numbers, and the cage hung with the clustered swarm for half an hour or so till they are led to call her "mother," then this large swarm can be hived where you please, and the queen allowed to run in with the swarm, and as a rule all will go well.

The why of this is that where two or more swarms cluster together, they seem to know that strange queens and strange bees must be thrown one with the other, and so are not so disposed to be such sticklers for their own queen, or go back to their brood if they cannot find her with them. But as very few wish to have two or more swarms together, so that it is possible thus to give a queen, only occasionally, did we so wish to do, this also is hardly practical. The chances are better where the swarm is hived in a new hive on the old stand, or allowed to return as our questioner suggests, and where you have the old queen so you can control her on account of her having a clipped wing; but even then they will sometimes become so dissatisfied that they will hunt up the old hive (unless moved quite a distance from its old stand), and all or nearly all go back to it, or worse still, go into the hives all about the apiary, where in many cases they will all be killed.

If the above large cage is used, placing the cage over the frames before the swarm returns or is hived, and the queen allowed to remain in this cage for a day or two, the chances of success are much increased. The reason for this dissatisfaction coming to the bees, is not so much that they desire a strange queen, as that ninety-nine-one-hundredths

of them consider that they have no queen at all, they thinking thus because when the first few bees come in contact with the strange queen they immediately cluster her so that the most of the bees cannot get near enough even to get a scent of her, and so the majority consider themselves queenless, and all know that it is very hard work to make queenless bees stay in a new hive.

The large cage places the queen so that the bees cannot cluster her so but what the main swarm can "catch the scent," and so they do not consider themselves as being without a queen. On the whole, I would not advise the changing of queens during the swarming season in any way or by any plan, for I find it to be much more annoying to try to change a queen with a colony about to swarm, or with those which have lately swarmed, than with any others, or at any other time of the year, and, besides, a failure more often results.

SUPERSEDING CLIPPED QUEENS.

QUESTION.—The other question I wish to ask is whether it is advisable to clip the queen's wings? Are such more liable to be superseded by the bees than those having perfect wings? What has been the experience with such queens.

ANSWER.—In nearly every apiary, where the manager can or is expected to be present during the swarming season, I should advise the clipping of all laying queens in any apiary; in fact, I should as soon think of going back to box-hives as to the managing of an apiary where the queens have their wings so they could fly out with the swarm, where I was working the same for comb honey. It will be noted that I said, "in nearly every apiary." Why I said this was, there are a very few localities in the United States, so I am informed, where ants are so thick on the ground, and about the hives, that it would not be safe to allow the queens to be out on the ground for any length of time, else they would be killed by these same ants. But as such a place or places are a rare exception, it would be safe to say that I would always clip the wings of all queens in the apiary as soon as laying.

Some seem to think that queens with clipped wings give far more trouble at swarming-time than do those having their wings; but I cannot think that such have had much experience with clipped queens; for with myself I would rather manage three swarms where the queens are clipped than one whose queen can go with the swarm. Especially is this the case where there are trees in or about the apiary, whose height exceed 15 feet; for where there are small trees near the apiary, some swarms will alight so high that it is often more than they are worth to climb for them, while the clipping of the queen's wings does entirely away with all climbing, if no after-swarms are allowed to issue.

Without going over the whole ground regarding the advantages arising from clipping, it can be summed up thus: Clipping the queen's wings prevent swarms decamping, as a rule; saves the climbing of trees after swarms or the marring of those trees by the cutting of limbs or the bruising of the same; makes it easy to separate the bees where two or more swarms come out in the air together; facilitates the hiving and managing of swarms; and gives the apiarist perfect control of the apiary during the swarming season.

As to these clipped queens being more liable to supersede, an experience of over 30 years says there is nothing in the claim put forth by some that such is the case, for during that time I have had very many such queens remain the profitable heads of colonies for three, four, and in a few instances five years. My impression is that superseding, as a rule, is caused by failure on the part of the queen as an egg-layer, and not on account of any clipping.

On one occasion in carelessly clipping a queen I cut off one whole leg, and one foot off another, besides nearly all of the four wings; but as far as I could see this made no difference as to the usefulness of that queen, for she did her duty with the best for over four years, and then lost her life by carelessness on my part. Onondaga Co., N. Y.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it

Honey and Beeswax—Considered by the Illinois Food Commission.

BY PROF. E. N. EATON, STATE ANALYST.

(Continued from page 345.)

VARIETY OF ADULTERATIONS.

HONEY-DEW.

In 1885, Prof. Wiley called attention to honey collected in pine regions, evidently collected from pine-tree honey-dew. It is now known that such nectar is obtained from secretions of aphides (plant-lice) which infest not alone pine-trees but most vegetation. Honey produced in this manner from flora of any locality is termed "honey-dew honey," and has the following characteristics: Usually dark in color, rank in flavor, and unfit for market. It is distinguished chemically from other honey by a dextro-rotary, or slightly levo-rotary, rotation of polarized light, a low percentage of invert sugar, and a high percentage of ash.

CANE-SUGAR.

Sucrose, or sugar of cane and sugar beets, was, before the advent of glucose, much used in the adulteration of honey. It has not altogether gone out of fashion yet.

There are two objections to its use from the fabricator's standpoint:

First.—Its cost; being nearly as much as California honey.

Second.—Its tendency to crystallize from solution. Cane-sugar does not crystallize readily, however, when mixed with 75 percent of honey.

The use of much less proportion of cane-sugar would hardly pay for mixing. If a smaller quantity than 15 percent is present in honey the sugar was probably fed and elaborated through the organism of the bee.

Another method of adulteration with cane-sugar is to feed the same to bees. Bees readily eat cane-sugar. It is a common and justifiable practice among bee-keepers to feed bees through the fall to winter them, especially if flowers be scarce. Some also feed at other seasons to stimulate the breeding of young bees. Last year a sample of extracted honey was secured from Aurora, said to be produced by Mr. Wheeler, of Plano, which, on analysis, was found to contain about 25 percent cane-sugar. It was reported as containing sucrose, either added intentionally or fed to bees, with probability in favor of former. Eight months afterwards the same honey was re-examined with practically the same result. Lately six samples of honey (three extracted and three comb) were secured directly from the apiary of Mr. Wheeler, and submitted to analysis. All the samples but one were normal in behavior. No. 6 (a comb honey) contained 23 percent cane-sugar. The comb consisting of pure beeswax, I reported the sample as obtained by artificially feeding bees. At this time I did not know the history of the sample. I am now convinced the previous sample was fed rather than mixed. Mr. Wheeler admits having fed sugar, but not for purposes of profit. He claims that it is not profitable to feed cane-sugar, as the bee employs one-half in the manufacture of wax. However, if this be true, and the honey is sold in comb it would seem as if a fair margin of profit is left, allowing six cents per pound for sugar and 14 for comb honey, 20 percent of which is water. Then, too, if old combs are used, little sugar need be diverted from the manufacture of honey. However, only a very small amount of comb honey is made in this way, and but two specimens have been identified by me—one in Minnesota and the other the sample secured from Mr. Wheeler.

INVERT SUGAR.

Invert sugar is produced by splitting up, with the aid of acids or ferments, cane-sugar (sucrose) into equal parts of two other sugars—dextrose and levulose. Although neither of these sugars is as sweet as cane-sugar, a mixture of the two is said to be sweeter. As the bee utilizes this identical chemical reaction to manufacture honey, it will be surmised that the detection of man-made invert sugar in natural honey is a matter of no little difficulty.

That the adulteration of honey with invert sugar has passed from the realm of possibilities to actualities was long ago suspected by the United States Department of Agriculture. I have also noticed samples which, I think, illustrate the fact that the busy bee has no monopoly of industry. However, the low cost of honey, the high price of sugar, and the expense of manufacturing, will, for the time being, safeguard honey from this form of sophistication.

GLUCOSE.

Glucose is produced by the action of dilute sulphuric, oxalic or hydrochloric acid upon starch, in an open or closed vessel, with or without pressure. The conditions of manufacture govern the quality of the syrup. If the boiling be conducted in an open vessel only a part of the starch will be converted into dextrose, the remaining portion forming dextrin. This forms the so-called glucose syrup of trade. If the boiling is conducted in a closed vessel under pressure almost all the starch is converted into dextrose. This product, after treatment and evaporation in vacua, forms the article of commerce known as grape-sugar. The liquid product is alone used as an adulterant of honey.

In Germany potatoes furnish the starch for the manufacture of glucose, but in the United States corn alone is used.

After the starch is converted into "glucose," the acid is destroyed. In case sulphuric or oxalic acid is used, lime is added, forming calcium sulphate (gypsum) or calcium oxalate, and these products being insolvent in the syrup may be separated by filtration. In this country, of late years, hydrochloric acid is generally used in manufacturing glucose, the acid being destroyed by soda-lye, which forms sodium chloride, or common salt, which, while it can not be removed on

necount of its solubility, is perfectly harmless, and is not in sufficient quantity to affect the taste of the syrup. Hydrochloric acid is also superior to sulphuric acid, as it is less likely to be contaminated with arsenic. The recent wholesale poisoning in England was attributed to arsenic in glucose used in the manufacture of beer. In the manufacture of glucose England manufacturers use sulphuric acid produced from pyrites, the original source of the arsenic.

Several grades of glucose are marketed, graded by degree of concentration and color. Confectioners' glucose is the best, and almost white in color.

Recently a grape-sugar has been placed upon the market consisting of almost pure dextrose, white in color. The product in a granulated form is being somewhat extensively used as a substitute for cane-sugar in baking and to mix (I am not aware of its being done fraudulently) with cane-sugar. It is a possible adulterant of honey.

Glucose is only one-half as sweet as cane-sugar, possesses a characteristic metallic taste, and is miscible in all proportions in water and solutions of other sugars. It does not readily crystallize. It tractably acquires the flavor of the substance with which it is mixed. Its cheapness and general properties make it an excellent adulterant for other sugars. Probably nine-tenths of all adulteration in honey and syrups consist of glucose.

Glucose occurs in Nature in combination with other sugars in many fruits and vegetables. An investigation performed at the instance of the United States Department of Internal Revenue resulted in finding glucose as made in this country not in the least detrimental to health; in brief, a proper food.

It may be mentioned that the glucose of to-day is superior to the product investigated by this Commission. Some grades of glucose, especially that intended for Southern trade, are decolorized and preserved by sodium sulphite, a substance not improving the healthfulness of any food into which it enters.

WATER.

Water is a very cheap adulterant of honey, but in excess is as patent as a label, and generally affects its market value. In case honey is not sufficiently ripened, or if much water is added, honey will ferment, thus destroying its market value except for vinegar manufacture.

HONEY IN THE HOME.

Honey is a necessary luxury. It is within the reach of the poor and not despised as a delicacy by the rich. It is produced largely by home apiarists, even in the cities, as almost 300 bee-keepers reside in the neighborhood of Chicago, some keeping colonies on the tops of tenement buildings, known as roof-aparies. The bees gather from the gardens, the groves and the grass-lands.

Surely, such an industry should be protected from the unjust competition of the food sophisticator. Such a name, honestly gained and honorably worn, should not be allowed to be used as a cloak to cover inferior products.

And, more than all, the consumer is entitled to receive the article for which he asks and tenders an equivalent in currency.

BEESWAX.

This appears to be one of the products obtained from the nectar and pollen of blossoms by their passage through digestive organs in the body of the bee. The bee builds up the cells of its comb from the undigested portion known as wax. The latter is rendered from the contained honey and east into cakes—the yellow beeswax of the market; or it is cut into thin ribbons and exposed to the bleaching effects of air and sun from 10 to 30 days, and is then known as white beeswax.

Beeswax is ordinarily of a yellow color, semi-transparent, brittle when chewed, and shows a slight taste of balsam. It melts in the neighborhood of 63 degrees C, and its sp. g. at 15 degrees C should be between .956 and .975. Bleaching it in the sunlight raises the melting-point to about 65 degrees C, but affects the density but little. In observing melting points in the capillary, the temperature was observed when capillary action started. This method gave very uniform results.

Beeswax is known to be essentially a mixture of two organic compounds—cerotic acid $\left\{ \begin{array}{l} \text{C H O} \\ 27 \ 54 \ 2 \end{array} \right\}$ and myricin (myricyl palmitate) $\left\{ \begin{array}{l} \text{C H OC H O} \\ 30 \ 61 \ 16 \ 31 \end{array} \right\}$, though smaller quantities of melissic acid $\left\{ \begin{array}{l} \text{C H O} \\ 30 \ 60 \ 2 \end{array} \right\}$ and myricyl cerotate $\left\{ \begin{array}{l} \text{C H OC H O} \\ 30 \ 61 \ 27 \ 54 \ 2 \end{array} \right\}$ are always present.

The quantitative chemical data most important to obtain in looking for adulterations of beeswax are the total saponification, acid and ester equivalents. These should respectively lie between the limits 90-95, 168-21, and 72-76. If a sample answers all of the above-mentioned requirements, it must be considered commercially pure.

Beeswax has been adulterated with tallow, stearin, paraffin, resin, as well as other waxes.

The following samples came up for analysis: No. 15058 was a section of honey-comb, claimed to be entirely artificial. The honey was found to give perfectly normal chemical data, as also did the wax. The examination of the comb by expert bee-keepers also established its genuineness, the frame showing the bee-cement. The wax, which was pale in color, revealed pollen under the microscope. Melting-point of the wax from various parts of the section, including the foundation, were determined by the capillary method, and gave normal results.

Sample No. 6 was a section of honey-comb. In this the chemical examination revealed the honey to be strongly admixed with sucrose. The organoleptical examination by experts showed the comb foundation to have been capped by bees. This verdict was borne out by the physical and chemical data of the wax, which was light in color.

Samples of pure wax were also obtained in the open market. One

from George W. York & Co., direct from producer, was quite dark in color, while one obtained from Richards & Co., Ltd., was of a medium shade of yellow. A sample of comb foundation from The A. I. Root Co. was also subjected to analysis. This latter wax was quite pale in shade. The following are the results in tabular form:

WAX.	M.P.°C.	Sp. gr. 15°.6° C.	Acid Number.	Ester Number.	Saponification Number.
No. 15058...	62.7	0.9700	20.02	72.60	92.02
No. 6.....	63.5	0.9569	16.80	76.16	92.96
Richards & Co.	62.0	0.9510	18.76	73.64	92.40
York & Co..	62.5	0.9540	21.70	77.0	98.70
Comb fdn.	62.0	0.9600	18.72	72.0	90.72
Limits for pure wax,	62 to 64	.950 to .975	16.8 to 21.6	72 to 76

The acid and ester number of York & Co.'s samples are slightly high, but as the ratio between them has the normal value, this wax must be considered pure. The melting-points of waxes from two other combs were found to be normal. In these combs the honey also behaved normally.—From Second Annual Report of State Food Commissioner, issued this month (May).

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

CANE SUGAR VS. BEET-SUGAR.

Sad to relate, governments sometimes go into systematic lying for a purpose. Without sufficient evidence I rather "smell" that the cane-sugar versus beet-sugar question is kept from being settled mainly by the British Colonial Office, and that they engaged in that sort of thing for the benefit of British colonies which produce cane-sugar. But certainly there may be one real difference. The two kinds of sugar quite likely go through different processes in contact with different chemicals. If so, they can be exactly alike only in the improbable case of getting all the chemicals out of the finished sugar. But does this amount to a practical distinction, or is it infinitesimal and non-practical? I don't claim to know. Page 259.

THE HONEY MARKET.

Large capacity for the reception of advice, eh? Well at this end, or corner, there is small capacity for finding anything better than we already have about the honey market. Might lose the meat we have if we plunge after all we see mirrored in the stream. Page 259.

DEEP FRAMES FOR WINTERING BEES.

It is easy to see why a deeper frame ought to winter bees better than the Langstroth; but we must also harken to the facts. I winter bees out-doors, and my Langstroth hives almost always better than the others that are deeper. Some other brethren find so, too, it seems. It just occurs to me that if I use more upward ventilation the reverse would appear. A healthy colony, strong enough and vigorous enough to go into the winter alone, has no difficulty in moving the cluster backward as they eat the honey, if they have enamel overhead, and the hive is tilted moderately forward. When warm air cannot go straight up it will compromise by ascending aslant. But the fact that my Langstroth hives are run for comb honey and the others for extracted counts sadly to obscure solutions. Page 260.

LONGEVITY OF WORKER-BEES.

On the longevity of worker-bees the Chicago Convention folks seem not to strike any oil worthy of Spindle-top. 'Spect they mostly kept the ages of their bees no more accurately than certain ladies are accused of keeping theirs. Page 260.

AMOUNT OF HONEY CONSUMED BY BEES.

On page 264 the colony of Adrian Getaz, which eats 200 pounds of honey per year, seems a little too much like the "Heathen Chinese" who had up his sleeve 24 packs. "Going it strong, yet I state but the facts." Let me, in my capacity of champion guesser, guess off a year's liberal rations: Nov. 1 pound; Dec. 1; Jan. 2; Feb. 4; Mar. 5; Apr. 8; May 20; June 30; July 28; Aug. 16; Sept. 10; Oct.

5. Total, 130 pounds. Presumably, for an earlier climate the figures should be readjusted so as to put more of the amount in April and May, and less in later months.

SUCCESS DEPENDS UPON THE QUEEN.

Good sentence from Ada L. Pickard: "A great deal of success for the coming season depends upon the queens we have put into winter quarters." Page 265.

FERTILIZATION OF FRUIT-BLOOM BY BEES.

I do not wonder particularly that Mr. Thaddeus Smith thought my last year's insect remarks a little rough. But such things have to be said; and sometimes they get said to persons who do not deserve them. Sincerely beg pardon; but won't promise to refrain from doing it again—to the very next fellow. *Most people* have talent for not seeing things which is immense—immense almost beyond belief—that is, when the things are such as they never tried to investigate. For instance, an intelligent farmer, my neighbor, once expressed astonishment to see me carrying by a white clover, that is, a red clover so far as species is concerned, with a pure white bloom. Had never seen such a thing. Well, there was a fine one growing not far from his gate that minute; and he had doubtless sat on his mower and mowed down hundreds of them without his mind taking any report from his eyes.

Actual observations are what we want; and I do not wish to discount Mr. Smith's or Mr. High's—any further than to remark that it takes a good many I-didn't-sees to head off an I-did-see.

That Pelee with bees has no better fruit than other islands without bees is pretty strong medicine, so far as it goes.

My observations last year on strawberry bloom were that lots of insects of a number of species visited the bloom. Many honey-bees were among them. Pistillate blooms were visited about as freely as the perfect blooms. If I remember aright, it was for denying that that I chucked Mr. Smith down in the see-nothing class with my neighbor the farmer. (Saw a honey-bee yesterday deliberately draw nectar from a pistillate strawberry bloom.)

Mr. Smith is again far astray in saying that nobody *claims* that bees improve the quality of fruit. Bees cross-fertilize; and it is claimed, and not only claimed but apparently proved up by photographs, that cross-fertilized fruit is sometimes very much larger and better than self-fertilized fruit. Not claimed, I believe, that it *always* shows any difference.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marango, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Transferring Bees—Producing Extracted Honey—Introducing Queens.

1. I am a beginner, having bought my bees last fall; they are in Langstroth hives, but the combs are not very correct, and I wish to cut them and make them straight. Please instruct me how, and when.

2. I intend to go in for extracted honey. If I put the top part of the hive on with starters will the bees go to work on them without any coaxing?

3. Would it be safer to introduce a queen in an artificial swarm than in a natural one? ONTARIO.

ANSWERS.—1. First take out any frames whose combs are straight enough to lift out. Then cut the comb enough to get out the rest. It is possible that all the combs are built crosswise in such shape that no frame can be lifted out. In that case take a knife long enough, or a saw, and cut away the attachments to the sides of the hive, then turn the hive upside down and dump out the whole of its contents. You will then fasten the combs in the frames as directed for transferring in your text-book. Before operating you may drum out the bees, so as to have them out of

the way, although if the case is not a very bad one it may not be necessary to drum them out.

2. Yes, but they will start sooner in the upper story if you put in it a frame of brood from the lower story, returning it below when the bees have started above.

3. There ought to be no difference, if both are alike as to queenlessness.

Introducing Queens—Hiving a Swarm.

1. How do you think it would work to introduce a queen from a long distance in this way? Place a frame of hatching brood in a wire cage, with the queen thereon, and let her remain for about 48 hours, then release her.

2. There was a swarm of bees that issued from my apiary about two weeks ago. I being away at the time, my friend, who was present, undertook to capture the swarm. The bees had settled in a large oak-tree, and he climbed up near them and sprinkled them with water, then sawed off the limb and proceeded to hive them, but on descending to the ground he found they had taken flight, and were settling on another limb of the same tree. He climbed up the tree again and gave another sprinkling with water, then sawed off the limb and descended to the ground; by this time they were settling on a small limb of a blackjack, to which he had easy access from the ground. He sprinkled them again and quietly sawed off the limb, being careful not to jar them off, and placed them near the hive, or decoy box, which they readily entered. The shutter was then closed, it being perforated with holes to give them air. They were kept in the decoy box about two hours, while we were making preparations to transfer them. Upon examination we found three-fourths of them dead. Can you tell the cause of their death, whether by water or too much heat? We found them very much besmeared with honey. TEXAS.

ANSWERS.—1. The plan is certainly good up to the time of releasing, and then it depends upon circumstances as to the reception. If the old queen had been removed just at the time of putting the new one in the hive, the reception might not be always satisfactory. If I understand you correctly, the whole frame is caged in, in which case there would be no harm in leaving it in the cage for two or three days, making sure of success.

2. Lack of air was the prime trouble, aggravated by the heat, and probably to some extent by the moisture.

Queens Going Out in the Spring.

It is a fact that occasionally the queen-bee goes out in the spring. I distinctly remember having once seen one which alighted on my hand while I was engaged watching the bees of a certain hive bring pollen on a very warm day of April. Another day I saw a queen returning home; I think it was in May, during fruit-bloom. But in neither case did I remark anything abnormal in her majesty, nor did I think of examining the hives to find out whether or not there were two queens in the same hive. Both queens looked very bright and young.

1. What was the reason of their coming out so early?

2. Is this a common occurrence?

3. Should it not discourage the early clipping of queen's wings? For if she is not clipped, she is likely to be lost every time she goes out alone.

4. Would not this account for the fact that several colonies which had a queen in March are found without one in May?

5. And while I am at it, don't you think that it is useless, to say the least, to clip queens' wings in the home apiary? Since the prime swarm which has the old queen, always alights on low branches and near the hive.

CANADA.

ANSWERS.—1. I don't know, but if you will allow me the privilege of guessing I should guess that the queens you mention were virgins out on their wedding excursions.

2. It is not a common occurrence so far north as Canada, to see a queen flying in April.

3. I hardly think so. Of course it would be a bad thing to clip a virgin queen in any case, but it is hardly to be supposed that any one with even a very little experience would make such a mistake. I have known a laying queen to fly out in spring occasionally, but always with the intention of deserting the hive, as with an absconding swarm, in which case the advantages and disadvantages of clipped wings would be the same as any swarm. That a laying

queen ever leaves the hive alone I very much doubt, although I do not know positively that such a thing never happened.

4. Yes, if such a thing as a laying queen leaving the hive alone ever happened. But are there not just as many queens missing in May in apiaries where there are no clipped queens, as in those where all the queens are clipped.

5. I don't see why it is not just as necessary in the home apiary as in an out-apiary, for swarms would be likely to alight in the same kind of places in one as in the other. If your prime swarms always alight on low branches and near the hive they are better trained than mine.

A Wire-Cloth Bee-Veil.

I wish to say a good word in favor of a bee-veil which I see recommended in foreign papers. It is made of wire-cloth, oval, such as are used to protect dishes of fruit against flies. A piece of cotton-cloth is sewed all around to protect the head and neck of the apiarist. In very hot days this veil is much more cool and comfortable, in my opinion and practice, than any other veil of tulle or silk, and, besides, insures an almost perfect vision. Of course a straw hat can be worn over it just the same.

This oval must be of a size a little larger than one's face (about a foot across), and need not cost more than 25 cents in any place. If kept dry it might last for about 3 or 4 years; but sweating or rain may cause it to rust rapidly.

I wonder why no one seems to know or suspect the comfortableness of this wire-cloth veil. CANADA.

ANSWER.—I have one of the veils you mention, and although I have not used it very much I have hardly thought it as good as other veils without the wire-cloth. Moreover, if I am not mistaken, some one (I think it was M. M. Baldrige) reported having his eyes seriously injured by a wire-cloth veil. If you have used one for considerable time, and it has been entirely satisfactory, it is possible that yours is of a superior quality.

Rendering Comb into Wax—Foul Brood, Etc.

1. I have burr-combs, cappings and some old combs. How can I get good wax from this without buying a solar-extractor?

2. Can you give a reliable method of getting candied honey out of sections so they may be used again?

3. How can I detect foul-brood for sure?

4. What is your plan for treating foul-brood?

5. Do you use Doolittle's plans for building up weak colonies?

6. What is your opinion of most of the dollar queens? A bee-keeper told me he had never seen one whose bees were not very cross.

7. I use Hoffman self-spacing frames. Would you cut burr-combs off, or will it do no good? ILLINOIS.

ANSWERS.—1. Get a steam wax-press, which will get more wax than the solar extractor. But it costs more than the solar. Take an old dripping pan and split open one corner to the bottom. Lay in it your old combs, but not one on top of another. Put the pan in the oven of the cook-stove with the split corner projecting out over a dish set on the floor to catch the wax. Put some thing under the corner which is

diagonally under the split corner, so the wax will run down hill to get out.

2. Let the bees clean it out, sprinkling with water as often as needed.

3. Pages have been written upon the subject in back numbers of this journal, and Howard's little book gives full information that could not possibly be given in this department, which has its limitations. The one symptom that may perhaps be relied upon more than any other is the elastic springing back of the matter in the cell when it is drawn out half an inch or more.

4. I never have been so unfortunate as to have any to treat. If I should ever become so unfortunate I should rely upon the McEvoy treatment as given in Howard's book.

5. I seldom have occasion to use it, for as a general rule my bees of their own accord have all the brood they can cover.

6. A dollar queen may be one of the best in the world, and it may be one of the poorest. It depends upon the stock from which it is reared, and the way in which it is reared. I know of no reason why such queens should differ in disposition from others.

7. If you clean off the burr-combs they will in time be replaced; but they will not be so bad as if they had never been cleaned off.

Storing and Caring for Honey.

1. In the storing and caring for honey, the greatest pest I have to deal with is the wax-moth. Do you recommend bi-sulphide of carbon as sure death to them? Please give the amount necessary to fumigate properly 100 one-pound boxes?

2. Would it be best, or desirable, to store the same in water-tight tin-lined boxes in which they were fumigated, with the finest window-screen wire over box as cover, which would seemingly be necessary as giving a reasonable amount of air for the proper ripening? Would moths get through this wire?

We small producers of honey living in villages and keeping only a few colonies cannot afford an up-to-date honey-house, for the storage of our honey through the ripening process, therefore I bother you with this (to us) perplexing question. MASSACHUSETTS.

ANSWERS.—1. Three or four tablespoonfuls will probably be abundant.

2. Now, look here, my good friend, you sit down till I talk with you. You have an exaggerated idea of the requirements for comb honey, and you are proposing to go into an expense that I couldn't possibly stand. Don't think of water-tight, tin-lined boxes. Instead of something air-tight, you need something airy. I don't try to keep the moth away from my comb honey after it is taken from the hive. The only danger from the moth, so far as section honey is concerned, where I live, is from the eggs that are laid before the honey leaves the care of the bees. If the larvae and the eggs are killed, no fresh eggs are laid in the sections, although there is nothing to hinder moths from coming into the room through cracks and crevices. If you have only 100 sections or so, keep them on an upper shelf of a kitchen cupboard. Perhaps better still, keep them in a hot garret next the roof. After getting a summer's roasting there, they will stand the winter's freezing all right.

We can furnish you with The A. I. Root Co's goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for beeswax. Send for our 1902 catalog. M. H. HUNT & SON, Bell Branch, Wayne Co., Mich

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested	1.50	8.00	15.00
Selected Tested	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

GENERAL ITEMS

Orange-Bloom Crop Good.

The honey crop from orange-bloom is excellent in quantity and quality in this vicinity. The sage crop is doubtful yet.

FRANK McNAY.

San Bernardino Co., Calif., May 19.

Bee-Keepers Stand the Stings.

MR. EDITOR:—On page 332 is given a cure for stings—five minutes' pressure with a half-dollar on the affected part. You suggest that bankers can use 20-dollar gold pieces. That might be a little expensive, but the most expensive part of the performance is that "five minutes." For a dozen stings that would take just an hour. Can a bee-keeper not better afford to stand the pain than to take so much time in the rush of the season?

C. O. WARD.

Country Not What It Was for Bees.

The bees are not gathering any honey now. I am feeding mine. Some are starving, I learn.

We always have a moderate flow during cotton-blooming time, which is from the middle of July until frost.

Our country is not what it once was for bees. All the land is in cultivation, hence scarcely any wild flowers, and the farmers all plant cotton to the exclusion of almost everything else, so we do not count on our bees making more than a living, until after cotton begins to bloom. Horsemint in the pastures generally furnishes some nectar, but it is a failure this year on account of its not coming up for some unaccountable reason this spring.

A. B. COX, M. D.

Fannin Co., Tex., May 16.

Bees in Kansas.

Bees did poorly last winter, but increased rapidly during fruit-bloom. They are at work upon alsike clover. Alfalfa will bloom in about 15 days, but the bees will not be strong enough to benefit by it much.

LESLIE HAZEN.

Nemaha Co., Kans., May 18.

Spraying While in Bloom.

I have had an experience with some of Wm. Stahl's work. I had 35 good colonies in an out-yard 6 miles from here, and the man where I had the bees got one of Stahl's sprayers and followed his directions and sprayed his plum-trees in full bloom, and, of course, the bees got it. Over half of the bees are dead, and also open brood. It is a big loss to me. The man that sprayed feels badly about it; he did not mean to hurt the bees. I was lucky in getting there in time to prevent him from spraying his apple-trees; he was going to do it the next day.

Now, I think Mr. Stahl might put in his directions that spraying trees in full bloom will also poison the bees. There has never been any spraying done here before, and this is something never thought of here.

DANIEL DANIELSEN.

Turner Co., So. Dak., May 5.

The Honey Prospect in California.

Thinking perhaps the readers of the American Bee Journal would be somewhat interested in a report from this dry country, and knowing how eager the honey-buyers are to get exaggerated reports started in the East in regard to the big crops of honey of Southern California, I thought I would give a few facts in regard to the present prospect.

I have 115 colonies in No. 1 condition, which ought to be storing at least a ton of

Elkhart Carriage & Harness Manufacturing Co., Elkhart, Ind.

honey every week. But not a pound of nectar is coming in. Honey-plants look fine—bloom in abundance, but nothing in them for the bees. The same condition prevails throughout this part of the country.

One good, heavy rain would save the crop, but it is too late to look for it now.

I think perhaps the middle part of the State will produce some honey, as they got more rain than we did. Very little, if any, surplus will be produced in the southern part.

So, together with foul brood, dry year, and low prices for honey, bee-keepers here are having a pretty hard time of it.

Not a swarm has been cast this spring from my whole apiary.

But in order to show you what can be accomplished here in a good year I will give you a report of what I did with 9 colonies, which were mostly cured for by my son, Lee, who is now only 16 years of age:

The last of October, 1900, I bought 9 colonies in double Simplicity hives. October 1, 1901, I had built them up to 72 good, strong colonies, and had sold just \$200 worth of comb honey from them. I increased by rearing queens and dividing.

In Michigan I always got some honey every year that I kept bees, but I have been in the business here eight years, having as high as 240 colonies, and have had only three crops of honey.

B. S. TAYLOR.
Riverside Co., Calif., May 14.

Rearing Long-Lived Worker-Bees.

Mr. EDITOR:—On page 331, Geo. W. Riker explains what he means by poorest queens, an explanation that is hardly needed, but does not throw any additional light. Will he kindly tell us his plan of procedure by which from a queen "whose workers are short-lived so their colonies are always weak" he succeeds in rearing queens that produce long-lived workers?

[Mr. Riker is invited to send a satisfactory answer to the above question if he really knows it.—EDITOR.]

A Report—Bees Selecting a Home Before Swarming.

I came through the past winter with 27 colonies in fair condition; they are almost all blacks.

The last winter was a hard one on me, as I was laid up all winter with sciatica, but I am out again, and have "dressed" my bees, or cleaned house for them.

It was the longest and most severe winter for 25 years. I kept a record of the snowfall, as my family and neighbors gave it to me, and I find we had over 150 inches of snow. April and May, until the 15th, was very cool, dry and windy, making a very hard spring on bees as well as the farmer.

I am a farmer, and keep a few colonies of bees for profit. I harvested about 40 pounds per colony the fall of 1901. I sold it in the

home market, the dark at 12½ cents, and the white or basswood honey at 15 cents per pound, cash.

I am also trying the cultivation of ginseng as a side-issue. I have about 1500 plants growing nicely under lattice or paling.

I wish to give my opinion and experience about bees selecting their future home before swarming, as I have read a good deal in the bee-papers in the past on this subject.

I think once in a great while they do select their home before they swarm, but probably not more than one time in a thousand, as only three cases of seeking their future home have come under my immediate notice in 50 years. So I will give you one as a sample:

Some years ago an uncle of mine had a few colonies of bees; late in June they showed signs of going to swarm, by lying outside of the hive. One Friday he was out in the woods above the house and found bees working nicely in a small white-oak tree, going in a knot-hole up about 40 feet. He bragged a good deal about his "find." On the following Sunday several of the neighbors and I were there for dinner. Just after dinner one colony swarmed; everybody present got a bell, tin pan or something that would rattle, and joined the band, but all to no purpose, they wouldn't or didn't settle at all. So after circling in the air awhile they struck for the woods, all the men and boys after them. They went up where uncle had found his beetrue, and plugged right in. Great excitement now prevailed, all thinking there would be a big bee-fight, so ax and hatchets were hastily got to cut the bee-tree and try to divide the bees and save them. When the tree fell and was cut open where the bees were, all were surprised again, as there was not a speck of comb built or anything done in the line of work, except the hollow seemed to have been cleaned out nicely. We got the bees in an old box, took them back home that evening, and all seemed satisfied and contented.

I know of two other cases like this one; it proves to me that once in a great while they do look out for their future home.

Do bees gather honey or pollen from white-oak bloom at this time, May 18? Bees seem to be bringing in lots of pollen and some honey. The white-oak is in full bloom.

IRA SNOCKEY.

Randolph Co., W. Va., May 18.

Hard Country for Wintering.

This is a hard country in which to winter bees, for the mild temperature of the Willamette Valley causes them to eat a good deal in winter.

Many bees died since last fall, partly owing to disease, I think. CLARK S. FUGE. Clackamas Co., Oreg., May 13.

A "Greenhorn's" Experience.

I can't remember when I was not fond of honey and bees. A friend gave me a colony of hybrids, June 1, 1900, in a home-made hive. I took from them in the fall 18 pounds of honey. They wintered well out-doors, and cast a swarm June 3, and another June 13, 1901. These I hived in eight-frame hives. I gave the first new swarm, which had the old queen, a super, and later I tiered them up, that is, I gave them another hive-body.

I kept watch of the bees this spring and found the combs in No. 1 crossed so I could not take out the frames, and there were plenty of wax-moths. The queen was laying in No. 2, and the cluster well covered the bottom-board. May 1 I set No. 1 on a new stand, after turning the hive bottom side up and taking out the frames and cutting out the comb and fastening it in new Hoffman frames. In transferring I got rid of some of the moths, and also got straight combs.

On May 12 I received a premium queen, and placed the cage in the hive. In 48 hours I put the queen under a screen-cloth cage on unsealed honey, and cut out five queen-cells. After 24 hours I liberated her, and to-day I found a nice lot of eggs and busy, contented bees.

To-day, May 18, No. 2 gave a large swarm. My other colonies are working in supers, and

Please Mention the Bee Journal when writing Advertisers *****

I expect they will swarm soon. I have five good colonies now; a year ago I had one.

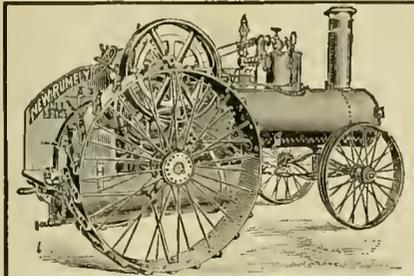

If all the bee-keepers knew how much better foundation is fastened by electricity they would never use a roller. If you would appreciate it I can describe how I do it with an outfit that anybody can use.

There is nothing better than the American Bee Journal for a beginner.

F. H. DRAKE.

Worcester Co., Mass., May 18.

[Yes, we would be pleased to publish your way of fastening comb foundation in brood-frames.—EDITOR.]

RUMELY

Rear Gear to the Fore.

This Traction Engine should receive the attention of all threshers. Investigate it. Modern in every part. Has all latest devices and appliances. Perfect in traction, unsurpassed in generating and supplying power. A full line of general and special purpose engines. Separators should interest you. The New Rumely is what you want. It threshes it all, cleans it all, saves it all. Catalog sent free.

Wanted Comb and Ex-tracted Honey!

State price, kind and quantity. R. A. BURNETT & CO., 199 S. Water St., CHICAGO 33A4f Please mention the Bee Journal.

3-Frame Nuclei For Sale.

We have arranged with a bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei of bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 or more at \$2.75 each.

All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white).....	\$.75	\$1.40	\$3.25	\$6.00
Sweet Clover (yellow)....	.90	1.70	4.00	7.50
Alsike Clover	1.00	1.80	4.25	8.00
White Clover	1.00	1.90	4.50	8.50
Alfalfa Clover80	1.40	3.25	6.00

Prices subject to market changes. Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack.

Add 25 cents to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

GEORGE W. YORK & CO.

144 & 146 Erie Street, - CHICAGO, ILL.

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you."—Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30) I never found these bees to show the least indication of unrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

Out of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chilly winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, Ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italians and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

Address, R. F. HOLTSMANN, Bow Park Co., Limited, Brantford, Ont., Canada 9D8t Please mention the Bee Journal.

Our Choice for honey-gatherers is a cross between the Italian and Carniolan. A limited number of Nuclei and full colonies for sale. Healthy, vigorous, and excellent workers. Address, 20A4t E. S. ROE, CLARISSA, TODD CO., MINN.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, May 19.—The market is without special change from that prevailing early in the month, with perhaps less doing than was noticed at that time. White comb honey sells in a small way at 14¢@15¢ for fancy, if white clover and basswood; other kinds at 12¢@13¢; ambers of all grades and flavors are dull at 8¢@10¢. Extracted unusually quiet with white ranging from 5½¢@6½¢; ambers, 5¢@5½¢; dark, 4¢@5¢. Beeswax still active at 32¢.

R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½¢@6½¢; better grades from 7¢@8¢. Fancy comb honey sells at 16¢; lower grades hard to sell at any price. Beeswax strong at 27¢@30¢.

THE FRED W. MUTH CO.

ALBANY, N.Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14¢@15¢. Extracted, 6¢@6½¢. Beeswax, good demand, 30¢@31¢.

H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15¢@16¢; A No. 1, 14¢@15¢; No. 1, 13¢@14¢; honey in glass-front cases about one cent less. Extracted, California light amber, 7¢@7½¢; Florida honey, in barrels, 6¢@6½¢.

BLAKE, SCOTT & LEE.

DETROIT, Apr. 8.—Fancy white comb honey, 15¢; No. 1, 13¢@14¢; dark and amber, 11¢@12¢. Extracted, white, 6½¢@7¢; dark and amber, 5¢@6¢. Beeswax, 29¢@30¢. M. H. HUNT & SON.

CINCINNATI, May 8.—As the warm weather set in, the demand for comb honey is as good as over. There are no settled prices; for whatever is left, prices are made to force sales. Extracted honey is in fair demand and finds steady sales. Amber is sold in barrel lots for 5¢@5½¢; water-white alfalfa, sells from 6¢@6½¢, and white clover brings from 6½¢@7¢. Beeswax scarce and brings 30¢@31¢. C. H. W. WEBER.

NEW YORK, May 19.—There is a limited demand for comb honey and prices range as follows: Fancy white, 14¢; No. 1, white, 13¢; amber, 11¢@12¢; no buckwheat or dark on the market and no more demand for any. Market on extracted remains very inactive. Plenty of supply with only fair demand. We quote: white, 5½¢@5¾¢; light amber, 5¢@5½¢; southern, in barrels, 50¢@55¢ gallon. Beeswax firm at from 30¢@32¢ pound, according to quality.

HILDRETH & SEIGELKEN.

SAN FRANCISCO, May 14.—White comb, 10¢@12½¢; amber, 7¢@10¢; dark, 6¢@7¢. Extracted, white, 5¢@—; light amber, 4½¢@—; amber, 4¢@—; Beeswax, good to choice, light, 26¢@28¢; dark, 24¢@25¢.

Spot stocks are not of heavy volume, but there is more offering than can be accommodated with prompt custom at full current rates. Business now doing is mostly of a light jobbing character on local account.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.
THE A. I. ROOT COMPANY, Medina, Ohio.
GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.
J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.
M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order as follows:

No. 1.—For sending us the names and addresses of two new subscribers to the American Bee Journal and \$2.00, we will mail you ONE of these queens free.

No. 2.—Or, for sending us one new subscription at \$1.00, and 30 cents more (\$1.30), we will mail you a queen, and the Bee Journal for one year to the new subscriber.

No. 3.—Or, send us \$1.60 and we will send to you the Bee Journal for one year, and also a queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., JUNE 12, 1902.

No. 24.

* Editorial Comments. *

Nominating National Candidates for the offices to be filled at each annual election seems to be a rather difficult thing to accomplish. Heretofore there has been no attempt made in that line.

In the American Bee Journal for Oct. 31, 1901, we had this editorial paragraph:

It might not be a bad idea for each annual convention to nominate three candidates for General Manager, and nine candidates to succeed the three whose terms expire with the following December. Then these nominations could be announced to the members when sending out the voting blanks. Of course, any others could be voted for if preferred, but very likely one of the three would be elected General Manager, and three of the nine would be elected Directors.

The words, "three whose terms expire," in the above, refers to the Board of Directors.

In the May Bee-Keeper's Review, Editor Hutchinson approves of our suggestion, with the slight exception that he would have two nominated instead of three, for each office. We have no objection to that.

The more we think of it, the more we feel assured that the plan we proposed would work out all right. It could very easily be tried at Denver, if those present so decided.

But there are one or two things that should be considered when making the nominations for Directors. It will be noted that at least one State has three members on the Board, while the whole South has not a single representative. Of course, that is manifestly unfair, though no one can be blamed for the present condition of affairs. It has simply happened so. Illinois has two members on the Board. One would be sufficient. Dr. Miller would be pleased to be omitted at any time. He also fully believes in passing the hours of office around. Probably no set of men should ever have a monopoly of the offices of the Association. It might be well, perhaps, to make an exception in the General Manager's office, and we could easily conceive of the necessity of an occasional change even there as well.

We would be pleased to have suggestions on this subject from members of the Association. As Mr. Hutchinson says, "Let us discuss it in advance of the meeting" at Denver. If the plan we proposed meets with your approval, why not say so? If you have something better, all right, send it on.

Prevention of Swarming is accomplished by some by simply anticipating the desire of the bees for an empty home to start in—taking away from them all the brood. As to the details of the after management, plans differ. Here is one plan that some may think worth trying:

Have the hives in pairs, the two hives of each pair not more than an inch or so apart. As late in the season as may be without running the risk of swarming, take from one of the hives of a pair half of its brood with adhering bees and queen, and put them in an empty hive on a new stand. Then into an empty hive provided with starters or full sheets of foundation brush all the bees of the other colony, queen and all. Brush into the same hive all the bees remaining in the other hive. Take all these frames of brood from both hives and put them with the queen that was put on the new stand. The hive into which the bees were brushed is to be placed centrally where the pair previously stood. The supers that were on each hive may be put on the

new stand where the brood is, and in three days returned to the old stand.

There is now on the old stand a rousing colony, made up of the flying force of both colonies and the greater part of the young bees. On the new stand are two stories of brood rapidly hatching out, and this will give extracted honey, while the colony on the old stand may be worked for either comb or extracted.

This plan is not given in the full assurance that it will be the best in all cases. If the colonies operated on are very strong, there is a possibility, at least according to the views of some, that there will be too many bees in the new hive for best results. If a cold night should come, there is a bare possibility that there may not be enough bees with the brood to care for it properly.

Are Drones from a Mismatched Queen Pure?—When Dzierzon gave to the world the doctrine of parthenogenesis, he announced that the drone-eggs being unfecundated, the drone progeny of a queen would be of exactly the same blood as the mother, without reference to what drone that mother might have met. The opinion, however, has prevailed with some that the blood of a drone is materially affected by the mating of his mother. The matter is a very practical one, and withal very important. Therefore, the article on telegony in this number will be read with interest. It is probably the fullest presentation of the subject that has ever found its way into bee-literature. Although Prof. Cook is not undecided as to his own view on the subject, he seems to give a fair hearing to both sides, leaving the reader to form his own conclusions.

A Button or Badge for the National.—This seems to be one of the questions for the Board of Directors to settle, as noted on page 28 of the Buffalo Convention Report pamphlet, where it says:

Mr. York—I move that the matter of selecting a badge be referred to the Board of Directors.

The motion was seconded by Dr. Mason, and carried.

Editor Hutchinson takes up this subject in the May Bee-Keeper's Review, and suggests what has, we believe, been mentioned by Mr. N. E. France and others, viz.: a button; and has this to say concerning it:

The button should be something that we would be proud to wear, simply for the sake of its appearance, aside from its emblematical nature. It should be handsome, but not gaudy. I would not have the button large enough to remind one of a sign-board. I think that three-fourths of an inch would be plenty large enough. Instead of having it round, I would have it hexagonal. As an emblem, I think of nothing more suitable than a bee on a clover head. If the body of the button were drab, the clover could be white, the bee leather-colored with hands of gold—*genuine gilt*. As a motto, above the bee and clover, I would suggest, "By Industry We Thrive." At the bottom I would have the initials, "N. B.-K. A."

We think the button idea is all right, but whether the Association should go to the expense indicated by Mr. Hutchinson's exquisite button is a question.

Then, again, the Denver Association may not wish to be deprived of the pleasure of furnishing elaborate buttons or badges, as did the Chicago Association in 1900, when the National met here. We understand that Denver is going to outshine Chicago so far that even the distance between the two cities may be greater than ever, after next September! And, so, if they contemplate furnishing a silver or gold badge—worth probably a dollar or two—don't do anything to head it off. Those who attend that convention will want something like that to keep it green in their memories. And yet, we believe the Colorado people are planning to do a lot of things for, and with, those who attend that convention that will make it the most memorable meeting of all. May they succeed.

Cure for Bee-Paralysis.—"Oil of naphthol, one teaspoonful fed with honey." is recommended by the Australasian Bee-Keeper.

Apiarian Exhibit at Nebraska Fair.—Hon. E. Whitecomb, the superintendent of the apiarian exhibit at the Nebraska State Fair and Exposition this year, has sent us a copy of the premium list, which, we believe, is the most liberal of all such lists now in this country, being over \$300. The following is a copy of the same:

LOT 1—BEES AND HONEY—OPEN TO THE WORLD.

	1st Pre.	2d Pre.	3d Pre.
Best comb basswood or white-clover honey, not less than 20 pounds, cased and in single-comb sections weighing not more than 2 pounds each.....	\$5 00	\$3 00	\$2 00
Alfalfa honey, the same amount and cased as above.....	5 00	3 00	2 00
Sweet clover honey, same amount and cased as above.....	5 00	3 00	2 00
Fall honey, the same amount and cased as above.....	5 00	3 00	2 00
20 pounds extracted white clover or basswood honey.....	5 00	3 00	2 00
20 pounds extracted alfalfa honey.....	5 00	3 00	2 00
The above to have been extracted previous to July 1.			
20 pounds heartsease fall honey, to have been stored after Aug. 1.....	5 00	3 00	2 00
20 pounds extracted alfalfa fall honey, to have been stored after Aug. 1.....	5 00	3 00	2 00
20 pounds extracted sweet clover fall honey, to have been extracted after Aug. 1.....	5 00	3 00	2 00
Largest display by any one, including bees, extracted and comb honey.....	15 00	10 00	5 00
Most artistic designs in beeswax.....	7 00	5 00	3 00
Exhibit of apiarian supplies and implements.....	15 00	10 00	5 00
Display of honey in marketable shape, products of exhibitor's own apiary.....	15 00	10 00	5 00
Display of honey-candy, honey-sugar, and sweets, by any one, in which honey is made to fill the place of sugar.....	3 00	2 00	1 00
Honey-vinegar, not less than 1/2 gallon.....	3 00	2 00	1 00
Display of bees and queens in observatory hives, and not allowed to fly, not less than five cages.....	10 00	5 00	3 00
Exhibition of extracting honey, to be exhibited on the grounds, under the direction of the Superintendent, not later than Thursday of the Fair.....	3 00	2 00	1 00
Honey-extractor, test to be made by actual extracting upon the ground.....	3 00	2 00	1 00
All-purpose single-wall hive.....	3 00	2 00	1 00
All-purpose chaff hive.....	2 00	1 00	50
Bee-smoker.....	1 00	50	25

The following are confined to exhibitors in Nebraska alone:

Best display of apiarian implements and supplies, including comb foundation drawn, and bees in cages, not less than five cages.....	10 00	5 00	3 00
Report of surplus honey stored by any colony of bees during the year 1901, the amount of stores, manner of building up, handling, kind of hive used, kind and quality stored, to be verified by owner. Entries to conform with other entries of this class, and report, with verification, to be filed with Superintendent not later than noon on Thursday of the Fair.....	5 00	3 00	2 00

LOT 2—COUNTY COLLECTIVE EXHIBITS.

The county in Nebraska showing the best collection of honey of all kinds, any or all ages, shapes and conditions.....	\$20 00	\$10 00	\$5 00
---	---------	---------	--------

The exhibits must have been produced in the county exhibiting, and the product of not less than five apiaries. Individuals composing this collective exhibit may compete for any or all minor premiums offered.

All competitors on honey must produce their own honey.

Points for the judgment of honey: *Comb Honey*—*First*, perfection of capping; *Second*, evenness of surface; *Third*, whiteness of capping; *Fourth*, general appearance to marketability. *Extracted Honey*—*First*, cleanliness; *Second*, clearness; *Third*, flavor.

Mr. Whitecomb has prepared the following announcement for bee-keepers:

BROTHER BEE-KEEPERS:—Your attention is called to the greatly increased premiums offered this year in Class K., Bees, Honey, and Apiary Goods. The officers of the State Agricultural Society have always responded to the wants of the bee-keepers of the State, and we are able, through them, this year, to present you a list of premiums in this class which can not be equaled in any State in the Union.

In return for these liberal premiums offered they have a right to expect from the bee-keepers and supply dealers such an exhibit as has never before been seen in this or any other State. Already about one-half of the available space in the Honey and Bee House has been asked for, but it is desirable to fill this building so full from cellar to garret, of the nice things produced in the apiary and manufactory, that it will be a palace of sweets, bees and supplies.

The superintendent of this class will be on the ground this year a day earlier than usual, fully prepared to make your stay at the Fair and the Bee and Honey House more pleasant and profitable than ever before.

The annual meeting of the Nebraska Bee-Keepers' Association will

be held on Tuesday and Wednesday evenings of the Fair, in the Apiary Building.

Respectfully,
E. WHITCOMB, Supt.

Surely, such an array of premiums should call out a large number of exhibits. The Fair will be held at Lincoln, Aug. 29 to Sept. 5. For further information, as well as copy of the complete premium list, address, Robert W. Furnas, Secretary of the Nebraska State Board of Agriculture, Brownville, Nebr.

Only One Night to Denver.—By going over the Chicago & North-Western and Union Pacific railways, you will need to spend only one night on the road from Chicago to Denver. There is a daily train leaving Chicago at 10 a.m. on the C. & N. W., and leaving Omaha, Nebr., over the Union Pacific at 11:30 p.m. of the same day. This train arrives in Denver at 2 p.m. the following day. That is, by starting from Chicago at 10 a.m. on Monday, Sept. 1, you will arrive in Denver at 2 p.m. the next day, or Tuesday, Sept. 2, in ample time for the first session of the National Bee-Keepers' convention, which begins that evening.

Now as to rates: The round-trip price at that time from Chicago to Denver will be \$25. By going over the route mentioned, the regular sleeping-car rate would be only \$3.00, because of being only one night on the way.

There is also another saving by taking the C. & N. W. and Union Pacific. There is a Pullman tourist car on this train from Omaha, in which the charge for a double berth is only \$1.50 to Denver. As no sleeping-car accommodations are required on this train east of Omaha, it will be seen that one can go comfortably by this route for a very small sum.

We may say that Dr. C. C. Miller and the Editor of the American Bee Journal expect to go over the route indicated, starting at 10 a.m. on Monday, Sept. 1. Who will join us? We would like to publish the names of all who will do so. It would be pleasant to have a large number go together.

*** The Weekly Budget. ***

"DER PAVILLON FAEHIGE DADANT-ALBERTI-BIENENKASTEN" is the somewhat involved name of a German book by A. Strauli, which contains an authorized translation of G. M. Doolittle's "Scientific Queen-Rearing."

AN APIARY OF SIMON P. MICHAEL, of Bureau Co., Ill., appears on the first page this week. It contained 60 colonies, spring count, in 1901, which were increased to 80 colonies, and 3000 pounds of No. 1 comb honey taken, with plenty left for winter stores. The picture was made a few days before the bees were put into the cellar, last fall.

MR. LOUIS CHARLES DADANT, son of C. P. Dadant (and grandson of Father Charles Dadant), is a member of the graduating class of 1902 of the University of Illinois, at Urbana. He kindly sent us an invitation to be present at the Thirty-First Annual Commencement, which occurred June 7 to 11, which we should have been pleased to accept could we have gotten away, but in June it is utterly impossible for us to leave our office for even a day, unless absolutely necessary.

We wish "Louis" every deserved success in life, which he will doubtless have, as he has done the right thing in making a careful preparation in advance.

THE APIARY OF PHILIP WEISNER, of Maricopa Co., Ariz.—or at least part of it—is shown on next page. The whole apiary numbers about 300 colonies, and 86 colonies of them are placed under this brush shed.

In that hot climate bees require shade, and the most practical and satisfactory way is to construct brush sheds. These are made wide enough for two rows of hives, allowing ample space for passage-way with the wheelbarrow, etc., between the two rows.

The Salt River Valley, of Arizona, is a most excellent bee-country. Where the land can be irrigated one continuous field of beautiful, and all ways green, alfalfa can be seen; and even the desert, where Nature stands unmolested, are flowers and trees, which, when in bloom, are covered with bees.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 358.)

EXTRACTING COLD HONEY—HIVE COVERS.

"How can one get honey that is stiff out of extracting frames in cold weather without spoiling the frames and combs?"

Dr. Miller—By warming it.

"Is there to be any improvement in the 1902 hive-cover?"

Mr. Horstmann—There is a cover on the table there now which I think is a good improvement. That will not warp; it has been in use for one summer; it answers as a shade-board as well as a cover, and it improves the appearance of the hive greatly. It gives the top a chance to expand without loosening a nail or cracking the board; it can be used for winter as well as summer. Anybody can see the advantage of it, if he will examine it, without any farther comment on my part.

REMOVING HONEY FROM BROOD-CHAMBER TO SUPER.

"Under what conditions can you get bees to remove honey from the brood-chamber up into the supers besides one of young queen? Or, in other words, can you get them to do it with the old queen? If so, how?"

Dr. Miller—Several years ago Mr. Baldrige advised taking a three-tined fork, and tie the tines together with wire, if they are not of the right distance apart. Make it so the three tines will strike about the center of the cells of honey, and scratch the combs of sealed honey with that. It will make the bees empty it. Another way to get the thing done is to take a wire hair-brush, and just, tap the comb all over, so as practically to open all the cells, and then the bees would be tempted to empty that. If the queen is so old that she is not doing any work at laying, that will make no difference, but if she is a queen two or three years old, the likelihood will be, if the honey is coming in plentiful or not, that will help to take it up.

Mr. Dadant—There was invented at one time what was called "invertible hives." You all know that when bees put honey in the brood-chamber, they put it at the top; when you invert the hive the honey is right at the bottom, and right at the entrance, and the bees must carry that honey away because it is where the robbers can get it, and they carry it in the super. That is the only advantage of invertible hives; and that is why some people use them.

Mr. Riker—To have the bees carry the honey above, I just take an uncapping-knife and slice the cappings, and the bees carry the honey up.

REPORTS OF HONEY SCARCE AND HIGH PRICES.

"Do bee-keepers benefit by giving the impression that honey is scarce and will be high-priced?"

Mr. York—It seems to me some one suggested a while ago it was a good idea to give out the impression that there would be lots of honey, and prices would be low, so that everybody could afford to eat honey.

Dr. Miller—I believe, Mr. President, it would be well to leave that for the American Bee Journal.

R. C. Aikin, of Colorado, Vice-President of National Bee-Keepers's Association, for 1901, who had been invited to contribute something on the production of extracted honey, kindly sent this paper, which was read by Secretary Moore:

KINKS IN EXTRACTED-HONEY PRODUCTION.

The apiarist that can take out or avoid all the hard kinks in extracted-honey production (or in comb, either) must be expert indeed. He who thinks that honey-production on modern lines is without kinks, will find it one of the kinkiest businesses he ever undertook. As time passes, and we get more experience, we find ourselves able to straighten out some of the knotty kinks, and I suppose that what is

PART OF APIARY OF PHILIP WEISNER, OF MARICOPA CO., ARIZ.

(See opposite page.)

wanted of me in this paper is, to tell some of the short, straight roads that avoid the kinks.

I will tell you first about the hive. There, don't get scared at the hive-question ghost. There is a difference between producing comb and extracted honey. Any hive that will succeed in working for comb will succeed for extracted, but when plenty of storage-room is given in ready-made combs in a super, the colony will freely begin storing there, and once a force of bees is in the extracting-super there is a great relief in the brood-nest, both of honey and bees; the queen has much laying-room, her work-shop is cooler, and less swarming results. As long as the apiarist keeps the honey out of the way so that there is never any lack of room, there will surely result a much greater amount of brood than will result in a comb-honey colony. As to whether that brood is desirable, depends upon whether the flow is long or short; whether it is to be followed by another flow wherein the brood being reared may become fielders to gather it; or whether it is late in the fall and you want those bees for winter stock. Even then there is a difference whether you winter the bees in the cellar or outdoors. This general rule applies: Extracted-honey colonies will not provision the brood-nest as does a comb-honey colony; and, going into winter with more bees and less honey, calls for a larger brood-nest for extracted-honey colonies than for comb.

One of the very curly places is getting the bees to take at once and so freely to the supers that the queen, having plenty of room, there will be little or no disposition to swarm. You can make that rough place to run much smoother by putting a little brood in the super, and also by having two supers, and the brood in the uppermost. With divisible brood-chambers that can be so nicely arranged by putting a dry set of combs on the bottom-board, on this one set half of the brood-chamber, putting the other half above the super for a little time, more or less, according to conditions.

No, no, never think of getting along without a queen-excluder when working for extracted honey. I have tried both with and without, and I must say that a lot of old zinc that leaks queens every now and then is almost more than I can stand, let alone being entirely without excluders. This is a very kinky place, and for the sake of common decency and cleanliness, for the best grade of honey, and for speed and easy manipulation, use queen-excluders.

Extracted honey is so low in price that there must be economy or no profit. Many, when taking off combs to extract, pull out a comb at a time and shake and brush off the bees. That is all right with a very few colonies, but when it comes to making an extensive practice of that it is too puttering. I take off extracting-supers without moving a comb separately, by smoking down most of the bees, then at once removing the entire super at one lift. If no excluder is used, I would in this way get much brood with the supers, sometimes a queen, too, and one of the crankiest kinks would be the fact that the bees would not leave that brood, and when I go to pick up the super I would have a fight at once. Set a super on the ground that is free from brood, and the bees soon leave it; but if it contains brood they stay, and after being quiet a few minutes will fight as if at home.

Smooth out the kinks by having a small bee-tight room at each apiary, the windows well screened—better double-

screens, and double or treble cone escapes on the windows, all made with a view to keeping bees out and facilitating the escape of those that by any means are in. If you are taking off supers when there is no robbing, just set them about the yard as open and airy as possible, and they are soon free; but if robbers, put into the shanty, but also as light and airy as possible, and let the bees go out through the escapes. If brood is in a super, only brushing will get the bees out.

Do not be afraid to have two supers to the colony; it pays to have plenty of room, saves having such a rush in extracting when the flow is on and you are so very busy you don't have time to eat. You can so much more easily and *quickly* drive bees down from a top super into a second one, the second being put under the full one; but have the second one on long enough so it will be licked dry and be occupied—you can not successfully smoke down into a wet, sticky super, and not very well through an excluder. Extra supers cost less than hired help—the hired man takes his pay and goes, the supers are paid for and you still have them as so much capital and wealth. If it is a question of hired help or more supers, it is *big* economy to get the supers.

Have your extractor and all the machinery at home. You have to go to and from the out-yards in any case, and also have to transport the honey, just haul it home in those extra supers, it is no more hauling to move the supers than to move the machinery and cans or tanks, and your extracting machinery being all set and arranged at home to the best advantage, makes it a pleasure to handle the product.

Doing the extracting at home, let the honey remain in the settling tank as long as the tank is not too full, or as long as the honey does not candy, and you have a gilt-edged product. Also, let the honey remain on the hive until all or nearly all is sealed; it is just as easy to uncup a solid sealed comb as one half sealed, and the wax from the cappings is as profitable as the honey, or more so.

Stop the old, fussy method of educating your consumers to expect honey always liquid. The same amount of effort and energy spent in educating to use (or buy) candied honey will accomplish the desired end, and save an immense amount of trouble and expense. Just imagine me having customers 500 to 1000 miles away sending back honey to have me melt it for them. I know you will say you can not do it, the people will not have it so; yet all the while you go right on educating them to have it the reverse. That our extracted can be marketed in the candied condition, and successfully, and a very large class of consumers reached that are not now eating honey, are two things I *know*. I also know that a good home trade at from 7 to 10 cents for the net honey at home beats selling delivered in Chicago at 5 to 6 cents, and producer furnish package and pay freights. That is the size of it, and you must face the fact.

Here are a few things to keep in mind: Producing extracted honey requires less skill as an apiarist, but it takes quite a considerable more capital invested in hives and machinery; takes more hard work, and, as intimated hereinbefore, unless you keep in mind that fact, of so much of the stores being put into the extra, and a vast amount of brood being reared in its place, you will starve your bees in winter and spring. Remember, too, that extracted honey will keep indefinitely, so that you have your time to accomplish its marketing; but with comb honey it must be sold and consumed within its first year.

Have abundance of super-room; plenty of tank-storage capacity to hold the product until well settled; do not rush to extract as fast as gathered, but use the extra super-room to hold the crop until after the rush is over; the rush over, extract at your leisure at home, having a warming-room in which to heat before extracting; after extracted and well settled, put into retail packages and set aside to candy; ship or market in retail packages that do not require a second packing after being drawn from your storage-tank, thereby lessening the vast amount of labor and expense that comes between the producer and consumer.

These things mean radical changes from the practices of many, but you will do well to think them over, and when you can get to it, practice in some way the principles. One plain fact must be evident to all, extracted honey sold in bulk, in cans and barrels, will not bring good prices nor be profitable. Produce for home trade, and in a retail way for table use; this is the solution of the problem that is now before the producer of extracted honey. R. C. AIRIN.

(Continued next week.)

The Premiums offered this week are well worth working for. Look at them.

Contributed Articles.

No. 2—Rearing Long-Lived Queens and Bees.

BY DR. E. GALLUP.

I don't know that I can get all I wish to say on the queen-rearing business into one article, but I suppose I will be allowed to write more if I live long enough.

To say that I was surprised at Dr. Miller's and Mr. Dadant's answer to the question, as to what is the cause of the longer or shorter lives of worker-bees, hardly expresses it. Why, gentlemen, don't you know that it is the longest-lived bees that do the most work, and out-of-door work at that? I know that the very best and most profitable colonies of bees are reared from long-lived queens—queens that live 5 or 6 years. On the other hand, the least profitable colonies and the shortest-lived bees are those that are reared from queens that live only from 6 to 24 months.

Perhaps no one has had any more experience in testing queens from as many different queen-breeders than I. As I have been a prominent writer, queen-breeders would send queens for me to test in the hope that I would recommend their stock, especially when the great fad was for fancy color. Now the fad is long tongues. But, gentlemen, and ladies, too, I want to see another fad, and let it be long-lived bees, both queen and workers. Neither their tongues nor tails will be shortened any by carrying out that fad.

When I came to California I took an apiary in Ventura county, to run on shares, and knowing how to rear long-lived queens and bees I selected two colonies that suited me to breed from, and having some dirty honey to stimulate with, and plenty of ready-made comb (the bees were all in 10-frame Langstroth hives), I began stimulating about the last of January, very gradually at first. But in February I attended to it more thoroughly, but not sufficiently to have them store any so as to restrict the queens in breeding. I diluted the honey to about the consistency of fresh-gathered nectar from the flowers, and sprinkled it in the top of the two hives every evening, right among the bees. Both hives were two stories, and each had one comb containing a patch of drone-comb; I spread the brood according to my notion as the queen required, and the first of March I had two rousing colonies. There being so many bees the queens could and did deposit eggs in any part of the hives, wherever they could find empty or vacant cells. Right here I will say that I usually get more queen-cells built than where the queen deposits her eggs in any one particular part of the hive, and I was not disappointed, as I got 36 natural queens from the two colonies. Both colonies sent out their first swarm early in March, before I had drones from other queens.

The proprietor thought they were not pure, because they were too dark-colored; but I called them dark leather-colored Italians, and I was not disappointed in them. "Why," said he, "their drones are all black."

Right here I will explain to our Eastern bee-keepers, that bees can and do gather pollen here the entire year. There was not to exceed four days the past winter that they did not gather pollen in some part of the day.

If the bees are left to themselves the queens usually stop breeding in November, and do not commence, to amount to much, until the last of January. February is about like your May and June weather. Of course, I mean here in the Santa Ana Valley, not in the mountains. It is now May 13, and for the past three weeks bees have been storing very rapidly, and swarming beyond anything I have seen before, since I came to this State. They are everywhere. A boy in the next block from me has 22 swarms, picked up in about as many days. One man has 12, another 42, another 24, etc. They have gone into barns, warehouses, chimneys, etc.

I told you in my first article (last week) how you could rear short-lived queens and workers. My calculations are to tell how I know, in another article.

I see Mr. Riker gives another touch on page 302, on the long-lives question. That is right, touch them up, as many of our queen-breeders need it, and need it very badly, judging from the number of worthless queens that I have received from different ones, many of them having been

worthless because they ruin any colony they are introduced into.

Well, another will follow this in due time, if I am spared. Orange Co., Calif.

Putting on Sections—Getting Early Swarms.

BY G. M. DOOLITTLE.

A correspondent sends in a couple of questions which he wishes answered through the columns of the American Bee Journal, the first of which reads as follows:

"I am a beginner in apiculture and wish to work wholly for section honey. When is it best to put sections on a hive having a new swarm?" That will depend somewhat on how you work, the size of the swarm, etc. If the swarm is large, and you have full sheets of foundation in the brood-frames, it is well to put on a super of sections at the time when the swarm is hived. And I think that I should fill the sections with foundations, as well as the brood-frames. But should you fill the sections with foundation, and use only starters in the brood-frames, the queen would be likely to go into the sections to deposit her first eggs, unless a queen-excluder was used, in which case she could not get into the sections, no matter how the hive was fixed below.

With nothing but starters in the brood-frames, and no queen-excluder used, then it is best to wait about putting on sections till the queen has commenced laying in the new comb built below, when the sections can be put on without fear of brood in them.

The plan I like the best, and the one I use more largely than any other, is to contract the brood-chamber to two-thirds its usual size, using only frames having starters in them of foundation about half an inch wide, on top of which is placed a queen-excluding honey-board. The new hive thus prepared is set on the stand of the parent colony while the swarm is out in the air or clustered on a limb, and the sections are now removed from the parent colony and placed over the queen-excluder on the new hive, when the swarm is hived in this new hive, now on the old stand, after which the old or parent colony is placed at some distance off on a new stand which we wish it to occupy.

In this way we not only get all the bees with the swarm into this new hive, but also all of the old or field bees which are in the fields at the time of swarming, as well as all the field-bees that come out from the old hive within a day or two later, as they return to the old location which they had marked, not realizing that their place of abode has been removed. This throws so large a force into the new hive that work does not stop in the sections at all, and, as a rule, prevents all after-swarms from the parent hive. As the larger part of the bees go to work in the sections, and have full room there for the honey they are securing, storing it in the partly filled sections removed from the old hive, comb-building progresses in the frames below only so fast as the queen can occupy the cells with eggs, and in this way, we, as a rule, secure the frames in this contracted brood-chamber filled with nice, straight worker-combs, at a less cost to us than the purchasing of foundation and fitting it into wired frames. But in any other procedure I think it best to fill the frames with foundation, for if we do not the bees build altogether too much drone-comb for the future prosperity of the colony.

The second question is as follows: "I am desirous of having just as many early swarms as possible. Would there be a gain or loss along this line by putting on the surplus arrangement or supers of sections early in the season?" It might be safe to say that, taking early swarms into consideration, there would be a disadvantage, or tendency toward a few days delay in swarming, if the surplus arrangement is put upon the hive before the bees swarm. Heat is one of the elements in forcing early swarms, hence, by putting on the surplus arrangement before the hive is crowded with bees, much of the heat from the colony will be distributed among the sections, which would to a certain extent retard swarming, as it also does brood-rearing?

If early swarms is of the utmost importance, even if we have to sacrifice other values, then it is best to keep the top of the hive as close as possible, and stimulate the bees by feeding, spreading the brood, and otherwise. Later on, when the hive becomes crowded with bees, and preparations for swarming are begun, the placing on of sections may not delay it. But if we count surplus honey a gain, then I can conceive where there would be a gain in putting on sections

as soon as our main honey-harvest opens, as it is often the case that, with all our crowding and desiring early swarms, the bees will obstinately refuse to swarm, when we not only fail in accomplishing what we are after, but lose a part or all of the honey crop we might have had if we had put on the sections at the proper time.

I verily believe that during the past, when conducting experiments along this line, I have sustained more loss by trying to force swarms by crowding the bees, than by giving them too much room. Therefore, it has always been my advice of late years to place the sections on the hives at the proper time, just when the first flowers of our main honey harvest are opening, no matter whether swarming is desired or otherwise, resting assured that, with the majority of bee-keepers, more swarms will issue, when doing our best to secure a good crop of section honey, than we had hoped for, or at least fully enough to satisfy any reasonable persons. And if this should not be the case, it is very easy under our present enlightenment to make a few "swarms" after the harvest of white honey is over, which will, as a rule, build up and secure enough dark honey for wintering. This latter, it seems to me, is much more reasonable than to sustain a loss of white honey through fear that our bees will not swarm as much or as early as we desire. Onondaga Co., N. Y.

Telegony—The Influence of the Male on Succeeding Offspring Not Sired by Him; is the Theory Proven?

BY PROF. A. J. COOK.

If telegony be true at all, I believe it speaks with muffled voice and never in loud accents. May I present the matter to your readers, as it is very important in practical affairs? The belief in it once reduced the value of a cow in my herd many dollars. I believe there were no just grounds for this loss.

The theory of telegony is very important to breeders. The name originated quite recently with Weismann. Telegony teaches that a taint is given a female by mating with a male of different breed or race. To illustrate, a mare bears a foal from a jack. If the theory of telegony be true, any subsequent foal from that mare, even though sired by a horse, will very likely show mule characteristics. Again, a shorthorn cow is crossed with a Jersey bull. All future offspring, even from pure shorthorn, are likely to show the Jersey taint.

That there was some such theory in the minds of people as early as Jacob's time is possibly true. The theory has been regarded by many of our scientists as a correct one, back even to 1820, when Lord Morton wrote to Dr. W. H. Woollston, President of the Royal Society of Great Britain, the results of his famous experiments. These experiments were substantially as follows:

A nearly pure Arabian mare was coupled with a quagga. The resulting offspring was a female hybrid quite intermediate in character between the sire and the dam. The mare was afterward bred to a pure Arabian horse. The resulting filly, in the words of Lord Morton, and also a colt a year younger, were fine specimens of the Arabian breed, as fine as could be expected when only fifteen-sixteenths Arabian; but in the color and the hair of their manes they bore striking resemblance to the quagga. The stripes seemed quite conclusive, but the evidence from the mane and tail was less so. This testimony from Lord Morton has been regarded as conclusive by many scientific men. Darwin, in referring to this case, says, "There can be no doubt that the quagga affected the character of the offspring subsequently got by the Arabian horse." It is significant, however, that Darwin wrote afterward that telegony occurred rarely; for he stated, some years before his death, that it was "a very occasional phenomenon."

Agassiz believed in telegony. He was fully persuaded, to use his own words, "that the act of fecundation is not an act which is limited in its effects, but that it is an act that affects the whole system, the sexual system especially, and in the sexual system the ovary to be impregnated hereafter is so modified by the first act that later impregnations do not efface the first impressions."

Romanes also believed that telegony was of occasional occurrence. His researches were quite extensive. He sums up his conclusions in the following words: "The phenomenon is of much less frequent occurrence than is generally supposed. I doubt if it occurs in more than one or two cases in a hundred."

Herbert Spencer believed in telegony. He not only has

a theory to explain it, but also makes the basis of an extended argument which he used in his controversy with Weismann. The latter, who gave us the term "telegony," writes as follows in the *Contemporary Review*:

"I must say that, to this day, and in spite of the additional cases brought forward by Spencer and Romanes, I do not consider that telegony has been proved. I should accept a case like that of Lord Morton's mare as satisfactory evidence if it were quite certainly beyond a doubt. But this is by no means the case, as Setegast has abundantly proved."

Setegast explained the case in question as an instance of "reversion." He says, "Cases are not rare where colts are born with stripes which recall the marking of a quagga or zebra." Many German breeders hold with Weismann that telegony is yet unproved.

The late Sir Everett Millais, an eminent breeder of dogs in England, was also a doubter. He says:

"I may further adduce the fact that, in a breeding experience of nearly thirty years' standing, during which I made all sorts of experiments with pure-blood dams and wild-blood sires, and returned them afterward to pure sires of their own breed, I have never seen a case of telegony, nor has my breeding-stock suffered. I may further adduce the fact that I have made over fifty experiments for Prof. Romanes, to induce a case of telegony in a variety of animals—dogs, ducks, hens, pigeons, etc., but I have hopelessly failed, as has every experimenter who has tried to produce the phenomenon."

Very recently Prof. Ewart used Matopo, a beautiful zebra stallion. He has secured eleven zebra hybrids, from mares of various breeds and sizes. Some of these hybrids were even more marked with stripes than the sire. The mares were afterward bred to horses. The progeny were for the most part very much like ordinary foals. There were, however, stripes, which in some cases were quite evident in certain lights, but even these in many cases disappeared later. It is interesting to note, however, that these faint stripes were unlike those of the sire or even the hybrids. Foals of ordinary breeding very often show similar stripes. Many of the colts show no stripes at all, nor any indication of taint. Prof. Ewart has also experimented with pigeons, fowls, ducks, and dogs. There were many cases of rabbits, and in every case the mother which had been impurely mated subsequently bred true upon being purely mated. Prof. Ewart does not claim to have proved anything. He is certain that it does not always occur, and believes with German breeders that, if it occurs at all, it is seldom. We quote from him: "The experiments, as far as they have gone, afford no evidence in support of the telegony hypothesis." He believes that the stripes are easily explained by atavism or reversion. Certainly we owe a great debt of gratitude to this Edinburgh professor. Very recently Prof. Ewart gave the results of further experiments to the same purpose.

The late Dr. Manly Miles, in his "Principles of Stock-breeding," accepts telegony. He gives a case in his own breeding. An Essex sow was bred to a Chester White boar. She was afterward mated purely, and produced a litter of pigs which were as much mixed black and white as the previous litter. I was at the time a colleague of Dr. Miles, and with many others had grave doubts regarding the experiment. A careless work-hand, the accidental opening of a gate, so many things would explain the result without an appeal to telegony. The taint was so great that it could not but make us skeptical.

As is well known, many poultry-men and apiarists argue that the law of telegony is as true of birds and bees as of mammals. I have long doubted its truth with poultry, or our pets of the hive. Telegony was at first explained as blood-taint in the case of mammals; but there is no intermixture of the blood of the mother and the embryo. An extensive membrane in the placenta separates entirely the blood of mother and fetus. Blood-taint is obviously impossible. The nerves were next appealed to to explain this phenomenon. This, however, is vain, as the nerves of mother and offspring are entirely separate. Dr. Miles called in cell-inoculation to explain telegony. We all know how inflammation spreads in the case of wounds. The explanation is evident. Poison, or possibly microbes, pass from the injured to the uninjured cells, and, with the spread of the cause of the disease, the disease spreads. In telegony there is no virus, and so there could be no inoculation. Herbert Spencer suggests that "germ plasma" passes from the fetus to the mother and becomes

a part of her body, and spreads to affect all the tissues, even the reproductive organs. This is surely very hypothetical.

I was led to question the truth of telegony, as the testimony seemed as conclusive with birds and bees as with mammals. Mr. Spencer's germ-plasm could not affect in these latter cases. With fowls, only the sperm-cells are lodged, and that for a brief space, in the oviduct of the hen. There is no organic connection, and it is hard to see how any influence could taint the hen. I know it is claimed with some show of authority that impure mating changes the color of the egg-shell. I can only say, very interesting if true. If such a change occurs, I believe reversion explains it. In the case of bees the connection is a little more obvious. Here millions of sperm-cells are lodged for years in the spermatheca, or sperm-sac, of the queen. There is, however, no difference in kind from the fowls—the only difference is in time. The sperm-cells are present in the reproductive apparatus for years instead of days.

So grave were my doubts that I experimented at length to see if I might decide the matter. My experiments with poultry were made with Light Brahmas and Brown Leghorns. These birds are different in limb, feather, form, habit, and color of egg. The fowls all ran together through the winter, mating promiscuously. In early spring I separated the birds, putting all the Leghorns, male and female, in one pen and the Brahmas in another. After three weeks I commenced to incubate the eggs, and raised over 200 chickens. There was not the least show of taint in either breed. We all know how persistent the feathers on the legs are with any show of Brahma blood. My Leghorns had legs that were entirely clean. At the close of these experiments I was more skeptical than ever as to the truth of telegony in birds. Noted breeders of long experience in our country make similar reports.

I next experimented with bees. I procured a queen all the way from Syria. I introduced her in my apiary where there were only Italians. I at once reared several queens from her which must have been mated exclusively with Italian drones, as there were no Syrian drones within hundreds of miles. As is well known, drones hatch from unimpregnated eggs. Here, then, if the drones from these queens should show any Italian taint, we should have positive proof of telegony in bees. The eggs, not being impregnated, can produce only drones that have the characteristics of the mother. If impure, then surely the mother must be affected. In this case we have examples, not by the tens nor the hundreds, but by the thousands. I examined these drones very carefully, as did my students and many others. Every drone was decidedly Syrian, and had not the slightest mark of an Italian. Have we not, then, good reason to doubt the truth of telegony in bees?

I have known several cases among mammals where telegony might be put in evidence if true; yet in every case the evidence was absent. I know this is only negative testimony. I went to the Chicago exhibition during the time that mules were being exhibited. I talked with many extensive breeders, and not one believed in telegony. They all said that they had had no evidence of its truth.

As stated at the beginning of this article, this is a matter of no little importance to the breeder. If telegony be true, then accidental cross-mating with any female for ever taints her blood. I am so firm in the belief that it is not true that I would not pay a nickel less for a shorthorn or Jersey because, at some time in the past, she had been impurely mated.—Gleanings in Bee-Culture. Los Angeles Co., Calif.

LAW AGAINST BAD HONEY-DEW HONEY.

And so the New York folks have got a law under which the man who puts on the market a bad article of extracted honey-dew can be fined fifty dollars? It would serve him right, and, so far, no cause of complaint. But some years, and through extensive regions, half the honey produced is more or less mixed with natural sweets *not nectar of flowers*

—and so not pure honey according to the wording of the Act—and yet not bad either as to taste or wholesomeness. Most of the producers do not themselves know whether their honey is New-York-pure or not. Of course, the experts who drew up the wording of the law “allowed” that no one, either for fun or for spite, would go around slaughtering these innocent lambs. This critic, however, doesn’t believe it’s wise to have legal power to slaughter lambs put in the statute books. Page 275.

CLEAN DIRT FROM THE BEES.

“Clean dirt,” is it, Mrs Axtell, that we get from the bees? Yes, I often try to console myself a little with that maxim, too. Unfortunately bee-dirt is rather worse than the average dirt as to being filthy *looking*. Those who constantly and tremblingly ask, “How do I look?” will find scant peace behind a nice white apron well propolized. Page 278.

VALUABLE REMEDIES THAT ARE NOT NEW.

Miss Wilson will not be able to patent her panacea—Get well by not thinking of your disease—too many before have recognized its curative value. Every mother knows a funny story heals a bump. Nevertheless it’s good and profitable to advertise afresh valuable remedies which are not new, as Miss Wilson does on page 279. Sometimes, and just right, give earnest study to your ailment. Sometimes, and just right, cast the whole thing off your mind, utterly and absolutely. As to our moral ailments, *same rules*. A vast number of people are greatly in need of a little self-examination. On the other hand, many (by counting here and there one) suffer terribly—suffer almost to the destruction of sanity and life—by ill-advised and too constant moral introspection. Don’t brood. Some chickens will die of cold and neglect if they are not brooded. Try it on that ineradicable sin, and that incipient cancer of the stomach, and that internal tumor.

CROWDING HIVES MAKES BEES CROSS.

The idea of Mr. A. Boomer and his friends, that crowding the hives makes the bees cross, is an idea not much in the papers. Is it that the children “sass” each other from yard to yard when the homes are thus near, or what? In manipulation, if we disturb other hives besides the one or ones we smoke, that might tend to general bad temper. The closer the spacing the greater that difficulty will be. It is tolerably plain that manipulation, if it ends pleasantly all around, improves the temper of the bees; while all ugly “musses” (especially if the bees think they have driven you off) have a contrary effect. Page 284.

MORE PROMENADE SURFACE FOR SWARMERS.

As a general approximation, 75 percent of the bees to go with a swarm and 25 for the old hive will do very well. I think the percentage varies very greatly; nearly all that can fly going sometimes, and on rare occasions not more than 25 percent. If you *want* more of the bees to stay I think I can tell you how to compass your desire without much trouble. Have a big, empty upper story. Set in several division-boards, or whatever “gingerbread work” you can lay hands on, with intent to increase the promenade surface there is inside. Fix the quilt so the bees can easily get above if they wish. Most beholders do not see all there is of swarming. While taking flight is going on at the door a grand promenade is going on inside, up and down and all over, entrance forced into every crack and cranny. Now, the idea is that the more promenade surface there is the more promenaders there will be that will satisfy their appetite for excitement without going to the door and taking flight at all. Page 291.

PUTTING BEES OUT AND RETURNING TO CELLAR.

Putting bees out and then returning them to the cellar—presumably most of the cases where that has been tried were cases where dysentery had become very bad—bees sure to die any way, in or out. This would naturally lead to the idea that the plan was a bad one. Bees in tolerable health, only uneasy and distended, would constitute a very different case. It would not be surprising if a partial reversal of doctrines should come in with more exact and discriminating experiments. Page 291.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

Questions and Answers.

CONDUCTED BY

DR. O. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Dividing Colonies and Introducing Queens.

I have 13 colonies of bees (blacks) that I wish to divide, and this is the way I thought of doing: About the time they are preparing to commence to swarm divide both brood and bees about equal, and have a laying queen ready for the queenless half. Now for the questions:

1. Which should I leave on the old stand, the old queen or the queenless half?
2. How long should I leave the queenless half before introducing the new queen?
3. I intend to use the old black queen this season, but want to Italianize all this fall, or in the spring. What would be the proper time to have them for the next season?

PENNSYLVANIA.

ANSWERS.—1. Better leave the old queen on the old stand. But if you want the two parts to be equal in strength you should put the larger part of the bees and brood on the new stand, for all the field-bees will return to the old stand.

2. With a provisioned introducing-cage you can give her at once, or you can wait a day or two.

3. Toward the close of the honey harvest is a good time.

Honey from Dogwood and Bitterweed.

DR. MILLER:—I notice on page 282, that in your reply to “Mississippi” you say that you do not think dogwood (*Cornus florida*) yields honey.

Dogwood, in Jefferson County, Ala., begins to bloom about April 15, and yields much honey. (You will notice that the showy part of the blossom is not a part of the flower, but only the calyx—the flowers proper are in a compact cluster, and are composed of petals, stamens and pistils, making a perfect flower.)

The honey from the bitterweed is intensely bitter.

I write you this hoping to aid you in a small degree in your work.

C. C. PARSONS.

Escambia Co., Fla.

I am very glad to be corrected, and to know that the beautiful dogwood is useful as well as ornamental.

Management for Extracted Honey.

DEAR DR. MILLER:—I have been reading articles from your pen for years with much pleasure, and sometimes with profit. But what I admire most is what you “don’t know.” When one has passed the “know it all” stage, he usually knows something, and can make a good guess at what he “don’t know.” But I wish to warn you against following the advice given by Dr. Miller in the American Bee Journal to “California,” in regard to putting the queen in the lower story on empty frames. Don’t do it. I tried it last year on 7 colonies, and had 7 failures. In every case the bees followed the brood in the upper story and left the queen. Two of them were allowed a flight-hole from the upper story, and they left the queens entirely, and they both died—starved, I suppose. The others were compelled to go in and out through the lower story, and they fed the queens, but were so slow in building combs that I lost the use of the queens for a long time, and the colonies, being practically queenless, stored but little surplus. It prevented swarming for a certainty.

This season I am practicing two methods, and both are proving a success as far as I have had time to test them. First, I took two frames of brood and the queen and put them in a new hive and filled up with frames, left them on the old stands, and put the remaining combs and bees on top of another one-story colony with excluder between, thus making a very strong colony that begins storing honey at once, and I think the old queen and returning bees will

build themselves up into a strong colony before the season closes. They are building comb well now. If they are not strong enough I can add to them at the close of the white honey from the "boomers."

My second plan is to make what Ernest Root calls "shook swarms," putting them on empty frames and giving the combs with brood and honey to another one-story colony.

Colonies that have queen-cells ready to seal do as well as natural swarms. I find it will not do to give the new swarms combs in the upper story until they have the frames in the new hive nearly full of comb. DELOS WOOD.

Santa Barbara Co., Calif.

ANSWER.—One of the things that help to lighten my work in the "Question and Answer" department of the American Bee Journal, is the fact that sharp eyes are upon my work, and back of the sharp eyes kind hearts ready to help out where I fall short. In the nature of the case it must be that questions will come that fall outside my own experience, and then I must rely upon what I have learned from others. After learning of the experience of Mr. Wood, I should advise that one who desires to try the plan of putting the queen in a lower story should try it at first on a limited scale, until he finds how it works in his case.

I am very much puzzled to know why the plan should work so differently in California, for it so happens that I have tried the plan in a good deal more than seven cases, with no sign of a failure in any case. I never allowed a flight-hole in the upper story; in fact, I allowed no possible entrance except through the lower story, but even if I had allowed an entrance above I should not have expected any different results, expecting the bees from habit to have continued to use the lower entrance.

I would give a good deal to be present to see the progress of a case in the hands of Mr. Wood, so as to find out if possible what makes the difference. Let me give a little in detail the course of a case, and if Mr. Wood can see his way clear to do so, I wish he would try just one more case, and then tell us wherein is the first departure of his bees from the course pursued by mine:

I wait till queen-cells are begun, then the brood is raised to the upper story, and the queen left upon foundation in the lower story, with an excluder between the two stories. The queen stops laying in every case, and I suppose she spends her time in the fruitless attempt to get up through the excluder. This cessation of laying I believe to be an essential part of the program, and without it I think the plan would be a failure. The bees, however, go right on gathering as busily as ever, and in two, three, or four days the queen begins laying in the foundation. I think I never had a case in which the queen sulked more than four days, but, certainly, she began within the week. If Mr. Wood should try another case, I wish he would tell us whether he finds eggs later than the fifth or sixth day. Also, the outcome of the first of the two plans he is trying this year.

Italianizing and Working for Honey.

I wish to Italianize and also work for comb honey. I understand that after a swarm leaves the hive there will be no eggs in the old hive for 21 or 25 days. Of course, the bees will not do much work during that period. The safe and proper way is to let the bees follow their natural instinct. Will I gain anything by introducing a laying queen in a Benton cage, and cutting out the cells?

MASSACHUSETTS.

ANSWER.—Are you sure, when you say, "Of course, the bees will not do much work during that period," that your "of course" is well founded? So good an authority as G. M. Doolittle is very positive that nothing is gained by doing as you propose. He is pretty certainly right for his locality, and it is not unlikely that the same thing is true for you. It might be a good plan for you to try some both ways and compare results. Then please be sure to give us your conclusion.

Not Foul Brood.

I mail you a sample of comb under separate cover, and will thank you if you will let me know what you think about it. I have never come in contact with foul brood, and did not know but what I had run up against a genuine case. If so, I shall be pleased to have you tell me how you would go at it to stamp it out. The colony that this comb

is taken from died out some time during the winter. The piece which I mail you is the worst in the hive. I have Quinby and Langstroth reversible hives. I have read the convention reports, but I am not sure that I am right, and ask for your valuable counsel.

I have so much to do that I can not give the bees proper attention, but I do the best I can, and will endeavor to clean them up if it is foul brood. IOWA.

ANSWER.—There is no appearance of foul brood, and I'm not sure there is any disease at all in the case, but it seems different from anything I ever saw before. The cells that are sealed, when the capping is picked away, seem to be entirely empty and clean, as if the bees had just sealed them up for a joke. Can it be that some very minute insect has eaten out the contents of the cells?

Bee-Paralysis.

"Past blessings do not suffice; I am still needy." I mean I have another question that I would like to have answered through the American Bee Journal.

I have a colony of bees that are afflicted with some malady, and I want a cure. The colony is a first swarm of last season; it was in good condition last fall and wintered all right, being strong this spring. About three weeks ago I noticed something wrong. Quite a number of bees—perhaps two to four dozen—each day crawl out, or are hauled out of the hive by the other bees. They remain on the alighting-board or crawl on the grass around the front of the hive, and are unable to fly, but keep up a constant motion with their wings for a few hours, then die. The most of them look natural, though some are very black, hairless, and shiny. In other respects the colony seems all right, working when the weather is fit, carrying pollen into the hive and rearing brood. What should I do in the case?

I find nothing in the books that covers it, unless it be "Bee Paralysis," mentioned in "A B C of Bee-Culture," and this, to my mind, does not quite cover it.

I am anxious to do what is needed as soon as I learn what that is. OHIO.

ANSWER.—If your name was Mississippi or Florida instead of Ohio, I would say that I could only condole with you without the slightest hope of helping you. Seeing you are as far north as Ohio, I can bid you dismiss your fears, and let things take their course. Your description so clearly given leaves no doubt that your visitor is bee-paralysis. I had one case so bad that I broke up the colony. But that was the only case so bad. I've had many another case, but the colonies suffered only temporary loss, and I never paid any attention to it. I'm not sure that I've seen anything of it for three or four years.

Preventing Further Swarming—Young Queens.

In the winter of 1900-01 I read one or two articles in the magazines and papers relative to bees, and caught the fever. I borrowed some late American Bee Journals and a text-book, and "read up" some more, and in May, 1901, I purchased a nucleus of three frames in a dovetailed hive, the rest of the frames with full foundation. The queen was a tested Italian, and proved very prolific, as she led out a good swarm, June 26, which was successfully hived.

August 1 the original purchased queen led out another swarm (colony No. 2), which was also secured and properly hived, thus giving me three colonies. We secured about 40 pounds of section honey.

I put these three colonies into winter quarters out-of-doors, and they wintered all right, and have been so industrious that on May 16 colony No. 1 (the purchased queen's first daughter) led out a swarm, and May 18 colony No. 2 (the purchased queen's second daughter) led out one also, both of which are now at work in their respective hives.

So much for the history of my bee business. Now for the questions I wish to have answered as soon as possible.

After the two swarms spoken of above were cared for in their new homes, to prevent further swarming for the season if possible, I proceeded to cut out all but one queen-cell in hives No. 1 and 2.

1. Was that a wise thing to do?

2. How soon should the new queens be hatched, and out on their bridal-trip, and the hives examined to find the queen?

NEW HAMPSHIRE.

ANSWERS.—1. Yes, if it was desired to have the strength divided equally as possible between the swarm and

the mother colony. In many cases it is better to throw the main force into the swarm, getting a good yield of surplus from that, and expecting the old colony to do nothing more than to get a good ready for winter.

2. I don't know, for I don't know the age of the young queen in the cell you left. When no cells are cut out, and no second swarm issues, the young queen may be expected to emerge from the cell in about a week after the prime swarm issues, and that would also be the case if you cut out the cells immediately after the issue of the swarm, leaving

a sealed cell. But if you waited several days before cutting out the cells, you may have left a younger cell, for the cells will vary as to the time of being started, and consequently as to the time of the emerging of the young queen. The queen will take her wedding-trip when five days old or older, and you may look for eggs when she is about twelve days old. She may begin laying when eight or ten days old, but it is well enough to delay looking, as it is not so easy to find the first few eggs, and if you do not find them easily when she is twelve days old, you may fear something wrong.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested	1.50	8.00	15.00
Selected Tested	2.00	10 50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Quirin the Queen-Breeder,

PARKERTOWN, OHIO.

[Parkertown is a P. O. Money Order office.]

15A26t Please mention the Bee Journal.

DAIRYMEN ARE DELIGHTED to meet those who work for us. Cow keepers also have money. We start you in business. You make large profits. Easy work. We furnish capital. Send 10 cents for full line of samples and particulars. DRAPER PUBLISHING CO., Chicago, Ills.

Please mention Bee Journal when writing.

3-Frame Nuclei For Sale.

We have arranged with a bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei of bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing.

□ The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 or more at \$2.75 each.

□ All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

To Boston and Return at One Fare

for the round-trip via Nickel Plate Road, for Christian Scientists' meeting in June. Tickets on sale June 12th to 14th, inclusive, with extended return limit of July 31st. Write John Y. Calahan, General Agent, 111 Adams St., Chicago, for detailed information.

9-23A2t

Getting Along Very Well.

I am getting along very well in the bee-business. I started three years ago with 9 colonies, came out this spring with 42, all in good shape. I have had a dozen swarms this spring, and am looking for more every day.

I had 1800 pounds of honey last year. The American Bee Journal has been a great deal of help to me, as I was a beginner and did not know it all, neither do I yet.

T. S. ELLIOTT.

Delta Co., Tex., May 18.

Prospects Good.

I prepared for winter last fall 20 colonies of bees, leaving them on the summer stands, by putting winter-cases over them. I lost 2 colonies. The balance are in fine condition, uniform in strength, with a large force of workers.

Prospects for a honey crop are good. Wood Co., Ohio, June 2. M. N. SIMON.

A Warning to Bee-Keepers.

The Arkansas Valley Bee-Keepers' Association desires to say, that except in a few localities this valley is overstocked to such an extent that any increase will sensibly augment the overstocking; that in the last few years the averages of the best located have decreased fully one-half, and that further coming of bees among us from abroad is not advisable, and by us not desired; that in all not fully occupied places the natural readjustment of apiaries will very soon fill all spots; that early cutting of alfalfa is the rule; and that large tracts of land are being turned to the raising of sugar beets, still further reducing pasturage.

Our Association, therefore, desires to lay the facts before the readers of the American Bee Journal, and expresses the hope that this communication may be of some good.

Adopted as the unanimous expression of this Association, this 3d day of May, 1902. Otero Co., Colo. J. K. WASSON, Sec.

Just Started With Bees.

I have just started in the bee-business. Last winter my father purchased 4 colonies of bees and 5 empty Langstroth hives. He gave them in my care, and I wish to do the best I can to take care of them.

They wintered well and came out strong this spring. They are nearly all Italians. In a shady place they hang out on the hives like swarming. I gave them ventilation according to the American Bee Journal. KYLE INK. Richland Co., Ohio, May 23.

Fastening and Cutting Foundation.

I told you how I fastened foundation in extracting frames some time ago, and requested an explanation of a better way, if any one had a better way. No one seemed to think the job needed any special instructions, or else they had no better way themselves. My way didn't exactly suit me, so I tried several other ways, and finally struck the following:

Take a common machine-oil can, with plenty of spring in the bottom, wrap it with a

QUEENS—Try Our Stock.

DAVENPORT, IOWA, Dec. 31, 1901.

Your queens are fully up to standard. The honey queen that you sent my brother takes the lead. She had a rousing colony when put up for winter. The goldens can be hand ed without smoke or veil.

Very truly yours, JOHN THOEMING.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

heavy coat of asbestos-paper to retain the heat longer and make it cooler to handle; fit a short, stubby, fine-pointed nozzle for the spout, fill it about one-half full of beeswax, and set it over the smoker until the wax is melted. The rest of the job needs no explanation, as any one intelligent enough to keep bees at all can invent some handy way to handle it in getting the foundation in.

While I am at it I am going to tell you how I cut my section foundation. I make 7 or 8 starters of each sheet of wax (I use none but the Extra Thin). Make a cutting box similar to a common miter-box, and cut the pieces about as much triangular as 7 or 8 starters to the sheet will cut. I have not found it necessary to use bottom starters. Should one prefer them a narrow strip can be cut from the sides of the sheets for such starters. Being somewhat proportioned like naturally built combs, sufficient bees are not apt to cluster on them to pull them loose at their greater proportioned fastening surface than if cut square; besides, if it is not set in the section perfectly square it will not matter, as the edges can not come in contact with the sides of the section, which will cause a square one to "buckle" if not exactly true.

Try a few my way and report. May be you have a better way; if so, out with it.

Sioux Co., Iowa, May 20. F. W. HALL.

A Corncob Bee-Feeder.

I wanted an available something to feed my bees early this spring with a view to encouraging brood-rearing to strengthen my rather weakened colonies. I thought over some of the suggestions that I had seen advanced—the wet cloth, the perforated cau, the sponge, etc., but somehow I stubbornly insisted there might be a better way.

Ah, I thought so. First I put on an empty super over the brood-chamber, then I shelled a dozen big ears of corn, brushed the fuzz off the large cobs, tied them together corduroy fashion that they might hold together, and, having my thick sugar syrup ready I soaked them in it and laid these cobs over the frames. Of course, every cavity where the grains grew was filled with the syrup, much like the cells in their wax, permitting the bees to sip out the syrup (honey would have been better) at their leisure without the fear of running over the combs faster than the bees could take care of it. In renewing the feeding after the first time I simply poured the syrup carefully over the cobs, without removing them, from time to time until the bees could gather from the blossoms.

The utility of this method must be apparent at first glance. The feeding is perfect, the cobs reasonably available, and the cost admittedly light. Result: Big colonies.

This is a hint for our farmer boys. Try it, and you will be pleased.

In trying them, alternate the big ends with the small ends of the cobs; they will then fit better.

YOUR UNCLE FRANK.

Hard Time for Bees.

This has been a very hard time for the bees. The winter was unusually severe, the month of April having only a few days warm enough for the bees to fly. The first half of May was very cold, and now apple-trees are in bloom, and during the past three days another cold wave has been here, and hardly a bee able to leave the hive. Unless next month is very favorable the crop of white honey will be very small. A. W. SMITH.

Sullivan Co., N. Y., May 30.

A Favorable Spring.

I bought 2 colonies in box-hives during the winter of 1900, and transferred to 8-frame hives in June, and increased to 4 by transferring the brood three weeks later, all of which made good colonies. My place is in Limestone County, about 18 miles from home, hence I am there but little of the time, which I find does not suit to make a success of bee-keeping, yet I have learned enough to believe firmly that an experienced bee-keeper can do well in that locality. There are a large number of sourwood trees there, and the honey

from them surpasses any I have seen, both in flavor and color, being as nearly pure white as it is possible to be, I think.

Owing to the dry weather last fall, and there being no clover fields, the fall flow was light, but so far the spring has been very favorable indeed. I have taken off several sections of nice honey, with the best flow yet to follow from sourwood.

(GEO. W. PARKER.
Morgan Co., Ala., May 28.

Honey for Horses.

Molasses is very much used for mixing with food for stock, and I don't see why our inferior grades of honey may not be quite, if not more, beneficial. One thing I accidentally noticed during the past season was that a horse can become very fond of honey. I extracted my Wyanleigh apiary in a tent, and when I finished and had the honey tinned and removed I removed the tent, but through want of cartage-room I had to leave the cappings, covered up, for another trip. During the night my horse, which is mischievously inclined, and does not stop at opening a gate, removed the cover and helped himself. I fastened the box, but the following night he again helped himself by upsetting everything and scattering the cappings all over the yard. Needless to say the bees started working on the caps. That did not interfere with the horse—he rolled the lumps of caps to one side to disturb the bees, and finished the spilt caps during the day. Altogether about 30 pounds of cappings were eaten by him in the two nights. Here is the point: That horse was troubled with an itchy skin, and was continually tearing the hair off his head, tail, and body, by rubbing on sharp projections. A few days afterwards he got all right and ceased to scratch the hair off. I believe the honey was the cause of the cure, though the wax may have had something to do with it. If honey was the cause, could not our inferior honeys be used for keeping horses and other stock in healthy condition?—Editor Pender, in the Australasian Bee-Keeper.

Long-Tongue Bees.

"A York County Bee-Keeper" says in the Canadian Bee Journal:

By the way, Mr. Editor, have you noticed how the "long-tongue" craze is slowly dying out? From the way the queen-breeders went wild over it we could expect nothing else, and then Prof. Gillette's experiment was the "straw that broke the camel's back." Last fall, while talking with a friend, I ventured to predict that in one year from that date, not one queen-breeder in a dozen would mention long tongues. Judging from the ads. up to date, I believe such will be the case.

The Swarthmore System of Nucleus Management.

This is reported upon unfavorably in Gleanings in Bee-Culture by "Queen-Breeder," who seems to have tried it on a large scale, having as many as 320 nuclei. He says:

In due time I found, by examination, eggs deposited in about 200 boxes, which I marked for convenience. The remaining boxes were, many of them, queenless, and others with queens evidently not fertilized. I gave virgins to the former, and awaited developments with the latter.

Of the 200 boxes containing eggs, I supplied 100 with queen-cards, to be kept until the brood hatched for warranted queens, etc. I had some orders for untested queens to be filled in a short time, and congratulated my-

An Italian Queen Free!

We would like to have our regular subscribers (who best know the value of the American Bee Journal) to work for us in getting NEW subscribers. We do not ask them to work for us for nothing, but wish to say that we

will mail ONE FINE UNTESTED ITALIAN QUEEN for sending us ONE NEW subscriber for a year, with \$1.00; or 2 Queens for sending 2 new subscribers, etc. Remember, this offer is made only to those who are now getting the Bee Journal regularly, and whose subscriptions are fully paid up.

In case you cannot secure the new subscribers, we will mail one of these Queens for 75 cts., or 3 or more at 70 cts. each; or the Bee Journal one year and a Queen for \$1.50.

(Please do not get these offers mixed up with our Red Clover Queen offers on another page.)

self on having the other 100 queens to apply; but, alas!

The best-kind plans of mice and men gang aft a-gley And leave us naught but fear and pain for promised joy.

Well, I went to these little colonies, expecting, of course, to find in each a fine, healthy queen. Out of the 100 I took 27 queens, all that could be found. The remaining 73 were queenless, and many with queen-cells in various stages of consumption. Here was a direct loss of 73 queens.

He continued his experiments until he had lost more than 200 queens, and thinks the loss largely due to the fact that the bees went visiting from one nucleus to another.

Carniolans and Swarming.

Here is an editorial from the Modern Farmer and Busy Bee:

A. H. Duff says in the Journal of Agriculture, "Carniolan bees are not given to swarming more than the pure Italians, and, perhaps, not as much." There is where you are off, Mr. Duff. If these bees are not properly looked after, if they are left to themselves, they are the worst swarmers we have ever banded.

No Foul Brood in Foundation.

Adrian Getaz says in the American Bee-Keeper:

In discussing the possibility of the transmission of foul-brood spores through wax foundation, a correspondent of a German paper remarks that even if the heat of the melted wax did not kill the spores outright, they would be imbedded in it, and never be able to get out, having no means to burrow their way through it. A coat of wax will eventually kill any living being anyway, by shutting air and moisture out altogether.

Points in the Introduction of Queens.

W. H. Pridgen says in Gleanings in Bee-Culture:

From my experience in introducing queens by using bees from the colonies to which they are introduced, I consider the plan outlined by Mr. Bonney far superior to the usual instructions that accompany shipping-cages. In fact, I have not attempted to introduce one in years with the cage in which she is received without first releasing the escort and caging some of the bees of the colony with her, which invariably treat the queen kindly if very young, or having filled themselves with honey. It also works equally well if the queen be caged in an odorless cage without any bees, but still better to use the bees and odorless cage, or the odorless cage without the bees, first scented by allowing the queen to be superseded to remain in it an hour in the hive; but I prefer scenting the cage with the old queen, and then using the bees with the queen to be introduced, either by placing her in it and selecting the bees one at a time, or allowing them to go in, which they quickly do in search of their mother, and close them up for awhile and then allowing the queen to run in.

One advantage worth considering in having bees with the queen is that she is less liable to be damaged by the outside bees by getting hold of a leg or wing. I am partial to side-comb cages, as the queen is placed right down in the cluster; but instead of relying on hatching brood, young bees are at once put into the cage with the queen, through a hole near one corner, as large as a leadpencil. The hole is stopped a day or two with a cork, and with candy when the cork is removed, thus allowing the bees to release the queen, and combining the good points in the different methods. A great deal of this is too complicated for a novice, and no doubt for that class the usual instructions are best; but before being too confident of uniform success by pasteboarding, it should be remembered that, when queens are sent by mail, bees, cage, and all partake of the scent of the mails, and from this source much of the

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

Queens Now Ready to Supply by Return Mail

Stock which cannot be excelled. Each variety bred in separate apiaries, from selected mothers; have proven their qualities as great honey-gatherers.

trouble arises, and there will not be the success that attends the same plan if the queen be changed to a fresh cage, thus removing much of the odor.

Bees will often destroy their own queen if given back after having been caged an hour or two with some of her own bees in a cage that has an odor that is transmitted to the queen.

Inasmuch as Dr. Miller was impressed by the fact that bees caged with a queen from a different colony were kind to her, I wish to say that, when robbers are bad, I often prepare a number of cages with escorts, by selecting the returning young bees that are taking their playspells, and find that it works well, as they always treat the queens kindly, are exactly the right age, and I have only to keep the nuclei open long enough to find the queen.

Upon this Editor Root comments as follows:

When Dr. Miller first spoke of his plan in his Straw (page 680, 1901) I did not take much stock in it; but I am free to confess that there must be something in it after all. Caging the bees, and keeping them so until they have a real sense of their confinement or loneliness, no doubt puts them in a condition where they are ready to take up with any queen. When they are given back to the whole colony having the same scent, the new queen with them, all goes on lovely. But, as Mr. Pridgen points out, it is doubtful if the beginner would be able to recage or change the escort. But the advanced bee-keeper may well give it a trial. I should be pleased to hear from others.

Queenless Colonies in Spring.

The following is taken from the report of the Ontario convention in the Canadian Bee-Journal:

QUESTION—What is best to be done with the queenless colony early in the spring?

Mr. Hall—If it has lots of honey I would simply pick it up and put it on top of one that had a queen and not much honey. If I hadn't one in the condition I would simply shake off the queenless bees and preserve the comb, honey and hive for future use. Beginners always fancy they must introduce a queen as soon as they find that a colony is without a mother. They are just wasting their time and money, as a rule. I used to be bothering about that sort of thing, but I haven't done so these 12 or 14 years.

Mr. Dickenson—I quite agree with Mr. Hall; that is my experience exactly. It does not pay to introduce a queen to a colony that you discover is queenless in the spring.

Early or Late Setting Out of Bees.

I mentioned in our last issue that we set out all the bees from both cellars along from the 20th to the last of March, and gave them one or two days of flight. The location of each hive was marked so that, when the bees were set out again, each colony would go back to its own stand. This may not have been a necessary precaution, but we felt that it was wise to err on the safe side. All the bees were kept in the cellar till along the first week in April. About 100 colonies or nuclei were set out of the home cellar, and left out. The rest were confined till about April 20, when they were put out. But in this case Mr. Wardell thinks the first lot of bees are in better condition than the second lot. The former have brood in all stages, while the latter have nothing but eggs, and it looks now as if the first bees had about two weeks' start over the others in brood. This seems to contradict my footnote on page 186 of this year, wherein I said I believed it was the best policy to keep the bees in until the first of May. A year ago, about this time, we set out some bees early, and some not till May. We thought the last lot of bees had the advantage over the others, because there was a storm on April 20, and the snow lasted for several days, with a good deal of cold weather.

It is hard to tell just when to set bees out; but obviously it would have been better this year if all the bees had been set out about

the first of April. Last year the latter part of the month would not have been too late.

We have determined that we will do this. Next year we will set the bees out the first of April, if the weather is suitable; and if it should turn cold we will put them back in the cellar and keep them there till it moderates again. From Editorial in Gleanings in Bee-Culture.

Split Hickory Vehicles—The Split Hickory Vehicle advertisement of the Ohio Carriage Mfg. Co., of Cincinnati, is still running in our columns. We do not know how many of our readers have availed themselves of the generous offer of the Company to sell one of their buggies on 30 days' free trial, to be paid for if approved, or to be returned without obligation or cost if not satisfactory. Certainly, the proposition must appeal strongly to them. The vehicles turned out by this company have a wide use and popularity, and the free trial plan of selling enables the proposed purchaser to examine and test thoroughly at his leisure, and to be thereafter guided solely by his own judgment as to whether he shall purchase or not. Coupled with the above is one other decided advantage, that of buying direct from the factory and saving the profits which necessarily go to middlemen in making purchases through dealers or local agencies. If the vehicle problem confronts any of our readers they would do well to write for the Company's free illustrated catalog. Look up the advertisement, and kindly mention this paper when writing.

"What Happened to Ted"

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 3/4 inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON, 227 EAST OHIO STREET, CHICAGO, ILL. Please mention Bee Journal when writing.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

SWEET CLOVER

And Several Other Clover Seeds.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 7.—The honey market is in a waiting attitude; there is more comb on sale than for several Junes of recent years; most of it is out of condition from one cause and another, chiefly by having grained; therefore a very light yield this year would not help the crop now on hand of last year. Prices are without special change in either comb or extracted honey from those given last. Consumers are not in the market for other than small lots. Beeswax is very scarce and brings 32c upon arrival. **R. A. BURNETT & CO.**

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5 1/2 @ 6 1/2 c; better grades from 7 @ 8 c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27 @ 30 c. **THE FRED W. MUTH CO.**

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Same comb honey is selling at 14 @ 15 c. Extracted, 6 @ 6 1/2 c. Beeswax, good demand, 30 @ 31 c. **H. R. WRIGHT.**

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13 @ 14 c; dark and amber, 11 @ 12 c. Extracted, white, 6 1/2 @ 7 c; dark and amber, 5 @ 6 c. Beeswax, 29 @ 30 c. **M. H. HUNT & SON.**

NEW YORK, May 19.—There is a limited demand for comb honey and prices range as follows: Fancy white, 14c; No. 1, white, 13c; amber, 11 @ 12c; no buckwheat or dark on the market and no more demand for any. Market on extracted remains very inactive. Plenty of supply with only fair demand. We quote: white, 5 1/2 @ 5 3/4 c; light amber, 5 @ 5 1/2 c; southern, in barrels, 50 @ 55 c gallon. Beeswax firm at from 30 @ 32 c pound, according to quality. **HILDRETH & SEGELKEN.**

CINCINNATI, June 7.—There is hardly any change in the honey market. Comb is not moving much, and whatever is left can be bought at cut rates. Water-white is selling from 14 @ 15 c. Extracted is in fair demand and finds steady sales, in barrels, 5 @ 5 1/2 c; water-white alfalfa from 6 @ 6 1/2 c; white clover from 6 1/2 @ 7 c. Beeswax is coming in more freely and sells for 28c. **C. H. W. WEBER.**

SAN FRANCISCO, May 14.—White comb, 10 @ 12 1/2 cents; amber, 7 @ 10c; dark, 6 @ 7 cents. Extracted, white, 5 @ —; light amber, 4 1/2 @ —; amber, 4 @ —. Beeswax, good to choice, light, 26 @ 28c; dark, 24 @ 25c.

Spot stocks are not of heavy volume, but there is more offering than can be accommodated with prompt custom at full current rates. Business now doing is mostly of a light jobbing character on local account.

WANTED!

Honey and Beeswax. Mail sample and state price delivered Cincinnati. **C. H. W. WEBER,** 2146-2148 Central Ave., CINCINNATI, OHIO. 21A1f Mention the American Bee Journal.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 23, 1902.

THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market. J. B. MASON, Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

* Editorial Comments. *

General Manager of the National.—We have received the following announcement from Acting Chairman E. R. Root, which is self-explanatory:

EUGENE SECOR STILL GENERAL MANAGER OF THE NATIONAL BEE-KEEPERS' ASSOCIATION.

Some little time ago it was announced that Mr. Eugene Secor, General Manager of the National Bee-Keepers' Association, had sent in his resignation, and that the Board of Directors had selected E. T. Abbott, of St. Joseph, Mo., to fill out his unexpired term. But the Board, in reviewing its work, after a great deal of writing back and forth, during which valuable time has been lost, finally discovered that Mr. Secor's resignation was never formally accepted; that the procedure was irregular and out of order by which Mr. Abbott was supposed to be elected. Some complications having arisen, it was decided by the Board not to accept Mr. Secor's resignation, and to request him to fill out the unexpired time, or till the next general election. To this Mr. Secor has agreed. All dues and membership fees, hereafter, should be sent, as before, to Mr. Eugene Secor, Forest City, Iowa, who is still the General Manager, and will continue to be such till his successor is elected and qualified.

E. R. Root,

Acting Chairman of Board of Directors.

The Honey Crop of 1902.—Editor Root says in reference to this:

From various letters that we have received from the southern counties, I am now convinced that this will be an off year, and that California will not cut much of a figure in the Eastern markets. There will be some honey, of course; but it will make no great flurry, and therefore prices all through the United States ought to be and will be reasonably firm.

There are some other reports from the East that indicate that the season has been very backward. It has been very much so in this locality. It has been cold and chilly. Brood-rearing has been held in check, and the bees are "snappy." Mr. Doolittle says the season has been very discouraging in his locality; and so, taking it all in all, there ought to be a general toning of prices, East as well as West.

Hon. J. M. Hambaugh, Foul Brood Inspector for San Diego Co., Calif., wrote June 4 as follows concerning the honey crop prospects in his locality:

"There has been no rain since my last. Bees are doing practically nothing. The crop is paralyzed, and our countenances elongated. Barber's fees exorbitant! Send us a fan! I am very confident if you were depending on this locality for your honey to speculate on, the demand would exceed the supply, and the 'bulls' would be on top."

The foregoing is certainly discouraging for some California bee-keepers. We hope it is not general throughout the State. We would like to see California have a good average crop this year. Of course, we wouldn't want her to have so much honey that the price would be lowered to

almost nothing—she wouldn't want that herself. But it would be encouraging to her many excellent bee-keepers if they could all average say 100 pounds to the colony.

There is no disputing the fact that in northern Illinois the season up to the first of June has been one of discouragement; and now when white clover has been in bloom a number of days, and honey should be going into the supers at a lively rate, the bees in some cases must be fed to prevent starvation. But there is no need to give up in despair, if only the colonies are strong. There have been seasons when bees were starving in the first half of June, and yet conditions changed and a good crop was secured. It must be admitted, however, that there have been seasons in which white clover abounded, and yet the bees seemed to get no nectar from it.

Cutting Out Drone-Comb has been recommended to aid in preventing swarming. On the contrary, Rud. Dathe (Centralblatt) says it hastens swarming, for the vacancy thus made gives a more convenient place for starting queen-cells.

Quality of Queens Reared in Cell-Cups.—Arthur C. Miller having said in *Gleanings in Bee-Culture* that since the introduction of the cell-cup plan there were increased reports of inferior queens, G. M. Doolittle replies in the same periodical:

"Yes. I noticed what Mr. Miller had to say in this matter; and my mind went back to the early 80's, when Mr. Alley's book on queen-rearing came out. I have been a careful reader of our bee-papers, and have noted many things; and one of the things which I have noted is that, in proportion to those buying queens, there are not nearly so many reports of poor queens to-day as there were during the 80's. In other words, the reports of poor queens are little if any greater now than were such reports during the 80's, while the queen-traffic of to-day has reached gigantic proportions beside what it was then. This shows that the cell-cup plan has been a success beyond anything previously known, does it not?"

Hiving Swarms With Dynamite.—Mr. Adrian Getaz sends us the following sad account of an attempt to hive a swarm of bees with the use of dynamite, as given in a Knoxville, Tenn., newspaper, dated June 6:

While attempting to hive a swarm of bees at his home on the Sevierville pike, six miles southeast of the city, Thursday afternoon, Matt Lopasser, a farmer, suffered the loss of his right arm near the elbow, several injuries about his face and body, and internal injuries which may result fatally.

Lopasser had been experiencing some difficulty in hiving a large swarm by the usual methods of beating on tin cans, ringing bells, throwing water on the bees, and others commonly in use. He secured several sticks of dynamite, and had been exploding these near the bees, thinking that the jar would cause them to settle, and hiving them would then be an easy process. A stick of dynamite which Lopasser was intending to throw among the bees, exploded prematurely before leaving his hand, and his right arm and hand were blown off below the elbow. His face was badly bruised and torn by the explosion, and it is believed that he

also suffered internal injuries which may result in his death.

Lopasser was rendered unconscious by the explosion, and was picked up and carried into his home, where medical aid was summoned. Physicians who attended the injured man pronounced his injuries of a very serious nature, apt to result fatally. Lopasser is yet very nervous from the shock given his physical system, and is suffering intense pain. He is known to many people in this city, and has the heartfelt sympathy of many friends.

We hope that no one else will ever be so foolish as to try to use dynamite to make a swarm of bees settle. About the only thing likely to be "settled" is the bee-keeper himself, as was Lopasser. Of course, we are all sorry for him, though no one will be able to understand how he could take such a fearful risk.

Cover Over Super.—"A Reader" sends the following clipping:

There is nothing better than enamel cloth over sections when on the hive. The bees do not glue it so tight as they do a board, and if you wish to see how the bees are progressing, just fold back one corner and peep in, keeping the bees back with a little smoke. With a board, one is compelled to open the whole top at once, and the bees rush out all over, and when putting the board on you are apt to kill some of them.

There is room for division of opinion, and some who have thoroughly tried enamel cloth over sections are emphatic in their preference for a board cover with an airspace. It is true that with the enamel cloth you can uncover only a small part of the sections while with the board cover the whole must be uncovered. But does it often happen that one wants only a corner uncovered? and will not the smoke that keeps the bees back when a corner is opened also keep them back when the cover is entirely removed? Of course, it will take more smoke for the whole than for a part.

That when enamel cloth is used "the bees do not glue it so tight as they do a board," is apparent rather than real. As a matter of fact, the cloth is glued down tighter than the board cover, but it is easier to remove, because the peeling off of the cloth raises only a small portion at a time. But a good deal more glue will be found in case of the cloth as compared with the board. Wherever the cloth touches the sections the bees will put propolis, and they will push up the cloth to crowd in the propolis, so that the tops of the sections will be much cleaner under the board.

An occasional thing that is perhaps the worst feature in the case is that the bees sometimes take the black matter that forms the surface of the enamel cloth, and incorporate it in the beautiful white cappings of the sections. But that does not often happen.

Keeping Honey in a Refrigerator.—A clipping received contains the excellent advice to keep honey in a hot and dry place, saying: "It should never be put in a cellar or refrigerator, for the honey will absorb moisture, become thin, watery and sour." There could hardly be a worse place to keep honey than in a cellar, unless it should be in a climate where cellars are remarkably dry, but it is not safe to jump to the conclusion that because the air in a refrigerator is cold the matter of moisture would be the same as in a cellar. The women-folks will tell you that cake and other things put in a refrigerator will dry up. Why not honey?

Annual Consumption of Honey Per Colony.—Adrian Getaz figured this at 200 pounds. Editor Root thinks it would hardly amount to more than 100 pounds in his locality, but admits the possibility of its being 150 or 200 pounds in localities farther south, where bees are active throughout a greater portion of the year.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 374.)

BEST RETAIL PACKAGE FOR HONEY.

"What is the best retail package for extracted honey to be sold in a grocery trade?"

A Member—Mr. Walker can answer that, as he knows more about this than any one else.

Pres. York—I suppose what is meant is the material to be used, size, etc.

Mr. Horstmann—I would consider one-pound jars to be the best.

Mr. Walker—I wish to take exception to that. In speaking of the Chicago market, one-pound jars are altogether too large for ready sale. Three-fourths pound is far better; there is five times as much handled in $\frac{3}{4}$ -pound jars as in one-pound. The average consumer doesn't want to put more than 15 cents into honey at a time, and a good many only want to put 10 cents in. Though I have used tin a great deal to put up honey, I find that at present there is very little demand for anything put up in tin. I think the 10 and 15 cent packages cover the ground pretty fully. We have some demand for large packages, but not very much.

SHIPPING COMB HONEY.

"What is the best way to ship comb honey long distances?"

Mr. Riker—By freight, and have it smashed up; it is pretty well smashed up when it gets to the commission men anyway you ship it.

Mr. Johansen—I have read that in order to ship honey long distances you would have to put top and bottom starters in the section, otherwise the combs will break. If there is any one who has had experience in shipping honey long distances, and there is a way to fix the sections, that is what I want to know.

Pres. York—That is a good way to begin, to put in top and bottom foundation starters. But I supposed the question had reference to the way it should be packed.

Mr. Moore—I would like to sum up this question of shipping comb honey; my experience runs back 15 years. I can remember the first comb honey ever shipped to me, in tight boxes two feet square. I suppose it went end over end, and every time it came down it went smash; the honey was running out at every corner when it got to me. I think it was about four years ago that I first heard of the very best way to ship comb honey. To ship comb honey safely, you want to begin right back to where Mr. Johansen suggested, by putting in starters, so that the combs will be built better; and don't ship any combs except those that are fastened well to the wood. There is just one way to ship comb honey so that it will always get there right, that is, to make a crate to hold six or nine 24-pound shipping cases, with handles the whole length of the crate, so that two men can take hold, one at each end, and carry it out of the car without dropping it or kicking it around, or dumping it down. I have seen persons handle large amounts and not have a section break. As I understand it, that is the only way to ship comb honey.

Mr. Johansen—I want to ask about the handles.

Mr. Moore—They should be at the top of the box. You go down to Mr. Burnett's and ask him to show you what he considers an up-to-date crate for shipping honey; in a glance you will see the whole thing. The honey that is being shipped that way comes almost invariably safely, and every day honey shipped the other way comes smashed up like pie would be if shipped, and in very bad shape.

Mr. Dadant—I want to tell you a little story in regard to shipping comb honey with handles on the boxes, that two men can catch hold of and carry. We struck that idea when we first shipped comb honey, 35 years ago. We

used to ship our honey to St. Louis on the steamboats on the Mississippi in the river boats, and we didn't go along, and could not understand why our honey should arrive broken. After three or four years of more or less failure, I went down with some honey, and found out that those big, strong darkies—those roustabouts—didn't think that it was worth while for two men to take hold, and one man took the whole thing on his shoulder and dropped it down when he got to the place where it was to be deposited, and usually broke every comb; that is all the good the handles did.

Mr. Purple—Mr. Dadant didn't make it heavy enough. If made like Mr. Moore said, two or three hundred pounds, they could not then pick it up in that way; it would take two men to pick that up.

Mr. Johansen—I want to know more about the starters in the sections. If the sections are filled with starters all through, wouldn't that be damaged by the sealing of the honey; would that be pleasant for the persons who eat it, if they found wax right in the middle of that section? Has any one had experience in that line?

Dr. Miller—I might say in answer to that, for a great many years I have filled sections almost literally full—a foundation starter at top and bottom, a little more than half an inch wide at the bottom, and the starter from the top coming down so they almost meet, making foundation from top to bottom when finished, and I never had any complaint about it. It tastes all right; I have no objection to it, nor my family. I suppose if you used a foundation heavy enough there might be trouble, but using a foundation as light as thin foundation—not extra thin—you would have no difficulty. I usually use the same grade top and bottom. If I thought it advisable to use the extra thin at the top, I should simply use the thin for the bottom, because the extra thin I should think would fall down.

WORKING UP A PAYING HONEY-TRADE.

“What is the best plan for working up a paying demand for honey in a city market?”

Pres. York—Mr. Moore ought to be able to give us something on that.

Mr. Moore—I have nothing to say, Mr. President. Why, a question like that is a little like a question I put in one time to make fun, and I was never more pleased with myself in my life than with the result of that question. I had a lot of fun over it. There was one question put in which I didn't give at all, and Dr. Miller answered that very finely. He said, “That is the Secretary who put in that question.” Then when my question did really come along the Doctor gave us the finest talk of his life, but I was not blamed for it! But this question is like, “How shall I make money in Chicago?”

Pres. York—Sell honey. (Laughter.)

Mr. Moore—It is a lifetime business. Above all, it means to get out and get acquainted with people you are going to sell honey to, and that, it seems to me, is a settler of the whole question. Get out and see them; go up and down the streets and get acquainted with people day after day, month after month, and year after year. If you are an honest man, and have good things, good goods, they will swear by you, and that is the way, the only way, to make a market for anything in this 20th Century. You can stand here and talk a week and not cover the subject, but I believe if you have the hustle in you, and energy, and go where there are lots of people, like in Chicago, and have a good article of honey, and will get out and keep at it, you will make a success. It is the eternally and everlastingly keeping at it: no matter if you don't sell this time you will another. Don't slam the door if you don't get an order. Just close it gently; give everybody a kind word. They will say, “That is funny; that fellow shut the door gently and I didn't give him an order.” You might say the same thing of the honey trade as of the hardware trade. Give good goods, and charge good prices for it; you don't gain either respect or money by selling things cheap.

Pres. York—I think Mr. Moore has reference to family trade; what about working up a demand in any other way?

A Member—Get an office on South Water Street.

Mr. Horstmann—I have been very successful in getting rid of my honey, and about 500 pounds of a friend's honey. I have my apiary right in the yard where everybody can see it, and I keep it as neat as I can. I have the hives nicely painted. People passing on the street can see it; some call it a graveyard, and others something else other than beehives. It is an advertisement for me. They learn that honey is produced there, and they come right to the house and get it. I sold over 2000 pounds of honey without canvassing. Next year, if I have success, I expect to produce

close to two tons, and I believe I will sell it all in the same way. You ought to have your apiary in as neat appearance as possible; that is what I try to do, so as to attract attention. People will see the hives and begin to talk about them; they will know that honey is produced there. Sell them a good article, and they will come back. If anybody comes around I always show them my apiary, and talk about bees. I think I am known for miles around for selling honey. I have sold my section honey for 20 cents a section, or six for a dollar. My extracted honey I sell for 10 cents a pound, the customers bringing their jars and get them full. I have had no trouble whatever in getting rid of my honey. I think I will have to buy some from somebody in order to supply my customers.

Mr. Moore—I would like to hear from Mr. Dadant; he told the story about selling nearly \$10,000 worth of honey in olden times. I would like to have him tell that.

Mr. Dadant—I wish I had a copy of the story, so I could tell the same one. I don't know exactly what I did say.

Mr. Moore—You told how you sold extracted honey in olden days, up and down the river to the boatmen.

Mr. Dadant—The first honey we sold was comb honey, and we shipped it to St. Louis; then we began extracting, in 1869, I believe. The only persons selling then were the drugstore keepers; they sold two or three ounce bottles for sick people. When I went to the drug-store to offer some nice clover honey for sale, they had never seen anything but strained honey; they said they didn't want that, it was too nice. They thought it was sugar syrup, I suppose. We put our honey up then in 10-pound tin cans. We had been transporting comb honey to St. Louis, shipping it on the boats, and the boatmen all knew us. When they found we were shipping honey in 10-pound cans to St. Louis, the boatmen wanted some. We sold about 1200 pounds of honey to boatmen at Keokuk, Iowa. We sold a great deal of honey in 10-pound cans; then we got up the 5-pound, 2½-pound, and 1¼-pound, and we stopped there, and now people want us to sell it in ½-pound cans. We have not come to that yet, but I suppose we will have to. All we have to say in our neighborhood is, “Mr. Dadant has some honey to sell,” and that is all that the man I have who draws out honey for me has to say, and they give him an order; he has placed in the city of Keokuk about 1300 pounds in a half day; everybody tells him, “Your packages are too large.” After a while the people will do as they do in Paris. There they take their salad-dish to the store, and get one cent's worth of oil, pepper and salt to dress the salad. I doubt that we will get that low. The time probably will come when we will have to sell it in ½-pound cans. I think we will have to come to using glass for putting up small packages of honey; 1¼-pound tin cans are nearly as expensive as glass, and the tin doesn't look so nice. But to sell honey, as these gentlemen say, you have to be known; make yourself known to people; you have to hang on, keep hammering at it; don't get discouraged; keep fighting and disputing. Don't be afraid when people say your honey is adulterated. Don't be afraid to fight; I do some hard fighting when they say my honey is not pure, and generally I convince them that it is pure. I had a gentleman say to me once that my honey was not pure. I told him he didn't know what he was talking about, and I knew that he didn't know, and that he certainly must know himself that he didn't know. I convinced him that my honey was absolutely pure, and he never doubted my word after that, and was very nice to me, although I called him a fool.

(Continued next week.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it

Contributed Articles.

CS₂

BY PROF. A. J. COOK.

To the one who has never looked into chemical science at all, the above will suggest a rebus, and he will whisper something like seeing crooked twice. But how inappropriate! for the bee-keepers who read our "old reliable" American Bee Journal. I take it, rarely see crooked even once. To the one who has looked but little into the marvels of modern chemistry, C suggests Carbon—that which forms much of gun-powder, most of coal, and nearly all of graphite, and all of the diamond. S also recalls Sulphur, the same that coats the end of the match. And CS₂ means to him Bisulphide of Carbon, or carbon bisulphide. The 2 indicates that in a molecule of the liquid there are two atoms of sulphur to every one of carbon; hence the word bi-sulphide. I have been thus explicit as this substance is coming to have a very important place in our fighting of insects. The bee-keeper finds it more pleasant to use in protecting against the bee-moth than is the sulphur alone. And so, before long, sulphuring will very likely be entirely superseded by sulphiding, which, by the way, is a newly-coined word, and will not be found, I take it, in the dictionaries.

The old-time use for this liquid was almost wholly as a solvent of rubber, and so the unpleasant odor of the vapor was rarely met except in the presence of the cobbler, who used it to form his rubber patch to shoe or boot.

The man in our country who has made the bulk of this liquid is Mr. Edward Taylor, formerly of Ohio. I visited this plant some years ago, and was much interested in his work and explanation of how he had improved the process of manufacture. He now makes it by a new electric process, which he has patented, and his factory in New York State is said to turn out 20,000 pounds daily.

It is made by passing the fumes of burning sulphur over red-hot charcoal. The gases of the two unite to form a vapor which cools into a liquid, and this is CS₂. This has a specific gravity of 1.29 at 30 degrees Fahr. It is exceedingly volatile, and when turned onto one's hand cools it greatly by the rapid evaporation. Of course, it will evaporate more rapidly in a warm atmosphere, and when a large surface is exposed. If we throw a spray into a room the evaporation would be almost instantaneous. As it is one-fourth heavier than water, a little water turned into a vessel containing it will largely prevent evaporation, as the water remains at the top. Of course, it must be kept in perfectly close or well-stopped vessels, or when we go for it we will be met by emptiness, as have many druggists of whom I have essayed to purchase a little to use in illustrating a lecture.

The usual bisulphide is not quite pure, and is sold as "Fuma Carbon Bisulphide," a quite appropriate name, as the disagreeable odor comes wholly from the impurities. When perfectly pure it is colorless as water, has a slightly acid taste and a sweetish odor, reminding one of that of ether and chloroform. When perfectly pure it can be poured on the most delicate fabrics, or on flour, and it will very soon evaporate wholly and leave not the faintest show of its previous presence.

The "fuma bisulphide" is slightly yellowish, and will, because of the impurities, often leave a stain, and so its use must be guarded. The vapor will not stain, and so in its use we are safe, if we do not pour the liquid on the cloth or food products. I use it much in ridding my insect cabinets of other insects that are lured to eat them up. I put the cases into the box, close it hermetically by shutting the cover on rubber, and then pour the liquid through an uncorked opening into the box, so that only the vapors strike insect or the paper lining the bottom of the cases.

The vapor which can be detected in all parts of a large room almost immediately after spilling a few drops, is 2.63 times heavier than air, so it of course tends to settle. Thus, unless we use enough to saturate a box or room, the lower portion will be much more dense. This is an important fact to remember.

With care there is no danger in breathing this gas or the vapor. If we are confined in it for long it results in dizziness, nausea, extreme congestion, insensibility, and

death. In filling a mill which it is desired to rid of insects with its vapors, one may suffer considerable inconvenience if they fill from the top to the bottom, while by going from the bottom to the top, no trouble will be experienced. In this case one leaves from an upper window. It acts quite energetically on the heart, so those with weak hearts should use it with extreme caution.

We should always remember in using this substance that the vapors are explosive and very inflammable. A lighted cigar or match in a room containing the vapors would result very seriously. We must use the same caution as we would in using gasoline or naphthaline.

Bisulphide of carbon is now used in killing ants in their under-ground tunnels, as I have often described; in killing other subterranean insects; in destroying insects in mills, warehouses, etc.: weevils in peas, beans, etc.; in destroying moths and beetles that eat our silk and woolen clothing; to some extent in killing insects on living plants by covering with close tent or box; and, last, in protecting our honey from the ravages of the bee-moth. It has strong disinfecting power. Meat will keep in its vapor.

USE TO PROTECT COMBS.

To destroy the bee-moth larvæ or caterpillars, we have only to turn the liquid into a close box containing the affected or suspected combs to be treated in a perfectly airtight enclosure. One pound is ample for 1000 cubic feet, or a room 10 feet each way; so we see it is not expensive. We must remember, however, to keep the cork—rubber corks should not be used—in the bottle or can holding the liquid.

It can be used with so much less trouble and danger than is required to fumigate by burning sulphur, that I feel sure its use is to become well-nigh universal.

The two cautions to be emphasized are: Be wary of fire; and exercise caution in reference to breathing the vapors.

No. 3.—Rearing Long-Lived Queens and Bees.

BY DR. E. GALLUP.

Nearly 40 years ago, or the next season after I moved into Iowa, I had some horses stray away, so I went to hunt them. After finding them it was so late that I dared not venture across the open prairie, so I sought a place to stay over night. I found a man that had some 20 colonies of bees in box-hives, all with large clusters of bees hanging on the outside. This was in July. So I made arrangements with him to stay over night, and in the morning I drummed out a swarm of bees, and explained all the paraphernalia of making artificial swarms, all of which was new to him.

In the course of our conversation he wanted to know whether a colony could be transferred from a log to a hive. He said he had a near neighbor that would give \$5.00 to any one that would do it for him. So we went over to the neighbor's, and he had a basswood log with a big colony of bees in it. The log was about six feet high, and had two hollow branches about 12 inches high above the main log. The log was nearly 18 inches in the clear inside the hollow, completely filled from top to bottom. So you can judge that it was a very large colony of bees, and I was the very chap to tackle them.

They could not see how I was going to manage them without getting stung very badly. The first drumming I got out a half-bushel measure full of bees, but no queen. She probably went up into the other branch. He had movable-comb Langstroth hives with bees in them, so I went to one of them and took out the queen and gave to the half-bushel of bees. In due time I hived them. I turned down the log, sawed it in two in the middle, turned the top half upside down, drummed out another half-bushel of bees, and this time I got the queen, so we had two large colonies of bees, and comb, brood and stores enough for two more colonies in 21 days.

I explained everything to them so they could transfer and fix all up in 21 days. I explained what the bees would do for a queen in the hive where I took the queen away.

In sawing the log in two I discovered one large queen-cell in the top half, and two in the bottom half. We cut one loose from the comb and it fell on the ground. I dissected that cell from the base carefully, and made what to me was a great discovery at that time.

I explained to Mr. Drake how to give one of those sealed cells to the queenless colony in 24 hours; told him how to handle it carefully, etc. He met with perfect success with

all my instructions, and had four excellent colonies; all wintered and came out strong in the spring. No spring dwindling there, you bet, as their queens and bees were the long-lived variety. Why? Because the queens were naturally reared at superseding time.

Mr. Drake had that log in his yard five years, and no knowing how long they had been there before he found it; and it had not swarmed in all that time. It would probably have taken 8 or 10 queens, such as we usually get, to keep the number of bees that were in that log, and 20 queens such as I have received would not do it.

That discovery I will explain farther on, probably in my next article.

A writer some time ago in the American Bee Journal said that he had purchased lots of queens, and but very few lasted one year; 80 percent of the very light-colored ones died the first winter, and none gave the satisfaction of those of his own rearing. I can fully endorse what that writer says; it is utterly impossible to receive the profit from such short-lived, worthless queens that one can from one long-lived, properly reared one; and the former are a loss to the party introducing them, every time.

In olden times we every now and then heard of some one discovering a tremendous colony of bees in a cave, so numerous that they in flying out and in darkened and obscured the sun. Well, there may be a grain of truth in such stories as well as several grains of imagination or falsehood. No one that has not seen as large colonies as I heretofore have mentioned—the basswood log, the colony that I saw taken out of a large dry-goods box at Decorah, Iowa, and my large hive, four times the capacity of a standard 10-frame Langstroth hive, where the bees have been in long enough to rear queens to suit the capacity of the hive—can realize the number of bees that one queen can rear, and that workers will live to be four months old in the working season instead of 30 days, as is the case of three months'-old queens and their workers. Now, by rearing your cheap, inferior queens in a very unnatural manner, you have shortened the life of the queen from 4, 5 and 6 years to from 3 to 18 months. You have shortened the life of the workers in proportion, consequently lessened the production; you have also lessened the vitality.

Last season I ordered 12 untested queens from six different breeders; some of them I received quite late in the season. One received late in May was superseded the first of September. Two reared paralyzed brood; two had winter dwindling—what our Eastern bee-keepers call "spring dwindling."

I sold 10 colonies this spring, and kept two and one black nucleus. One of the Italian colonies is summer dwindling now, that is, the bees are dying off with old age as fast as the queen can supply the loss. She is fairly prolific, but the deaths keep about even with the births. The other is a fairly average colony. The black nucleus has built up to a good colony, having a two-story hive completely filled. It was a starved-out swarm that I picked up last fall, and gave them three frames of comb and two combs filled with honey, one on each side of the empty combs. They went right to breeding, and bred all winter.

A neighbor has 12 colonies, or swarms that he picked up, the first one a very small one taken out of a house, and it is small yet and always will be, as it was somebody's starved-out cheap Italian queen, from all appearances. The bees die of old age as fast as the queen supplies their places; she will never fill the hive.

(To be continued.)

A Bee-Cellar Blasted from the Rock.

Read at the Wisconsin State Convention, held in February, 1902,

BY C. H. PIERCE.

My apiary at Kilbourn is situated at the east end of sandstone bluff, said bluff fronting the Wisconsin river at The Dells, and running due east about 80 rods. The east end of the bluff, where my yard is situated, is about 25 feet above the general level of the ground.

I began at the ground level and dug a trench to the face of the bluff, about 20 feet long, and 6 feet wide. The earth, next to the rock or bluff, was about 8 feet in depth. I then began and blasted out a tunnel, with dynamite, 4 feet in width 6 feet in length, and 6½ feet in height. Then putting the charges in the corners, I widened the tunnel to 8 feet in width and 12 feet in length, making a room 8 x 12 feet.

The rock, being soft sandstone, went all into sand at each

blast, for a space of about 1 to 1½ feet each side of the drill-hole, and as deep as the drill-hole, generally from 24 to 36 inches. We then shoveled the sand into a wheelbarrow and wheeled it outside. The cellar went in very quickly and very cheaply—I believe the last 3 feet we went into cost about \$2.00 for material, sharpening tools, etc.

Two men who understand blasting could very easily go in 3 feet or more in a day.

There are three doors leading into the cellar, also 2 ventilators—one ventilator that brings in fresh air from inside the second door, starts from the floor, and passing into the cellar and escaping near the ceiling; and one for foul air, starting from about one foot from the floor near the center of the cellar, going to the ceiling and passing out-of-doors. There is a door in the foul-air ventilator near the ceiling that can be opened when the air in the cellar becomes too warm.

Last winter I had but 2 doors and 4 inch ventilators, this winter I have 3 doors and 8 inch ventilators.

Now as to its merits as a place to winter bees: Being but the second winter it is hardly a fair test, however. Last winter I put in 30 colonies, 4 of them nuclei on 3 frames. A few days after being put in, the thermometer in the cellar stood at 48 degrees; it gradually went down until the lowest point reached was 39.

There was considerable moisture in the cellar, showing in drops on the ceiling, dead bees in the hive-entrances and on the floor showing mouldy; a long, hairy mould on the door-jamb and ventilators, but apparently no moisture inside the hives. I removed the bees from the cellar April 1, all in excellent condition, with no loss.

This winter I have 57 colonies, 16 of them nuclei on 4 frames. They were put in November 16. A few days after being put in the thermometer stood at 47; lowest point reached so far 43. January 20 the bees were quiet and all doing well. There is very little moisture to be seen this winter; no drops upon the ceiling; scarcely any mould to be seen; moisture shows some upon the inner door, which is painted; also the ventilators feel damp. I lay the little appearance of moisture to the third door and the larger ventilators.

I winter my bees with hive bottom-boards on and no covers. I leave the queen-excluders on for a bee-space over the combs. In the place of covers I put on 2 thickness of a grain bag—a bag cut in two in the middle makes a cover for 2 ten-frame hives.

The hives are tiered up in the cellar with 2-inch strips across the top of each hive, for ventilation.

I expect next fall to widen the tunnel of the cellar where the doors are situated, to 8 feet, the same as the main room; then widen the trench and build two stone walls, with timbers across the top, some porous material on the top of the timbers, and dirt over all, with a board roof over the dirt, giving about ½ of the cellar a porous roof. This will allow all moisture to escape, and, I believe, make a perfect wintering-place for the bees.

Dane Co., Wis.

Making Rapid Increase of Colonies.

BY MRS. F. S. A. SNYDER.

If you have only one colony and wish to increase to 4, just as early as possible begin to feed, and it will pay you to buy a few pounds of extracted honey and feed through a feeder all they will consume. I say extracted honey because bees will decline to store sugar syrup just as soon as the nectar-yields begins. I have experienced this repeatedly, and I think uncapped frames placed in brood-chamber invariably cools the brood and retards hatching.

Now, when the hive is just boiling over with bees, honey and brood, make a box exactly the length of the hive you use, and just wide and deep enough to hold 5 of the frames. Place 5 of the frames containing the most brood, bees and all, in the box, and shake the balance of the bees on a white cloth at the entrance of the box, or really contracted hive, thus crowding all the bees and the queen in on the 5 frames, and close them down with a bee-quilt and one or two newspapers over the quilt, and cover up warm.

Take the 3 remaining frames with the old hive and keep in a warm room with division-boards and a thick blanket—anything to keep the brood from chilling. This is best done just at the commencement of the honey-yield, and if you open the contracted hive with the 5 frames and all the bees and queen towards the evening of the following day, you will be surprised to find from 30 to 40 queen-cells started; mine started 46 in one night.

Now remove the contracted hive off the old stand, and

place the hive with 2 of the 3 combs with no brood, or as little as possible, on the old stand, and let the worker-bees return to it. Now catch the queen and place her with the worker-bees. This makes one colony by adding either combs of foundation, or built-out combs, if you have them.

Now you have 6 frames or combs full of brood, and queen-cells started under the swarming impulse. Place 2 combs each in 3 nuclei hives with division-boards, and by feeding and adding new combs by degrees you will soon have 4 strong colonies. If you have more than one hive you can place the 3 remaining combs over a strong colony, and then it might be better to keep the bees in the contracted hive on the 5 frames for say 3 days, until the queen-cells were more fully matured before returning the queen and worker-bees on 2 or more frames to the old stand; though you must watch them closely or they will swarm out, leaving the completion of the cells to the nurse-bees.

If you have 10 or more colonies you could take 2 frames of brood from each hive and thus utilize the queen-cells before they hatch out, place the remainder of the queen-cells one in each cage in a frame with a little cream candy made of confectioners' sugar and honey, and mixed very thick; put a little of the candy in the corner of each cage, and a queenless nucleus will care for and feed 21 queens. Thus you will have an extra queen to replace any losses during marriage-flight.

If you have more than one colony, and want to stimulate by feeding, close the entrance of each hive to the size of one bee, then tack wire-net right over the entrance, leaving the entrance through the wire at the end. I place the wire-netting right over the entrance. Now have two sticks an inch wide and just the length of the width of the hive, and tack the sticks over the wire, thus keeping it in place. Now tack one end and leave the other end open, just the size of one bee. This prevents the bees from taking a noisy flight in the air and proclaiming to the whole apiary that in some mysterious manner their stores have increased; and in their endeavor to find the outlet they quiet down, and thus prevent the robber-bees from gaining an entrance and making havoc among the nuclei before they are strong enough to defend themselves.

Sonoma Co., Calif.

Killing Bees for Tongue-Measuring.

BY PROF. C. P. GILLETTE.

On page 327, my good friend, Prof. Cook, suggests that my method of killing bees by plunging them into boiling water might set the muscles so as to prevent the full extension of the tongue for measurement. The lengths obtained do not indicate that such is the case, and I am quite certain that the hot water has quite the opposite result.

Some years ago, while a student under Prof. Cook, I was making a study of mites and other very small insects that I wished to mount as microscopic objects. In order to have the specimens suitable for examination, it was important that the legs be fully extended, and not curled beneath the body. I was able to find just one method by which this could always be accomplished without injuring the tissues, and that was to thrust the insect into boiling-hot water, or dash the water upon the insect. It was that experience which suggested the hot-water plan of getting the bees' tongues extended to full length for measurement. If hot water caused the contraction of the muscles, it would result in the bending of the joints of both legs and tongue, and these parts would not be perfectly extensible.

And then, one can not very well wait 24 hours for the tongue to die so it will lie still for measurement; and all this time it would have to be kept in a moist place, or it would be in danger of becoming so dried that it would not fully extend.

I also like to be as merciful as possible in handling lower animals for scientific purposes. When the bee is thrust into boiling water it dies about as quickly as if struck with a hammer; but if the head is simply pulled off, the head and body live for hours. Whether or not these severed parts really suffer pain we can not know. The movements which antennae, mandibles, legs, and wings, still undergo suggest, at least, that sensibility may still be present. The nervous system of the bee is not so centralized in the head as it is in the higher animals.

I am still studying bees' tongues. I have received bees from a goodly number of readers of the American Bee Journal already, but would be glad to receive more. I am specially anxious to have more samples of genuine black bees, of new races of bees, as Carniolans, Cyprians, Syrians,

Caucasians; and bees from best and poorest colonies in an apiary. Also bees that are supposed to have specially long tongues. Fifteen or 20 may be put in a queen-cage and sent by mail.

Fort Collins, Colo.

Bee-Keeping for Women—An Experience.

Written for a New York State Farmers' Institute,

BY MRS. C. A. BALL.

In these days when machinery has taken the place of much of the farm labor that used to be employed, and the milk of the dairy is taken to the creamery, instead of being made into butter and cheese at home, the farmers' wives and daughters have been relieved of much of the labor and care that fell to their lot under former conditions. Yet there is enough to do in every farmers' home; and the round of duties is so nearly the same each day that the monotony becomes a weariness, and some kind of business to occupy a part of the time may prove a diversion, and help earn a little pin-money besides; and it seems to me that keeping a few bees would be a great help.

The other day a gentleman said to me, "Who takes care of your bees for you?" I replied, "No one. I take care of them myself." "But," said he, "what do you do when they swarm?" "Why, I hive them," I replied.

"That is strange," he said. "I did not suppose a woman could do that. When I was a boy my father kept bees, and when they swarmed every available man and boy on the place was called upon to help hive them."

I find that this gentleman's opinion of bee-keeping prevails to a great extent; that running an apiary is too hard work for a woman. Yet the work is no harder than much that falls ordinarily to our lot. But whether a woman can successfully run an apiary depends upon the person herself. A delicate, sickly woman would need some help, but one in ordinary health can do it alone if she is interested in the work. And right here I wish to say if your bees do not possess a fascination for you, you would better let the business alone.

It is like every other business, requiring patient attention to small details. Your bees will not prosper if neglected, any more than other stock. A little care at just the right time may insure a fine yield of honey, or, neglect, a total failure.

For a beginner I would advise starting with one or two colonies, then if you fail the loss will not be so great.

I will give a little of my own experience: In 1895 I bought one colony, for which I paid \$6.00. That summer I got 60 pounds of surplus honey, but no swarm. In 1896 that colony cast two swarms and the three gave me over 100 pounds of nice honey. 1897 was a year of swarming, and my colonies increased to 11, but the honey-flow was a short one. Yet the surplus more than paid expenses. 1898 and 1899 were bad years for bee-keepers throughout the country, but 1900 was the most disastrous of all, yet each year my bees gave me some honey.

At the close of the season of 1900 I had 25 colonies, but I was obliged to move that fall and could not pack the bees for winter, and the result was that last spring I found that fifteen colonies had died, leaving me only ten, and of these only two that I considered valuable. Yet they gave me last season between 400 and 500 pounds of honey, and cast five swarms; another swarm came to me, so that at present I have sixteen colonies, all in good condition. The honey I sold for ten, twelve and fifteen cents per pound, the most of it for fifteen cents.

Some of the dark honey I kept to stimulate the colonies in the spring while rearing brood.

And here let me say that it is not the number of colonies that counts, but the number of bees in each colony, and early spring is the time to strengthen so that the hives will be just running over with bees when the honey-flow begins. Then put on the supers and let them work.

With regard to swarming: Prime swarms usually come out from 10 to 2 o'clock and need close watching. I manage the issuing swarm with water, and can drive them so that they will not cluster out of reach. Last summer I used a dipper to throw the water, but a spraying bucket is better.

When the swarm has clustered I take and shake them on a white cloth in front of an empty hive, then may be seen a wonderful sight. A moment after the tumultuous fall, you will

see them as if obeying some order, turn their heads toward the entrance of the hive and march like a vast army in and upward until they reach the top of the hive, hanging on to each other until they form a dark curtain, and wait for the mysterious secretion of wax to take place with which to build the walls of their new city. Some of the swarm are detailed as guards to the entrance, and some inspect every crevice of the hive and clean and glaze the walls and fill every seam with propolis. The guards at the entrance keep out intruders, and woe to the stranger who comes. But if any of the worker-bees come from the field with soiled wings these guards act the part of dressing-maids, and carefully attend to their toilets, for no bee may enter the immaculate city of the queen with soiled garments, for bees are almost fanatically cleanly.

When I began bee-keeping I used chaff hives, but found them too heavy to handle. Now I use the single-walled dove-tailed hives, which I can handle alone, and use outside cases for winter protection. These hives being bought in the flat, and every part so nicely fitted any one who can drive a nail can put them together.

When working among the bees a beginner needs a beehat with veil, a pair of thick gloves and a good smoker, and the very best is the cheapest in the end, because a poor smoker may fail you when most needed.

With regard to taking off the honey, when I find a super about full I pry it free from the hive with a screwdriver, puff in a little smoke, and place another super with empty sections on the hive, under the full one. In a day or two, about 3 o'clock in the afternoon, I sally forth with smoker and bee-escape board, and, raising the upper super just enough to blow in a little smoke, slip the escape-board between the two supers and leave them until about 5 o'clock the next morning. Then I take off the super full of honey from which every bee is gone, and the colony does not know it has been robbed. Everything is peaceful.

I do not know that I ever enjoyed greater satisfaction than when walking through the dewy grass last summer carrying burdens of white honey, before the majority of people were stirring. With me it has been both success and failure, but the bees have quite a balance in the credit column, and I hope to go on with a work that has been of more value to me than can be reckoned by dollars and cents, in the lessons of patient faithfulness under difficulties learned from the bees.

Oneida Co., N. Y.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

SULPHUR AS A GERMICIDE.

Sulphur smoke is pretty severe medicine for live bees; but those who have been so wicked as to kill light colonies in box-hives in the fall with it know that it takes a strong dose of it long-continued actually to kill. Of its powerful germicide powers there is no doubt. Smoking hive, bees, and all, just to the last point of endurance looks more hopeful than feeding or sprinkling drugs. Seems to me I'd do it the third time, the last time taking the combs alone and smoking them in a box. Page 291.

OLD GRIMES' TOO MUCH TONGUE.

Say, Old Grimes, if too much tongue on the bee is going to make it tumble to the ground from lack of balance, we'll quickly remedy that by breeding on a little more tail. Give us something harder. Hustle is all right, but, you see, we propose to drive Tongue and Hustle in span.

No wonder they thought Old Grimes was dead;
He moved like the clock-hand, void of bustle;
And never a mile did he get ahead,
For his tongue was so long that he couldn't hustle.

KEEPING BEES ON THE "SLY."

Frontispiece, May 15, is what might be called, Keeping Bees on the Sly, or, A Clergyman Queer in His Upper Story. We trust that the queens of surrounding domiciles will not cause any hegira by their "quahking."

MORE ROOM TO DISSUADE SWARMING.

Anent the oft-repeated advice to give the bees room, it may be remarked that they do not consider that matter of room exactly as we blunderingly expect. Nothing is room to them (at least not in any full sense) unless it has comb in it. They do not walk on air any more than men do. Suppose you dwelt in a lowly cabin, 12x20 and 6 feet high, and were about to move for lack of room. Suppose, then, some practical joker of a fairy queen should touch your cabin and, presto, it is 12x20 and 20 feet high. "Now, you have plenty of room, be satisfied," quoth she. You would quickly answer, "The cubic feet are all right, but my feet can not perambulate in cubic feet so far from my head." Empty space may at times help *some*; but it is usually very inadequate as a swarm-dissuader. Page 307.

EXTRACTED HONEY FROM DARK COMBS.

It is a matter of some importance whether honey does or does not extract color from black combs. The general impression one would get from reading the Chicago convention report on the subject is an impression of doubt whether there is a slight discoloration, or whether that is all pure imagination. Evidence of serious discoloration seems to be lacking. Page 309.

ROBBER-BEES STOP THE APIARIST'S WORK.

As may be inferred from Miss Wilson's article, on page 309, danger and damage to the bees aren't all by any means that is involved in a robbing muss. Some seem to think it is—and that ignoring robbers is a nice kind of bravado. Often the real, main thing when work presses is the annoying and expensive loss of the apiarist's time. Once they get the robbing bee in their bonnet nothing can be done that does not involve stopping work. Extreme care from outset on might have purchased the right to go ahead—too late now.

BEES FERTILIZING BLOSSOMS.

Mr. Thaddeus Smith (being good on the skirmish) will abandon the cucumber kopje when he reads Dr. Miller, page 811—but he'll shoot "allee samee" from the fruit and berry territories.

BEES STORING IN BROOD-CHAMBER FIRST.

'Spects that part of Mr. Doolittle's dissent, on page 311, is because he runs a different strain of bees from those some of the rest of us keep. As for the rest, I guess (being a Yankee) that Dr. Miller's mind was mainly on breaking an idol in his own yard, perhaps not thinking very much of other people's idols. Had no further faith that *his bees* would contract any *bad habit* of storing below that would interfere in the least with starting in the sections when conditions were right for that. To that extent I can go with him heartily. In fact, I can go somewhat further. I am willing my bees should put some of the first surplus below, and serenely confident that they will carry it up a little later on—but then, I run with 7 frames, not 9 or 10.

Only One Night to Denver.—By going over the Chicago & North-Western and Union Pacific railways, you will need to spend only one night on the road from Chicago to Denver. There is a daily train leaving Chicago at 10 a.m. on the C. & N. W., and leaving Omaha, Nebr., over the Union Pacific at 11:30 p.m. of the same day. This train arrives in Denver at 2 p.m. the following day. That is, by starting from Chicago at 10 a.m. on Tuesday, Sept. 2, you will arrive in Denver at 2 p.m. the next day, or Wednesday, Sept. 3, in ample time for the first session of the National Bee-Keepers' convention, which begins that evening.

Now as to rates: The round-trip price at that time from Chicago to Denver will be \$25. By going over the route mentioned, the regular sleeping-car rate would be only \$3.00, because of being only one night on the way.

There is also another saying by taking the C. & N. W. and Union Pacific. There is a Pullman tourist car on this train from Omaha, in which the charge for a double berth is only \$1.50 to Denver. As no sleeping-car accommodations are required on this train east of Omaha, it will be seen that one can go comfortably by this route for a very small sum.

We may say that Dr. C. C. Miller and the Editor of the American Bee Journal expect to go over the route indicated, starting at 10 a.m. on Tuesday, Sept. 2. Who will join us? We would like to publish the names of all who will do so. It would be pleasant to have a large number go together.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Apt to Make the Cross Crosser.

I see that some one is trying to cross bumble-bees with honey-bees, to increase the size! I have been trying to cross my bees with lightning-bugs, to enable them to work nights!

We crossed our strawberries with milkweed last year, and this year we have a fine crop of strawberries and cream on the same vine!

I have been unable to arrive at any good results with crossing the bees; if you can give any information on the subject, I would be greatly obliged. NEBRASKA.

ANSWER.—I advise you not to make any further effort in that line, for crossing bees makes them cross, and if you cross a cross cross with another cross cross, the resulting cross will be a still crosser cross.

Honey-Dew—Cockroaches—Swarming.

1. Explain honey-dew.
2. What harm to the hive do cockroaches do? and how can one get rid of them?
3. When bees swarm does the queen come from the hive first, or last? NORTH CAROLINA.

ANSWERS—1. It would be going beyond the limits of this department to say all that can be said about honey-dew, but it is likely that you desire to know its source. In some cases it is a secretion of plant-lice, in others it seems to be secreted directly on parts of the leaves or stems of plants.

2. I never could see that they did any harm, although I don't like to have them about the hives; perhaps more for their looks than anything else. I suspect that like ants they make their stay in and about hives for the warmth. I think they might be destroyed by poison, *providing* the bees did not also have access to the poison.

3. Neither. She may come along in the crowd at almost any time, but I think I have oftener seen her issue after than before half the swarm was out.

How a Beginner Should Begin.

As I am somewhat interested in bee-keeping, I would like to ask a question or two in regard to learning bee-keeping.

My grandfather and father have had bees for about 20 years, but I will confess that neither they nor I know scarcely anything about them, in fact nothing in regard to handling them for profit in the honey-line; as we have kept them simply as agents for distributing pollen for fertilizing small fruit, and they have done their work well.

My father has been a subscriber to the "Old Reliable" for some time, and I have read each copy with a great deal of interest, but with not as much as I would if I knew more about bees so I could understand it better.

What would be the best way for a beginner to learn something of bee-keeping? What, and where, could I procure, and what would be the cost of, a good book of instruction in bee-keeping for a beginner? KANSAS.

ANSWER.—You have done two important things toward becoming an up-to-date bee-keeper. You have become interested in the bees themselves, and all the more because intelligent enough to recognize that their most important work is that of fertilizing the flowers; and, second, you have been reading the American Bee Journal. A third item you have omitted, and that ought to have been done before reading bee-papers—but you are on the track of it—and that is the study of a good text-book. Send to the office of this journal, and get "Root's A B C of Bee-Culture," for \$1.20; Cook's "Bee-Keeper's Guide," for \$1.20, or Dadant's Langstroth for \$1.25. Any of these is clubbed with the American

Bee Journal a year for \$1.75 for the two. Become familiar with your text-book, let your study go hand in hand with your practice with the bees, and when you run across something that neither your practice nor your text-book helps you out with, as you surely will, send the conundrum to me, and I'll do my best to help you out—if I can. Success to you.

Making Honey-Vinegar.

How can I make good vinegar from the waste honey around an apiary? Can it be made so that one can detect the honey-flavor? Is such vinegar good for pickles? WISCONSIN.

ANSWER.—From honey you can make vinegar of best quality, good for pickles or for any other purpose for which good vinegar is used. Minute instructions are given in some of the bee-books, and there is not room in this department to go into the matter fully, but it may be said that you can make vinegar from diluted honey just the same as you would make it from cider. Indeed, if you dilute honey and let it stand in a warm place it will make vinegar probably in spite of you. Add to the honey a sufficient quantity of water so that when a fresh egg is put into it there will be a spot of the egg about the size of a dime above the surface. It should be understood, however, that honey of objectionable flavor will not make as good vinegar as will honey of good quality.

When To Put On Supers.

Dr. Miller says, "Put on supers when you see first the white clover bloom." Here's the bloom, but we will wait 2 or 3 weeks before following his advice. This is fully 2 weeks earlier than I ever saw the bloom in Northern Iowa. All well here, and waiting patiently for the bloom. IOWA.

ANSWER.—Probably it may be all right not to put on supers until 2 or 3 weeks after the appearance of the first clover bloom, but in a good many cases it might do a good deal toward forcing bees to swarm. Unless I have been mistaken in my observation, bees begin working in earnest on clover about 10 days after the first blossoms are seen, and with any considerable number of colonies I always feel safer to have supers on about 10 days before they will be needed, so the bees will be sure to commence promptly in them when they are needed. Weak colonies, or those with scanty stores, may not need supers so soon, but a strong colony, with plenty of stores, so that there are no vacant cells in the brood-chamber—well, my friend, if you have a number of colonies of that kind, please report how much more than 10 days after the first clover bloom they are ready to work in supers, and I'll make my teachings to fit the case in the future. If swarming is desired, then it is all right to put on supers not till 2 weeks after first clover bloom is seen.

Sowing Sweet Clover—Preventing Increase—Hive for Comb Honey.

1. When and how should sweet clover seed be sowed? and which kind is the better for honey, yellow or white? How much per acre is best to sow?

2. You recently said in answer to a question of mine that one way to prevent increase would be to take all the brood from the bees just before they were ready to swarm. Now, what would I do with about 500 frames of brood, if I did not want increase?

3. I use Hoffman frames and our flow here is from white and red clover, and lasts from four to eight weeks. Which hive do you think would be best for the production of comb honey, the eight or the ten frame? Give reasons. INDIANA.

ANSWERS.—1. You can sow the same as farmers in your neighborhood sow red clover, using half the amount of seed. If the ground is very mellow, however, there is danger that in the following winter the frost may heave the sweet clover out of the ground. If you can have the ground beaten or tramped down as hard as the roadside, your chance for a crop will be better.

2. I'm afraid I made rather careless work in answering that question. Prevention of swarming is one thing, prevention of increase another. Some want to prevent swarming but do not want to prevent increase. Some want to

prevent increase, but are not anxious to prevent swarming. As a means of preventing swarming, taking away all brood works well, but it is not so easy to see on the face of it how it prevents increase. It is not an easy thing to start with a given number of colonies and keep that same number every day of the year for a series of years. Indeed, it is probably impossible. But it is possible to have the same number each year at some given date. There will be more or less losses in different ways, and these losses must be made good. There are losses in wintering, losses through queenlessness, and perhaps losses in number through uniting. When a man does not wish to go above a certain number, he may find it advisable in the spring to unite all his weaker colonies; because it is the strong colonies that give the best harvests. Thus it will be that in any case there will be some increase to make each season, although the number each fall may be the same.

So you will see that you will be able to use up a good deal of brood to make good your number of colonies. But that will not account for the 500 frames of brood you men-

tion. After you have given a reasonable amount of brood to each of the weak colonies you have to build up, or to each of the nuclei you have started, there will still continue to be brood to be disposed of. Well, after you have given a reasonable amount, keep right on and give an unreasonable amount. Pile up until each pile has 40 frames of brood or more. That will allow you to use some of the earliest and strongest for supers, reducing them to one story, or you may allow them to store frames of sealed honey for future use.

There will thus be an increase in the number of combs, and these can be used the next year to take the place of foundation when you take away all brood.

3. I don't know. After having tried both on a pretty large scale, I have some doubt whether there is any difference. The two principal points are these: It is easier to manage the larger hives so as to avoid the danger of starving in winter and spring, also the danger of weak colonies; and it is easier and more convenient to handle the smaller hives and their supers.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gaudy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested.....	1.50	8.00	15.00
Selected Tested.....	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

GENERAL ITEMS

Plenty of Rain—Later Swarming.

We are having plenty of rain here, and prospects are good for honey, if nothing happens. Swarming will be somewhat later than usual, on account of cool, dry weather this spring.

J. M. LINSOTT.

Gage Co., Nebr., June 6.

Discouraging Outlook.

I will write a little about the honey crop that some of the good people with supplies to sell told us about. Mr. C. Dayton, who was around among the bee-men, says no one has extracted yet, and is not likely to do so. He has moved his bees back into the valley, so he can watch them.

Bee-keepers say they will be lucky if they do not have to feed. There are lots of flowers, but it is too dry for nectar. Of course, we can tell what bees might do with alfalfa in central California. The sumac bush may yield some nectar for winter stores. There is more brood than honey in our hives now. Black, white and silver sage are in bloom, and so is wild buckwheat, but it yields very little this year. It is possible that along the ocean, where the fog is more dense, they may get a little honey.

E. ARCHIBALD.

Los Angeles Co., Calif., May 25.

Introducing Queens—Hard Winter.

I will give my quick way of introducing queens. I have introduced 20, and have not had a failure, but I do not say it is infallible.

I go to the colony about sundown in which I want to introduce the queen, and open up the brood-chamber carefully, so as not to frustrate the bees. I hunt their queen, take her off, and then put all the frames back in place. Then I smoke them for a few seconds, so the bees will all rush to the honey and fill themselves; then I smoke them again enough to make them scamper all through the hive, and then give them a few puffs of smoke at the entrance. I then give them enough smoke again to clear the bees from the top of the

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Please Mention the Bee Journal when writing Advertisers *****

frames, then I open the cage and let the new queen run down, and, as she goes I send two or three puffs of smoke with her. I then close the hive and the work is all done, and the bees do not know that their queen has been taken out.

I can change quicker than I can write and tell how, if the first queen is not too hard to find.

Bees in this part of the country had a hard time getting through last winter, several bee-keepers losing almost all. One I know of started with 8 colonies, and lost all of them; another with 7 colonies lost all but one; and one with 36 had only 5 to get through the winter all right. I moved nine 12 miles, to the farm, the last of February on a sled, and lost 19 of them. They all left enough honey-dew and other stuff to feed them more than through the winter, if they had been able to get out; but the long, cold winter with honey-dew, and what some mean people fed them last fall, made it hard on the bees.

ARTHUR A. HOUSER.

McDonough Co., Ill., May 28.

Bee-Keeping in Oklahoma.

The bee-industry here is nothing, as there is not a honey-bee in this country that I can find, although I have looked in every direction: in fact, I have just returned from a trip in the country, looking for some that I was told were kept by a farmer about two miles from town, but I was disappointed again, and now I will give up looking and send away for a colony, as I believe they will do well here, but I do not wish to try more than that, for the people say that they will not do any good here. They are not bee-keepers, and I put but little reliance in what they say, but still they may be right, and one colony will be enough to lose trying it; but I will not give up until I try one colony, as there seems to be all kinds of flowers here, and honey sells in the stores for 20 cents a pound, but everybody thinks it is manufactured. I have tried to tell people, any number of times, that it is impossible to make comb honey by hand or machine, and have been laughed at for being so innocent. A case in point: When I moved from Illinois I brought some second-class honey (unfinished sections) with me, and gave some to my new-made friends; the words of praise for it I can not remember, but they were many. One was so much infatuated with it that he got the address of the man I sold my bees to (in Illinois), and has written to him and contracted for some for his winter's use, at a price that will make it cost about 25 cents a pound delivered. The stores are selling now some of the finest white honey that I ever saw at 20 cents, but I can not convince him that it is "real bee honey," as it looks too white.

WENHAM, MASS.

Demaree's Plan for the Prevention of Swarming.

Some years ago G. W. Demaree gave a plan to prevent swarming the putting of all the brood in an upper story, leaving the queen below upon foundation, an excluder between the two stories. The plan has gone so many years unchallenged, that to many will come as a surprise the following in Gleanings in Bee-Culture, by C. Davenport :

With a number of colonies I removed all the brood to the upper story, and filled the lower story with frames containing full sheets ; and every colony so treated swarmed. Five of these colonies were in 10-frame hives that I bought a year ago, and one was in a 12-frame hive. Two of these colonies swarmed before any cells in the upper stories were sealed, and no signs of cells below.

Some claim that a swarm will never issue with cells in the upper story when there is a queen-excluder between the two stories unless they have also started cells below. But I am absolutely certain that three of my colonies did last season, and I feel morally sure that five or six more did.

A method that did in all cases prevent strong colonies from swarming, whether they had contracted the swarming-fever or not, was to remove all the brood, give empty frames below, and use either drawn comb or full sheets in the upper story ; and when this was done the bees drew out the foundation more readily than they did when there was brood below, probably because they had no intention of swarming, and this method gave us the largest amount of surplus of any plan I tried. But almost all the colonies so treated built a large amount of drone-comb below.

Quality of Extracted Honey.

The difference in the quality of extracted honey is strongly put in the words by "X Rays," in the Rocky Mountain Bee Journal :

Some bee-keepers extract from combs partially filled with brood. This is not only filthy and unsanitary, but positively vicious. Honey can not be very healthful or palatable that contains chyle, essence of grubs, and the thin watery stuff gathered from filthy places that is stored next to the unsealed brood. The queen should be confined to the brood-chamber with a sheet of queen-excluding zinc, and never, upon any occasion, be allowed to enter the supers, which she will do if not restrained.

It is the custom very generally among large producers to extract several times during the flow. Some of them wait until the combs are entirely sealed, but the majority extract when they are half to two-thirds sealed. Let me say right here that a first-class

J. R. Watkins

THIS IS J. R. WATKINS,
the president and founder of the J. R. Watkins Medical Company, Winona, Minn., U. S. A., the proprietors of the world famous

Watkins' Remedies.

You will find this picture of Mr. Watkins and his signature as above on every label, wrapper, cartoon and package of Watkins' Remedies. It is the trade mark—the stamp which marks the genuine from the spurious and worthless. Some unscrupulous men will attempt to sell you other preparations for the genuine Watkins' Remedies. They will declare that others, which they are trying to sell, are "just as good" as Watkins' Remedies. In order that you may not be deceived we put on the picture and this signature to protect you from fraud. Always insist upon the genuine, with the portrait and signature of J. R. Watkins, as above. Take no others, for no others are so good as the original and only Watkins' Remedies.

Please mention Bee Journal when writing

article of extracted honey can not be produced in this way.

Every extracted honey equipment should include not less than three sets of extracting-combs, Langstroth size, or their equivalent. The number of these sets of combs must be governed by the locality and the yield anticipated. There should be enough to hold the entire season's crop. When one is partly filled, raise it and slip in another between that and the brood-chamber. Keep this up until the end of the flow, and get as many filled as possible, but leave them all on the hive until you are ready to extract.

Rearing Choice Queens in a Super-seding Colony.

The following is part of a conversation between G. M. Doolittle and a visitor, as reported in Gleanings in Bee-Culture, Mr. Doolittle being the first speaker :

"If you can find any colony which shows by its building queen-cells outside of the swarming season that the bees are about to supersede their queen, you can rear as good queens from that colony, during the time that the old queen lives, as can be reared under the swarming impulse."

"I am glad to hear that, for I found one of my strongest colonies building queen-cells yesterday, some having royal jelly and larvæ in them. But this colony has not my best queen in it, and I wish to rear my queens from my best queen. How can I overcome this difficulty?"

"By doing what is known as grafting the queen-cells, which is simply transferring larvæ from your best queen over into the royal jelly in the queen-cells the bees have started, after first removing the larva that floats on this royal jelly. In this way you fool the bees, and they go on and perfect a queen from the substituted larva, the same as they would have perfected their own."

"But how can I be sure that the grafted cells are not torn down, or that others are not completed which I have not grafted?"

"By sticking a slim 1¼-inch wire-nail through the comb immediately over the grafted cell you can tell all about this; and if you wish to secure as many queens from this colony as possible, while the old queen lives, you will open the hive twice a week and graft all cells having royal jelly in them at each time of opening, and, later on, take out the ripe cells before the queens emerge. In this way you may get as many as from 25 to 100 splendid queens from this colony before the queen dies."

American Queens in Australia.

There is one peculiarity about American-bred queens that I have always noticed, and that is a most decided disposition to curtail laying operations on the approach of winter. On account of the long winter's rest in America, this is simply following an inherited tendency, but is certainly one that I do not look on as too desirable in this climate, still I am well aware that many look on this disposition on the part of the queen to rest through the

Rumely Threshing Machinery. — While advanced methods in agriculture are gradually unfolding themselves, the demand is keeping pace for the best implements and machinery that the market affords. It is but natural that this should be true in all lines, but there are especial reasons why it should be true in a matter of the magnitude of threshing machine outfits. Chief among them is the amount of money that must be invested. In no other implement that has to do with the seeding, cultivation, harvesting of the crop, preparing for the market or

other farm use, is there such a considerable outlay required as in the matter of threshing machinery. It is not purchased for a season's work on a single farm, but usually for many crops for all the grains and grasses, and to make a profit for its owner above first cost and operating expenses, it must do duty for a series

of years. If for no other reason it would seem to be imperative, in this account alone that machinery of the widest uses and the best adaptation to each as embodied in the best makes to be found, should be sought by the thrasher men. In this connection and always when speaking of threshing machinery the mind reverts to the Engines and Separators manufactured by the M. Rumely Co., of La Porte, Ind. Having been

in the threshing business since 1853, their machines have been put to a good, long test. Their popularity as told by the number of sales annually as compared with those of other threshing machine manufacturers, has outrun even what their long years would seem to warrant. The reason must be sought for in the intrinsic worth of the machines themselves. We have not the space to enter upon a recitation of the many distinguishing points of excellence of the Rumely machines. We are reproducing a cut both of the New Separator and the Traction Engine herewith. The advertisement is running regularly in our columns. Any of our readers anywhere, who are interested in threshing machinery, should look it up and write to the Rumely Co. for their catalog. It will be gladly sent free for the asking, and will put the inquirer in the way of possessing a threshing outfit of the highest type of usefulness.

winter as a very desirable feature. I must say, however, that some of these American queens produced *splendid honey-gatherers*, but they are crowding the brood-nest rather too much to suit me; but I am quite sure that this infusion of fresh blood is going to have a decidedly favorable effect on my strain.—H. L. JONES, in the Australasian Bee-Keeper.

Plan for Starting Queen-Cells.

W. H. Pridgen is an acknowledged authority in matters pertaining to queen-rearing. In getting cells started he uses a "ventilator," or bottom-board consisting mostly of wire-cloth, to use when fastening bees in a bee-tight hive; and to prevent the excited queenless bees from rushing out when the cover is lifted to admit the cell-cups, he has a slotted cover, so that a part of the cover can be raised sufficient to admit only the frame having the prepared cups. As to the manipulation, he says in *Gleanings in Bee-Culture*:

To get a colony in readiness to accept cups, simply shake the bees from enough combs of brood to fill a hive, and place it over a populous colony with only a queen-excluder between, with a laying queen below, as has been so often described for cell-building. These combs of brood are drawn from any colony or colonies in the apiary, and replaced by frames filled with foundation or empty combs. The bees are simply shaken and brushed from them without having to find the queen or queens.

The bees in the bottom story over which they are placed will at once take possession, and, as soon as the brood is all sealed in this top story, it can be placed on the ventilator and the combs thoroughly examined for queen-cells. Better shake the bees from them, to be sure none are overlooked; and, besides, this shaking process and rough handling tends to hasten matters, as a search for the queen immediately follows. Remove all cells, and place the slotted cover on, enough combs having been removed to leave spaces for the reception of the cups. While it is not essential that bees be broodless to accept cups, provided there be no unsealed brood present, it may be necessary for them to be prepared a few hours longer before giving the cups, and the preparation of the bees can be done the evening before, or earlier in the day than recommended in the first case, with the other manipulations to follow at the time given.

As soon as the accepted cups are given to the cell-builders, the hive of queenless bees used over the ventilator can again be placed over the same colony as before, with the excluder between, and the operation repeated as often as desirable.

To keep this colony in a condition for continuous work as cup-accepters, it is necessary to fill another body with combs of brood as before, and place it on an excluder with the first one above it, until the brood is all sealed in the second lot of combs. After this is done, and before the brood in the second lot is sealed, the bees should be

shaken from two or three of the second lot of combs into the one placed on the ventilator, to start the necessary excitement in it, when the latter is set off to make ready for the acceptance of cups. By the time the brood in the second set is sealed, the bees will have emerged from the first set, and the latter can be disposed of, the queen-cells removed from the second set as recommended, with the first, the second used over the ventilator, and another set placed under it for the brood to become sealed. Thus managed the same hive can be used the season through, and the combs and adhering bees, whenever a set is removed as above described, can be used in forming nuclei.

The idea is to use bees for accepting cups that were only a few hours previously deprived of unsealed brood and queen, either by taking them from the queen and brood, or the brood and queen from them, and thus have them in a condition to accept larvae at once, in a hole in a block, or wherever found, regardless of the crudeness of the transfer or preparation.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens

FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Italian Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order as follows:

No. 1.—For sending us the names and addresses of two new subscribers to the American Bee Journal and \$2.00, we will mail you ONE of these queens free.

No. 2.—Or, for sending us one new subscription at \$1.00, and 30 cents more (\$1.30), we will mail you a queen, and the Bee Journal for one year to the new subscriber.

No. 3.—Or, send us \$1.60 and we will send to you the Bee Journal for one year, and also a queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, June 7.—The honey market is in a waiting attitude; there is more comb on sale than for several Junes of recent years; most of it is out of condition from one cause and another, chiefly by having grained; therefore a very light yield this year would not help the crop now on hand of last year. Prices are without special change in either comb or extracted honey from those given last. Consumers are not in the market for other than small lots. Beeswax is very scarce and brings 32c upon arrival.
R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5 1/2 @ 6 1/2 c; better grades from 7 @ 8 c. Fancy comb honey sells at 10c; lower grades hard to sell at any price. Beeswax strong at 27 @ 30c.
THE FRED W. MUTH Co.

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14 @ 15c. Extracted, 6 @ 6 1/2 c. Beeswax, good demand, 30 @ 31c.
H. R. WRIGHT.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13 @ 14c; dark and amber, 11 @ 12c. Extracted, white, 6 1/2 @ 7c; dark and amber, 5 @ 6c. Beeswax, 29 @ 30c. M. H. HUNT & Son.

NEW YORK, May 19.—There is a limited demand for comb honey and prices range as follows: Fancy white, 14c; No. 1, white, 13c; amber, 11 @ 12c; no buckwheat or dark on the market and no more demand for any. Market on extracted remains very inactive. Plenty of supply with only fair demand. We quote: white, 5 1/2 @ 5 3/4 c; light amber, 5 @ 5 1/2 c; southern, in barrels, 50 @ 55c gallon. Beeswax firm at from 30 @ 32c pound, according to quality.
HILDRETH & SORLEKEN.

CINCINNATI, June 7.—There is hardly any change in the honey market. Comb is not moving much, and whatever is left can be bought at cut rates. Water-white is selling from 14 @ 15c. Extracted is in fair demand and finds steady sales, in barrels, 5 @ 5 1/2 c; water-white alfalfa from 6 @ 6 1/2 c; white clover from 6 1/2 @ 7c. Beeswax is coming in more freely and sells for 28c.
C. H. W. WEBER.

SAN FRANCISCO, June 4.—White comb, 10 @ 12 cents; amber, 7 @ 10c; dark, 6 @ 7 cents. Extracted, white, 5 @ —; light amber, 4 1/2 @ —; amber, 4 @ —. Beeswax, good to choice, light, 27 @ 29c; dark, 25 @ 26c.

The market is quiet, with no heavy quantities offering on the spot or to arrive. That values will incline materially in favor of buyers the current season is not probable. The yield in this State will undoubtedly prove much lighter than was generally estimated a few months ago. Prospects are that high-grade honey will meet with a tolerably stiff market.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.

THE A. I. ROOT COMPANY, Medina, Ohio.
GENTLEMEN—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.
J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

AMERICAN

BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., JUNE 26, 1902.

FORTY-SECOND YEAR
No. 26.

WEEKLY

APIARY OF C. E. KNOTT, OF BUFFALO CO., NEBR.—(See page 404.)

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

An Italian Queen Free!

We would like to have our regular subscribers (who best know the value of the American Bee Journal) to work for us in getting NEW subscribers. We do not ask them to work for us for nothing, but wish to say that we will mail ONE FINE UNTESTED ITALIAN QUEEN for sending us ONE NEW subscriber for a year, with \$1.00; or 2 Queens for sending 2 new subscribers, etc. Remember, this offer is made *only* to those who are now getting the Bee Journal regularly, and whose subscriptions are fully paid up.

In case you cannot secure the new subscribers, we will mail one of these Queens for 75 cts., or 3 or more at 70 cts. each; or the Bee Journal one year and a Queen for \$1.50.

(Please do not get these offers mixed up with our Red Clover Queen offers on another page.)

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we will close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

A New Edition. 19th Thousand.

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

* Editorial Comments. *

The Season is a rather discouraging one in some parts of the North. Cold weather continued late in spring, retarding brood-rearing, and up to the middle of June, in spite of occasional hot days, cool weather has ruled. Instead of being busied putting on additional supers, some have been obliged to feed to keep the bees from starving.

Mistakes in Queen-Rearing are likely to be made by beginners. One mistake is in thinking that good queens can be reared at times when the weather is chilly, or when bees are not busy bringing in nectar. Rightly managed, feeding may be made to take the place of a natural harvest, but there is nothing the bee-keeper can do to make up for the lack of good weather. Another mistake it is to think that a weak nucleus can produce good queen-cells. The royal larva should be flooded with royal jelly, and this is best attained in a strong colony. Up to the time the young queen is about ready to emerge, there is no better place for her than in a strong colony, and at no time before she begins to lay should there be any risk of her being chilled.

General Manager of the National.—We have received the following announcement from Emerson T. Abbott, which is self-explanatory:

St. JOSEPH, Mo., June 17, 1902.

EDITOR AMERICAN BEE JOURNAL—

Dear Sir:—The notice of Acting Chairman Root (see page 387) with regard to the General Manager of the National Bee-Keepers' Association seems to call for a statement from me.

First, the Board has or has not a right to receive Mr. Secor's resignation and elect his successor. If they have a right to do this, then one was elected some time ago, for eight members of the Board voted to elect his successor, and seven of them voted for one man. The three New York directors and myself refrained from voting. The vote was declared, and Mr. Secor was duly notified by the Acting Chairman as to the result, and was requested to turn the funds over to the newly elected General Manager, and he wrote that he would do so. However, later, at the solicitation of a disgruntled member of the Board in New York, he refused to do so. If the Board has any authority to act in a case like this, then every member of it who voted to elect a successor to Mr. Secor, formally voted at the same time to receive his resignation. As a majority of the Board so voted, of course he is out, and it is all nonsense to talk about reviewing a vote which has been canvassed and the returns announced. Therefore, Mr. Secor is not General Manager, and has not been since the day the vote was announced.

Mr. Abbott was not "supposed" to be elected—he was legally and clearly elected by a majority of the members voting, and is the only legal General Manager in existence to-day, if the Board has any authority to act on the question. If it does not (and I am inclined to doubt if it has), then Mr. Secor's resignation is before the membership, and

they should be given an opportunity to elect his successor at once. As soon as the membership selects another General Manager, the funds in my hands will be turned over to him, but they will not be turned over to Mr. Secor unless he is elected by the membership. The majority of those voting elects a General Manager, according to the Constitution.

The Buffalo amendment, in my opinion, gives the Board authority to remove a General Manager only for cause, and then to fill his place, but it does not give them authority to fill his place in any other case. If it does, then all the members of the Board having received notice of his resignation, and eight of them having voted for his successor—in fact, nine of the twelve, if my vote should be counted—that ended the matter so far as the Board was concerned.

A deliberative body may review a vote, but any sane man knows that a vote by ballot is final, if any one receives a majority of the votes cast.

It seems from the statement of the Acting Chairman, that the Board has decided that they have a right to act on Mr. Secor's resignation. If so, then I am General Manager. This is all I care to say at present.

EMERSON T. ABBOTT.

Prevention of Increase comes sooner or later to be a desirable thing for every bee-keeper who is very successful in wintering and does not wish to sell bees, unless his bees do not swarm to any appreciable extent. What may best suit one may not suit another. One of the old ways to limit increase—so old that it may be new to some—may be worth repeating here:

When the first colony swarms, hive the swarm in the usual way. When the second colony swarms, hive the swarm in No. 1, that is, in the hive of the colony that first swarmed. Then as each successive colony swarms, hive the swarm in the hive of the colony that previously swarmed.

The question arises, however, How long must a colony have swarmed before it is ready to receive another swarm? If a swarm is immediately returned to its own hive, it will only result in the swarm issuing again the same day or the day following, and it would seem that the same result would follow putting in a swarm from some other colony. Will some one who has had experience in the matter tell us how long it is necessary to wait after a colony has swarmed before a swarm can be given to it without the danger of having the swarm re-issue? Or is the plan one not to be commended?

* The Weekly Budget. *

MR. THOMAS G. NEWMAN, who for so many years previously to June, 1892, edited this journal, had the following paragraphs concerning the condition of his eyes, in his Philosophical Journal, under date of June 14:

Kind inquirers ask for news concerning the editor's vision, as nothing has been printed about it for several

months. In reply he would say that while a slight improvement is noticeable, he is still unable to read any ordinary printing or writing.

The best magnetic healers have been employed—including mental scientist treatments, suggestion and hypnotism, but all have failed to cure. The case is stubborn, and we doubt if any of these can cure, while we have to use our eyes so persistently.

HENRY DADANT, second son of C. P. Dadant, dropped into our office recently. He had been in Chicago looking up some work along his line—that of civil engineering. He found a position with the Illinois Central Railroad Company. He expects to hustle during his vacation months, and then return to the State University at Champaign, Ill. "Henry" will get along all right. He is well mannered, alert and cheery. Quite like his "dad" in these respects.

THE APIARY OF C. E. KNOTT, of Buffalo Co., Nebr., is shown herewith, concerning which Mr. Knott writes this:

I send a picture of my bee-yard, showing my wife, two boys, and myself. The boys are a great help to me; they are hiving a swarm apiece, one on a limb, the other between the legs of a saw-trestle. One boy is 10 years old and the other one is 11.

I have kept bees for three years, and like it first-rate. I have not lost any during the winter. Last summer I got 300 sections of comb honey and 250 pounds of extracted from 21 colonies. I winter the bees in open sheds on the summer stands. Our pasturage is nearly all alfalfa and sweet clover.

I am always glad to get the American Bee Journal. I read it the first of the papers. I wish it success, as usual.

C. E. KNOTT.

MRS. ANNA E. DANZENBAKER, wife of F. Danzenbaker, died at Claymont, Del., June 11, 1902, aged 63 years. When sending us this sad information, Mr. Danzenbaker wrote thus tenderly concerning his departed life companion:

CLAYMONT, DEL., June 11, 1902.

DEAR FRIEND YORK:—The sufferings of my saintly wife ended at 4 o'clock this lovely June afternoon, filled with bird songs and roses' perfume. How sadly we miss the inspiration of her sweet voice and kindly ways, that for 42 years have been the chief corner-stone and crowning joy of our life and home. How sacred in memory her sterling worth, her purity of soul and life, her sacred devotion to truth, duty, and right, for the very love of right.

She won the esteem and love of all who knew her. We were always proud of her. She taught us in life how to live for others' good; in death—too dear the lesson—to die without a fear.

F. DANZENBAKER.

For 42 long years to tread life's pathway together—and then to stop. How lonely will seem the way to our brother who now goes on without her who was thus long the delight of his life and home. Bee-keepers everywhere will sympathize deeply with Mr. Danzenbaker in his sad bereavement. The American Bee Journal desires to unite with them in their feelings of sorrow for a stricken brother.

THE RED CLOVER QUEENS which we have been booking orders for during the last six months or more, are now being mailed by our breeder. He has been greatly delayed by unfavorable weather, but he expects to get caught up with the present orders by about July 1, so those whose orders have been received lately can not expect to have their queens until July, for the orders were taken "first come first served," as will be noticed by referring to the Red Clover Queen advertisement previous to this week's issue.

Orders for regular Italian queens we are filling almost by return mail, at terms quoted on page 402.

ADVANCED BEE-CULTURE is the title of a 90-page (6x9) pamphlet on practical bee-keeping, by W. Z. Hutchinson. The first edition was issued about 10 years ago; the second edition is just off the press, and we have a supply at this office. It is sent post-paid for 50 cents; or with the American Bee Journal one year—both for \$1.35.

BY A SHORTHAND REPORTER.

(Continued from page 389.)

SHIPPING-CASES FOR HONEY.

QUES.—"What kind of shipping-cases is the most desirable?"

Mr. Burnett—The case that has come into general use now is known as the non-drip case; it is perhaps the best I know of. We prefer cases that hold 12 and 24 sections. Of course, we probably sell honey in other sizes, but people rather like uniformity of packages. They like to call for a package of honey, and know about what they are going to get. The non-drip case has certainly been the best thing that has come to my knowledge during my time in the honey-business, and I sometimes think it would be a little difficult to improve upon it; however, there are some people who don't understand how to manage it, even as simple as it is, and put the strips in without fastening them at all, and, at times, despite the fact that the honey is in that sort of a case, it is injured. I know it is something the bee-papers have called attention to a great many times, and I think it is a fact that the manufacturers do give directions to fasten in those strips before the honey is put in. Is not that a fact?

Pres. York—I think they do.

Mr. Burnett—I think I have seen some advertising calling attention to the fact that the strips should be fastened in the case, and it certainly is not of great value unless it is done, but if the combs are injured the paper that is in the bottom prevents the honey from getting out of that case, as a rule, and smearing the others. So far as some honey is concerned, I think it is the best thing now in use.

Mr. Walker—I have a few words to offer in regard to the shipping-case question. While I sanction all that Mr. Burnett says about the superiority of the non-drip case, I can't say I regard the cases now on the market under that name as deserving of such a name. Possibly I was among the first instrumental in the introduction of such a case, and I have used these cases largely—what I call the non-drip case—for perhaps 15 years, and after using them for a good many years I had them made to order by the Root Company, and succeeded in getting that company to list them in their price-list. When they first sent them out they made them after the pattern I was using. Of late years they have adopted something quite different. Possibly some of you remember my criticising them several years ago. I think it is stated in Gleanings, that the drip-sticks that are used in common shipping-cases are worthless, and that possibly two different kinds of drip-cases should be used, one for the careless bee keeper, and another for the other sort. The inference was that it was good enough if bee-keepers would only be careful enough. The point I wish to make is, the drip-sticks commonly used are altogether too shallow—only about $\frac{1}{8}$ of an inch in thickness; I have always used them about 5-16 inch deep. The reason for this is, if there is any drip to amount to anything, for instance, a couple of spoonfuls of drip in the bottom of the case, it will spread, and when you lift the sections up, you will find them half filled, while if the drip-sticks were 5-16 of an inch, or $\frac{1}{4}$ thick, there would be no trouble in that respect. I consider that a very essential point, and one that has been overlooked, and thus causes a great amount of money to be lost in handling honey that has been dripping more or less, to put it in condition. There are some very careless freight-handlers as well as bee-keepers. I had a consignment the other day, and the sections were thoroughly fastened all around—the combs were thoroughly fastened—they were the plain sections, averaging about 15 ounces to a section; the honey was packed in the common style of non-drip cases, with drip-sticks about $\frac{1}{8}$ -inch deep, and nearly all of them were fastened so they could not move about, and nearly every case

had a few sections that were broken more or less—just a few spoonfuls of drip—and it took hours of time to clean up those sections. Sometimes the drip would be in the corners of sections, and had to be gotten at. It has cost me at least \$50 to handle over cases like that, and I can see no sense in having those shallow drip-sticks. Mr. Root wrote me on the matter, that so many bee-keepers wanted shallow drip-sticks because their honey was so thick; I replied that thick honey required more drip-sticks. The shipping-cases that are so commonly sent out have paper in them that won't hold the honey, in case there is a drip; it is not manilla paper; it will tear easily and soak through, and if there is any drip to amount to anything, it is apt to get in the different cases. The original non-drip cases had manilla paper.

Mr. Moore—The honey is not dripping when it leaves us, why is it that it is when it reaches its destination? What is it that makes the drip? Is it because the sections break down? or why is it you have the drip?

Mr. Burnett—I arose to endorse what Mr. Walker has said. It is a fact that we find now that the best honey is thick honey, and that the space between the sections and the bottom of the case, that is the drip sticks, are not thick enough; they do not raise the honey enough, so that when it drips out, it gets up against the section, and it causes the difficulty that he mentions; it had not occurred to me to be as technical about it as he is; he has evidently thought the matter out carefully. As to the leakage, there ought not to be any leakage in comb honey at any time, and I suppose the reason for it is that these drip-sticks are not large enough. We are pleased to have the inventor with us; it is a very great privilege to have heard from him. The calculation is that the combs should not be broken; if they do the drip-sticks would not be of much service, but it is for the little drip that may get out of the injured cell or cells that has not been capped properly.

Dr. Miller—Now, if these men who receive the honey find that there are so many unsealed cells, and that the honey is so thin that it runs out, then there is something wrong on the part of the bee-keeper. It seems to me that it ought not to be a matter of necessity that unsealed cells containing honey so thin it will run ought to be shipped. Do all the sections break out alike? Will a section that is thoroughly fastened, top and bottom, break out?

Mr. Dadant—Yes, lots of them.

Dr. Miller—Fastened on all four sides?

Mr. Dadant—On all four sides, yes.

Dr. Miller—I believe the great trouble is, a section is put in that is not thoroughly fastened.

Mr. Dadant—I have known of honey being shipped in car-load lots all the way from California, and not get broken, but in single packages they break often. The railroad companies manage us, we do not manage the railroad companies, and we have no recourse. I do believe we have not gotten hold of the railroad companies as we ought to; they ought to handle the honey so as not to break it. Our attention should be directed towards compelling them to transport our honey safely. They charge us well for it, and they ought to pay if they break the sections.

Mr. Burnett—I should be sorry to have a false impression go abroad. Where there will be some apparently not well fastened sections that do not break down, I have noticed that, as Mr. Dadant says, apparently a well-filled section will be broken out; but on examination I find that it was not really well fastened; it was fastened, as it were, down the center where the foundation was, but not outside of that. And then, again, I have thought that a section had at times been put in a case that had been jarred loose after it was put in there. As to the light weights breaking down, that is accounted for by the fact that the weight is not there to break it out, even though it is only fastened partially on two sides, and fairly well on top, and open on the bottom; the weight is not there, but the heavy section will be full, and it would seem as though it was fastened on the section, but it is only slightly fastened there, and not fastened on the outside. Years ago—when I was young, like Mr. York—I used to go to the depots and try to have the honey handled carefully, especially when it would arrive, and we sought various ways of getting honey from the railroad company with the least possible breakage. We got the men so that they would carry it out of the cars instead of dragging it out. The warehousemen had been accustomed, in carrying out the honey, in setting it down, to stoop over and then let it fall to the floor the rest of the way. Nearly all of the railroad companies now notify us when any honey arrives for us, if it is any considerable amount, and some railroad companies will for only one

case, and we will go and get it out of the car; they leave it in the car until we send for it, and we have very little breakage of honey in that way; the breakage is nearly all where it is unloaded, as a rule very nearly always at the destination.

Mr. Dadant—Or at the transfer?

Mr. Burnett—Or at the transfer. Of course, the railroad companies now have gotten fairly well educated on that; they won't transfer it if they can help it.

Mr. Walker—I wish to ratify what Mr. Burnett says about fastening combs in sections; those that are well fastened in proportion to their weight are the ones that usually come through in good shape.

Mr. Dadant—I imagine it is a case of luck if they come through all right only slightly fastened.

"How would you fasten the strips in the no-drip cases?"

Dr. Miller—Use light nails.

(Concluded next week.)

Honey-Crop Prospects—Finding and Clipping Queens.

BY C. DAVENPORT.

The season here, so far, has been about the most unfavorable I have ever known, it being cold and windy most of the time through April and the first part of May. The bees secured but very little from the spring flow of soft maple, fruit and dandelion bloom, as it was so cold and windy while they were in bloom that they were not able to fly much, and since the weather has warmed up there has been nothing for them to work on.

For some reason, unknown to me, basswood has failed to bud. Although, as I have said, the spring has been exceptionally cold, there were no hard frosts late enough to kill the basswood buds, if they had started.

Last summer we had the worst drouth known since the country was settled. Possibly this may be the cause. This spring there have been an unusual amount of rain and floods. A good deal of the white clover died out last season, owing to the dry weather. What was left started up well this spring, but all the low pasture lands, where the most of it was, have been flooded and under water a number of times, which has greatly injured it, for a good deal of it is buried under mud and sand. What will the harvest be? It looks now as if it might not be anything, but if the season is a failure it will be the first one here in my time, and I have a number of times seen the prospects fully as unfavorable looking as they are now, when a fair crop—and in one case a big one—was secured before the season closed.

I have been going ahead, getting things right side up, and am about ready to handle anything in the way of a crop that may come. I am glad to say that at this date the queen in every colony I own is clipped, and clipped short, too. The last few years I have not practiced clipping to any extent, for I practice artificial swarming mostly, so there was no climbing for swarms, anyway. But last year I was ill at the time this work should have been done, and was unable to secure any one that was competent to do it.

Swarming was soon on in full blast; of course, I had men to hive the swarms, but they were not able to handle all of them. One day, when I was not able to walk around, I lay under a tree, near one of the yards, and watched swarm after swarm fly off to the woods. There were two men for this yard, both of whom were a failure, but the best and all I could get at the time. I resolved then that another season I would have every queen clipped, but I had a hard time doing it this spring; in fact, I had to clip the most of them in the night. It was so cold the most of the time early in the spring that I disliked opening the hives and exposing the brood as much as is often necessary to find a queen, and when the weather became suitable there was nothing in the fields for the bees to work on, so they were all at home ready to rob and pounce on a colony the minute a hive was opened.

I have said before that whenever I wished to open a hive and handle a colony for any purpose I always did so,

no matter how crazy the bees were to rob. I wish to modify this by saying that there are times when it is not practical to expose a colony long enough to find the queen, especially with German or black bees, for one disadvantage about this race of bees is that they sometimes become so frightened or excited when being handled that they race and run all over the combs and hive, and finally cluster in bunches on the bottom-bars, so that it often takes a long time to find the queen, and in some cases, this spring, before the queen could be found, the great horde of robbers following me around would have a good share of the exposed stores carried off. But I will say that, bad as the robbers were, a medium to a strong colony never failed to expel them after their hive was closed. Although I have Italian bees from some, and, in fact, from almost all the noted strains, the majority of my colonies are of the German race, and I say that to find the queens in all of them would be a big job, even if there were no robbers.

I have done a good deal of studying over this problem, which was finally solved in a most satisfactory way by the use of zinc and Rambler's famous jouncer. About sundown, on warm evenings after the bees had ceased to fly, entrance-guards would be attached to a large number of hives, and the bees jounced out and allowed to run in through the zinc. Myself and assistant timed ourselves one evening, and found that one of us could attach the entrance-guard and jounce out a colony in three minutes. It was such a simple, quick and easy way to find black queens by this method that I was afraid there must be a catch about it somewhere, and thought that perhaps it might be that the jouncing would injure the brood or eggs, for the jouncer I use is not the elaborate padded affair that Rambler invented; so I went slowly until I had time to watch and notice if there were any bad after-effects on the brood. A frame in a number of hives was marked, and the brood carefully inspected before and each evening after the hives were jounced. No ill effects whatever could be noticed, and this is the method I shall practice to find queens after this, whether robber-bees are bad or not; if they are not the bees could be jounced out during the day, which would save night work, for it takes the bees some time to work through the zinc.

I used to go around with a lantern two or three hours later, and the queens were easily found among the bees that were still outside.

I have had experience enough with clipped queens before, though, to know that when natural swarming occurs everything does not always go just right, for I have had swarms without queens cluster and hang for some time before returning to the hives they issued from, and in numerous cases they would try to enter some other hive, usually one in which a swarm had been hived shortly before. Again, I have had them break or divide up and try to enter a number of hives; in such cases they would usually all get killed, if the colonies in the hives they were trying to enter were not well smoked. Such cases, while by no means rare, are exceptions; the majority of swarms will, if their queen is clipped or confined by zinc, return to their own hive without clustering. But going over a yard, in the spring, and clipping all queens, does not insure that all queens that issue with the first or prime swarms will be clipped, for it is not very rare for a colony to supersede its queen just before or during the swarming season, and, when this is done, if they are fairly populous they are almost sure to swarm with the first young queen that hatches.

Now, I will give beginners in clipping a little advice that may in time pay them for the trouble of reading this article.

When a swarm issues and clusters, if you can't find the queen don't decide they will come back anyway until you raise or tip the hive up so you can look along and up between the bottom-bars of the frames. If they have superseded the old, clipped queen there will be ripe queen-cells in sight. Cells from which young queens are nearly ready to hatch look considerably different from those that have only been sealed two or three days. If not able to tell in this way, by taking the frames out and looking them over the cell from which the young queen has hatched can be found. If no such cell is in the hive the bees can be depended upon not to leave for the woods, provided no young queen from some other hive on her wedding-flight, or one driven out, has not joined them. This only happens in quite rare instances, but I have lost swarms in this way, and so have others.

The bright side, or the ease and simplicity of handling natural swarming on the clipped-queen plan, has been told

by others. I have told about the balks and difficulties that one will sometimes encounter when practicing this plan in a large way. Southern Minnesota, June 7.

Foul Brood in San Diego Co., Calif.—Needs of Legislation, Etc.

BY HON. J. M. HAMBAUGH.

"During the years 1859 and 1860 there were upwards of 6000 colonies of bees imported from the East into this State [California]. They arrived in better condition, apparently, than those of former years, yet, owing to the fact that large numbers of these were infected with *foul brood* prior to their purchase and shipment, together with the effects of so long a voyage, probably half of the whole number was lost. Many of the remainder have since died, or now linger in a diseased condition, which is infinitely worse for the parties owning them than if all had died at once.

"Thus the result has been bad for all concerned, for while some have lost their money, others have injured their reputation, besides paralyzing for a time an important branch of productive industry."

So wrote Mr. Harbison, in 1861, as quoted from his "Bee-Keeper's Directory."

Just think of it! Three thousand colonies of *foul-broody* bees allowed to enter our State, and be indiscriminately scattered all through the country! From the reading we would infer that the 3000 colonies were a putrid mass of dead brood, germ-inoculated honey, wax, etc., and this with the "many that lingered in a diseased condition," destroyed the reputation of many bee-keepers, and, for a time, paralyzed the bee-keeping industry.

This, you will notice, was over 40 years ago, and the bee-keeping industry has survived this calamity, and many might imagine that we were safe from a return of this extremely dangerous contagion. Let us not deceive ourselves. The hydra-headed monster is abroad in the land, and I very much doubt if it has ever been thoroughly banished from our State since its introduction over 40 years ago.

Like Mr. Dadant, I never had any acquaintance with this disease until I came to California, and was appointed foul-brood inspector of our county (San Diego). Feb. 13, 1900, is the date of my first introduction. I had often wondered if I would recognize the disease. I had already come in contact with many badly afflicted bees, and worried Prof. Cook's patience (thanks to him) with various samples, but they all seemed to lack the chief characteristics, viz.: "The elastic ropiness, coffee color, and glue-pot smell." Here was a case, however, that would not admit of a doubt, and I was obliged to put my first seal of condemnation upon 30 colonies. Since that time I have found over 300 cases, and it extends over an area of 70 miles square, and approximates a total of nearly 7000 colonies. This will make one diseased for nearly every 23 healthy colonies. This, of course, does not include many apiaries not visited, which would naturally lower the percent.

I also found the disease in spots, with a central locality, traceable to imported diseased bees from foreign parts, pointing very clearly to the need of a law prohibiting the moving of bees from one locality to another without a certificate from a duly authorized inspector, that such bees are free from contagious diseases, etc. The bee-keeping citizens in these unfortunate localities are vehement in their expressions, and do not request such a law, but simply say they *demand it*. They are the victims of unscrupulous parties, who have simply unloaded their venom upon an innocent purchaser, not only to poison him, but to contaminate and possibly ruin, an entire community.

In the name of justice, bee-keepers of California, will you not co-operate with us and see that our law-makers frame and enact a law that will protect us from such an unnecessary source of contagion among our bees? The dread disease (*foul brood*) is among us, and without a proper knowledge of it, and its cure, it is to be dreaded.

Let me tell you, Mr. S. was a purchaser of over 100 colonies of bees in an adjacent county, two or three years ago. There was always trouble among them, and, not being informed as to the gravity of the situation, he took no pains to read up. I found him, about one month ago, with 35 colonies, and the surrounding dead ones bore strong evidence of the man's careless incredulity and ignorance. Of the 35 colonies, 33 were in all stages of the disease, and one of the remaining two was queenless; hence, he had but one sound colony in the yard. And this is not all. Every neighbor's bees within reach of this apiary were more or less afflicted. A widow moved 23 colonies within one-fourth of a mile of him last fall, only six or seven months

previous to my visit, and I found 19 out of the 23 inoculated with the disease, and had to be condemned.

I could give other instances in which we have reason to be apprehensive, but I will close by reiterating my previous position, that box-hives and stationary combs should be done away with by legislation. They are a nuisance to the industry, and exceedingly unprogressive.

Let us hear from some of our inspectors upon this subject.
San Diego Co., Calif., June 5.

Production and Care of Extracted Honey.

Written for the Wisconsin State Convention, held in February, 1902.

BY ELIAS FOX.

The preparation for a future crop of extracted honey begins soon after the close of the present season. This preparation consists in having an abundance of stores which varies with the season. Should there be no flow of honey after basswood, each colony should have from 40 to 50 pounds of honey, but should there be a fall flow, a less quantity would be sufficient. The point is, not to have less than 25 pounds of good honey in each hive when the bees are placed in their winter quarters.

Next to plenty of good stores is the necessity of having a young, vigorous, and prolific queen.

Then comes proper wintering, which consists in placing the bees in suitable winter quarters at the right time.

In my estimation, after 18 years of practical experience, my method of manipulation is as nearly successful as the average.

Late in the season I remove the oil-cloth from the hives and place over them a piece of factory cloth. Then, as soon as cold weather begins, the bees are carried to the cellar and the covers are removed. The first hive is placed upon 2x4 studding lying flat upon the bottom of the cellar. Two sticks $\frac{3}{4}$ -inches thick are placed crosswise on top of the first hive to support the next one, and thus they are tiered up six hives deep.

The covers of the top hives, however, are left on, and one end slightly raised to allow the escape of accumulating moisture.

The cellar should be as near underground as possible in order to control the temperature. It should be dry and well ventilated with at least two doors three feet apart. The temperature should range from 40 to 50 degrees above zero. Prepared thus the bees come out in the spring with combs as dry and free from mold as when put into the cellar. The bees should be removed from the cellar as early in April as the weather will permit. You will, no doubt, be surprised to see them bringing pollen, and perhaps you will wonder where they get it so early. But if you make investigation you will find them working upon willow, tag-alder, poplar, or hazelnut, or perhaps all of them. This will be a week, or perhaps two weeks, before elm and soft-maple are in bloom. Thus, some bee-keepers make a mistake by leaving their bees in the cellar till the latter trees bloom. If these simple instructions are implicitly adhered to our winter loss, as a rule, will be nearly nothing.

As soon as the bees are removed from the cellar and have a cleansing flight, each hive should be cleared of all dead bees. The frames should be rearranged by placing a frame well filled with honey at one side of the hive, and the queen and brood should be placed next to this frame, and then another well-filled frame should be placed upon the opposite side of the brood. Place oilcloth over the factory cloth, and put on a tight-fitting cover to exclude robber-bees, storms, and wind.

Then, in ten days or two weeks, should the weather prove favorable, go over them again, and if the bees are sufficiently strong, spread the brood and insert one empty frame of worker-comb in the center of the cluster. In one week repeat the operation, adding two empty combs in those hives having bees enough to cover them well. Continue thus until the brood-chamber is over-flowing with bees and brood in at least six of the eight frames. Then put on an upper story with at least three or four frames of worker-comb, and let the queen have access to this also.

As soon as the honey-flow begins, confine the queen to the brood-chamber with a queen-excluding honey-board, and if there is any honey to be had I will guarantee the bees will get it. At least this has been my experience. Should the colonies be sufficiently strong add a third story, and as soon as the honey is capped remove and extract.

Have a sufficient number of large barrels to hold two or three pounds of honey. Remove the heads and insert

molasses-gates near the bottom of each barrel. Place these barrels around the walls of the extracting room on strong benches of sufficient height to draw off the honey into 60-pound cans.

Have the head of each barrel covered with fine cheese-cloth, through which every ounce of honey should be strained. Leave the honey in the barrel as long as you can conveniently do so, as by so doing, should the barrel contain any thin honey, it will rise to the top and ripen by evaporation. Then draw off the honey into 60-pound cans. (In my estimation the 60-pound can is the only perfect package for storing and shipping honey.) Screw down the caps on the cans as tightly as possible. Then place the cans in cases holding two each, which makes a 120-pound package, net. Securely nail down the covers of the cases, and you can safely ship your honey to any foreign country should you so desire. This package is convenient to handle, free from leakage, and consequent unsightliness. Also, there will be no danger of having fermented honey in any climate.

You should get all of your clover honey out of the hives by the time the basswood season begins. At the close of the basswood season clean all the combs out again, in case there should be a fall flow of honey. Thus, you have each variety of honey separate from the others, and should there be a better market for one variety than the other, you are in a position to take advantage of it without any extra expense.

The secret of success in the honey-business is to do the proper thing at the proper time; as our seasons here in the North are short, at the best, we must make honey while the sun shines.
Vernon Co., Wis.

The Cause of Spring Killing of Drones.

BY G. M. DOOLITTLE.

"I have been keeping bees for about a year and a half now, and read the American Bee Journal. I want you to tell me through the columns of that paper what is the trouble with my bees. I have ten colonies that wintered well in the cellar, coming out strong in bees. They are strong now, and I see plenty of them working on the opening heads of white clover to-day, but they are killing off their drones. What could the drones have done that they are thus killed? They are making a business of killing them as much as they did last September. What is the cause, and what will be the result? Two of the ten colonies swarmed a short time ago."

The correspondent seems to think that his drones must have done something very wrong to cause the bees to kill them; but I hasten to assure him and the readers that his drones were not "sinners" above other drones, for all drones are treated in the same way under like circumstances. The failure of flowers, or with a "sea" of bloom and the flowers failing to secrete nectar on account of unfavorable weather, or the atmosphere not being favorable for the secretion of nectar, no matter if the weather appears all right, often causes the bees to kill their drones in May or June, as well as later on in August and September; and if the scarcity of nectar is great enough, drones just ready to emerge from their cells have the cell-covering gnawed open, and they themselves ruthlessly dragged out just before their wings are formed, and before they get even a sip of honey.

And if the failure of nectar-secretion continues, no matter how nice and fine the weather may appear, till the colony is on the verge of starvation, drone-brood, in its milky condition, is torn from the cells and sucked dry so as to prolong the existence of the colony, the refuse, not having any life-supporting qualities left, being cast out at the entrance to puzzle the bee-keeping novice who is not acquainted with these things.

The questioner did not tell us anything about what kind of weather he had been having in his locality, nor in which quarter the prevailing winds were. But I suspect that it was very much the same as we frequently have in this locality at about the time of the opening of the white clover bloom, namely, cool, cloudy, and windy, with more or less rain; or, what is nearly or quite as bad, all clear weather with the air in the northeast. I do not know why it is so, but in this locality we rarely get any secretion of nectar from any source of bloom, when the wind or air continually hangs in a northeast direction. I have known colonies to be killing their drones and dragging out drone-brood right in the very height of white clover bloom with seemingly nice weather for nectar-secretion, except that there was a northeast air day after day.

During cool, cloudy weather the bees rush out every

time the sun "breaks the clouds," and appear to be working well, while they are not getting a living for themselves and the brood, to say nothing about storing sufficient to afford the presence of drones, or these "gentlemen of leisure," as one bee-keeper calls them. After our questioner has studied into matters long enough he will know that such a state of affairs as this during white clover bloom is not an uncommon occurrence; and I believe a failure of nectar in the clover blossoms, in our correspondent's locality, is the cause of the killing of his drones.

The fact that only two of the colonies have swarmed, when all came out strong from the cellar, and that no swarming is being done at the time of writing, shows that there is no secretion of nectar to amount to anything, else his colonies would keep on swarming. Only two swarms, with the bees killing off their drones, is proof to my mind that the clover he saw his bees work upon is yielding little else save pollen, even though it appeared to him that his bees were working well.

As to what the result will be, I see no reason to fear anything bad, unless this honey-dearth continues so long that his colonies starve from his neglect to feed them. Nature makes no mistakes, and bees never kill off drones where they are needed. The colonies which have not swarmed have given up all idea of swarming for the present, without doubt, so they have no need of drones; and I will venture the assertion that, if he will look into the hives of the two colonies that have swarmed, he will either find drones or a young fertile queen, for a colony having queen-cells or a virgin queen will preserve their drones till the very last, even though the whole colony perish with hunger. If the failure of nectar continues, then the drones in these two colonies will be killed off as soon as the young queens have become fertile or laying queens; but our correspondent can rest assured that, until said queens have been mated, the drones in those hives will not be driven out as useless consumers.

My opinion is that whenever drones are being killed off in the spring of the year, or in early summer, it will amply pay to examine the colonies, and all not having sufficient stores to warrant them in keeping their drones, should be fed. In this way we not only preserve the drones so that they will be present should a sudden flow of honey come on so as to cause the bees to swarm before drones started after this flow arrived, were perfected; but it would also cause the bees to keep up the rearing of worker-brood to a greater or less extent, thus providing the bees for the basswood honey harvest. In fact, it never pays to allow colonies to come anywhere near the starvation point at any time of the year, and especially is this true during the forepart of the season.

Onondaga Co., N. Y.

No. 4.—Rearing Long-Lived Queens and Bees.

BY DR. E. GALLUP.

Now for the discovery in dissecting the queen-cell that I found, in the before mentioned basswood log hive. The queen was in the embryo stage, pretty well advanced, and had what I will call an umbilical cord attached to the point of the abdomen and the outer end glued to the bottom of the cell, with a large amount of royal food in the cell. I never have seen this fact mentioned by but one writer, and that I think was in the proceedings of the late Canadian convention. I never have seen this cord attachment to any nymph reared from an egg laid in a worker-cell in all I have ever examined, but have seen them from eggs laid in queen-cells by the queen.

Two weeks ago (May 3) my youngest boy brought home two small black swarms. In having them one had no queen so I gave it a frame of brood to hold them until I could fix them to suit. In 7 or 8 days, perhaps more, I gave a sealed cell from a superseding colony, and cut out 6 cells carefully from the comb I gave them, so I could examine them thoroughly at my leisure. This comb was taken out of the superseding colony. Five of those nymphs had no cord attachment, but the 6th one did; this nymph was a little farther advanced than the other 5. This must have been a superseding cell that I had overlooked. The 5 were started in worker-cells; they never have the cord, neither does a worker or drone nymph. Now, here is a kink that queen-breeders would better look into. When I first made the discovery I intended to follow it up, but soon had to leave bee-keeping for my other occupation. I claim that the queen draws nourishment from this large amount of food through this cord, in a somewhat similar manner to human beings and animals. Who knows?

Now, no one need dispute the fact that the queen deposits the eggs both in the cells built by the workers at natural swarming and superseding time. The cord is attached inside of the abdomen just at the very point, and extends nearly if not quite a 16th of an inch inside. Cut the cell out of comb whole, and then dissect carefully from the base of the cell in making your examinations.

In dividing colonies for increase, and allowing one part, or compelling one part, of the colony to rear queens from a worker-egg never was satisfactory to me. Queens thus reared are short-lived, and consequently their colonies cannot come up to the scratch.

I have received two queens from a party that started out well, but they did not hold out satisfactorily, at all.

I have already told you that bees stop breeding here for a while but can forage all winter. Well, towards spring I noticed that they were not showing up right, and on opening out one hive I found the queen and about a single handful of workers. The other hive had about twice as many, so I broke up both colonies. You can readily see that they were so short-lived that when the queens stopped breeding there was where the spring dwindling came in. I had one queen that reared extra-fancy colored bees, but she could only occupy a piece of comb about the size of my hand. There was no dwindling, for there was nothing to dwindle. Another queen kept her hive fairly full of brood, but the workers did not live long enough to store any more honey than they consumed from day to day, and early in the fall dwindled to nothing. I could tell of dozens of colonies that were about as worthless as the above. My object of sending for queens to different breeders last summer was to try to select a good strain to breed from. In selling, I kept one queen from one breeder that is holding out well so far.

As a boy I was a great and intense fancier of pets. Some 12 years ago I went into the Brown Leghorn business, paying \$5.00 for a sitting of premium eggs, and had a good hatch. But all got the swelled head. That was easy to get along with. I had lots of sure cure, warranted to cure swelled head, so I cured up a trio—two pullets and a cockerel. In breeding from those I had lots of swelled heads for 5 years, and, by the way I had one chick hatch from that first sitting with as beautiful a swelled head as I have ever seen.

I went into fancy pigeons; purchased a pair of Nuns; kept them three years and never raised but one young one—all died with canker when from one to three weeks old. I exchanged eggs with other pigeons, and the Nuns could raise the other pigeons everytime, but the other pigeons could not raise Nuns. I had lots of fun trying to cure canker with "sure cures," and I learned that the disease was transmitted in the egg. Cut the heads off; don't breed from diseased chickens that you have cured. I have had no diseased chickens of any kind for five years.

I have had several cases of bee-paralysis. Take an ax and cut the queen's head off; introduce another queen and the cure is complete—providing you do not introduce another diseased queen.

I was born in Canada, 65 miles north of the Vermont line; I kept bees there, and they wintered on the summer stand, usually in a small open shed built for that purpose. They were frequently confined to their hives from November 1 until May 1, and there were very few dead bees on the bottom-board in the spring. They wintered splendidly, providing they were ventilated right, and had sufficient stores. The thermometer often showed 40 degrees below zero. One time in particular it was 40 degrees below zero for 8 days and nights in succession. The bees came out nearly as strong in the spring as they went in in the fall. No spring dwindling or bee-paralysis was known there then. They swarmed naturally, and reared natural queens. No monkeying with them to try to beat Nature. They were long-lived bees.

I might have given my ideas in a short article and right to the point, and not pestered the editor and readers as I have, but my object is to get up a new fad—get all interested enough to go at it with a vim that will make success instead of a failure of the business.

Rear long-lived, healthy queens, and rear them in a natural manner. I care not how long you get their tongues or tails. We want bees for business, not for fancy.

Orange Co., Calif.

(Continued next week.)

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Swarming Indications.

When should one begin to watch bees for swarming? and at what time of the day are they most likely to come out?

OHIO.

ANSWER.—There can be no fixed rule. It is a matter of conditions rather than a matter of the almanac. I don't know enough to tell exactly what the conditions are; but before a colony thinks of sending out a prime swarm it must be strong, and there must be a good yield of nectar. As you are probably in a white clover region, you may begin to watch for swarms as soon as the bees get to work on white clover. A prime swarm will not usually issue more than three hours before or after the middle of the day. An after-swarm may issue as much as six hours before or after noon. Probably you will find that nearly all the swarming will occur between 8 a.m. and 4 p.m.

Getting Increase and Transferring.

I have 7 very strong colonies in large box-hives. I want some increase without regard to surplus of honey. I intend to let them swarm, hive the swarm in a frame hive on the old stand, set the box-hive back after four or five days, open the box-hive and divide equally (as nearly as I can) in two parts—bees, brood, stores, and queen-cells—and put in frame hives. Will this work?

OHIO.

ANSWER.—Yes, it will work, but you may expect a messy job with so much brood and honey present. If you are not after honey, you would have a more equal division not to set the swarm on the old stand (which will make the swarm very strong, leaving the mother colony proportionately weak), but to put the swarm on a new stand. Then there is a likelihood that it will swarm again in about eight days, and 21 days after the time when the prime swarm issued you can transfer with no worker-brood in the way.

Oxide of Zinc for Hive-Covers.

I saw an article in the American Bee Journal in regard to commercial oxide of zinc being so good to cover hives. Can metal roofs, that are leaky, be patched with that material? How would the oxide ground in oil do? If you know of anything really No. 1 for patching up old, leaky, rusty, tin roofs that can't be soldered, please let me know it.

MISSOURI.

ANSWER.—I don't know, and respectfully refer the question to be answered by any one of the fraternity who can answer.

Introducing Queens at Swarming-Time.

As I am just a novice in the handling of bees, I wish to ask if at swarming-time one could move the old hive to a new location, and, waiting until all the old bees had gone back to the old stand (if they will go back), then introduce a queen to what were left in the old hive? Would there be any danger of her getting killed?

NEBRASKA.

ANSWER.—Introduction of queens is such an uncertain matter that there is almost always some danger, but if all queen-cells are removed and the new queen is introduced a day or two after the swarming, you will have the danger reduced to a minimum.

Referring to the implied doubt in your parenthesis, it may be said that there is no room for doubt, that when, after swarming, the mother colony is removed to a new stand, and the swarm put on the old stand, the field bees will return to the old stand unless you take some special precaution to keep them on the new stand. But it will be a day or two before they will all have returned.

The Use of the Queen's Sting.

I herewith send you some clippings that I think are good information for the public, except several lines that I will draw my pen around. I do not recollect ever seeing them in the American Bee Journal. If there is any truth in it some of the readers will certainly know. How one would find out I am anxious to know.

OHIO.

ANSWER.—The sentence referred to reads as follows:

"The sting is an organ of use to the queen-bee in disposing of rivals, though mainly used in depositing eggs in their proper position during the working season."

The writer of that sentence is not alone in his belief, though what ground there may be for the belief I do not know. In the scientific part of Cheshire's work one would expect to find a pretty full exposition of the subject if anything were positively known about it, but there is only one possible reference to it, which is in these words:

"It has been remarked that the decided curvature of the queen's sting, in contrast to the straightness of that of the worker, is intended to give her such an advantage in combat, that, while her sting is applied, her antagonist should be powerless to reach her, so that a queen duel may not be fatal to both; but the curvature appears to me rather to refer to mating and ovipositing, as the extremity of the sheath can be turned far more completely out of the way through its deviation from the straight line."

That can hardly be understood to mean that the sting is a help either in mating or ovipositing, but rather that its curved shape makes it less a hindrance than it otherwise would be.

Getting Brood-Combs Built.

This is my first year with bees. I have Danzenbaker hives. If at the close of the white honey harvest I double the brood-chamber, putting full sheets of foundation in the upper story, will the bees build comb suitable for brood-rearing next spring? If not, how shall I best proceed?

MICHIGAN.

ANSWER.—Bees will build comb only as they need it. If, after white clover, there is a sufficient income from other sources, they will build all the comb they need to occupy. If they gather nothing, they will do little more than to daub the foundation with propolis so as to make it less fit for use. The simple rule is to give foundation when they need more room, whether it be early or late.

Alfalfa in Tennessee.

Does alfalfa yield honey the first year? I sowed some two years ago; it came into bloom, but the bees did nothing with it. Last fall I sowed alsike, which has not fared much better, and buckwheat this spring, that bloomed nearly a month ago, with like result.

TENNESSEE.

ANSWER.—As far east as Tennessee you will probably find that alfalfa yields no honey the first nor the twenty-first year. It seems strange that a plant that stands so very high as a honey-yielder west of the Mississippi, should be of no value in that regard farther east. As to alsike and buckwheat, you may find them behaving differently other years.

Only One Night to Denver.—By going over the Chicago & North-Western and Union Pacific railways, you will need to spend only one night on the road from Chicago to Denver. There is a daily train leaving Chicago at 10 a.m. on the C. & N. W., and leaving Omaha, Nebr., over the Union Pacific at 11:30 p.m. of the same day. This train arrives in Denver at 2 p.m. the following day. That is, by starting from Chicago at 10 a.m. on Tuesday, Sept. 2, you will arrive in Denver at 2 p.m. the next day, or Wednesday, Sept. 3, in ample time for the first session of the National Bee-Keepers' convention, which begins that evening.

Now as to rates: The round-trip price at that time from Chicago to Denver will be \$25. By going over the route mentioned, the regular sleeping-car rate would be only \$3.00, because of being only one night on the way.

There is also another saving by taking the C. & N. W. and Union Pacific. There is a Pullman tourist car on this train from Omaha, in which the charge for a double berth is only \$1.50 to Denver. As no sleeping-car accommodations are required on this train east of Omaha, it will be seen that one can go comfortably by this route for a very small sum.

We may say that Dr. C. C. Miller and the Editor of the American Bee Journal expect to go over the route indicated, starting at 10 a.m. on Tuesday, Sept. 2. Who will join us?

GENERAL ITEMS

A Veteran Bee-Keeper.

My bees all came through strong, and commenced to swarm on May 30. I am sorry I did not put supers on all of them before I did. There is a good show at present for honey this year.

I have had 4 swarms from those I did not put on the supers: the rest are all working nicely in supers.

I am nearly 79 years old, do not use glasses, and am quite nimble as yet. I go out with dog and gun when in season. My bees are on the farm, so I have one mile to go every day.

HENRY WHITE.

Humboldt Co., Iowa, June 10.

Awful Winter for Bees.

We have had an awful winter for bees. I lost 17 colonies out of 28. Bees did not have a flight from Oct. 15 to Feb. 22. Some days the snow in front of the hives would be black with bees, and I used to tell my wife I did not see how they could possibly live and waste themselves so.

We had very cold weather all the spring; things are white with frost this morning. I am afraid everything is frost-bitten in the garden.

C. G. ASCHA.

Berkshire Co., Mass., June 9.

Discouraging Outlook.

The outlook is very discouraging indeed for this section of country. The incessant rains and cool weather have reduced the bees to the verge of starvation.

My bees were in swarming condition a month ago, but in spite of all the feeding I have done they have dwindled until it looks as if there would be but few bees to gather honey, if there were any to gather.

Everything is late here, and the prospect may brighten a little later on.

MRS. JENNIE TOWLE.

Clark Co., Wis., June 7.

Tick Trefoil.

What relation is bush-clover to alfalfa and other clovers? I enclose another sample of a plant without root. It began blooming about May 15, and will continue until about June 10. The bees have not had anything from it yet, as it has been too wet.

CHAS. M. DARROW.

Vernon Co., Mo., June 4.

[This specimen, which is much more mature than the first, shows the plant to be a Tick Trefoil, probably *Desmodium paniculatum*, and not a bush-clover. The ripened pod is curved with minute hooked hairs which catch on the wool or hair of animals, or to clothing; hence the name, "Tick." "Trefoil" refers to the leaf being made of three leaflets, or being trifoliate.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested	1.50	8.00	15.00
Selected Tested	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Quirin the Queen-Breeder,

PARKERTOWN, OHIO.

[Parkertown is a P. O. Money Order office.]
15A26t Please mention the Bee Journal.

Low Rates to Atlantic Coast Points.

July 5 to 9, inclusive, the Nickel Plate Road will sell tickets to Portland, Me., and return, at one fare for the round-trip. It will be to your interest to obtain rates via that road before purchasing elsewhere. Three daily trains. Write John Y. Calahan, General Agent, 111 Adams St., Chicago. 26-26A2t

liate. The Tick Trefoil belongs to the large and important pulse or leguminosæ family, to which bush-clover, alfalfa, and other clovers belong.

The family, as a whole, is rather sweet, as among its most promising representatives might be mentioned the clovers, trefoils, lupine, locust, vetch, and false indigo.—C. W. WALTON.]

Bad Spring for Bees.

The spring has been very bad for bees here, and the losses from spring dwindling have been very great. I have a few colonies in fine condition, but more very weak, besides a number of them dying out entirely since the first of March. JAMES P. HOWARD.

Milwaukee Co., Wis., June 9.

Basswood or Linden Tea.

Europe and American linden or basswood are just the same—the blossoms can be gathered for tea in case of sickness. The tea is good for fevers, all kinds of sore throat, measles, whooping cough and chicken-pox. Take the tea as a drink in time and it will save many a long sick spell, and a large doctor's bill.

The blossoms are in full bloom about July 10; gather them when they are in bloom, with the stem, then dry them in the shade. They are then all right for tea. Just put boiling water over the blossoms, and in 10 minutes the tea is ready for drinking. The hot water can be put on the tea a second time. In case of sickness the tea needs to be made fresh two or three times a day. It needs to be sweetened with honey. (See page 170.)

CATHARINE WAINRIGHT.

Poweshiek Co., Iowa.

A Beginner's Experience with Bees.

I am a "tenderfoot" in the bee-business, having had but one year's experience before the present one. I will not stop to tell of the disappointments and mistakes, but proceed to display my ignorance by propounding a few questions.

Very many of the natives keep bees in the "native" way, in boxes and hollow logs, and if they "rob" out 20 to 30 pounds of honey, bee-bread and brood, they think they are doing fairly well.

Please tell me why, this year more than usual, about $\frac{2}{3}$ or $\frac{3}{4}$ of the swarms fly away? Many come out and leave after having been hived in new "gums."*

My man, who works in the shop for me, has had some years' experience with bees, in the regular Georgia way, and we are transferring all our colonies into the regular 8-frame Langstroth hives. One was transferred in good shape, and in 21 days we drove out another fine swarm, and in cutting out the old comb we found brood enough to fill 7 frames, which was properly arranged in another hive, and a sufficient number of bees induced to enter, and now the seventh day they appear to be doing well. Besides this we secured $2\frac{1}{2}$ gallons of honey. I will report on this colony later.

Another colony had the super nearly

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

Thousands of Hives, Millions of Sections, ready for Prompt Shipment.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Please Mention the Bee Journal when writing Advertisers *****

full in 24 days after they were transferred to an 8-frame hive, with full sheets of foundation, and are working on the second.

We are endeavoring to introduce the regulation hives with foundation in frames, and starters in the section, but the people consider it a useless outlay; but when they come to see our product next fall they may think differently.

F. S. DUNKLER.

Haralson Co., Ga., May 26.

[*It is quite possible that more swarms desert their hives than usual because of unusual heat. The thermometer may stand higher, or with the same height there may be more moisture in the atmosphere. It is possible, also, that you do not give as much ventilation and shade as you ought. Leave the cover partly off for a day or so after hiving.—EDITOR.]

Poor Prospects for California.

On page 347, I notice an item by A. J. Cook, in regard to California prospects for 1902. I must say it surprised me very much. Perhaps his means of getting knowledge of the situation are much greater than mine. Up to this date my bees have not stored a pound of honey more than their wants, and from inquiry and observation I am well satisfied the bee-men in Southern California are not going to reap much of a harvest this year.

I have been around a little also in San Bernardino, Riverside, and Orange Counties, and I could not see that prospects looked any better than in Los Angeles County. There may be a few local places where some honey will be gathered.

I am sorry that I must disagree with Prof. Cook, but the facts, so far as I know, compel me to do so.

A. ROZELL.

Los Angeles Co., Calif., June 6.

Managing Swarms and Swarming.

I have a method of handling bees which is different in some respects from the general custom in regard to swarming and hiving of swarms. I have practiced this method for several years with complete success.

How to produce the largest possible amount of fancy white comb honey, also the most extracted honey: We try to get all colonies as strong as possible before raspberry and clover bloom. At the commencement of raspberry bloom we put supers on all colonies, and they usually swarm when the supers are about two-thirds full. This is just what we want them to do. As the queen's wings are clipped we go to the hive that is swarming, cage the queen, and if we conclude to run the swarm for comb honey we hive them on the old stand in a brood-chamber containing starters only.

Take the super from the parent colony and place it on the swarm. The following evening we take the parent colony and place it beside its swarm, and leave it there for six or seven days, then move the parent colony to a new stand. The brood is all sealed in seven days, and it is better to have the flying bees from the parent colony enter with the swarm, as it gives the swarm wax-

workers, which is very important at this time, and it gathers later; the parent colony is prevented from casting a second swarm, and all goes well.

There are several reasons why we should get more honey than we would had they not swarmed. The swarm has nothing to do for several days but gather honey, as they have but little brood to care for; as the combs in the super are drawn, and the frames in the brood-chamber contain starters, they commence work in the super at once, and build combs in the brood-chamber only as fast as the queen needs cells to deposit eggs and pollen, and the cells will be of the worker size, and but little, if any, drawn comb will be built.

For extracted honey we give the swarm full combs or full sheets of foundation on wired frames, as this prevents the queen from entering the super.

If there is anything that is not made plain I will be pleased to try to make it so.

E. E. COVEYOU.

Emmet Co., Mich., May 27.

Good Queens from Poor Ones.

EDITOR YORK:—Please tell me what Geo. W. Riker means when he says, on page 302, "I found I could rear queens from my poorest queens that produce long-lived workers."

INQUIRER.

[Give it up. We'll have to refer it to Mr. Riker himself. Perhaps he can and will tell.—EDITOR]

Second-Hand Oil-Cans.

On page 339 is something on "Honey in Old Oil-Cans." In 1871-72 I kept bees in California, 12 miles from Los Angeles. I commenced in the spring of 1872 with 48 colonies, increased to 100, and that season got eight tons of honey, all extracted, and I shipped it to San Francisco, all in second-hand oil-cans, and all to one commission merchant, and got the top price. It netted me 12½ cents, freight and commission paid. There was not one complaint made. The cans were as clean as new, with no odor of the oil after they were cleaned. All the bee-keepers there used them. The trouble with the cans was referred to on page 339, they were not cleaned well. After cleaning with concentrated lye they have to be left in the sun for several days, and there will be no odor left.

J. BECKLEY.

Rice Co., Minn., June 2.

[If you know how, and will do it right, it may be all right. But it hardly pays to risk using old, second-hand oil-cans for holding honey. That is, if you care anything about your honey and your trade.—EDITOR.]

A Discouraging Spring.

When it comes to booming bees here we are not in the business. They have not made a living. They came out strong in the spring, in grand shape, but they have been on a strike and refuse to work, and it is a hard matter to arbitrate with them.

I do not believe I will get any increase or an ounce of honey this year unless things change, as they are not

as strong now as when they came out in the spring.

We have had an off year in this section of the country, with high, cold winds, and freezing weather.

I live in the village near the Scioto Marsh, in the onion-raising district. I keep bees, raise onions and fruit, and garden for a living, and to say that I have been on the anxious seat this spring is putting it mild.

Onions—the wind blew them out of existence. Then I rescued them again, and the wind and freeze had them all except one acre. All vegetation is frozen. We had no rain this spring until June 6, and the dirt was blown in great clouds, and did thousands of dollars damage to the onions and other crops. So with the dry weather, cold and bad high winds every day for the last six weeks, and clover and linden blown down, we are not in it for a honey crop this year, from this place in Ohio, anyway.

If it were not for the "Old Reliable" and Gleanings in Bee-Culture I would go out of the bee-business and hire out as a cheap errand-boy.

F. MCBRIDE.

Hardin Co., Ohio, June 9.

Caves vs. Cellars for Bees.

The following from Editor Doolittle, in the Progressive Bee-Keeper, will make some wish they could have caves instead of cellars:

The consumption of stores from the latter part of September, at which time they were prepared regarding their winter's supplies, to the time of putting out, averaged about six pounds to the colony, for those here at home, while those in the out-cellar consumed nearly or quite twice as much. Those in the out-cellar were in a house-cellar, with a family in the rooms above, while those here at home were in a special cellar dug in the side-hill, so that an even temperature of 45 degrees was maintained during the whole time they were in winter quarters, which was from Nov. 15 till April 15 to 17th, or approximately five months.

How Cubans Take Honey.

The native Cubans have log-hives 40 inches long and 8 or 10 inches square, the hives being made by sawing the royal palm into sections and cutting out the center, which is a tough pith. A board is nailed on to close the back end of the hive, the front being left entirely open. So says Rambler in Gleanings in Bee-Culture. As to securing the crop, he says:

The owner approaches a hive much as we do with smoker in hand; and if not a modern smoker it is something like a stew-pan arrangement; or (as Cubans all smoke) the ever-present cigar may be used.

After the bees are driven back, a thin

REVERSIBLE WALL MAP
 OF THE
UNITED STATES AND WORLD,
 WITH SPECIAL INSET MAPS OF

China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,

Epecially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. **Very useful in every Home and Office.**
66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map
 Ever Issued.

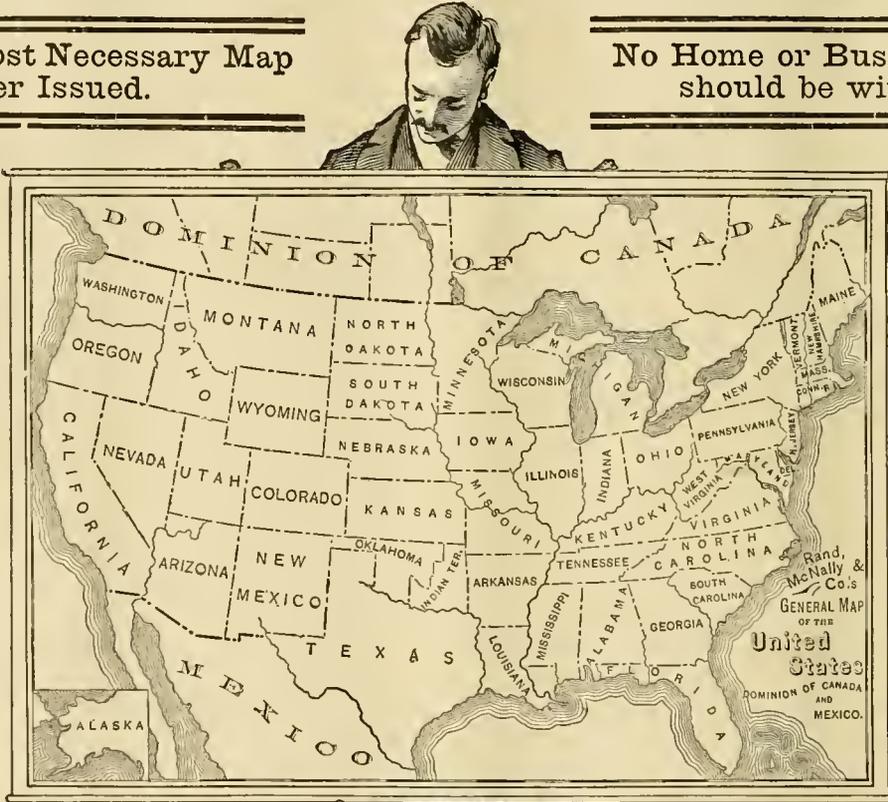

No Home or Business House
 should be without it.

The Plates

are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance

a salient feature of this map not approached by any similar publication.

A Marginal Index

is one of the invaluable features.

It gives an alphabetical list of countries, their location on map, style of government, population, area, products, minerals, imports, exports, etc.

It has been pronounced a **Photograph of the World**

The 1900 Census of the largest American Cities is given.

One side shows a grand map of our great country, with **counties**, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, capitals, rivers, mountains, products, business, etc., a veritable photograph of the UNITED STATES AND WORLD.

The map is printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

1901 EDITION.—Every reader should consult it every day. The plates show all the new railroad lines and extensions, county changes, etc. Especial attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahama Islands.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. **The Inset Maps** are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps on one sheet, all for only **\$1.50**, sent by mail or prepaid express; or we will forward it free as a premium for sending us **Three New Subscribers** at \$1.00 each; or for \$2.00 we will send the Map and the American Bee Journal for one year. Address,

GEORGE W. YORK & CO.,

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, June 18.—The market is practically over in comb honey until the new crop comes forward, so far none has appeared in this city. A little of the extracted is on sale, but it is chiefly of a low grade of amber selling at about 5 cents per pound. There is a large amount of the white extracted honey of the crop of 1901 still on sale bringing 5@6c, according to body and flavor. Beeswax sells upon arrival at 32c.
R. A. BURNETT & CO.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.
THE FRED W. MUTH CO.

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14@15c. Extracted, 6@6½c. Beeswax, good demand, 30@31c.
H. R. WRIGHT.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

NEW YORK, May 19.—There is a limited demand for comb honey and prices range as follows: Fancy white, 14c; No. 1, white, 13c; amber, 11@12c; no buckwheat or dark on the market and no more demand for any. Market on extracted remains very inactive. Plenty of supply with only fair demand. We quote: white, 5½@5¾c; light amber, 5@5½c; southern, in barrels, 50@55c gallon. Beeswax firm at from 30@32c pound, according to quality.
HILDRETH & SEGLKEN.

CINCINNATI, June 7.—There is hardly any change in the honey market. Comb is not moving much, and whatever is left can be bought at cut rates. Water-white is selling from 14@15c. Extracted is in fair demand and finds steady sales, in barrels, 5@5½c; water-white alfalfa from 6@6½c; white clover from 6½@7c. Beeswax is coming in more freely and sells for 28c.
C. H. W. WEBER.

SAN FRANCISCO, June 11.—White comb, 10@12 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4½@—; amber, 4@—; Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There is not much of any description coming forward at present or being offered for sale. To purchase freely, better figures than are warranted as quotations would have to be paid. No evidences are displayed, however, of large operators doing any noteworthy competitive bidding so far on this season's product, although the crop is not coming up to expectations in point of quantity.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.
THE A. I. ROOT COMPANY, Medina, Ohio.
GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.
J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.
M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

An Italian Queen Free!

We would like to have our regular subscribers (who best know the value of the American Bee Journal) to work for us in getting **NEW** subscribers. We do not ask them to work for us for nothing, but wish to say that we will mail **ONE FINE UNTESTED ITALIAN QUEEN** for sending us **ONE NEW** subscriber for a year, with \$1.00; or 2 Queens for sending 2 new subscribers, etc. Remember, this offer is made *only* to those who are now getting the Bee Journal regularly, and whose subscriptions are fully paid up.

In case you cannot secure the new subscribers, we will mail one of these Queens for 75 cts., or 3 or more at 70 cts. each; or the Bee Journal one year and a Queen for \$1.50.

(Please do not get these offers mixed up with our Red Clover Queen offers on another page.)

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we will close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

A New Edition. 19th Thousand.

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the postpaid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

* Editorial Comments. *

Fears Poisoning from Spraying.—We have just received the following letter from a large bee-keeper in Richland Co., Wis., dated June 24, 1902:

EDITOR AMERICAN BEE JOURNAL.—

Dear Sir:—We have been having quite an experience in the bee-business, and I write you for some information. Our bees have been very strong, and I never saw more healthy looking bees, or more of them, than we have had all spring. About three or four weeks ago we noticed a few bees looked ragged. Their wings were all frayed out, and they looked badly. Last week there were large numbers of those bees, and the colonies weakened down in quite an alarming manner. We have been studying and thinking of all sorts of causes, and at present we have settled down on the spraying of fruit-bloom as being the cause of the bees going to pieces as they have. The young bees seem to disappear, and now we wonder if it could be possible that the brood reared during fruit-bloom could have been poisoned.

Can you tell what the effect of spraying fruit-trees when in full bloom would be on bees? Would it affect the working bees? And could it affect the brood? Would the brood hatch fed on poisoned pollen, providing there was only a slight poisoning? or would the brood die if there was any poison in the food at all? If it should hatch, could it produce healthy bees?

Now, Mr. York, it has become an alarming subject to us, and we are very interested to know all we can on the subject. The sick bees seem to have flown away. There are no bees crawling around the yard as they do with bee-paralysis. The brood hatching now seems to be all right, and the young bees in the hives look as healthy as any bees I ever saw.

This will be enough to start on.

Yours truly,

Now, we don't know a thing about this, as we never saw any bees that were poisoned by spraying fruit-bloom, nor do we remember having read a description of such result. But there may be a number of our readers who have had just the experience this bee-keeper is having. If there are any such, will they please sit right down and write to us the answers to the questions in the foregoing, and also add any other information bearing on the subject? We should be pleased to publish very full replies to the questions asked in the foregoing, as it appears to be a very vital matter, one in which all bee-keepers would be deeply interested. It certainly is a serious affair, as described in the above, and needs to be understood thoroughly so that proper measures can be taken to prevent a recurrence of the disastrous proceedings.

Young Queens and Swarming.—At one time it was held as a safe rule that when a colony contained a young queen of the current year's rearing there would be no swarming. Then it was learned that with Italians exceptions were too frequent to allow any dependence on the

rule. Perhaps, however, there is little difference in this regard as to the behavior of Italians and blacks. The truth seems to be that a colony will not swarm if it contains a queen reared the current year *in the colony itself*, but if a young queen reared elsewhere is introduced it makes no difference as to swarming, even if the young queen should not have been laying two days. Just why there is this difference has not been explained, but it is well to know the fact that a colony inclined to swarm will not be diverted from its purpose by the introduction of a young queen reared elsewhere.

The General Managership of the National.—We have received the following from the former Acting Chairman of the Board of Directors of the National Bee-Keepers' Association, which refers to a statement made by Mr. Abbott, on page 403:

TO THE MEMBERSHIP OF THE NATIONAL BEE-KEEPERS' ASSOCIATION.

In the statement made by Mr. Abbott to the public there are two propositions: First, the Board of Directors of the National Bee-Keepers' Association has the right to receive the resignation of Mr. Secor and elect his successor; or, second, it does not have such right. Let us consider the first proposition. I was appointed Acting Chairman of the Board of Directors by Mr. E. T. Abbott, who was then Chairman, to put the vote on the selection of a new General Manager, Mr. Secor, the old Manager, having sent in his resignation to Mr. Hutchinson. I did so, and the result of that vote on the part of the Board showed six votes for E. T. Abbott, one vote for E. M. Abbott, and one for W. Z. Hutchinson.

I was in doubt whether I could declare this an election or not. I finally turned the matter over to Mr. Abbott, who was Chairman of the Board, saying that I thought that E. M. Abbott was intended for E. T. Abbott, and could be so construed as the "intent of the voter." Mr. Abbott then issued a circular letter to the Board, declaring an election for himself as General Manager, and at the same time announcing that he had resigned as Chairman of the Board. I was then appointed by him as Acting Chairman until a permanent Chairman had been elected.

Subsequent developments showed that the Board was very much dissatisfied with the procedure. The contention was that E. M. Abbott was not E. T. Abbott, and that there were only six votes—not a majority. I was criticised for not declaring the vote myself instead of turning it over to an interested party. In the meantime it developed that the resignation of Mr. Secor had not been accepted either by the Executive Committee or the Board of Directors. Some thought that Mr. Secor should have sent his resignation to the Chairman of the Board. To avoid complication Mr. Secor then sent his resignation to me. This I placed before the Board with the result that every member voted not to accept. It was further contended that because this resignation had not been accepted Mr. Secor was legally General Manager at the *very time we were trying to elect his successor*, and that, therefore, the procedure was irregular and the election void. At the time of submitting this resignation I also stated that an appeal had been made from Mr. Abbott's decision to the effect that he was elected General Manager, and inquired whether that decision should be sustained. To this there were ten negative votes and one affirmative. I then announced to the Board that Mr. Abbott's decision (or mine, if Mr. A. prefers to have it so) was overruled, and declared Mr. Secor General Manager.

Let us take the other horn of the dilemma, or the second proposition, viz.: the Board did *not* have the power to accept Mr. Secor's resignation and elect his successor. Mr. Secor tendered his resignation and elected his successor. Mr. Secor tendered his resignation the second time to the Board of Directors, and the Board unanimously declined to entertain it. Mr. Secor has notified the Board that he will continue in office till his successor is elected and qualified. This avoids all complications; and if the Board can not fill a vacancy caused by voluntary resignation, then it has done the proper thing by refusing to entertain a resignation it could not accept (if Mr. Abbott is correct), and leave the man in office who was elected at the last *regular* election, when every member of the Association had a chance to vote. If Mr. Abbott's claim is correct, then the only thing that can be done is to leave the matter as it is, and wait till the next general election—only six months away.

My understanding of the matter is that Mr. Secor's resignation is not "before the membership." It has been returned to Mr. Secor marked "Not accepted." He has been unanimously requested by the Board, to whom he is responsible, and from whom he receives instructions, to fill out his unexpired term, and this he has consented to do.

For the complication that has arisen I do not wish to shift all the blame on Mr. Abbott, by any means. Among other things I should have made it my business to see that the resignation of Secor was accepted *before* I called for a vote for his successor, and then I should have declared the vote myself. While it is easy to see what *might* have been done it is not always easy to rectify past mistakes.

To go into all the details of this would require a good-sized volume, and I forbear. It is a matter of deep regret that Mr. Abbott, an able and capable man, should so persistently go against the Board of Directors. If he had quietly acquiesced in the first place, it is my opinion he would have been finally elected General Manager by the Board.

I will conclude by saying that this business has been the most disagreeable of any I have undertaken.

E. R. ROOT,

Former Acting Chairman of the Board of Directors.

Prevention of Increase.—A plan that is in use in Germany with box-hives may also be used with movable-frame hives. When a colony swarms remove the old queen and return the swarm. Eight days later cut out all cells that can be reached but one. (In a box-hive only part of the cells may be within reach, but in a movable-frame hive all are accessible.) If a swarm issues, hive, and in the evening return to the old colony. That will be the end of swarming for the season, and the whole force of the colony will be left to make good work at storing. A variation of the plan that has been recommended in this country is to destroy the old queen and return the prime swarm, then wait till the young queen is heard piping in the evening, and in the morning of the next day cut out *all* queen-cells.

* The Weekly Budget. *

MR. WM. ROHRIG, of Maricopa Co., Ariz., wrote us, June 17, that "there will be very little honey produced in Arizona this year; it is so very dry."

A. I. ROOT has gone back to his cabin in the woods of northern Michigan, interesting himself in peach-trees, chickens, angle-worms, etc., leaving the younger fry to run things at "The Home of the Honey-Bees."

THE APIARY OF C. C. CHAMBERLIN—the owner wrote us as follows when sending the picture shown herewith:

"I commenced keeping bees when I commenced taking the 'Old Reliable,' in 1893. My hives are all the 8-frame Langstroth size, and my own make. You will notice in the picture that they are all packed in outer cases. The pack-

APIARY OF C. C. CHAMBERLIN, OF MACOMB CO., MICH.

ing material is leaves from the forest, and wheat chaff cushions on top.

"My entire crop of honey last year was 1000 pounds, mostly white clover in plain sections. Nearly all was sold for 14 and 15 cents a pound. From 23 colonies, last spring, I increased to 46, and lost one in wintering.

"To-day (March 29) the bees are gathering pollen from the willow, and the weather is fine."

A LIVE EXHIBIT AT ST. LOUIS.—"The liveliest live exhibit at the Louisiana Purchase Exposition in 1904 will come from Colorado." Thus spoke Van E. Rouse, the Colorado Springs mine-owner and capitalist, during his visit to St. Louis lately with the Colorado World's Fair Commission, of which he is an active member. "The world generally knows that as a mining country Colorado leads all nations on the globe," continued Mr. Rouse, "and this has naturally created the impression outside of Colorado that all the wealth of our magnificent State is hidden underground. Our exhibit at the World's Fair will show Colorado to be not only great in mining, but that it is a world-leader in horticulture and agriculture.

"The World's Fair management, in their plan and scope of the Exposition, declared they wanted live exhibits, so in casting about for plans to make our exhibit conform to that idea, we interested one of our wealthiest and most public-spirited citizens—Hon. G. W. Swink, of Otero County. Mr. Swink is an apiarist, and he has one of the largest bee-plants in America. He is going to bring his bees to the World's Fair, and they will work here from the time the Exposition opens until it closes. Mr. Swink's plan, which will cost fully \$10,000 of his own money, is to bring to St. Louis enough hives containing bees to construct in miniature a counterpart of the Colorado State House at Denver. The bees will then be turned out to find material for honey in the country surrounding the World's Fair grounds. It will require about 640 hives to construct the little State House, and in it about five and one-half million bees will work. It will be a great exhibit. In Colorado we have the finest honey in the world. We have one bee-man who works his bees all the year through. In summer they work in his alfalfa fields in Colorado, and in the fall he ships them to his plantation in Florida, where they work among the flowers and orange-groves until time to return them to the West in the spring."

THE APIARY AND HOME OF THADDEUS SMITH, on Pelee Island, Ontario, appears on the first page. Perhaps we would better say that the picture shows a part of the apiary, with a view of the residence in the background. It will be seen that the hives are all chaff hives, or other double-walled hives. The location is on the northwest point of the Island, and this point is surrounded by water almost on three sides, making it very much exposed to the wind from off the Lake. There is no windbreak, and such a location makes outdoor wintering much more difficult, so Mr. Smith generally suffers some loss. For several seasons he has greatly reduced the number of colonies now kept.

Mr. Smith certainly has a beautiful home.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 405.)

PRODUCING UNIFORM QUALITY AND FLAVOR.

"Can a bee-keeper be certain that from season to season his bees will produce honey of uniform quality and flavor?"

A Member—No, sir.

Mr. Burnett—That is one of the reasons why it is not required to have your name on sections of honey. People get accustomed to a certain flavor, and if they don't get that again, "Oh, well," they say, "this man's honey used to be good, but it isn't any more." It is one of the strong arguments against putting your name on honey.

Mr. Dadant—We have had bees in apiaries (and have now) three or four miles apart; we used to have six; we have four at present. It is hardly ever that the honey from one apiary is an exact sample of the honey in another at the same date. In some parts the honey will be white clover; further on there is basswood next to the honey-field, and this will all affect the taste of the honey. Each apiary will have a special brand of its own. A person who is not accustomed to honey will call it not good, if it tastes different from that he has been accustomed to. There is a difference in honey according to the location of the apiary.

Mr. Moore—Not only would Mr. Dadant find that his two apiaries are not alike, but he will find, if it is as it is up by my house, that the honey this year will not be exactly the same as next year. Another thing you will find is, that the weight will be different from year to year; and that is one of the reasons why some people will ask what size the sections are. If you find a locality will produce exactly a pound section of honey this year it may not produce exactly a pound next year; that is one of the reasons why it is not the right thing to sell honey by the case. One case will be plump full and heavy, and another case will be lean, and if you sell by the case they will come in and be placed on the market at the same price, and there is no fairness about it. It is not quite the right thing to sell sections by the piece, so long as you can't get the bees to make them of equal weight, and the time has not come when you can get them to do this.

Mr. Spring—Is it not a fact that the quality and flavor of honey from different colonies, even in the same apiary, will differ quite materially, and at the same time?

Mr. Dadant—Yes. A gentleman right by my side called my attention to that fact, which I know to be the case. I knew of a most interesting case of this kind, when bees stored from honey-dew, which is produced on the trees early in the morning or at night. The bees gather it late in the evening or early morning. I remember some colonies of bees being a little earlier than others, and they would go out and get it every morning, while a lot of the colonies near by didn't get any of it, because they got out too late; and some hives had honey almost like molasses, while others had white clover—black and white, side by side.

Mr. Moore—I remember years ago I had an apiary that was working on buckwheat; two colonies stored white honey and the rest buckwheat.

Mr. Blunk—I had one colony this season right the reverse; I had dark honey right through on white clover.

GETTING COLONIES READY FOR THE HONEY-FLOW.

"Will a good queen starting to lay April 15 have her colony in good condition for the honey-flow June 10?"

Dr. Miller—That depends upon the strength of the colony April 15.

AMOUNT OF STORES FOR WINTER—BEST SIZE OF HIVE.

"Is 45 pounds, gross weight, enough to winter a colony of bees?"

Mr. Dadant—Our hives weigh 50 pounds, empty.

Dr. Miller—That depends again upon the weight of the hive and the age of the combs; upon the amount of pollen present. A lot of old black combs will weigh very much heavier than fresh, new combs. Taking the average colony, I should say 45 pounds is rather light.

"What is the best size of hive to use in producing comb honey? Is a 10-frame hive too large for comb-honey production?"

Pres. York—Limiting it to Chicago locality, how many think the 10-frame hive is the best size of hive to produce comb honey?

Ten favored.

Pres. York—How many think the 8-frame hive is the best?

One favored.

Pres. York—Is a 10-frame hive too large for comb-honey production?

Mr. Horstmann—I don't think any hive is too large. The question is, Can you produce comb honey to better advantage in a large hive than a small one? I will use an 8-frame hive until I can prove that the 10-frame hive is better.

Mr. Dean—In regard to the production of comb honey, I don't think it makes very much difference only in this respect: A 10-frame hive leaves the bees in better condition after winter; they will have more ripe sealed honey in the lower story than in an 8-frame hive; consequently I think the 10-frame hive the better.

A Member—How about the 12-frame hive, Mr. Dunn?

Mr. Dunn—I have not tried it long enough to tell.

MISCELLANEOUS QUESTIONS.

"Is the fall section of any advantage in the Chicago market?"

Mr. Burnett—No.

"Does the clipping of the queens lead to supersedure?"

Dr. Miller—No.

"What has been the average winter loss in Cook County?"

Pres. York—Pretty hard to tell; I guess not as heavy as in some other places.

"What is the best temperature for a bee-repository?"

Dr. Miller—About 45 degrees. Judge by your own thermometer; find out where they keep the most quiet; find out for yourself.

Pres. York—In other words, attend to your own business.

[Laughter.]

"How close can apiaries be located? and how many colonies should an apiary consist of?"

Dr. Miller—That depends.

A Member—Depends upon the flowers.

Pres. York—Suppose the bee-pasturage is pretty good, how near?

A Member—Say within two miles.

Dr. Miller—Three miles.

"How many colonies should be in each apiary, or can be?"

Mr. Hintz—Not over 50.

Mr. Dadant—80 or 100.

Dr. Miller—There is no rule about it. You have to study up your locality; 40 or 50 will overstock some places; you have to find out by experience. After you have had an experience of 15 years in that place then you can make a guess on it.

"Is it advisable to leave the 3/8-inch hive-entrance open when wintering bees out-doors?"

Dr. Miller—Yes.

"With the 10-frame hive for comb honey, can you successfully contract to six or eight frames at the beginning of the honey-flow?"

Dr. Miller—I don't know.

"While being very fond of honey I have not bought any for years, because all that I did buy tasted like syrup. How do you account for this taste?"

Pres. York—It would be pretty hard to account for some peoples' tastes!

Mr. Burnett—There is considerable in that question, although I didn't ask it. The facts are, that if you supply people with honey that they are not acquainted with, they will stop using it. Buckwheat honey is preferred by some (of course, they are in the minority, nowadays), but if that has been the honey they are accustomed to, no other will do. Some prefer mild, white clover, some honey from Illinois, others from Wisconsin, and Minnesota and Iowa, and nothing else satisfies them. If you give them Utah, Colorado or California white honey, and they are not accustomed to using it, they at once say, "Oh, that is manufactured honey; it has no taste," etc., and they stop using

honey perhaps for years. Therefore, it is the duty, really, of every one who sells honey, to find what kind of honey the people want who are buying it; if you sell your customer honey that they don't like you lose them.

"How can I keep bees from swarming?"

Mr. Riker—The way I manage it is to give them lots of room and comb to work with.

Pres. York—Does it keep them from swarming?

Mr. Riker—Yes.

Mr. Dadant—All but about 5 or 6 percent.

Mr. Riker—Give them about 40 good combs to work on.

Mr. Blunk—What time do you give those extra combs?

Mr. Riker—Just as soon as spring opens.

Mr. Blunk—Set one hive on top of the other?

Mr. Riker—Yes, and put the bees in the very upper story.

Mr. Blunk—I have just found out how I can go a-fishing!

Mr. Riker—I have 300 fixed up in that way, and never have them swarm.

(The End.)

[Owing to the Briggs House people being compelled to use the club-room for a guest chamber, with cots, the convention had to break off the interesting discussion suddenly. Mr. Blunk could have started off on a fishing excursion that very minute, had he so desired. He probably did "fish around" for a bed at once.—EDITOR.]

Influence of Worker-Bees on the Offspring.

BY L. STACHELHAUSEN.

On page 246, Adrian Getaz says that to one possessing even an elementary knowledge of physiology it will appear as an error, that the worker-bees have any influence on the coming generation. His arguments are about as follows:

1. The food in which young animals or plants develop has no influence on the characteristics of the animal or plant.

This is generally true, but not always. If corn is raised in a fluid containing hyposulphide of magnesia the young plant will bear blossoms quite different from that of corn. Frog-eggs develop into quite other frogs in water containing salt, from sweet water. In the animal kingdom we have another example in our bees. An impregnated egg can develop into a queen or into a worker-bee, and which one will develop is decided by the nourishment of the larva. We know a worker-bee is not simply an undeveloped or crippled queen, as in the worker-bee the digestive organs are fully developed, which are missing or not fully developed in the queen; the same is true with other organs. - But this is not the most important point in our question.

2. He thinks that queens, drones and larvæ are fed by worker-bees, and this food is only a secretion of glands, consequently can not transmit more qualities than the milk of the wet-nurse to the baby—that is, nothing at all.

It is a mistake that the food given to the queen and young larvæ is a secretion of glands simply. Certainly the eggs are produced out of the blood circulating in the body of the queen; but the production of this blood is something quite particular to bees. How the food in the bee-body is digested, and how the blood is formed, it seems Mr. Getaz does not know—only so much, that from the food the chyle is prepared in the true stomach, and for assimilation this chyle simply passes the wall of the stomach and is blood then, without being changed in any way. Now, in the queen all the organs for digestion are either entirely missing or rudimentary, only in such a degree that the queen can't digest at all—and can't renew her own blood; nevertheless, for laying so many eggs as she does, she needs an enormous quantity of new blood. This is possible only because a number of worker-bees prepare this chyle, feed it to the queen, and it passes the wall of her stomach. So we can truly say that the digestive and blood-forming organs of the queen are in the bodies of the worker-bees.

Now, we have to consider a deciding point. Except with the lowest organism, life is connected with cells, which

grow and multiply by splitting. Where we find such cells we have life. In the intima of the chyle-stomach are a great number of such cells which split, and a part of them is mixed with the chyle in the stomach. The same cells we find in the blood of the bees, and they represent the blood-globules of higher animals. Consequently the chyle fed by worker-bees to the queen is not a simple food, or a secretion of glands, but an organic, living part of the worker-bees, and identical with the blood. It is the same as if the blood from the veins of one man would be pumped over into the veins of another man. Mainly this particular quality of the bees forces us to consider the whole colony as a unit organism, while the single bee is only a part of this organism. The worker-bees and the queen belong to an individual organism in the same sense as the sexual organs, digestive and other organs, belong to one and the same mammalia. The fact that two important functions of life are separated in two separated bodies as yet hindered this conception, till we found the way in which connection is secured.

For this conception it is not more difficult to explain how worker-bees can transmit through egg or sperm-cell, or through both, their qualities to the young bees, as it is to explain how the quality of the brain or the color of hair of men is transmitted from parents to children and grandchildren. Neither the brain nor the hair produces something like an egg or a sperm-cell (as Mr. Getaz erroneously says is necessary), but the connection is secured by the blood, especially by the blood-globules, and we do not know as yet how the qualities of these organs are transmitted to the sperm or germ-cell and through them to the offspring. With bees it is quite the same.

We may say what we please, the fact that queens and drones never gather honey, never build combs, never feed larvæ, etc., forces us to suppose an influence of the worker-bees on the egg or sperm-cell, or on both. From these cells nothing else can develop but something very similar to the ancestors. The fact that from an unimpregnated egg a male bee, and a male bee only, can develop, is no proof against this. The drone has no father, but he has a grandfather. Do you see?

Mr. Getaz tries to explain the different characteristics of bees by saying they follow the example of other bees. If you take a comb of capped brood and set it in a nursery, and let the bees gnaw out there, these bees have never seen any other bee, nevertheless they will nurse given brood, rear queens, build combs, will afterwards gather pollen and honey, etc., and will occasionally sting you just like other bees in your apiary. How could this be possible if these instincts should not be transmitted to them? All this can not be explained if we do not suppose an influence of the worker-bees?

As I said above, from an impregnated egg a queen or a worker-bee can develop according to the nourishment given to the larva. This does not prove that by this food any quality of the worker-bees is transmitted to the larva; to the contrary, I am like Mr. Getaz, of the opinion that this is very improbable. The power to develop into a queen, a worker bee, or into a drone, must be inherited in the egg. If the egg is impregnated the power for development into a drone is getting dormant, but is still present and latent. The environment of the larva decides whether the development takes place in the direction of a queen or a worker-bee. This can be proven to a certain degree by the bees, which are between queen and worker, not only in size but in consideration of the inner organs, too. They will appear when a larva a short time before the cell is capped is selected by the bees to rear a queen. The digestive organs have already commenced to develop, and this can not be stopped any more; the ovaries develop better than in worker-bees, but not quite as well as in good queens. This proves that the environment of the embryo (the larva can be compared with the embryo of higher animals) has some influence on the development, but that hereby any quality can be transmitted is doubtful, if not impossible.

We see that a general knowledge of physiology is not sufficient to decide such questions—a special knowledge of the physiology of the honey-bee, too, is necessary. In all these questions we should not simply condemn *ex cathedra* another man's opinion. With all our knowledge a new discovery may change that—prove what we believed to be correct to be an error. Mr. Getaz's opinion was generally accepted as correct until about 20 years ago, when the above-mentioned particular qualities of the honey-bees were discovered. Bexar Co., Tex.

No. 5.—Rearing Long-Lived Queens and Bees.

BY DR. E. GALLUP.

Degeneration is, growing worse, or a losing of good qualities; a decline from the virtue and worth of ancestors; a decay of the natural good qualities of the species; a falling from a more excellent state to one of less worth. The thing degenerated.

Now, I am going to call those queens that breeders are sending out, "Degenerates." For the majority of them have degenerated to a remarkably low state of worthlessness; so worthless that they will ruin any good colony that they are introduced to.

Now, the question is, What are we going to do to renew our stock again? "Why," one says, "send to Italy and get fresh stock again." Well, let us see how that works. A number of years ago A. I. Root ordered and received some 50 queens in the fall. The following spring he offered them for sale. I ordered two, received them some time in May, introduced them to strong colonies successfully, and about the middle of June I thought I would rear some queens from them; on examination I found but very little brood in each hive, and both queens superannuated and worthless, and colonies very much reduced in numbers, etc. Now, those queens I have not the least doubt were degenerates; reared on the nucleus plan, for lots of the queens we get die the first winter, and nearly all of the balance die the following season. The Italian breeders have "caught on" to our methods of rearing degenerates.

Mr. Adam Grimm personally went to Italy and selected his own queens from colonies that had cast natural swarms that same season. Consequently he got all young, vigorous, prolific, and long-lived queens. He was well informed how to keep his stock up to the standard. When he shook hands with me and bade me good-bye at the Cincinnati convention, he said, "Gallup, I will send you a queen next summer that is a queen." The following June I received the promised queen. She lived to be six years old, and kept up her prolificness without one particle of diminution until the sixth season. She was one of the very best queens I ever received from any one. I reared my Iowa stock from her. The queen whose bees produced upwards of 700 pounds of surplus honey in one season was the mother of that colony.

The swarm was put into the hive on May 10, and never received any help from other colonies except filling out the balance of the hive (as soon as the bees commenced building drone-comb) with empty ready-made worker-combs. The hive contained 48 Gallup frames, all on the ground floor. That queen and progenitors had never been degenerated, consequently her workers were long-lived, and they did work, too. But according to Dr. Miller and Mr. Dadant they ought to have worked their lives out in short order. Work does not make short-lived bees by any means; it is the long-lived bees that do the most work, every time.

I now have one of those degenerates of last season's rearing, at least I ordered her untested, and I do not dispute it, for her workers are so short-lived that the colony can not get on at all, and the queen is now failing. The bees are dying off with old age so rapidly that the ground is continually specked with dead bees, so that I sweep them up every day, and there are from 50 to 100 dead bees pushed out of the hive in front of the bottom-board early every morning. It is your spring dwindling, only here it is summer dwindling. There is no disease about it. It is simply degeneracy of the worst kind—for breeding for fancy color, as the bees are beauties. I prefer bees for profit, not fancy.

Now, you fellows that wish for a strain of bees that do not swarm, and wishing for some one to breed out the swarming habit, just send to that breeder for your queens. He will certainly satisfy you. But your non-swarmers will produce no profit. It makes no difference if their tongues are six inches, or even a foot long, if they have not the strength, longevity or vitality to handle that long tongue where is the benefit coming in? I have not the least doubt but the longevity of that class of bees is only about 30 days, and the longevity of the Grimm queen's workers were at least 90 days in the height of the working season. I have had them—at least a portion of them—live from the first of May until the first of September, and they did not sit around doing nothing, either.

Some of the bee-keepers here are in the habit of re-queening with untested cheap queens from the South every spring. I am aware that many of those cheap degenerates start out quite well the first season, but if they do not die the first winter they dwindle so low in numbers that we lose

the orange-blossom flow entirely, which is quite an item here in the valley.

To illustrate: I obtained a small, starved-out black colony last fall, but they had a natural queen, and they filled the hive and two supers with combs, honey, etc., and are now a rousing colony with lots of bees from bottom to top, and 13 Langstroth frames well filled with brood.

Now, here is another fellow who jumps up and says, "Didn't I tell you so? The blacks are the best bees for me." Don't you know that one swallow does not make a spring? I have seen him try to do it in Canada, but he froze to death in the attempt.

We have had three days of cool, dry northwest wind which stopped the honey-yield, and those blacks have to fall back on the stores, and so do the Italians from my purchased queens. I have two queens of my own rearing that have been in their hives long enough to have their workers old enough to work outside, and they keep right on working, and are storing more than they consume. It is just fun to see them work late and early, while the others are sitting around doing comparatively nothing. This black queen was reared at natural-swarving time. My purchased queens are all degenerates, even a long-tongued one purchased this spring has, by coaxing, filled just two combs with eggs in the same time that my own queens have filled nine each.

I am not satisfied that I can rear the best of queens from these degenerates, either in the first or second generation. Now rear your black and Italian queens under the same conditions and then you will be a better jury-man to decide the case.

I have seen seasons when the blacks would starve to death and the Italians would make a living and store some surplus. Degenerate your blacks in the same manner that the Italians have been, and see where you come out.

Orange Co., Calif.

(Continued next week.)

The "Singing" or "Piping" of Queens.

BY G. M. DOOLITTLE.

"I have something strange to tell you. I have something in the way of queens which I never heard of before, although I have devoured everything I could find on bees for several years. I have an Italian queen that sings like a hen. She sings when moving among the bees as well as when still, and so loudly that she can be heard five feet away when the hive is closed. The day before I heard this strange noise I cut out all the queen-cells, but could not find the queen. The next day I resumed the search for her, and very soon, upon opening the hive, I found her singing as happy as a lark. It was not a piping noise, but a regular singing, something like a laying hen; and, besides, it was an old queen; and, as I read, it is only young or virgin queens which pipe. What do you think is the cause of it?"

I am inclined to believe that it was what is called the "piping of the queen" which our correspondent heard, and nothing else, notwithstanding that he says, "It was not a piping noise" which he heard. I believe it a mistaken idea which many adhere to, that virgin queens are the only queens that pipe; for I have heard queens two and three years old pipe many times, although the noise made by them is not quite so sharp, or so shortly cut up as that of the virgin queen, where there are rivals in the several queen-cells still remaining in the hive. There seems to be more intense hatred toward rivals on the part of a virgin queen than with laying queens, but, when thwarted in her purpose, a laying queen will resent it as well as a newly-hatched virgin.

I think I am justified in saying that there are few queen-breeders who have not heard laying queens pipe, or call to each other, where a number of cages containing queens ready for shipment were placed near together and left thus for a short time, although I have never heard any breeder say so, or talked with one regarding this matter. And I doubt not but that very many who are not queen-breeders, who have ordered several queens so that they have received them at the same time, and have left them near each other preparatory to introducing them to different colonies, have heard this piping or singing noise produced by said queens while in the confinement of their cages. I have heard it hundreds of times with laying queens when preparing them for shipment, and many times from the cages of those I have received. Our postmaster often remarks about how the queens I put in the office "sing," and, only a few days ago he said in handing me some which had come in the mail, "This is a singing lot. They have kept it up ever since I opened the mail-bag they came in."

Anything which enrages queens and causes them to

cease laying will sometimes cause them to go to piping; and the cutting of the queen-cells from the hive, as did our correspondent, at a time when the queen had a great desire to swarm, will cause this result. Years ago, when I was told that the cutting off of the queen-cells would stop the issuing of prime swarms, I often had instances of "singing queens," and in every case where the old queen was incensed enough (over herself, and the colony not being able to carry out their purpose of perfecting queen-cells) to go to piping, the result would be the issuing of a swarm, sooner or later, without the construction or completion of queen-cells, providing the weather continued favorable for swarms.

Another thing I found was that any queen which was enough enraged so that she began piping, would not lay any eggs while this piping continued, or during the time of her enragement, which was shown by her continued piping or singing.

Again, I have had queens which would begin to sing or pipe as soon as put on the combs, in any effort to introduce them to a strange colony, and as soon as this was done the whole colony would be set into a commotion, which resulted in the bees balling this queen almost immediately on her piping, while she had walked about unmolested until she began to sing. And after releasing her from the ball of bees with smoke, and putting her into a cage, the bees would give the cage very little notice until the queen again began to make angry demonstrations through her piping, when a rush for the cage would be made, so that, where the cage had been left on top of the frames, a cluster of angry bees would form over it three or four inches deep.

Of all the hard queens to introduce it is one of these which persist in going to piping as soon as they come in contact with strange bees. In one instance I was three weeks in trying to introduce such a queen, which came from the State of Kentucky, and, after the bees had apparently accepted her, she began to pipe on my opening the hive, and was stung and killed right before my eyes, before I could release her from the ball of enraged bees, which were treating her kindly when I first opened the hive, and before she began to sing. In looking her over after she was dead, I could not help remarking to myself, "You sung just one too many times for your good, old lady."

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

CYPRIANS AND PUNICS.

If I didn't use those "unreliable glasses" once in a while I wouldn't be living up to contract. And when I illustratively kick the emptiness of a hive of Cyprians, and they come out at me, am I not getting my full dues? [B. E.] Good enough for me! So Cyprians still have some keepers and champions, it seems, and are not universally abandoned. Here's a kick for the Punic hive; let us see if they come out. Cheap way of getting information. Page 316.

SUNFLOWERS AND ARTICHOKEs.

So in Atchinson Co., Kans., they combine against sunflowers as dangerous weeds, and "labor" with a neighbor if he inclines to plant a few. Queer. Mr. Wiltz's way of checking the spread of an artichoke patch by clipping the tops below the bloom, is of interest and value. Page 317.

THAT DENVER DINNER—OTHER COMMENTS.

The hungry bee-men can have a dinner by going to Denver after it. The idea!

The bottom lines of my column, on page 361, are criticized from a literary point of view. Ashamed of them.

Dr. Miller's reversible bottom-board seems to be the bottom-board—now he has got it so it does not reverse. Page 325.

So alfalfa honey is splendid to dilute all honeys of too decided flavor. Evidently correct, and a valuable idea, Mr. Chaney. Page 328.

GIANT CACTUS FRUIT AND THE INDIAN.

And the fruit of the giant cactus, agreeable to the palate, but too poisonous for white men to eat, is eaten by the Indian. Our friend "Lo" also eats freely of wolf-meat

poisoned by strychnine. A white man would hardly want to try it. I wonder whether there is *really* any difference in the races of men, as to their susceptibility to poison, or whether a pack of white outcasts and tramps would hold their own with the fattest—or say the leanest—of them. Page 324.

EXPERIMENTS IN RENDERING WAX.

When we have a man with money to scatter around, *a la* C. Davenport, page 327, let's pick up what we can of it. Old style of rendering wax had the floor—voted not good enough. New Ferris press obtained—voted in need of improvement. Massive improved Ferris built—voted not good enough, and sold cheap. A wholly-under-boiling-water press built at a cost of \$29—voted to sell it for \$7.00—sorry afterward he didn't keep it. Root-German steam press also—voted not good enough. Three or four machines built, at odd times, and for good measure—voted not good enough. Lastly (in this world there must always come a lastly) came a two-stand, two-man, long lever, screw press and boiler—and left the wax in, even when the amount of power applied smashed the big screw. Bare hand could squeeze some wax out of the warm refuse even then. Conclusion: Repeated moderate pressure between stirrings better than immense pressure once for all. The perfect method seems not to be here yet.

THE TRUST AND INDIVIDUAL LIBERTY.

We would fain be a trifle ashamed for the witlessness of some of our fellow craftsmen—think they can have the consolidated power of a trust and individual liberty, too—ride without getting on. Page 327.

SECOND-HAND OIL-CANS FOR HOLDING HONEY.

Thunder wanted! Sad that thunder, even when the weather furnishes it most plentifully, can't be used second-hand. Oil-cans can. The genuine thunder not being in stock, give 'em the best fraudulent thunder in the office, Mr. York. Page 339.

THE BEST RACE OR STRAIN OF BEES.

There are so many things which affect the apparent value of a colony of bees, and make it seem better than its neighbor when it is not, that I would not set a beginner at extinguishing one strain and booming another. Should he flip a coin to decide which one to boom he would hit right just about as often. Tough problem for old heads; and they can't solve it without more than one year to do it in. Page 339.

HONEY IN CUBA AND JAMAICA.

Pounds of honey per square mile: Cuba, 113; Jamaica, 358. I think this is because Cuba just now is a great part of it unoccupied with bees. Never fully occupied, and the war destroyed nearly all. Page 340.

HUNGER, NOT HUNGRY, SWARMS.

On page 346 I am made to designate the little swarms which come out in early spring—come out because their honey is gone, or nearly so—as "hungry swarms." Doubtless they are hungry; but the term as I have seen it used is "hunger swarm;" and hungry in that connection is the opposite of an improvement.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Running for Comb and Extracted Honey.

I have a question to ask you in regard to a plan I have for running my apiary for comb and extracted honey, and at the same time wish to keep down swarming.

I put on top of the queen-excluder all frames of brood, leaving the queen below on empty frames. Our main white honey is from alsike clover and basswood, which I would like to get in the sections.

If I raise the upper hive and place a super of sections on the excluder during the white honey-flow, removing the

same when nearing the close, allowing the bees to finish up the season in an extracting super, would it be likely to work satisfactorily? If not, why not? NEW YORK.

ANSWER.—I should expect the plan to work satisfactorily if there was a sufficient harvest to fill both the extracting combs and the sections, but if there is not enough for both you may expect the sections and not the extracting combs to be neglected. There have, however, been some reports of failure when the queen has been left below on empty frames.

Keeping Ants and Moths Out—Superseding Queens.

1. How can I keep moths and ants out of my hives?
2. Can I get them out after they get in? If so, how?
3. What makes the bees come out and seem to fly in front of the hive as if they wanted to go in?
4. If a queen is superseded is it advisable to requeen, or will the bees rear one?
3. How can I tell when she is superseded? MAINE.

ANSWERS.—1. A moth can go wherever a bee can, so there is no possible way to shut the moths out without shutting the bees out. But you may depend upon the bees to keep them out. With a strong colony of Italians you need not give the least thought to moths; even a weak colony of Italians will not be troubled much. A strong colony of blacks will take pretty good care of itself; but a weak colony of blacks is in much danger. Better have Italians, and keep them strong.

2. Take a sharp-pointed nail and pick open one end of the gallery of the worm, then start at the other end of its burrow and chase it along till it comes out, and then dispatch it.

3. They are trying to fix in their little heads the location and surroundings, so that when they come home in a hurry from the field with a load they need not spend any time in hunting for their home, but make for it in a beeline. It is only the younger bees that you will find thus "marking their location."

4. If the bees supersede their queen the only thing for you to do is to let them alone. A young queen is always reared before the superseding.

5. Clip your queens' wings; then if you find a queen with whole wings you will know she has been superseded. It will pay you to study well your text-book.

Why Don't They Swarm?—Swarms Leaving After Being Hived.

1. I have a strong colony of bees which I have been expecting to swarm. To-day (June 8) I examined the hive and find no queen-cells, but worker-larvæ and drone-cells. They are storing honey in brood-frames and supers. What is the reason they do not swarm?

2. What is the reason for a swarm leaving a hive after being successfully hived? SOUTH DAKOTA.

ANSWERS.—1. Sometimes bees appear to get so much interested in a strong flow of nectar that they can not spare time for such matters as swarming. Sometimes certain strains of bees are so little given to swarming that if they have plenty of room, are well ventilated and well shaded, they will seldom swarm, whatever the conditions may be. If you have such bees, be thankful.

2. The chances are that they are too warm. See that there is abundant ventilation, perhaps leaving the cover partly off for a day or two and having the hive raised on blocks, and providing good shade. Some take the swarm into a cellar for a day to let it cool off.

Prevention of Swarming More than Once.

1. What are the best methods of swarming after increasing once?

2. What is the best method of artificial increase by dividing?

3. Can swarming be prevented by the use of queen-traps? WASHINGTON.

ANSWERS.—1. When the prime swarm issues hive it and put it on the old stand, putting the old colony close as possible beside it. A week later remove the old colony to a new location at least six feet away. That will weaken it down at about the time the young queens will be emerging, and that weakening, together with the fact that no honey

will be coming in (because the field-bees have all joined the swarm) will so discourage the old colony that there will be small chance for further swarming.

2. That depends upon circumstances, and it would take too much room to give all the plans here. In late numbers of this journal you will find the question answered more than once, and it may be repeated here that perhaps for most persons the nucleus plan will prove as good as any. When you have succeeded in getting a young queen to laying in a nucleus, gradually add brood to build it up, unless it be early enough in the season so that it will build up without any help.

3. No. The queen can not leave, but the swarm will issue all the same, generally returning, and after a week or ten days a young queen will emerge and the old one will be killed. Then, *theoretically*, after several days more, all the young queens but one having been killed, the trap should be removed to allow the young queen to make her bridal trip, and all would be serene and lovely. *Practically*, it is a failure. It will do no harm for you to try it in a few cases and see how it works with you.

Bees Killing Each Other Off.

I have 3 colonies of bees and they seem to be killing each other off. There are hundreds of dead and dying bees outside of each hive. At first I thought they were robbing each other, but that does not seem to be the case. It looks to me as if they were killing off the young bees, both drones and workers. What is the reason? and what can I do about it? I think they have plenty of honey. I thought perhaps they wanted to swarm, but the weather was not favorable. WASHINGTON.

ANSWER.—If they are not robbing or starving, I don't know what the trouble can be, unless they are poisoned. In the latter case, the probability is that you can do nothing.

Kankakee Co., Ill., as a Honey Locality.

I am a beginner in the bee-business, and have 54 colonies—quite a beginning. Two things I did right, I am sure, for I bought the "A B C of Bee-Culture" and subscribed for the American Bee Journal. My bees are nearly all pure Italians. I am thinking of putting in all my time caring for the bees, and would like to increase my apiary to 200 colonies, or more, if I find it can be made to pay. May I ask you a question or two?

1. Is this county (Kankakee) a good honey-producing territory?

2. In what section of Illinois is the largest honey-yield, per colony, obtained? ILLINOIS.

ANSWERS.—1 and 2. I am sorry to be obliged to say I don't know the right answer to either question. If any one has the information I will gladly yield the floor. Some one in that region who has had experience, or who has had opportunity for observation for a series of years, may be ready to report as to the character of that county; but I am not very hopeful as to obtaining a reliable answer to the second question.

Starting with Bees in Mississippi.

I have been keeping bees for something less than a year, and as my limited experience, supplemented by such scraps of arbitrary information as I am enabled to gather from the natives here, is somewhat at variance with statements made in the papers, and other advanced sources, I beg permission to state my case so far, and ask to make such comments as you see fit, that I may know where to look for improvement.

In this section "patent gums" (as hives are called) were unknown until I came, and I was assured that bees never would work in them. But wild bees are very abundant here, and when any one wants honey (which is when they develop sufficient interest in life to want anything), they simply go a little way from their homes in the woods and cut a beetrue.

Well, I bought 5 colonies of bees last December from up the road, and when they reached me all the combs were broken out of the frames and lay in a mass of honey, bees, etc., on the bottom-boards. I was too busy at the time to give them any attention further than to place them on stands and let them alone. During March they all swarmed

twice, and I now have 15 colonies. I have since transferred them to new hives. Only one of the parent colonies gave any surplus, and the other 4 seem to be dwindling away, though they have a little hatching brood.

Now for the swarms: The first were large prime swarms, and the second about a quart of bees each. Their history is about the same, so I will describe but one. I hived it about March 15 on inch starters; April 1 I gave it a super, which was promptly filled. April 15 I gave another with ditto results; April 25 I gave a third, and some filled this, but when I gave the fourth all work in the entire apiary suddenly ceased, and only a few burr-combs were made in the sections. The old colonies also did nothing at all. I might mention that the weather has been very dry.

1. Now, is the honey-flow over?
2. Will any more honey be gathered in the fall? The natives assured me that bees never build comb here after May 15.

ANSWERS.—1. I don't know. I never can tell for sure when the honey-flow is over for my own bees. Sometimes the flow will stop for two or three days, and then start up again from the same flowers.

2. That depends upon the flora in your neighborhood, and upon the season. On general principles I should make a guess that there will not be an entire dearth of pasturage from May till winter. However, some dependence should be placed upon the word of the natives, especially if the natives are experienced and observing, and it is just possi-

ble that generally there is little pasturage for the bees except very early. Make observations for yourself, however. You may rely upon it that bees will build comb at any time they need it.

Requeening at Swarming-Time.

Suppose you have inferior queens in a few colonies, and you want to replace them at the time of swarming by using the swarms of your best colonies; that is, without going to the expense of buying queens, neither increasing the number of your colonies. How would you proceed?

CANADA.

ANSWER.—Here's one way: When one of your best colonies swarms, live the swarm on the old stand, and brush into the swarm all the bees from the brood-combs. Set this hiveful of combs on or under a hive containing a poor queen, destroying the poor queen. A young queen will be reared from one of the queen-cells of good stock. Look out for a swarm when the first queen emerges from her cell, returning the swarm in the evening of the same day on which it issues. Or, seven or eight days after the issuing of the prime swarm, listen in the evening for the piping of the young queen, and if you hear her, destroy all remaining queen-cells in the morning. Or, cut out all but one queen-cell before it is time for the first young queen to emerge. Of course, you can divide up the brood and cells, and treat more than one of the colonies having poor queens, if you so desire.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

BARNES' FOOT POWER MACHINERY

Read what J. I. PARENT, of Charlton, N. Y., says: "We cut with one of your Combined Machines, last winter, 50 chaff hives with 7-in. cap, 100 honey racks, 500 brood-frames, 2,000 honey boxes, and a great deal of other work. This winter, we have double the amount of bee-hives, etc., to make, and we expect to do it with this Saw. It will do all you say it will."

Address, W. F. & JOHN BARNES, 995 Ruby St., Rockford, Ill.

Danzenbaker Hives.

In flat and made up—at very low price. 50Ct In O. C. MASTIN, Trent, S. D.

GENERAL ITEMS

Bees Doing Nothing.

Bees have done nothing since May 30. White clover was never more abundant. It is cold and cloudy, but no rain.

HENRY ALLEY.

Essex Co., Mass., June 17.

Vervain or Verbena.

I enclose a flowering weed which seems to be a favorite with our bees in this section of country. What is it? Is it valuable as bee-pasturage?

EAST TENNESSEE.

[The specimen is a member of the Vervain or Verbena family—Verbena angustifolia—and along with its more conspicuous relative—the white and blue vervains—it is a good honey-producing plant. Prof. Cook, in his "Bee-Keepers' Guide," pages 374-5, mentions the vervains as good honey plants.—C. L. WALTON.]

Bees and Pear-Blight.

I want to ask how it is that trees that have never blossomed are all at once attacked and die outright in a short time? I once had a seedling, near bearing age, turn black and stop growing, and die in a few days.

I had a large Bartlett orchard, and most of it turned black. It had had high culture. I seeded it to grass, and the next season the blight struck half of the upper portion. I have had Dwarfs blight the same, and not a blossom on them.

Why, it is nonsense and all bosh to talk about bees doing the spreading of blight. How much more reasonable to say the many insect-catching birds carry the germs, for we know they are

Low Rate Excursions.

On July 5 to 9, inclusive, the Nickel Plate Road will sell tickets at one fare for round-trip to Portland, Me., and return, with final return limit Aug. 15th. Particulars at City Ticket Office, 111 Adams St., Chicago. 25—26A2t

searching for insects, and in doing so have to grasp branches and spurs all through the trees. I have seen them search even the blossoms.

I am a bee-keeper and quite an extensive fruit-grower I have looked into the matter quite a little, and I am very sure the bees have nothing to do with blight.

I am sure the bees are of great value as pollenizers, and it is an awful mistake to spray during blooming time; it is sure to kill the pollen as well as the "goose that lays the golden egg"—the bees. E. P. CHURCHILL.

Kennebec Co., Maine.

Too Much Rain.

This is a very poor season for the busy bee to gather honey from every opening flower, as it rains or pours almost every day or night, so that it washes the nectar all off of the flowers. There is an abundance of white and alsike clover, and basswood is budded ready to blossom. The bees are not swarming any to speak of.

IRA D. HYDE.

Washtenaw Co., Mich., June 15.

Moved Bees on Wagons.

I have moved the greater part of my bees from Columbia County to Wood County, and will be here the most of the time. I moved them on wagons 75 miles or so, over all kinds of roads. We repaired bridges, forded streams, went through mud and chuck holes up to the axles. We did not break a comb, but the bees suffered a good deal, and there were a great many dead ones when we arrived.

We were from Tuesday morning (May 20) until Friday noon getting here. The weather was very hot.

White clover is quite thick here; it has been coming into bloom quite fast the past week. E. M. HAYES.

Wood Co., Wis., June 13.

Wiring Comb Foundation with Electricity.

To fasten foundation I place a Hoffman frame, inverted, in the jaws of a vise and string the four wires tight. I next lay in a sheet of wax and insert the wedge.

I have two flexible wires attached to six dry batteries, such as are used for ringing door-bells and telephones connected in series, that is, the wire from a zinc pole leads to the carbon of the next. I make a hook on the end of one of the battery wires to hang the wire on in the frame. With one hand apply the other battery wire to the other end of the frame, and heat one cross wire at a time, using the free hand to press the wax against the wire which is warmed. F. H. DRAKE.

Worcester Co., Mass., June 12.

Sulphur for Bee-Paralysis.

I wish to tell "Ohio" (page 378) that his bees have bee-paralysis, and that sulphur will cure it. I have had it in my apiary for three years. I have tried salt but it did not do any good, and in rainy weather it makes the hives too damp.

This spring I tried sulphur; it cures every time. I take a flour-dredger and dust it over the combs. You will see

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

—BEST—

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

□ We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

Please Mention the Bee Journal when writing Advertisers *****

an improvement in less than two weeks, and it is seldom that I have to give more than one dose. If it makes its appearance again give them another dose. The sulphur has the merit of being harmless.

When they go into winter quarters with that disease they are reduced very weak in the spring, and if they build up they do not seem to have any energy.

What a bad spring for bees in this part of Minnesota—cold and rainy. The maple buds were frozen, and the bees did not gather pollen for a long time after leaving the cellar. It is now June 15, and cold and no swarms. They commenced swarming June 4 last year.

MRS. E. B. HAWKINS.
Wabasha Co., Minn., June 15.

Hardest Spring on Bees.

This has been the hardest spring on bees since I have been in the business. I lost 20 colonies—almost all dwindled. The spring was cold and windy.

I have not had a swarm this spring. Quite a number of colonies are weak. The weather has been so cold that they don't build up fast.

G. W. BELL.
Clearfield Co., Pa., June 12.

Bees Starving.

Bees are doing poorly on account of the wet weather. There is no white clover yet, and they need to be looked after or they may starve. They are killing the drones, and that is a sure sign of starvation.

L. HIGHBARGER.
Ogle Co., Ill., May 12.

California Crop Over-Estimated.

The honey season has been grossly over-estimated in Southern California. I do not think it will average one-fifth of a crop, and in some localities that are considered among the best in favorable seasons will produce none at all. The weather was so unfavorable during orange-bloom that little surplus was stored, and then there was an excessive amount of swarming in both comb and extracting apiaries.

L. L. ANDREWS.
Riverside Co., Calif., June 6.

California—"Boom, or Busted."

As I promised a report of my last year's honey crop I will turn it in now. It is rather late, so I don't think it will do any one any good, neither will it do harm.

I think we can as individuals come nearer an estimate of a crop, after it is harvested, rather than before. Apropos Prof. A. J. Cook's California crop report, on page 347.

Now, every one who knows Prof. Cook, either personally or through his writings, knows what a great, big heart he has, and that it is exactly in the right place, and if he makes any mistakes they are of the head and not of the heart.

From all that I can gather the honey crop of Southern California will be very, very short. I have reports from San Diego County, Los Angeles, San Bernardino, and I am situated in about the center of Riverside County. All reports are for a total failure, or very light crop in my own vicinity. Bees

will just about make enough to carry them through to next year in four counties of the seven of Southern California that produce large crops, and Orange County lies contiguous to Los Angeles, San Diego and Riverside Counties, so that puts it in the doubtful list. As I said, the bees in this vicinity will just about make a living; quite a fall from last year, but this is California—"boom, or busted."

I began the season of 1901 with 147 colonies in three different sizes of frame hives and various sizes of boxes. I had built 1000 new combs in Langstroth frames from 1 1/2 inch starters of foundation; at the end of the season I had all of my bees (150 colonies) in Langstroth hives, had 30,500 pounds of extracted honey, and 536 pounds of beeswax.

I increased just 3 colonies, and I did all of my transferring after the honey-flow was over. My honey was well ripened, and of first-class quality.

From June 3 to July 1 I extracted six tons. That was one of my successes; later I will tell how I manipulated to obtain that result.

I run every tenth colony as a reserve, and as they filled one super up I would put on another, and tiered them up to the end of the season, then distributed the honey through the apiary, and quite a lot of it is there yet.

J. W. GEORGE.
Riverside Co., Calif., June 7.

Sweet Clover.

As a plant for green manuring, Prof. S. M. Tracy, formerly of the Mississippi Experiment Station, says of it in Farmers' Bulletin 18, of the United States Department of Agriculture:

"As a restorative crop for yellow loam and white lime lands this plant has no superior, and for black prairie soils it has no equal. The roots are very long, penetrating the soil to a depth of three or four feet; are quite large, and by their decay at the end of the second year leaves the soil with innumerable minute holes which act as drains and loosen the soil, so that the roots of other crops can go deeper and find more abundant supplies of food, and bear drouth better."

Makeshifts—A Paper Honey-House.

It seems that F. L. Thompson has conceived the idea of a paper honey-house, and the following conversation regarding it between Mr. Smith and Mr. Thompson is given in the Progressive Bee-Keeper:

Mr. S.—Whoever heard of such a thing as a paper honey-house? And no floor!

Mr. T.—Yes, this is a makeshift; that is, at present. But when the rest of it is built this part will do just the way it is for storing empty supers, and it will not be a makeshift; because for

that purpose you don't need anything better.

Mr. S.—The idea of a paper-house for any purpose! It won't last any time.

Mr. T.—At the other places I have an 8x8 paper shanty, tarred paper without and resin-sized within (both outside of the frame-work), with a lath roof to hold the paper up, but no laths in the walls, nothing but the paper and the frame-work, and it has stood 15 months, and seems almost as good as ever. It seems likely to last two or three years without renewal; and then I would simply add another layer of tarred paper and let it stand another two or three years. The frame-work is permanent, and the cost of the paper is so trifling it hardly matters. I much prefer that kind of a makeshift to a canvas tent over a frame-work. I have had two tents two years, and they are now full of holes.

Mr. S.—But don't you punch holes in the paper every little while?

Mr. T.—Not a hole. Why should I? A tramp punched a hole in it once to steal some food, and some kind of a bird pecked two holes in the roof. I just put new panels of paper over those places.

Mr. S.—But it can't last; now, you can't convince me of that; it is unreasonable. Paper!

Mr. T.—Two small studdings of inch lumber, two inches wide, about a foot apart, between each pair of two-by-fours, make it last long enough to suit me. Confess you are just theorizing. You may think me a crank, but from my actual experience with paper I wouldn't have any other sort of a building for this purpose, unless it were a fire-proof one. It is a real money-saver. Just think of the amount of room—most of it, in fact—that is taken up for storage of empty receptacles of all sorts in a honey-house, for which matched flooring and walls, and a shingled roof, and carpenter's work generally, are wholly unnecessary. Mr. Jones, you know, has built a \$300 honey-house. No doubt it is a good one; but that money is locked up for good and all. With \$50 of that I could have built a house, and had money enough left for repairs on it, that would, with the occasional repairs, last me as long as I live, and then I would have had the other \$250 to use in other practical and remunerative ways, or to buy books with. I tell you, this makeshift question has two sides to it. If all makeshifts are not good, some are, and it is worth while to consider what they are. Many things are to be considered in answering the question of what pays. When everything is taken into consideration, any old shanty pays Mr. Coggs better as an extracting-room than to spend money on a special apartment. Now, I think my paper shanties are still better than his board ones, for they cost less, and are beehive-tight besides.

Mr. S.—Do you mean to say that when you build the rest of this it is going to be of paper, too?

Mr. T.—Certainly. When a thing has proved good what more do you want? Of course, there ought to be a floor in the shop part, and where the comb honey is stored, to prevent dust.

Mr. S.—But dust ought to be kept out of the supers that are prepared before the season begins.

Mr. T.—Those supers ought to have a newspaper between each one, anyhow, no matter where they are; and a cover above and below each pile will keep the mice out.

Mr. S.—But you want a place to store empty combs.

Mr. T.—I would have the comb-honey room a little larger than suffices for the comb honey, and store them in there. The point is, not to have any part of the house too good for what part holds. You don't put on a collar to milk your cow.

Sweet Clover as a Fertilizer.

Prof. C. E. Thorne, Director of the Ohio Experiment Station, says:

The appearance of sweet clover is a signal that the soil is out of condition. Its mission seems to be to occupy the waste-places and neglected spots of the earth, and to prepare them for the growth of other plants.

Address as follows, very plainly,
GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

REVERSIBLE WALL MAP

—OF THE—

UNITED STATES AND WORLD,

WITH SPECIAL INSET MAPS OF

China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,

Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. **Very useful in every Home and Office.**

66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued.

No Home or Business House should be without it.

The xx Plates

are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance

a salient feature of this map not approached by any similar publication.

xxxx Marginal Index

is one of the invaluable features. It gives an alphabetical list of countries, their location on map, style of government, population, area, products, minerals, imports, exports, etc.

It has been pronounced a **xxxx Photograph of the World**

The 1900 Census of the largest American Cities is given.

One side shows a grand map of our great country, with **counties**, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, capitals, rivers, mountains, products, business, etc., a veritable photograph of the UNITED STATES AND WORLD.

The map is printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

1901 EDITION.—Every reader should consult it every day. The plates show all the new railroad lines and extensions, county changes, etc. Especial attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahama Islands.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. **The Inset Maps** are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps on one sheet, all for only \$1.50, sent by mail or prepaid express; or we will forward it free as a premium for sending us **Three New Subscribers** at \$1.00 each; or for \$2.00 we will send the Map and the American Bee Journal for one year. Address,

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

Low Round Trip Rates, via Union Pacific, from Missouri River,

- \$15.00 To Denver, Colorado Springs, and Pueblo, Colo., July 1 to 13, inclusive, Aug. 1 to 14, 23 to 24, and 30 to 31, inclusive.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, June 18.—The market is practically over in comb honey until the new crop comes forward, so far none has appeared in this city. A little of the extracted is on sale, but it is chiefly of a low grade of amber selling at about 5 cents per pound. There is a large amount of the white extracted honey of the crop of 1901 still on sale bringing 5¢@6¢, according to body and flavor. Beeswax sells upon arrival at 32¢.
R. A. BURNETT & CO.

KANSAS CITY, June 23.—There is very little doing in honey at this time. The supply of comb on the market is not large, although there is a very good supply of extracted. We quote: Comb honey, 13¢@14¢; extracted, 5½¢@6¢. Beeswax, 25¢@30¢. No new honey in market.
C. C. CLEMENS & CO.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½¢@6½¢; better grades from 7¢@8¢. Fancy comb honey sells at 16¢; lower grades hard to sell at any price. Beeswax strong at 27¢@30¢.
THE FRED W. MUTH CO.

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14¢@15¢. Extracted, 6¢@6½¢. Beeswax, good demand, 30¢@31¢.
H. R. WRIGHT.

DETROIT, Apr. 8.—Fancy white comb honey, 15¢; No. 1, 13¢@14¢; dark and amber, 11¢@12¢. Extracted, white, 6½¢@7¢; dark and amber, 5¢@6¢. Beeswax, 29¢@30¢. **M. H. HUNT & SON.**

NEW YORK, May 19.—There is a limited demand for comb honey and prices range as follows: Fancy white, 14¢; No. 1, white, 13¢; amber, 11¢@12¢; no buckwheat or dark on the market and no more demand for any. Market on extracted remains very inactive. Plenty of supply with only fair demand. We quote: white, 5½¢@5¾¢; light amber, 5¢@5¼¢; southern, in barrels, 50¢@55¢ gallon. Beeswax firm at from 30¢@32¢ pound, according to quality.
HILDRETH & SEGELKEN.

CINCINNATI, June 7.—There is hardly any change in the honey market. Comb is not moving much, and whatever is left can be bought at cut rates. Water-white is selling from 14¢@15¢. Extracted is in fair demand and finds steady sales, in barrels, 5¢@5¼¢; water-white alfalfa from 6¢@6¼¢; white clover from 6½¢@7¢. Beeswax is coming in more freely and sells for 28¢.
C. H. W. WEBER.

SAN FRANCISCO, June 11.—White comb, 10¢@12 cents; amber, 7¢@10¢; dark, 6¢@7 cents. Extracted, white, 5¢@—; light amber, 4¼¢@—; amber, 4¢@—, Beeswax, good to choice, light, 27¢@29¢; dark, 25¢@26¢.

There is not much of any description coming forward at present or being offered for sale. To purchase freely, better figures than are warranted as quotations would have to be paid. No evidences are displayed, however, of large operators doing any noteworthy competitive bidding so far on this season's product, although the crop is not coming up to expectations in point of quantity.

WANTED!

AMERICAN

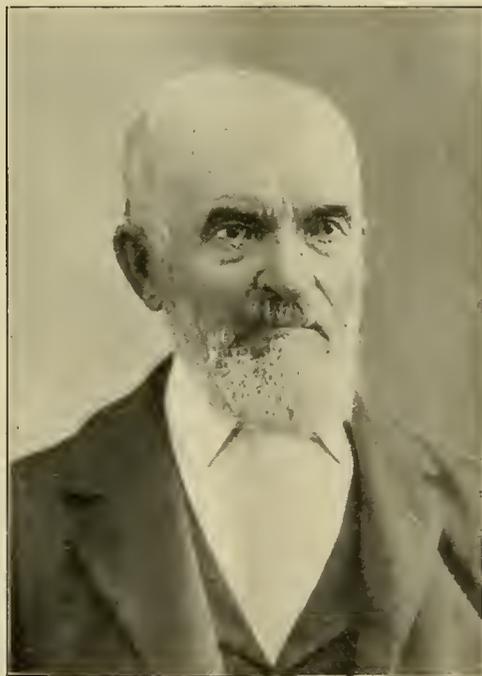

BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., JULY 10, 1902.

FORTY-SECOND YEAR
No. 28.

WEEKLY

DR. E. GALLUP, OF ORANGE CO., CALIF.,

Who is writing for the American Bee Journal a series of articles
on "Rearing Long-Lived Queens and Bees."

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.

DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

An Italian Queen Free!

We would like to have our regular subscribers (who best know the value of the American Bee Journal) to work for us in getting NEW subscribers. We do not ask them to work for us for nothing, but wish to say that we

will mail ONE FINE UNTESTED ITALIAN QUEEN for sending us ONE NEW subscriber for a year, with \$1.00; or 2 Queens for sending 2 new subscribers, etc. Remember, this offer is made *only* to those who are now getting the Bee Journal regularly, and whose subscriptions are fully paid up.

In case you cannot secure the new subscribers, we will mail one of these Queens for 75 cts., or 3 or more at 70 cts. each; or the Bee Journal one year and a Queen for \$1.50.

(Please do not get these offers mixed up with our Red Clover Queen offers on another page.)

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we will close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

A New Edition. 19th Thousand.

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., JULY 10, 1902.

No. 28.

* Editorial Comments. *

"The Bee-Keeper's Guide: or Manual of the Apiary," is the double title of Prof. A. J. Cook's text-book on bees, which has now reached its 17th edition. The present edition is improved as to its outward appearance, and still more as to its contents, much of it being written anew, thus enlarging the work to 544 pages, and bringing it up to date.

Prof. Cook writes from the standpoint of a scientist as well as a practical bee-keeper; so it happens that in one respect no text-book on bees published in this country can compare with this—that respect which relates to the natural history of the honey-bee. This occupies Part I, and covers 167 well-written pages, 81 of the 295 illustrations of the book being used to illuminate this first part.

It is true that a man might keep bees and produce honey without knowing whether a bee belongs to the class hexapoda or myriapoda—men have profitably produced honey without knowing whether the drones or the workers, or something else, laid the eggs—but the ambitious young person who enters the ranks of bee-keepers will have some desire to be intelligent upon the subject in general, and even if he has all the other text-books he will want the one that is so full upon the natural history of his pets.

Preceding Part I is an introduction discussing who may keep bees; inducements to bee-keeping—recreation, profits, etc.

The introduction to Part II advises as to starting an apiary, the proper preliminary study, procuring first colonies, kind of hives to adopt, where to locate, etc.

Part II gives practical instruction in bee-keeping, its successive chapters treating on Hives and Sections; Position and Arrangement of the Apiary; Transferring Bees; Feeding and Feeders; Queen-Rearing; Increase of Colonies; Italianizing; Extracting; Working for Comb Honey; Handling Bees; Comb Foundation; Marketing Honey; Honey-Plants (with 55 illustrations of honey-plants in bloom); Wintering Bees; The House-Apiary and Bee-House; Evils that Confront the Apiarist; Calendar and Axioms.

The beginner of the present day is greatly blessed in being able to have a text-book the study of which before he ever handles a hive can put him on equal footing with the bee-keeper of much experience who has nothing but that experience on which to rely. Those who think a bee-paper will take the place of a text-book are making a mistake. Better have a good text-book, even if the favorite paper must be stopped for a year.

Prof. Cook's book is sent by mail for \$1.20; or we mail it and the American Bee Journal for a whole year—both for only \$1.75. See other offers on page 434.

Do Not Leave Sections On Too Long.—If comb honey is to bring the highest price in the market, it is of first importance that the cappings be snowy white. Generally in a crop of light honey a certain proportion of the sections will be so dark as to lower the price a cent or two on each pound. This darkening, in nine cases out of ten, if not in 9 cases out of 100, is the result of leaving the sections too long on the hives. Bees make slow work generally about finishing up the outside sections in a super, and if the super is left on until these outside sections are entirely sealed, the middle sections are pretty sure to be darkened, the darkening being caused by bits of dark material carried up from the black combs beneath. Late in the season the matter is made still worse, especially in some localities, by the deposition of bee-glue on the surface of the sections.

The remedy is not difficult in the hands of those who are willing to give the proper care. As soon as all but the outside sections are finished, and while the central sections still retain their snowy whiteness, remove the super. Sort out all sections that require further sealing, mass them in a super, or in as many supers as are necessary, and return them to the bees to be finished. These returned supers, to which has been given the name "go-backs," will probably need to be taken off before all the sections are properly finished, the unfinished ones sorted out and again returned to the bees.

Not only will this plan result in a minimum of darkened combs, but in a small number of unfinished sections.

A Bee-Keeper's Button for members of the National Association is advocated by Pres. Hutchinson, and the matter will probably come before the convention at Denver. Why not? The American Bee Journal has sent out a large number of button-badges having on them a queen-bee, and they have no doubt served in many a case to introduce to each other bee-keepers who would otherwise have remained as strangers. A National Association button or badge would serve the same purpose, with the additional advantage of distinguishing the members of the Association.

Transferring.—L. E. Kerr, in the American Bee-Keeper, says if a number of colonies are to be transferred, first drum out the bees of No. 1 and run them into a frame hive filled with combs; then take empty No. 1 into the honey-house and transfer the combs at leisure. Drum the bees out of No. 2 and run them into the combs of No. 1; then transfer the combs of No. 2, and so on.

Stings for Rheumatism.—Dr. Sere de Marburg says in Prager Med. Wochenschrift that in acute cases of rheumatism not serious in character, the effect of stings is rapid, a cure being effected by a few injections of the poison. Chronic cases may require hundreds of stings, and in such cases it is not advisable to try the sting-cure unless all other means fail.

Spraying to Thin Fruit.—The following is clipped from an editorial in the Farmers' Review:

Trees sprayed at the time they are in bloom will not set as much fruit as those sprayed either before or after blooming. The pollen that is struck with any sprays of common strength is doomed practically. It may put out a feeble effort toward germination. When trees are sprayed in blossom of course the pollen in a good many flowers escapes, for the reason that all flowers do not open at the same time, and many will not have opened sufficiently to receive the spray. It has been suggested that this is a good way to thin the fruit on trees. The suggestion has been entertained by scientists, and if it is ever put into practice it may result in the finding of an easy method or thinning.

Upon second thought better counsels are sure to prevail in the office of the Farmers' Review. To say nothing of the criminality of the act in some States, well-informed horticulturists would hardly be willing to poison the honeybees that are now considered in horticultural circles as important helpers toward a good crop of fruit. Besides, such thinning would very likely result in an undesirable quantity of deformed fruit.

Steam for Bee-Stings.—Mrs. Burns—a lady bee-keeper near Chicago—says she finds that steaming the part stung gives relief from swelling and pain. Simply hold it over the nozzle of a boiling tea-kettle, perhaps first putting a piece of cloth over it, as the issuing steam might be hotter than the sting itself. This is a simple remedy, only it involves the necessity of having the water "biling" when stung. And a bee-keeper with a hundred colonies might have to spend too much time "steaming up" his fingers or hands. We believe we would prefer to stand a few stings, and go on with the work. Still, the "steam cure" may be just the thing for some bee-keepers or bee-keeperesses.

* The Weekly Budget. *

RED CLOVER QUEENS DELAYED—Several times we have had to refer to the delay in rearing and mailing the Red Clover queens, orders for which we have been taking for a number of months, expecting that our breeder would be able to begin sending them about June 10. Here is what he wrote us June 30:

FRIEND YORK:—Say, I am at times almost desperate, when this cold, rainy weather goes on without ceasing. To-day and yesterday it has been very good, and I am hoping for nice weather. There has not been enough honey coming in, until the last three or four days, to keep the bees from starving. I sometimes think I will never try to rear any more queens after this season, but perhaps this season is to give us the disposition of Job—to learn to be patient.

Bees are now taking to cell-building, as the season for swarming approaches, but I can't promise to be up with orders before the last of July. It is awful, but I can't make weather. I have had over 200 queens lost in flying out to be fertilized. Just think of it! You can't imagine the time we are having. Clover is nearly over and no surplus. You see, the young queens go out and a cold wave and rain catches them.

Well, we must do as we would like to be done by.

Yours trustingly,

The delay is simply too bad, and yet our breeder of Red Clover queens can not help it. He is doing the best he can. As he well says, he can not "make weather."

We trust those who are entitled to these queens will be patient. Some have already been mailed, and the balance will be sent as rapidly as possible. A card notice will be mailed to each a day or two before sending the queens.

ON TO DENVER.—Secretary D. W. Working, of the Colorado State Bee-Keepers' Association, is true to his name. He is indeed at it early and late, to make the next meeting of the National a great success in Denver, Sept. 3, 4 and 5. It won't be his fault if it is not the biggest bee-keepers' convention ever held in America. Just listen to these temptations to the "tenderfeet" of the East and South:

DEAR MR. YORK:—You may tell the readers of the American Bee Journal that those of them who attend the National convention in Colorado next September will have a chance to sit in the seats of the mighty. It is officially decided that we are to have the Hall of Representatives of the Colorado State Capitol for our Big Joint.

You are to understand that our State Capitol is worth seeing on its own account. It lacks a little of being finished, and has already cost more than two million dollars. So you may guess that it is no cheap affair. Moreover, it is surrounded by the most beautiful of lawns; and when you come to Denver the grass will be a sight to rest your eyes and make your tongue tired talking about its beauty. So, there!

You might mention the fact that the bee-keeper who has worked faithfully all summer is sure to be in debt to himself and his wife. One of the best ways to cancel such a debt is to take a vacation—go some place. Thousands of people come to Colorado merely to see the sights and have a good time—and that, too, without knowing anything about our alfalfa honey and our Bee-Keepers' Association! Your readers, knowing about these additional attractions, can be the more easily persuaded that they ought to go to Colorado at the time of the big meeting of bee-masters. Tell them to get ready.

Yours truly,

D. W. WORKING.

Say, Mr. Working, are there any signs there of the "Keep Off the Grass" sort? If so, we have the same thing here in our Chicago parks. But we want to see Colorado just the same, and its many big bee-keepers. We believe they are the best "crop" of that State. Of course, many other things out there are also worth seeing, besides grass, and honey, and bee-keepers. Get ready for a bustin' big crowd of bee-folks.

WISCONSIN BEE-KEEPING compared with other Wisconsin products of 1897 to 1899:

59,855 acres bearing orchards—45 lbs. of honey for each acre.
 1,412,963 bearing apple-trees—1.8 lbs. of honey for each apple-tree.
 166,720 bushels apples, 1899—16 lbs. of honey for each bushel of apples.
 260,549 bushels of apples, 1897—10 lbs. of honey for each bushel of apples.
 89,543 bushels of strawberries—3 lbs. of honey for each bushel of strawberries.
 42,829 bushels of timothy seed—1 lb. of beeswax for each bushel of seed.
 85,423 bushels of clover seed, 1899—31 lbs. of honey for each bushel of seed.
 1,502,444 tons of cultivated grass, 1899—1.7 lbs. of honey for each ton of grass.
 510,570 acres of wheat, 1898—5.2 lbs. of honey for each acre of wheat.
 1,145,351 acres of corn, 1898—2.3 lbs. honey for each acre of corn.
 1,928,366 acres of oats, 1898—1.3 lbs. of honey for each acre of oats.
 411,278 acres of barley, 1898—6.4 lbs. of honey for each acre of barley.
 253,190 acres of potatoes, 1898—10.5 lbs. of honey for each acre of potatoes.
 27,521 acres of tobacco, 1898—97 lbs. of honey for each acre of tobacco.
 722,933 milch cows—6 cows for each colony of bees.

\$107,170 for support of poor—25 lbs. of honey for each dollar for the poor.

\$3,631 for diseased animals slaughtered—\$7.26 for each dollar the State pays to protect bee-keeping.

\$8,537 for diseased animals slaughtered and veterinary surgeon and help—\$17 for each dollar State pays to protect bee-keeping.

\$2,535 for Horticultural society—\$5.07 for each dollar State pays to protect bee-keeping.

A CORRECTION.—At the bottom of the first column of the excellent article by Mr. Elias Fox, on page 407, it should read: "Have a sufficient number of large barrels to hold two or three thousand pounds of honey." It was printed, "two or three pounds," which was plainly incorrect.

Methods of Caring for Old Brood-Combs.

BY EMMA M. WILSON.

It is not to be expected that the beginner will have a very great number of extra brood-combs to look after. Still, it often happens, even with a few colonies, that some die, and then the extra combs must be taken care of or they will soon be destroyed by the bee-moth. These combs are too valuable to allow any to be destroyed, consequently they must be looked after sharply, and upon the first indications of worms at work they must be attended to promptly.

I know of no better way to take care of them than to give them in charge of the bees, by putting an extra story filled with these wormy combs below the colony, where the bees are obliged to pass through them every time they go in or out. You may be sure the worms will be routed in short order, and everything kept in good shape as long as they are allowed to remain. It would be an ideal way to keep combs, only for one thing: The bees will proceed to fill these combs with honey the first thing they do after they have nicely cleaned them up, providing that honey is coming in freely, and that is not the place we want our nice white honey put; if we are working for comb honey we want it in sections instead. Now, how are we going to take care of our combs and have our honey put where we want it, too?

Worms will make slow headway in combs that are kept in a cool place, such as a cellar, and spread so that there is an inch or so space between the combs, but you must look them over frequently to see that the worms are not getting a start, for when they once get started they work very rapidly, and your nice combs are soon destroyed unless attended to.

Burning sulphur has been much used in destroying worms. It is very effectual in killing the young worms, but it takes a great deal to have any effect on the old ones, and has no effect on the eggs, so the combs must be fumigated again after the remaining eggs have hatched out. Bisulphide of carbon is better, as it kills eggs as well as worms. If, after the combs have been treated, they are shut up absolutely moth-tight they will be safe.

The past spring we had a good many extra combs to look after, and as we were pretty busy they were not looked after quite as sharply as usual, and when I came to look them over I found quite a number that needed attention.

Dr. Miller had been reading to me about the fumes of gasoline being effectual. I did not have much faith in the fumes of gasoline, but I did have a good deal of faith in the gasoline itself. So, without consulting Dr. Miller I concluded to experiment a little. I had about 50 combs that were wormy. Some of them had full-grown worms, some about half size, and some just commencing work, so I felt I had a good chance to experiment.

I took a bottle of gasoline and a small oil-can, such as is usually used about the sewing machine, as my outfit. I filled the oil-can with gasoline, and was ready for work. I inspected each comb carefully, and whenever I saw the least suspicion of worms I squirted the cells full of gasoline from the oil-can. It was very quickly and easily done, and was most effectual even on the very large worms. I treated the whole 50 combs, and was sorry afterward that I

had not kept track of the time it took me, as I was surprised to see how quickly it was done.

I felt sure it was a success as far as killing the worms was concerned, but I had a little misgiving as to the effect the gasoline might have upon the combs, and as to what the bees would have to say about accepting them after they had been so treated. I am happy to say that the combs were not injured in the least by the gasoline, and the bees made no objection to accepting them, so I am inclined to think it a pretty good way to treat them. Of course, one must be very careful not to use gasoline anywhere near a fire, as it is very inflammable.

Combs that have been out over winter and thoroughly frozen will be very little bothered, if any, by the worms in this locality. Combs from hives in which colonies have died will need the closest watching, as such combs are sure to be infested.

Old, black combs which have been in use many years seem to be much preferred by the worms, probably on account of the cocoons. The presence of pollen in a comb will also increase the danger of its being riddled by the worms; while a comb that has never had any brood in it is not likely to be troubled, so I always pick out our old, black combs and put them in use first. I do this for two reasons: First, the bees prefer them every time for brood-rearing, and in the spring we are anxious to increase our bees as much as possible. I have actually known the bees to skip over a light-colored, rather new comb in the center of the brood-nest and fill an old, black comb on the other side of it with brood, thus making a break right in the center of the brood-nest. This shows how very strong is their preference for the old, black comb. The other reason is, that the worms prefer them, too, so it is desirable to get them in the care of the bees as soon as possible.

McHenry Co., Ill.

Prevention of Increase During Natural Swarming.

BY C. P. DADANT.

Permit me to reply to your inquiry on page 103, on the prevention of increase during natural swarming. The prevention of increase by returning swarms to the parent colony shortly after swarming was tried by me accidentally on a large scale a number of years ago—I believe it was in the years 1877-78. It happened in the following manner:

We had at that time made arrangements with an apiarist some 14 miles from us to furnish him hives for his swarms and take care of his bees at the same time, taking one-half of the honey and of the increase for our pay. He was to harvest the swarms as they issued. The season was exceedingly favorable, and we were crowded with work. The number of swarms was greater than we had anticipated, and our man found himself short of hives for two or three days. When I arrived at his apiary with a load of some 15 or 20 hives, he had been hiving his swarms in all sorts of boxes, nail-kegs, etc. Upon my arrival at his apiary I at once went to work to transfer, to the new hives that I had brought, all the swarms that had issued within the past two days, as they had but little comb built. But each of them did have several pieces of comb with eggs in them, in almost every instance. They were so ill-pleased with my unceremonious transfer into freshly-painted, empty hives that every swarm left those new hives and returned to the parent hive from which it had come forth a day or two previously.

Subsequently we ascertained that none of those colonies swarmed again that season. I thought that I had made a discovery, and used this method repeatedly afterwards with very frequent success, but I later found that my original

discovery had been put into practice years ago in Europe, by the box-hive bee-keepers.

In his *Cours D'Apiculture*, the first edition of which was published in the '50's, Hamet, the well-known champion of the box and eke hives in Paris, describes his method of returning the swarm to its parent colony. This method he uses for all secondary swarms, and he considers it necessary in order to secure strong colonies, or rather to prevent the "swarming to death" that weakens the parent colonies and furnishes worthless swarms. His method is to hive the swarm as usual in a plain box, and on the evening of the following day return this swarm to the hive from whence it issued, by shaking it in front of that hive.

His explanation of what happens is that by the end of the second day the bees have usually destroyed all queen-cells and have kept but one young queen. When the swarm is returned thus unexpectedly, the two queens come together and have a duel, in which one of them is killed. It would perhaps serve the purpose still better if the queen of the swarm that is returned was killed by the apiarist at the time when the swarm is returned.

As I said before, Hamet used this method only upon secondary swarms. It is quite likely that he had never tried it on primary swarms, for the reason that natural swarming was considered by him as the best method of increase, but my accidental trial and further experiments have convinced me that it works nearly as well on a primary swarm as on a secondary swarm.

Bear in mind, however, that this method is not infallible. The conditions which cause the bees to make preparations for swarming being still there, it is quite likely that other preparations may be made a few days later, but if the apiarist takes the pains to increase the space, giving room and additional ventilation so the bees may not find themselves too crowded—if he sees that the hive is as well sheltered as possible from the heat of the sun during the warm part of the day—this method will prove most successful. Returning the swarm on the same day will not do; the excitement is not over, and several young queens may be roaming about the hive, or the additional queen-cells may still be intact. It would be better to wait two days, if for some cause the swarm can not be returned on the second day.

This method I gave several years ago in *Gleanings*, and perhaps also in the *American Bee Journal*, and a number of apiarists have reported favorably upon it, though it has not been uniformly successful in all instances. But there is nothing which is at all times a success, and exceptions only strengthen the rule. If in dry weather all signs fail, it is also true that in a crazy swarming-time all methods will fail to keep the bees within reasonable bounds. But this method is worthy of a trial by those who have small hives and wish to keep down the increase as much as possible.

Hancock Co., Ill.

History and Condition of Bee-Keeping in Brazil.

BY F. GREINER.

The original stock of bees now kept in Brazil was imported from Europe in 1839 by Carneiro. Of the 100 colonies he started with from Portugal, he lost 93 in transit. Later a German emigrant, whose name is not now known, brought several colonies with him to the province Rio Grande. These few colonies, it seems, were sufficient to stock up the immense forests of Brazil. A few old inhabitants are still keeping the small, native Brazilian bee with some profit, but the products are principally used for preparing medicines. On the whole, her European sister has crowded the native bee out.

The climate of Brazil is quite favorable for keeping bees, especially as to obtaining increase. Drones are found in nearly all strong colonies the whole year around. Several swarms are cast by every colony, and every prime swarm again swarms several times. This excessive swarming, however, is of no advantage to the ordinary bee-keeper, as many swarms fail to store enough honey to bridge over the rainy season, and die. The apiarist who understands his business, however, can reap bountifully.

Mr. A. Hannemann developed the method of hiving ten or more swarms in one large, giant hive, caging all queens. Thus he has immense quantities of honey stored, practically exchanging the bees for honey, for in the end he has scarcely enough bees left to make one good colony. American bee-keepers try to accomplish the same object by contraction of the brood-chamber and uniting at the close of the season.

In the mountainous part of the province Rio de Janeiro the bees begin to fly in July, and the main harvest comes in August, at the time of orange-bloom. The swarming-period has its beginning also at this time, and continues till away into October. After this month there is little honey to be gathered. Soon the rainy season commences, which often extends into January or February. The then following dry and cool spell does not hinder the bees from flying and leaving their hives, but they find so very little bloom that their stores become wonderfully reduced, and many colonies starve and die. June is the coldest month of the year, and is the trying one for the bees and their keeper.

The hives mostly used by the common run of bee-keepers consist of all sorts of miserable boxes, which often fail to give sufficient protection. They leave them scattered about wherever it happens to be. Only a very few bee-sheds may be found which provide shelter and shade, and give some comfort to the bees.

Natural enemies of the bees are numerous. Ants and moths are at all times ready to embrace every opportunity to put in their destructive work, and are a constant annoyance to the bees. The bee-keeper himself, who should be the protector, is of questionable advantage to them, and often robs the poor creatures of all their sealed stores, leaving them only the unsealed, poor honey gathered late in the season. In consequence the bees do not remain healthy, and often die with the dysentery during the wet season.

The lack of proper bee-supplies, and the general ignorance of the masses, are responsible for the fact that Brazilian honey is in no demand. The wealthier land-owners do not seem to take any interest in bee-culture. Their coffee-plantations take up their whole mind and being, and they look down upon other branches of agriculture with contempt, especially when such do not promise large returns. A change for the better in the near future is inevitable. Since the abolition of slavery (1888) many land-owners found themselves without the necessary help to work all their land, and had to dispose of the greater part of it, dividing it up into small farms. Many of these were bought up by European immigrants, who brought with them the knowledge of apiculture. Through this element the progress is expected to come. In particular will this be the case in the State of Rio de Janeiro, where conditions are most favorable for a most extensive production of coffee.

So far, then, apiculture is not in a very flourishing condition nor of great importance in Brazil, but as knowledge increases apiculture will come to the front. When better constructed hives are adopted some of the pests will be more easily held in check. The native small bee is much inclined to rob; she has the very best chance with such hives as are now in use, and which are usually full of cracks and holes. With well-made hives her European

sister need have no fear. The hives may be raised and put on legs to get the better of the ants, etc.

Die Brazilianische Bienenpflege—a bee-journal printed in the German language—will in no small degree be the means of distributing knowledge and help raise apiculture to a higher plane.

The most important nectar-secreting plants in Brazil are the orange-tree, peach-tree, tamarind, and other numerous fruit-trees; also the coffee, tea and cotton plants.

The foregoing is largely taken from the Leipziger Bienen-Zeitung. Ontario Co., N. Y.

No. 6.—Rearing Long-Lived Queens and Bees.

BY DR. E. GALLUP.

Now let us look into the question of requeening every spring with young queens from the South. Your queens are all reared on the degenerating or contrary-to-nature plan. Many of them do fairly well the first season, but their workers, being short-lived, dwindle down through the winter in this climate so that it is almost impossible to get them up numerous enough to take advantage of the orange-blossom honey, which is quite an item. The second season those forced or degenerate queens almost invariably fail, and if they are superseded their young queens are reared in a small, weak colony, and they lack vigor and prolificness. Now suppose we take said queens in the East, where they lie comparatively dormant through the winter; as soon as spring opens and they commence working, they dwindle down very rapidly with old age. There is where your spring dwindling comes in.

I will have to ask a question: Why do not the bees from a natural queen dwindle just the same? I think I would better answer that question in my own manner, and right here: Simply because the bees from the natural queen are longer-lived, and the bees from the degenerate queen are very short-lived.

The natural queen is just as prolific the second season as she was the first. She fills the cells with eggs so rapidly, and her workers are long-lived enough so that the young brood comes on more rapidly than the old bees die off, and the colony is kept up to its working strength at all times, providing they have honey enough in their hive to fall back on in an emergency, such as a cold, rainy spell, etc. A good, rightly-reared queen ought to keep up her full prolificness well into the fourth season. I have had them last until the sixth season, and I could not see any difference between the fifth and first; and when the queen was superseded in the sixth season the colony was strong and numerous, so they could rear a vigorous and perfect queen.

Now, don't you think you had better keep that old, prolific, long-lived queen that rears long-lived workers that are able and willing to work both outside and in, rather than to supersede her with one of those degenerate queens—cheap ones from anywhere?

I want to tell you that those cheap queens are dear ones as a gift, for you have to furnish a colony, and with lots of them you have to furnish another colony and queen to rear bees to keep the first colony in strength, in order to have them do anything at all. I have had them where it would take eight to keep up a colony as strong in numbers as one good queen would do.

I received a queen this spring reared last fall, and all the coaxing I can do for her she only partly occupies three Langstroth frames; while I have two queens of my own rearing, one occupying 16 frames and the other 15. I have one naturally reared, black queen that occupies 15 frames fully, and the 16th one partially, and this is her second season.

To illustrate further: Late last season a young boy that had no previous experience with bees, undertook to take a colony out of a tank-house. Not knowing how to handle them he got badly stung, but succeeded in getting the queen and a small quantity of the bees. One of my young sons made a hive for them; not knowing the value of ready-made comb he destroyed most of the combs, but I patched up part of a frame with pieces, then hived them on three frames. They filled four frames last fall. Some time about the first of April I looked them over and found that they had filled two frames outside of the division-board, and the queen had all packed with brood. Now, at this time none of my purchased queens had done anything to gain in numbers—in fact, were rather decreasing. My small, starved-out, black colony, that I obtained last fall, was building comb rapidly, and the queen was occupying the cells as fast as they were made deep enough to occupy, and they have now two supers and the hive completely full, and every comb built but three—the ones they were first hived on built by themselves—and the queen had 15 combs filled with brood. I introduced a mature cell, built at superseding time, from one of my Italian colonies, and the young Italians are now working outside (June 2). I do not expect a better queen, but I want the Italians, as they will not meddle with the drying fruit or the canneries as the blacks will. The Italians always find flowers of some kind to keep busy on.

I have never reared Italian queens for sale, as my other business prevented, and I never could see my way clear to satisfy myself, let alone purchasers. I said, years ago, in the American Bee Journal, that I did not believe that one could rear cheap queens and have them all good ones, and I have seen no reason to alter my mind yet. Although one man said in a convention that, assure him of a market for them and he would agree to rear them at 10 cents each. My strong impression is that they would be only 10-cent queens, any way you could fix it.

Here the oranges commence blossoming in March, and continue until the latter part of May, and if we have the right kind of queens and weather we get a good quality and quantity of honey.

I said, years ago, that upon the queen nearly everything depends in bee-keeping, and I have not yet changed that opinion. Orange Co., Calif.

Convention Proceedings.

Affairs and Interests of New York Bee-Keepers.

Read at the meeting of the New York State Association of Bee-Keepers' Societies, held at Genesee, N. Y., in February, 1902.

BY PRES. W. F. MARKS.

Members of the New York State Association of Bee-Keepers' Societies:—

It is my duty and privilege to address you again on matters pertaining to the affairs and interests of our organization. I shall aim to be brief.

This meeting is, to all intents and purposes, a congress of bee-keepers. You come here by authority and direction of your local societies, and represent to the best of your ability their wishes and desires. Your coming is the result of organization—organization for a purpose, an object, many purposes and many objects. There are so many problems for us to solve, and solve rightly, that it will require your undivided attention and thought.

Objects to be accomplished, and methods to be employed, toward increasing the usefulness and efficiency of our organization, is a problem you must all help solve with a view to the future; and in order to encourage thought and study on this subject I would suggest that it be one of the chief subjects for every convention. It is a subject that requires thought and study, and I trust you will give it such.

It is my opinion that the time for discussions at these conventions should mostly be devoted to questions pertaining to the upholding and advancement of our commercial interests; and questions pertaining to the work or management of the apiary should be left for the institutes.

I announce with pleasure progress in organization in this State. Since our last meeting, Monroe, Oswego, and Onondaga Counties have organized auxiliary societies, and bee-keepers in other counties have signified their intention of doing likewise.

It has been the aim of this Association to deserve the respect not only of the bee-keepers in the State and out, but of all classes and of every vocation. That you have achieved such respect is no more a source of gratification than the fact that you may deserve it. It is not my intention to boast of what, as an organization, you have accomplished, but I mention these facts as

"Footprints, that, perhaps another,
Sailing o'er life's solemn main,
A forlorn and shipwrecked brother,
Seeing, shall take heart again."

It is not necessary for me to dwell upon the results of experiments conducted by the Experiment Station in 1900, as they were given by Prof. Beach and Prof. Lowe at our last meeting, and are a matter of record. Prof. Lowe, the Station Entomologist, is on the program, and will give you an account of his experiments that are of interest to beekeepers, and which were conducted last season.

Article II of our Constitution fixes the time and place of the annual meeting of this Association. Present or future conditions may make it desirable to amend said article, so we can meet at some other time and place. It has been suggested that we meet at the same place the day following the State Fruit-Growers' convention. This would enable those who wanted to attend both conventions a chance to do so without additional traveling expenses. It would give all the benefit of reduced railroad rates. It would be a mutual benefit to members of both Associations; and the secretary of the Fruit-Growers' Association assures me that in arranging for reduced railroad rates he can look out for both associations as easily as for one. I would respectfully call your attention to the matter.

The premiums offered by the State Fair Commission on products of the apiary are not equitable or just. A committee should be named by this Association to confer with the State Fair Commission, and insist that justice be done our pursuit in this matter; or such other steps taken to secure the desired result as you may deem advisable.

At your last annual meeting you recommended that the enforcement of that portion of the pure-food law relating to adulterated honey be transferred to the Department of Agriculture. As chairman of your legislative committee I took immediate steps to comply with your wishes. The attention of the Commissioner of Agriculture was called to the matter, and I was assured that a bill would be introduced, which, in connection with other matters, would accomplish the desired result. Such a bill was introduced, Senate Bill No. 196, familiar to most of you as "Senator Ambler's Pure-Food Bill;" but owing to the determined opposition of the baking powder manufacturers it was finally defeated.

On investigation I find there is a question if our present

law on adulteration could be properly enforced—in fact, I am convinced it is not what we want. There is much complaint of adulteration, and you are urged to take steps to prevent it if possible. The recent advance in the price of honey will have a tendency to increase the practice. Samples analyzed by the Connecticut Experiment Station, in 1898 and 1896, are suggestive; here are the figures: Out of 37 samples analyzed in 1898, 5 were pure, 22 doubtful, and 10 certainly adulterated; in 1896, out of 48 samples analyzed, but 7 were pure, the balance either adulterated or doubtful; and several of these samples were manufactured in this State. We can not afford to wait longer for a general pure-food bill.

All things considered, after taking counsel and advice of chemists and others of experience in this work, I would recommend that we secure, if possible, a new law relative to the adulteration, misbranding, imitation of and deception in the sale of liquid or extracted honey. As chairman of your legislative committee, I have prepared a bill for your consideration, which, if it meets your approval and becomes a law, is intended to prevent misbranding and adulteration; such bill is not yet before you, but with your permission I will depart long enough from the regular order to explain some of its provisions, with a brief explanation of the whys and wherefores; so you will more readily understand them when it is reported.

It is intended strictly as a honey-producers' and honey-consumers' bill; it is intended to affect no other product as long as such product is not branded with the word "honey." Briefly stated, it does not prohibit the mixing of other ingredients with honey; but it does prohibit the branding of such mixture as "honey," and the branding of any product "honey" which is not pure honey. If the glucose-mixers want to raise the grade of their product by the addition of honey, I do not believe we can prevent them doing so if they sell it for just what it is, and I know of no reason why we should want to prevent them or anybody using honey; but we can and should prevent their branding their mixture "honey," or the branding of any product honey which is not pure honey.

In order that my position may not be misunderstood, let us look at the question from another standpoint and say that glucose is adulterated with honey. Now, I do not believe such adulteration would hurt us, or anybody, if such product could not be sold for "honey." "Honey" is the natural product of the honey-bee and the trade-mark of the honey-producer. I believe the courts will sustain that position without exception, and we should zealously maintain it against all comers. Perhaps further explanation at this time will be improper. I trust the matter will receive your earnest consideration at the proper time. If we have a law it should be *honey-tight*, enacted with a view of being enforced; there should be no holes in it, and the bill must be carefully drawn.

In conclusion, let me urge you to combat the idea that honey is a luxury. We know it to be a valuable saccharine food, and why should we not maintain such fact at every opportunity? Encourage home consumption; no person is worthy of the name of honey-producer, no matter how extensively he is engaged, who will not do all in his power to increase consumption at home.

Now that the price of honey has advanced, try to maintain prices. There is no reason why the producer should not receive good returns for his time and money invested.

A word in regard to the series of Bee-Keepers' Institutes may not be out of place: A speaker is furnished for these institutes by the Department of Agriculture, through its Bureau of Farmers' Institutes; dates, places, and speakers for the same must be arranged for some time in

advance of the meetings, and approved by the Director. If you do not ask for an institute until the series has been arranged and the dates fixed you will be disappointed; much of this work should be done to-day. Your thanks are due the Department for favors received.

It is important, and a source of gratification to the beekeepers and the several societies, to be largely represented at this convention; but it is not necessary that we should be noted for the numerical size of our conventions; but rather by the value to our pursuit of the work accomplished. Our time is limited; there are live issues to be discussed; be thorough, but brief and pointed in your discussion.

Thanking you for your attention and for the loyal support and aid you have rendered, I await the pleasure of the convention.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

COMB HONEY AND SWARMING.

Yes, sir, no doubt of it; a living blanket of bees on top of the sections and all round, is one of the very best incentives toward getting them finished promptly and in the best style of bee art.

To deplete the old hive of bees after swarming, and to use it finally to hive a swarm in, is a method of restraining increase that commends itself highly. Still you must remember that it might play capers with you, in your yard, providing you have never used it before. Article of G. W. Stephenson, page 343.

PERCENT OF WATER IN HONEY—FLAVOR AND COLOR FROM POLLEN.

If we can not know *exactly* how much water there is in honey, here is an approximation stake to tie to which is tolerable. Prof. Eaton tells us on page 345 that 23 percent should be the high-water mark. Above that it's honey and water rather than honey.

Wonder if he intended to say that *flavor* and color of honey depend in part upon the pollen. If so our goat, methinks, ought to give him another degree of bee-masonry.

THE SCIENTISTS AND GLUCOSE.

It worries me a little when I hear the scientists tell what the different sweets are that compose honey. These pronouncements, of which we have had quite a number, sound very different the one from the other. How much of this disagreement is real disagreement, and how much a different use of language merely, a layman can not tell very well. It's plain that scientists, when they get criss-cross at each other, rather take pains to have their language disagree. I am not accusing Prof. Eaton of this, but just honestly and squarely quoting him below; and those "unreliable glasses" of mine can see "just as easy" that none of our learned and respected teachers know quite as much about the composition of honey as they let on:

"Glucose, in a chemical sense, signifies a group of sugars having common characteristics, and includes almost two dozen varieties, the most common of which are dextrose and levulose. Honey, therefore, contains glucoses, but no 'glucose.' 'Glucose' also contains glucoses, dextrose being common to both products." Page 345.

PROPER TEMPERAURE FOR HANDLING BROOD.

As to the temperature at which brood should or should not be taken out of the hive, the answer on page 347 is conservative, and to that extent good. I will remark, however, that for 20 odd years I have been in the regular habit of

going through my hives whenever I wanted to (and that has been to a total of a great many cases), at temperatures very much below what the authorities set. Instead of keeping my minimum at 65 degrees it would be somewhere about 25 degrees, I reckon. No wind, you understand; and a protecting case made on purpose to put the frames into as soon as taken from the hive; the exposed side of the case to hold a broodless comb; and the quilt laid loosely on the top of all if things are severe. I may have done much harm by this conduct, but I have yet to run across the first evidence of it. Tender brood lies at the bottom, or at least half way to the bottom, of a narrow, warm cell, which takes quite a while to get cold. And my idea of how matters work in a calm atmosphere is that a warm, empty comb *holds* its inclosed air—somewhat as a floating thistle-down holds its inclosed globe of warm air. The cooling of the inner walls of the hive is to be regretted, in case you take everything out; but then the bees go back in a stirred-up condition, like a stirred-up fire, and soon warm things up again.

A HARD SPRING FOR BEES.

Worst spring for bees in 33 years—Doolittle, Onondaga Co., N. Y.; May 15. Bring it down to June 19, and say worst spring I remember in my locality for lack of nectar in the flowers. Not so very exceptionally cold, or dry, or wet, or stormy, but just barren. Perhaps the number of days of rather cold weather has been exceptional. But in my garden one or more cucumber plants, planted May 3, and coming up with reasonable promptness, still live, having had no protection whatever. Page 348.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Superseding or Swarming-Out?—When to Put on Supers.

Why so much superseding of last year's reared queens? On opening the hives I find two capped queen-cells, frames well filled with brood, equal to the work of a well-regulated queen, no drone-brood. The bees will ball the queen, and I find them on the entrance-board. I have not been tampering with them or bothering them. All are clipped. I would think nothing of it if they were old queens.

I had hives booming with bees, and saw the first clover bloom May 21. I put on supers June 10, and to-day there is scarcely anything being done in them. The reason is the cold and wet weather. I said I would wait before putting them on, because I thought the weather would continue cold, and it has, and will remain cool throughout the season, as it did in 1882.

There is very little swarming, what swarms there are issue when young bees are out for a flight. I get about enough of the returned ones to make a coporal's guard. The swarm will settle and go in with others; I can't blanket all the entrances.

I find the bee-men have troubles as well as the fisherman.

I had my stakes set for 100 colonies, but have concluded that a whole lot less will make me plenty of trouble.

It is enough to make one hot under the collar to have the natives swarm in to buy honey and have none to supply them with, and to hear them say, "What, all of these bees and no honey! I would get rid of them." IOWA.

ANSWER.—I've looked over my assortment of answers carefully to find one to fit your question as to the loss of queens, and can't find a single one to fit the case except that one I have to use so often—"I don't know." I doubt

its being supersedure, for I doubt there ever being a case of intentional supersedure without the rearing of drones. It looks more like swarming-out. Sometimes bees swarm out with plenty of honey in the hive, and with plenty of brood, as in a case of spring dwindling, and I've never seen any satisfactory explanation for it except the possible one that there is not a sufficient force of bees to care properly for the brood. Sometimes bees swarm out because they run short of stores. In either case, with a clipped queen, the bees would be likely to return to the hive, and the queen might be lost. If conditions are the same with you as here, it would be nothing strange for bees to swarm out because short of stores.

You are entirely right in thinking there was no necessity for putting on supers this year for a long time after the first white clover bloom. I saw the first clover bloom this year May 20, and there seems no likelihood that there will be any need to put on supers until more than a year after that date. The rule, however, to put on supers at first sight of clover bloom is a good one. If there is no nectar in the clover, of course it doesn't count. Neither is it necessary to put on supers so soon if the brood-chamber is entirely destitute of stores, for the bees will first see that the brood-chamber is filled before storing in supers.

Folding Sections—Winter Packing in Alabama.

1. What do you make or fold your sections with?
2. Do you *think* you would use any packing on or around bees in this latitude? or just see that they had plenty of stores and the upper story off? The thermometer only once in five or ten years goes below zero, and then not over 1 to 5 degrees.

ALABAMA.

ANSWERS.—1. I have been using the Hubbard section-press for a number of years.

2. I don't think I would use any packing for winter in Alabama, but before being too positive about it I should want to inquire of you and others in your locality as to your previous experience. If you have had success without packing, then packing would be hardly worth the while. And yet, if you have not had entire success without packing, that by no means proves that the lack of packing is to blame for your want of success. In that case, I should want to try packing on a small scale, and see whether the packed colonies did any better than others.

Bees Not Storing Much Honey.

I have 12 colonies of bees, and they have not stored any honey in the sections this season so far (June 25.) Half are pure Italians, and the other half are mixed Italians. I have the 10-frame hive. I have a little brown bee and the mixed Italian, and only two colonies that have stored any honey in the sections. Last season did not seem very good for bees, and also this season. It is hard to understand why they don't do better. I am located near some good farms within less than 300 or 400 yards from my place. I have made 10 hives of 10-frame style. I am expecting next season to do better. If I do not, I will have to move to some other locality.

If you can give me any information that will help me about the queen-bees, I will appreciate it very much. It may be the bees, the reason that I do not get much honey.

GEORGIA.

ANSWER.—It is hard for any one to make a guess as to why your bees store so little. It is possible that the bees are not at all to blame, the trouble being that there is not sufficient nectar for them to gather. It is also possible that the bees are to blame, and that if you had a different strain you might have more honey. This is perhaps to what you refer when you ask for information about queens. All that is necessary is to get a queen of some reputable queen-breeder, such as advertise in this journal, or get one of the

queens offered as premiums, and then see whether the new stock does any better than the old. But do not depend upon the first trial with a queen obtained through the mails. A queen of the very best kind may be so injured in the mails that she will not do as good work as inferior stock, while if young queens be reared from her they may show the very best results. If you mean something else by "help about queen-bees," please be a little less general and it will be a pleasure to answer your questions.

Inducing Bees to Build Comb.

I want to know what will induce bees to build comb. With us it is hard to get any comb built after July 10. Could I induce bees to build comb in brood-frames where foundation starters are used, say 3 or 4 inches wide? Would feeding do it? We have very little trouble in wintering bees, if we can get the frames full of comb.

VIRGINIA.

ANSWER.—Bees will build comb only when they need more. Yes, feeding will make them build comb, if you feed more than they have empty cells for. The reason they do not build comb after the 10th of July, is probably because after that time they do not gather enough to need any more room to deposit what they gather.

Colony Refusing to Accept a Queen.

I have a colony that refuses to accept a queen, though I have tried twice, and lost the queen in each case. What would you do with the colony? Shall I distribute it around among the other colonies, or unite it with a weaker one that has a queen? If the latter, how shall I do it?

ILLINOIS.

ANSWER.—Either plan will be good. If you have several weak colonies, divide it among them; if only one, unite with that one. First give to the weak colony a single frame of brood and bees from the queenless colony; next day give two more frames, and the following day the remainder.

Inducing Early Swarming.

1. What will induce early swarming?
2. How soon will bees swarm after being hatched?

IOWA.

ANSWERS.—1. Do everything you can to favor building up the colony early; keep it as warm as possible; give frames of brood from other colonies; keep off surplus arrangements so it will be crowded for room; and, if there is still vacant room in the hive, either feed to fill empty cells, or give dummies in place of empty combs.

2. Perhaps the same day they are hatched if a swarm happens to be issuing at that time. When a swarm issues, bees of all ages go with the swarm, and bees of all ages remain with the old colony.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

GENERAL ITEMS

Bees in Good Shape.

I have 60 colonies of bees all in good shape, up to date. I have had only 4 swarms, and do not want any more. I run for comb honey, and not for swarms. They are doing well on white clover, and I never saw as good a supply before.

E. B. HUFFMAN.

Winona Co., Minn., June 25.

Most Unfavorable Season.

The season has been most unfavorable so far. It is aggravating to see the profusion of white clover bloom everywhere and no chance for the bees to get out and gather the nectar which is present in large quantities, judging from what our bees do whenever there are a few moments when it is possible for them to be out. There have been not more than 4 days in all this month when it was warm enough and dry enough for bees to work. I have not been able to do much in the line of queen-breeding because I did not consider it safe to open hives.

Basswood bloom has been ruined by frost, and I feel afraid that buckwheat will be all we may now depend on for honey.

F. GREINER.

Ontario Co., N. Y., June 28.

Hot Weather Needed.

I never saw so much white clover, but the weather is too cold for bees to store any nectar. We must have hot weather soon, or the honey crop will be very light.

EUGENE MANNING.

Tompkins Co., N. Y., June 30.

Dogwood and Bitterweed Honey.

I thought, as did Mr. Parsons, that I'd tell you about dogwood and bitterweed, but as he has done it I'll just go a little farther and say that dogwood gives considerable honey, but it, too, is slightly bitter, enough so that it is objectionable in the section honey, but as it blooms a *little* before poplar it rarely gets into the sections. If I ran for extracted honey I fancy it would bother a good deal. If Mr. Parsons had written all he said about the *bitter* part of bitterweed honey in *italics*, and closed with a big *BITTER*, he'd have hit it. Quinine is a sweet morsel by the side of bitterweed honey. Fortunately, it grows only in cities or small towns, and the farmer bee-keeper is immune from it.

R. V. GOSS.

Walker Co., Ala.

Late Swarming—Pleekpocketed.

I can report my bees strong in numbers, but late in swarming and storing honey in the supers. White clover blossoms were in evidence the first day of June, and at this date are plentiful, but the cool, cloudy and damp weather which has prevailed the most of the month has prevented the bees gathering much honey. But when a good day does occasionally appear, I am encouraged to see them going for the white

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

clover and alsike blossoms, proving there is nectar in both. I am quite anxious for a good honey crop this season, to make up for a loss I met with the 13th of this month. My wife and I went on a short excursion, by train, and I "fell among thieves" for the first time in my life. In the rush of getting off the train, pickpockets got my pocketbook containing \$40.00 and over—enough to have paid my fare to the convention at Denver next September; but "misery loves company"—"there were others," the thieves getting about \$300 on the different trains to and from the place. A lone dollar-bill that I was keeping for an emergency went with the rest. I am glad I have paid so far in advance for the American Bee Journal.

A. F. FOOTE.

Mitchell Co., Iowa, June 23.

Bees on Verge of Starving.

The outlook for honey is very poor at present. The clover season is almost gone, and the bees are on the verge of starving. It is too cold and wet. Basswood trees are full of buds, and will be out in 8 or 10 days. I hope for better weather then.

C. A. HATCH.

Richland Co., Wis., June 27.

Short Honey Crop.

The honey crop is short in this part of the country—about half. Cause: cold, wet spring and hot, dry summer. Dry winds from the North are now parching up everything.

H. D. MURRY.

Rankin Co., Miss., June 24.

Worst Year for Bees.

This is the worst year for bees that I have ever known, and I have kept bees for 25 years. No honey, and very little brood. This is the worst week of the summer; no honey from white clover. Bees will starve in a few days unless there is a change in the weather soon. We may get some honey from sweet clover. Will it pay to feed bees at this season of the year? E. L. GLOVER.

La Salle Co., Ill., June 27.

[Certainly; it will pay to feed bees whenever they need it.—EDITOR.]

Do Bees Hear?

This is a question that has been ventilated by the most profound bee-keepers in America. From my observations I believe that everything that has life and moves on top of the earth has the senses of hearing and seeing, for the protection of themselves. It may be that the mole and angle-worm, and a few other animals and worms, depend upon concussion of the earth to alarm them. I have my reasons for believing that bees hear, viz:

When bees locate a home only about one-fourth of the swarm leaves as scouts in search of a home. These scouts, after locating the home, will return to the swarm, and by a peculiar noise notify them that a home is ready, the carpets are down, and all the cracks are glued with propolis. Now, the swarm comes off the bush, or where they are hanging, and takes a bee-line to their future home. One-fourth of

the swarm leads three-fourths. By what means do they do this without hearing the scouts that are leading the main swarm? They don't follow them by sight, for the bees all look alike, unless the scouts were painted red.

If you have hunted wild bees and put a little honey on a stump in the forest, and burned old comb, soon a bee will alight on the honey; as soon as she is full she will make a few circles and leave for home. In a few minutes she returns with a sister bee. Now, did she follow her by sight through the thick timber or the noise made by the vibrations of her wings?

When it thunders, and the rain is 4 miles away, the bees come pouring in the hives by thousands long before they would have time to fly 4 miles out of the rain.

Does the queen pipe for fun, or can she hear, and not hear her children?

GEORGE POINDEXTER.

Dewitt Co., Ill., June 19.

Late Season—Cold and Wet.

The season is late here; too cold and wet. No swarming. White clover is in abundance, also blue thistle. It seems now as if we would have a poor season. The bees came through the winter in good shape, but have built up very slowly on account of the cold weather.

F. J. WILSON.

Washington Co., N. Y., June 23.

Worst Season Ever Known.

This is positively the worst season ever known here for bees. It rains nearly every day, with very little sunshine, and a temperature that averages more like October than June. No honey, very few swarms, and bees nearly starving, or living from "hand to mouth," they securing almost enough for their wants the few sunny hours that come between our floods of rain. Corn, which usually stands a foot high at this time of year, does not average 3 inches, and looks so sick that farmers are beginning to think we will get no corn. I wish the Texas roasted and drowth-stricken people could have a part of the cool and wet in exchange for some of theirs.

G. M. DOOLITTLE.

D. J. BLOCHER, Pearl City, Ill.
27Atf Please mention the Bee Journal

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal

1902—Bee-keepers' Supplies!

all off with sulphur. I would not do that; I would unite them with some weak colonies, which bee-men generally have, that is, bee-men who do not make a business of looking after their colonies. They just put them any old place, slap on the sections, and then let them go at that. Now, I always give my bees the best care. You cannot make money in stock if you do not take care of them, and it is the same with bees.

I know of a bee-man that put 3 big swarms in an old salt-barrel, and got a barrel of honey; he killed the bees and took the honey that the bees worked so hard to store away. He could have put them in other hives and kept them for another year.

I am a reader of the "Old Reliable," and could not do much without it. I enjoy the pictures of the apiaries very much; they are up-to-date.

G. B. WILLIAMSON.

Jones Co., Iowa.

Repairing Hive-Covers.

Tell "Missouri," on page 409, first to paint the bad place in his old cover thick with white lead, then stretch on a piece of muslin, and paint over it well. I mend cracked covers that way, and it is very successful.

Lafayette Co., Wis. **H. LATHROP.**

Rates to Denver—A "Bee-Bonnet."

I have been interested in the meeting of the National Bee-keepers' Association at Denver. The Editor gave the rate from Chicago last week, but that does not do us much good down here. Can you give rates from Kansas City, Mo., Wichita and Hutchinson, Kans.? Also, are women bee-keepers eligible to membership in the Association?

I will enclose a snap-shot of my apiary. The picture does not show all the colonies. I had been working among the hives and did not have the yard fixed up for a picture. The lady that took the picture stopped on her way home from a picnic, and it was just about sundown, the wind was blowing quite hard.

I have some fine Italians which I purchased last year. They are the best workers in the yard.

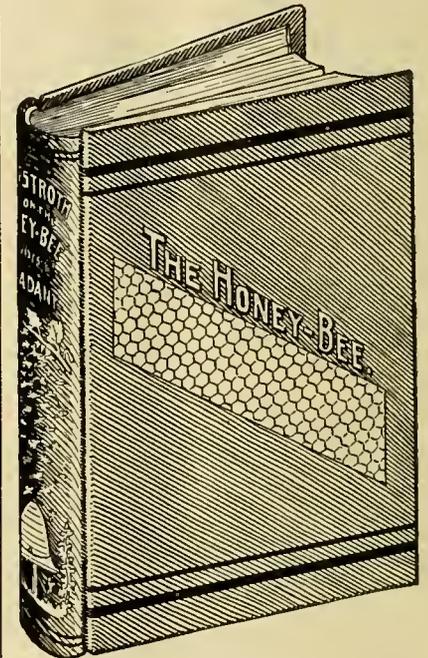

I have a little different kind of a bee-bonnet from any I have seen. I took a wire hat-frame and covered it with muslin; around the edge of the hat I sewed screen-wire, and fastened it together at the back; to the lower edge I sewed muslin and ran a draw-string in so as to draw it tight around my waist. I cut armholes and sewed sleeves in; I made them large, and put a draw-string at the wrists. When I get my gloves on, the bees may get as mad as they please, but they can't get at me. I have strings sewed to the crown of the hat which I tie under my chin, and with the hat-pin stuck through into my hair I have it pretty solid. To keep it from hanging loose in front, I pin the muslin part to my dress with a safety-pin. I can see so much better through the wire than through any kind of a veil, as a veil wavers and blows about.

The last month has been very hard on the bees; we have had so much rain. There have been only 6 good working days. The colonies are quite

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly ex-

plained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Eric St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

ABC of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Italian Queens—bred for business, by the best methods, and from the best honey-gathering stock. My bees are free from disease, and are hustlers. No small or inferior queens sent out. Untested, 75c; tested, \$1. 28A4t D. E. ANDREWS, Bloomington, Ind.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, June 18.—The market is practically over in comb honey until the new crop comes forward, so far none has appeared in this city. A little of the extracted is on sale, but it is chiefly of a low grade of amber selling at about 5 cents per pound. There is a large amount of the white extracted honey of the crop of 1901 still on sale bringing 5@6c, according to body and flavor. Beeswax sells upon arrival at 32c.
R. A. BURNETT & Co.

KANSAS CITY, June 23.—There is very little doing in honey at this time. The supply of comb on the market is not large, although there is a very good supply of extracted. We quote: Comb honey, 13@14c; extracted, 5½@6c. Beeswax, 25@30c. No new honey in market.
C. C. CLEMONS & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.
THE FRED W. MUTH Co.

ALBANY, N. Y., May 1.—Honey market is dull. Very little call now for any grade. Well cleaned out of stock and season practically over. Some comb honey is selling at 14@15c. Extracted, 6@6½c. Beeswax, good demand, 30@31c.
H. R. WRIGHT.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

NEW YORK, May 19.—There is a limited demand for comb honey and prices range as follows: Fancy white, 14c; No. 1, white, 13c; amber, 11@12c; no buckwheat or dark on the market and no more demand for any. Market on extracted remains very inactive. Plenty of supply with only fair demand. We quote: white, 5½@5¾c; light amber, 5@5½c; southern, in barrels, 50@55c gallon. Beeswax firm at from 30@32c pound, according to quality.
HILDRETH & SROELKEN.

CINCINNATI, June 7.—There is hardly any change in the honey market. Comb is not moving much, and whatever is left can be bought at cut rates. Water-white is selling from 14@15c. Extracted is in fair demand and finds steady sales, in barrels, 5@5½c; water-white alfalfa from 6@6½c; white clover from 6½@7c. Beeswax is coming in more freely and sells for 28c.
C. H. W. WEBER.

SAN FRANCISCO, June 25.—White comb, 10@12 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4½@—; amber, 4@—. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

While the market presents a firm undertone, owing to the season's yield proving much lighter than was generally anticipated, the inquiry is not active at full current rates. Buyers are slow realizing that they are not going to be favored this summer with heavy offerings.

A STANDARD-BRED QUEEN-BEE FREE

To Our Regular Paid-in-Advance
Subscribers.

We have arranged with several of the best queen-breeders to supply us with **The Very Best Untested Italian Queens** that they can possibly rear—well worth \$1.00 each. We want every one of our present regular subscribers to have at least one of these Queens. And we propose to make it easy for you to get one or more of them.

In the first place, you must be a regular subscriber to the American Bee Journal, and your own subscription **must be paid in advance**. If it is not already paid up, you can send in the necessary amount to make it so when you order one of these fine Queens.

A Queen Free for Sending One New Subscriber

Send us \$1.00 and the name and address of one **NEW** reader for the American Bee Journal, and we will mail you one of the Queens free as a premium.

Now, go out among your bee-keeping neighbors and friends and invite them to subscribe for the old American Bee Journal. If you want some to show as samples, we will mail you, for the asking, as many copies of the American Bee Journal as you can use.

Should there be no other bee-keepers near you, and you desire one of these fine Queens any way, send us \$1.50 and we will credit your subscription for one year and also mail you a Queen. Of course, it is understood that the amount sent will pay your subscription at least one year in advance of the present time. So, if your subscription is in arrears, be sure to send enough more than the \$1.50 to pay all that is past due.

As the supply of these splendid Queens is limited, we prefer to use all of them as premiums for getting new subscribers. But if any one wishes to purchase them aside from the Bee Journal subscription, the prices are as follows: One Queen, 75c.; 3 Queens, \$2.10; 6 Queens for \$4.00.

We expect to be able to fill orders by return mail, or almost as promptly as that, so there will be no great delay at any rate.

Now for the new subscribers that you will send us—and then the Queens that we will send you! Address,

CHICAGO, ILL., JULY 17, 1902.

No. 29.

* Editorial Comments. *

Bee-Growers is a term that Editor Root thinks it would be well to use so as to avoid the constant repetition of "bee-keepers." But is the frequent use of the same word objectionable if the thing itself is frequently referred to? The word "bee" is used with much greater frequency than "bee-keeper." Does our good friend of the Buckeye State object to allowing the word "bee" the monopoly of representing the thing that we speak about so often? We prefer to be a bee-keeper or honey-producer rather than a "bee-grower."

The Change in Weather throughout a large scope of country came suddenly, but there was nothing of a compromising character in the change. It was from cold to hot, sudden, distinct, unreserved. In the latitude of Chicago the feeding of bees was the order of the day throughout the month of June with those who were wide enough awake to be aware how stores had disappeared. Then just about the same day with the opening of linden came a welcome rise in the thermometer. No matter how much clover was in bloom, the bees got nothing from it during the dreadfully chilly time, and they will be more or less uncertain now whether bees are getting honey from it, and will wait with no little interest to find out after the cessation of linden bloom. Whoever may grumble about the hot weather, bee-keepers will hardly do so.

Honey Crop Prospects in California.—A leading bee-keeper of San Diego County sends us the following, taken from the San Diego Weekly Union, dated June 19:

SAN DIEGO COUNTY HONEY PROSPECTS.

The latest estimate of the honey crop in this county by those who make a business of dealing in it, is that there will be about 20 car-loads this season. The average yield is about 75 car-loads, so that there will be a quarter crop this year, if the estimate is correct. It is very difficult, however, to forecast just how much honey the bees will gather. This will depend to a considerable extent on the life of the plants and flowers from which the honey is taken.

Some new honey is already being brought to market, but the quantity is very small. One commission man said yesterday that he was not buying new honey, and when asked for the reason, he said there was none to buy. Between 4 and 4½ cents a pound is being paid for the new honey. The bee-men themselves think that the estimate of 20 car-loads for this year is a little high. There have been seasons when this county produced more than 100 car-loads. The other day Simon Levi shipped 48,000 pounds of last year's crop to eastern points. This honey had been stored since last season.

JULIAN BEE-MEN ORGANIZE.

The honey-producers of the Julian section have organized themselves into a local association for their mutual

protection, and for the purpose of marketing their honey in car-load lots. F. A. DeLuca was appointed sales agent, and John Stevens honey inspector, to grade the honey and assist in making the sales.

The motion was carried that all honey-producers of Julian and vicinity not present at the meeting, who wish to avail themselves, through this agency, of selling their honey by car-load lots, where it is not convenient to deliver their honey in Julian, they can deliver it at Foster or Lakeside, but must have their honey inspected or graded and bring their receipt from railroad agent and deposit the same with the agent at Julian.

ORANGE COUNTY'S CROP.

Orange County's honey crop for the current season promises to be particularly small, says the Santa Ana Blade, and instead of 20 car-loads, as was the aggregate output last year, the figures for this season are put by well-known and reliable authorities at not more than one-fifth of that amount. For the promise of the beginning of the season has not been fulfilled, and instead of having "honey to burn," or to sell, many bee-men are already buying sugar to feed their bees, and many more are undecided whether to incur the extra expense of feeding the colonies over the season in the hope of more favorable conditions another year, or to let them take the chances.

J. N. Smith, probably one of the best informed men in Orange County on the subject, says he has made a careful canvass of the county in the interest of the honey-business, and from information obtained from reliable sources, he feels confident that not more than four cars of new honey will be available for shipment the present season, and he further says he will not be surprised if the yield for last season is 16 or 17 cars less, or reduced to figures more easily understood, is a shortage of between 200 and 250 tons from last season's output. For from 12 to 15 tons is considered a car-load, and thus the weight is roughly arrived at.

The leading bee-keeper referred to when introducing the above quotation, has this to say in a private letter to us, under date of June 26:

EDITOR AMERICAN BEE JOURNAL—

Dear Sir:—Enclosed please find a clipping from the last San Diego Union, about the honey crop this year. The estimate of 20 cars for this (San Diego) county is, in my judgment, very high.

Julian, the place where they expect some honey, is on the extreme summit of the highest mountain range in the county, and some 75 miles back from the coast. Up there they have few bees and fewer honey-plants, and as they get no late rains, they will find, as it is lower down toward the coast, that flowers do not necessarily produce honey. I have just returned from up that way, and although I saw thousands of acres of our best honey-plant—the wild buckwheat—white with bloom, the bees did not touch it.

The fact is, our honey-plants are now at their best, but they yield very little—so that scarcely any are extracting, and they are doing it, feeling that their bees will not get enough later to carry them over.

I looked through about 500 colonies 40 miles back from the coast, this week—where they are surrounded by millions of flowers—and found only about one-fourth of them with enough honey to justify extracting.

I get reports from all over Southern California like mine. The north half of the State never has cut any figure in honey. In considering the crop from this State, you should realize that California is a long State—as long as from Louisiana to Chicago, or Savannah to Maine—and

that the only *real* region where honey is produced is in the southern half.

Honey-buyers agreed with each other, as soon as it was given out that we had a prospect of a honey crop, to pay but 3½ cents here, f. o. b. Their mouths watered for the crop, and they agreed to cinch us.

You may be certain that our crop will not enter into the East at all this year.
Yours very truly,

This is indeed a sad condition of affairs for California bee-keepers. In all probability, then, what seems to be their loss may be the gain of the bee-keepers east of the Rocky Mountains.

In view of the honey prospects throughout the country, we should say that honey certainly should not be any lower in price than last year, and it may be a trifle higher. Still, it must not be forgotten that there was considerable honey carried over from last year, and this may aid in holding the price down somewhat.

We would like to see all our bee-keepers prosperous and happy—not only for their own welfare, but for the good of all mankind. None of us liveth to himself. We are all of one body—one humanity—and so no one should rejoice over the probable or real prospects that may result in adversity even to a portion of our fellows.

Let us all hope that there may yet be a fair harvest of honey for every worthy bee-keeper in this great country of ours.

* The Weekly Budget. *

Mr. N. E. FRANCE, the energetic inspector of apiaries for Wisconsin, wrote us June 30, as follows :

"Bees in southern Wisconsin are starving. One year ago we were talking basswood honey. No clover in 1902. There is plenty of clover in central Wisconsin."

THE APIARY OF WILFORD CHAPMAN appears on this page. Mr. Chapman wrote us :

"I send a photograph of my apiary of 145 colonies. The person shown is my son "Harry." The bees did fairly well here last year, considering the dry weather. I had about 5000 pounds of comb honey.

"I think the American Bee Journal is just right—full of good for the bee-keeper."

DR. C. C. MILLER, of McHenry Co., Ill., wrote us recently as follows :

"I think June, 1902, was the worst June for bees I ever knew. So cold that throughout the entire month I wore the

suit of clothes I wore in winter, only I shed my underclothes. Clover seemed to yield only pollen, and I fed nearly a thousand pounds of sugar to prevent starvation. Suddenly there came a change July 2, and now for several days we have had delightfully hot weather. Whether there is any nectar to be had from the clover is not yet determined, but after the manner of bee-keepers I am hopeful."

MR. GUS DITTMER, of Wisconsin, wrote us July 7 :

"I am thinking of going to Denver in September with the rest of you."

Good! Keep on thinking about it, Mr. Dittmer, and we are sure you will then go. We would like to have such a representation there from east of Denver as will simply overwhelm those "windy" Coloradoans. Of course, we want to see a lot of people from west and south of Denver, too—in fact, from everywhere. Wouldn't it be a fine joke on those Denverites if there would be such a crowd that they would simply have to allow all to walk on their "beautiful grass," whether they wanted to allow it or not. You know that "Working" secretary of the Colorado Bee-Keepers' Association, said they had such restful grass to *look at!* Pshaw! we want to *walk* on it, and all over those alfalfa-honey chaps out there. They're "just too sweet" for anything, and need to have some of it "extracted." Let's go for them!

MR. THOMAS G. NEWMAN, in a letter to us dated June 30, had this to say in reference to attending the Denver convention in September :

"Had my health increased and given me strength enough to have borne the journey, I might have put in an appearance at Denver, which I fully hoped to have done, but I am in no condition now to take such a journey, and must, therefore, give it up. I shall be with you in spirit, and hope for a pleasant and profitable convention."

With many others we regret that Mr. Newman will be unable to go to Denver. It would be a nice thing if all of the old friends, who are in the West, might be present at the next National convention. We hope that as many as possibly can do so will be there, and make it a grand union.

MR. SANFORD HARTMAN, of Lincoln Co., Nebr., wrote us June 18 :

"If Providence permits, my wife and myself will join your party when you go through to Denver, and help you take in the sights. You want to take time to take in some of the excursions up into the mountains. It's the grandest thing you ever saw."

We hope that a large number will join our party on the way to the Denver convention. Remember, our train leaves Chicago at 10 a.m. on Tuesday, Sept 3, on the Chicago & North-Western road, and arrives in Denver on the Union Pacific at 2 p.m. Wednesday. A little later we will likely

APIARY OF WILFORD CHAPMAN, OF CHIPPEWA CO., WISCONSIN.

have more to say about the sights along this route, and also about the attractions in and around Denver.

SANTA CLARA VALLEY, in California, is one of the most fertile and productive localities of the world. Its fruit has a wide reputation for excellence, and its flowers are incomparable. The bee-keepers in that delightful climate met on June 26 for the purpose of organizing an association. There are over 300 bee-keepers in Santa Clara County, and they should have an effective organization, to advance their interests, and protect the pursuit. After some informal discussion an adjournment was taken until July 5, when a permanent organization was to have been effected.

Table of Contents and Index to Books.

BY PROF. A. J. COOK.

I have just been indexing the 19th 1000 of my "Bee Keeper's Guide." This leads me to pen a few words on "Table of Contents" and "Index." To me, no part of a book—especially a really helpful book—is of more value than a good index. The table of contents is not quite so valuable, but is, to my mind, a far too valuable part ever to be omitted. I believe it will not be amiss to say a word in suggestion of how these parts of a book can be best utilized.

When I get a book that promises to be useful in my work, I first study carefully the table of contents. If this is well thought out and planned by the author, its thorough study will make one very conversant with the entire contents of the book. He will thus in an hour learn what it would take days to compass by the slow process of careful reading. Indeed, it will take a year or more of reading, verified by actual practice in the apiary, for one to become conversant with the whole text so he may know what a mine of wealth he has in good suggestion, fact and valuable history. Whereas, a thorough but brief study of the contents will make them keenly alive to these treasures of information. He will know that they are there, and the chapter that contains them.

To illustrate: Take Chapter XVI in my own book. It treats of marketing the products of the apiary. The table of contents gives the subjects treated as follows:

How to invigorate the market; preparation for market. Extracted honey; how to tempt the consumer. Comb honey; rules to be observed. Marketing bees; selling queens; selling bees by the pound. Vinegar from honey. Fairs and the market: What they should be. Effects of such exhibits.

A few minutes of careful, thoughtful study of this series of topics gives not only what this chapter has to give the reader, but suggests the methods and treatment throughout the entire book. Any book which is to serve at all adequately is seriously handicapped unless it offers its readers a good table of contents.

The index may well be studied from the same point of view. A good index, however, has other and even better use. It serves as a wondrous time-saver. Even though we have the best of memories, and have been most faithful students of our text, there will yet be points that we shall not keep in memory, and which we shall wish to use when time forbids much study or chance to find what is in demand. At such times a good index is invaluable.

The index, to be perfect, should present every subject under every possible head that would be suggested to the person who comes for light and information. Again, to take my own book for example. A person may come upon something that suggests "foul brood;" the ill-odor, the sunken cell-cap or the perforated capping to the brood-cell. He wishes at once to know what the trouble is. He may know nothing of foul brood, when he will turn to the index for diseases of bees, when will be treated, dysentery, spring dwindling, bee-paralysis, new bee-diseases, black-brood, sour-brood and foul brood. Or, if he has foul brood in mind, he turns at once to that in the index, and finds under foul brood: illustration of; nature of; remedies for; fasting, phenol, salicylic acid. He

can turn at once with no loss of time, to the very theme that most concerns his present needs.

In case of the young bee-keeper, robbing may come as a very practical theme in his experience. The index directs him at once to the very page where the cause and cure are to be described. The novice may commence his work when the bees are busy. Later the nectar-flow ceases, and the bees cross and irritable, being a new and not so pleasant experience to his life and work. Possibly he turns to stings, and finds where to look for prevention and cure. Or, if his desires are in line of protection, he will find under bee-dress, bee-veil, veil, bee-hat, hat, smoker, Bingham smoker; etc.—just what he needs in his extremity.

I doubt if any of us realize to the full the value of a good index. As in making a book, it is the most arduous and trying part of the work, so to the owner of a book it ought to be the most valuable and helpful portion. I suggest to all our bee-keepers to give a little time to the index of their bee-book, and I am sure it will open their eyes to the wealth of information they have right at hand.

Akin to the last is the Glossary. This is also valuable, as we may judge by the more and more frequent place that it finds in our text-books, especially the practical manuals that are to help in the every day work. A good glossary, well-paged that every theme may be quickly sought out and fully studied, is a valuable part of any manual, and will richly repay close and frequent study. This will make our reading and study more accurate and valuable.

Los Angeles Co., Calif.

Does the Rearing of Queens as Given in "Scientific Queen-Rearing" Have a Tendency Toward a Race of Non-Swarming Bees?

BY G. M. DOOLITTLE.

Among other things, in a very interesting letter from a correspondent, I find this:

"I should like to know if you claim that queens reared by the plan given in 'Scientific Queen-Rearing,' have a greater tendency not to swarm than those reared by the bees during the swarming season, as most bee-keepers allow their bees to rear them. I purchased your book a few years ago, and have reared a few queens each year in accord therewith, and very few of the queens so reared have led out swarms, while my other colonies have kept up an excessive swarming each year. The queens in these swarming colonies were reared under the swarming impulse, by colonies casting swarms, as are the most of the queens in any apiary where the bees are allowed to swarm. Then, four years ago I purchased a queen which I supposed was reared by the plan given in your book. This queen has done well for me; but the point of interest to me just now is this: Although she has kept her hive full to overflowing with bees, they giving me a good surplus each year, fully as much so as any queen I have amongst my 150 colonies, yet only one swarm has issued from her colony since I got her. Can you enlighten me in this matter through the columns of the American Bee Journal?"

I have never made the claim that queens reared by the plan given in my book, where the queen-cells are brought to perfection in upper stories, while the reigning queen was doing good work at egg-laying below, were less inclined to swarm than were those reared when the bees were preparing to swarm, as I formerly reared all queens before perfecting the plan as given in "Scientific Queen-Rearing." At that time I was quite certain that queens reared under the swarming impulse were the very best possible, just as some still claim, but I now believe that it is possible to rear queens by other methods which are every whit as good in every respect, and perhaps better in some, than queens reared from natural-swarming cells.

Some 25 years ago I noticed that queens reared without the bees having any intention of swarming—where this was done to supersede a failing queen—were less inclined to swarm than were those reared during the height of swarming, and so jotted down this fact in my diary at that time; and during the time intervening since I first noted this matter, the queen by supersedure cell, whose bees have been given too much swarming, has been the exception, not the rule. Queens, where reared by the plan as given in my book, are brought to perfection in very much the same way as are those reared where a case of supersedure happens; and I have thought that the bees from them were less inclined to swarm. In any event, I have had far less swarming in my apiary during the past 12 or 14 years, during which time I have reared nearly all of my queens over queen-excluders, than I formerly had; yet I would not think it best to put forth the idea that a continuation of thus rearing for a quarter to half a century would give a race of non-

swarming bees, as my apiary has been managed much different during the time mentioned than it formerly was, queen-rearing being more in evidence now, while before the "race" was wholly for comb honey.

When God told all animated nature to "go forth, multiply, and replenish the earth," He implanted in the same a nature to do so; and if that nature is not carried out in bee-life, through the issuing of swarms, it will come about through the intervention of men, by way of such manipulation of hives as will throw the colony out of its normal condition, in my opinion, rather than by breeding for a race of non-swarming queens and bees. At least, that is the way I am inclined to think after all of my efforts along this line during the past.

I have received several letters similar to the above, relative to less swarming occurring since those writing had practiced the plan of rearing queens as given in "Scientific Queen-Rearing." But it must be remembered that for several seasons past, taking the country as a whole, we have had rather poor seasons, and such seasons would be conducive to less swarming. Of course, there is no harm in watching this matter; but to put forth the claim that a persistent rearing of queens over a queen-excluding honey-board, or in a part of the hive partitioned off by queen-excluding metal, will bring forth a race of non-swarming bees, would, I fear, in the end, only result in disgusting those who went into such a trial with a full belief in the honesty of the one making such claim. However, I must admit that no news would sound more joyful to me than to hear it as a settled fact, that we had accomplished what has so long been sought after—a race of bees which are non-swarmers, no matter by whom bred, in what locality they were found, and under any and all circumstances in which they were placed.

No. 7.—Rearing Long-Lived Queens and Bees.

BY DR. E. GALLUP.

Now, I am not writing this series of articles in a spirit of fault-finding, but in a spirit of trying to get at the truth in the matter of queen-rearing.

A queen may start out the first season and do fairly well, no matter if she is improperly reared; but she almost invariably fails the second season.

Yesterday (June 10) I examined two colonies that had queens that I obtained last season; one had scattering brood in one frame, and the other in two frames, while one natural queen had brood in 14 frames, and every cell occupied as far as she went. The first two are decreasing in numbers, while the other is rapidly increasing. The first two are Italians, and the other is a black of the same age as the first two queens of my own rearing. This season they have from 8 to 16 combs well filled, according to the amount of room I have given them and the time they have been in the hive.

Now, some one says the Italians are more reluctant to take possession of the supers than the blacks. Are you sure? or is it because the Italians have been degenerated by artificial or improper rearing?

In receiving so many queens, and from so many different breeders, the queen-breeder is at the first end of the line, and I am at the second. In ordering queens I prefer the untested, because I want to test all the qualities—purity, longevity, etc. In getting queens from an old, established breeder, the percentage of impurely mated is quite small. Then the chance of an untested queen being injured in the mail is not so great as is the tested one, and all she is tested for is for her purity. She is not tested for longevity and other qualities; it takes at least two seasons to test a queen properly. In ordering 12 queens from six different breeders, last season, only two were improperly mated, and not one of the 12 was worth keeping the second season.

When I first started in to making artificial swarms, it was with the greatest kind of enthusiasm, but it did not take long to find out that the artificial queens did not begin to come up to the natural ones, especially the second season.

On page 92 of Cook's Manual, he says the time when queen-rearing is naturally started by the bees we should conclude that queens reared at such seasons are superior. His experience—and he has carefully observed in this connection—most emphatically sustains this view.

Now, I will make a statement, that only queens reared under the swarming or superseding impulse, and in strong colonies (the stronger the better), are perfect. There is a

missing link to all queens reared in any other manner, whether reared on the Doolittle, Alley, or any other plan. I have reared very good queens, that is, they were very good the first season, but the second season they invariably failed.

By building up a strong, extra-populous colony, then taking out a frame of comb containing the old queen, without disturbing the colony with smoke or in any other manner, at a time when they are gathering an abundance of stores, so as to have them in as natural condition as possible, they would make a large amount of royal jelly, but the missing link would be lacking. Queens reared in that manner failed the second season.

Some 35 years ago I dissected a queen-cell that was built in an extraordinarily strong colony, under the superseding impulse. In that cell I think I found the missing link. The embryo, chrysalis, or nymph, had what I called at that time, an umbilical cord attached to the vulva at one end, and the other end attached to the side of the cell, near the base, by three or more small rootlets adhering to the side of the cell, and extending to very near the base. I then "went gunning" for more of the same sort, but found none, as I searched for them in cells built over worker-larvæ or forced or unnaturally reared queens.

About that time I went out of the bee-business entirely, but kept up a strong thinking "why" I should find one, and only one, with that attachment. Was that a freak, or was I mistaken? Now, Prof. Cook, you are a scientist, which I am not; I ask you to look into this matter scientifically, and give the bee-keepers the result. Select cells from colonies that are built under the swarming or superseding impulse, dissect carefully, beginning near the base, and open it so as to get at the back of the chrysalis, for if you open it at the front you will be likely to destroy the roots, or misplace the cord so you can not make a careful examination of all its parts in their natural position. Those roots or tendrils do not go wandering around through the mass of royal jelly, but closely adhere to the wall of the cell. They suck up substance from the jelly and convey it to the queen through this tube, so she is receiving nourishment all the time. She is in the embryo stage after she has done, taking nourishment through the mouth.

Right here is partially where the longevity comes in, extra-prolificness, etc. If you examine one of those natural cells immediately after the queen has emerged, you will find the jelly that is left completely dry, tough and leathery-like, whereas examine one where you have reared an unnatural queen, before the workers have had a chance at it, and you will find it still quite moist. The missing link was lacking to convey the moisture up to the embryo. I have often wondered why there was such a lavish expenditure of seemingly useless royal jelly made by the bees. But from my present knowledge even a blind man with his eyes shut ought to see that the blessed bees know what they are about. They even do their share where they are compelled to rear a forced or unnatural queen.

Upon the quality of the queen depends the profits of the apiary. There is a vast difference between a queen that will deposit from 3 to 6 eggs in a minute and one that deposits an egg every 10 or 20 minutes. The first-mentioned compels the workers to store in the supers by their numbers and longevity, while the last-mentioned will not for lack of numbers. Of course, I mean when they are gathering sufficient to store.

A number of years ago I took an unusually strong colony of bees out of a house about 4 feet square and 6 feet high; they had been in there so long, and reared their queen to suit the capacity of the house, that the bees lived to a great age, and had become regular bandits or pirates, and a nuisance in the neighborhood. Whenever there was a dearth of forage for them to gather from natural sources, they would pitch into standard colonies in the neighborhood *en masse*, and rob them outright. They tried it on my bees, but I fixed a trap for them, and caught and kept a good, strong colony of them. I notified the owner, and he finally employed me to take them out, as the neighbors made such strong complaints about their depredations that it was disagreeable for the man to stand it. Now, what I am getting at is this:

In that colony there were not only a few old black, hairless, shiny bees, but there were thousands of them. They were so long-lived that they would forget their bad habits from one year or season to another. I have had a grand chance, in many instances, to look thoroughly into this theory. Long-lived queens make long-lived workers, and short-lived queens make short-lived workers.

Orange Co., Calif.

Convention Proceedings.

Benefits Derived from Attending Conventions.

Read at the Wisconsin Convention, in February, 1902,

BY JACOB HUFFMAN.

Our annual meeting has proved to be a great pleasure and profit to each of us, and I feel that as a result we receive valuable help for future work.

There are so many interesting and instructive features connected with, or, in other words, discussed at our annual gatherings that I am puzzled to know where to begin. To me they prove a school of no small importance.

I have been able to write down these among the things gained: Helpful thoughts suggested; experiences that have been given—given by men of talent, men who have succeeded in bee-culture, men who have accumulated wealth, simply through skill in practical bee-keeping. If a man chooses to be a mere cipher in the bee-industry, he can possibly afford to let our conventions go unattended; but if ambitious he will seek a wider outlook, take up bee-culture with its diversified activities, educating the head and strengthening the judgment. It is at these gatherings we get the very extract of success, possibly given in a nut-shell.

I would like to be able to point out a few of the advantages as they appear to me.

The question relating to our becoming consolidated, forming laws and restrictions by which the State, through legislation, is bound to protect the industry. It was in our conventions the question of foul-brood law was agitated. The discussions are full of useful suggestions, beneficial to bee-keepers all over the State.

Through our organization we have been able to kill bills introduced, which, if passed, would have been detrimental to the bee-keeper. We must admit that a vast amount of fraud has been perpetrated through unjust legislation. In this organization we have men of back-bone who are not afraid to inquire into the situation, put in our protests, and demand our rights. It is possible through the medium of our society to educate apiarists so that they may be able to take a great step in advance of where they are even at the present time.

Through these discussions we are able to distribute light and practical information which leads to scientific queen-rearing, successful wintering, the building up of a trade for our products; the hive found to be the most convenient and practical; the best and safest packages for shipping. Thus, we are enabled to make our dealings so plain, straight and honest that no outside concern can gain any foothold upon our transactions—a code of fair, honest and equitable prices.

As we confer together it is inevitable that we differ in opinion, but the current of friendship and brotherly love courses through all our transactions—important not only as regards dollars and cents, but important as regards social acquaintance. It is a mistake to think we are smart enough to "go it alone." You are far more likely to succeed if you confer with others who are working along similar lines. It is the listening and inquiring mind that paves the way to results. The whys and wherefores are always to be thoroughly considered. We live in an age of progress, when success depends more upon brain than muscle. God pity the man who is not progressive.

The thought I wish you to get hold of is, that much can be done through organization—the exchanging of thoughts without which no individual could otherwise hope to do.

The young must eventually take the place of the older ones. I know of no place where they can be better educated in bee-culture than by attending our annual gatherings, for combined efforts are always most effective.

Another feature: Through the medium of our State organization we are enabled to become members of the National Association; thus giving our members the benefit of the two for the same rate of membership.

The social part of our gathering is by no means to be omitted; to pass it by unnoticed would be unjust, although the last feature spoken of is by no means the least. These meetings are an endless source of pleasure as well as profit to the many who avail themselves of their opportunities. Speaking for myself, I never go home without feeling a great deal better friend with myself and with those whom I

meet. We are quick to recognize the pleasure we derive from these gatherings, and from the friendships made. The hearty handshade of our editors—it is with pride we welcome them at each session. We feel honored by a visit from so worthy a body of co-workers. And doubtless they, too, pride themselves that we are possessed of such a thriving, enterprising society. The two great aims of life that actuate the most of our movements are pleasure and profit; these noble men bring both to us.

The knowledge and ability of each officer and annual member of our Association have enabled us to gain the most out of each passing event. Let us all take home what we gather here, and we shall be better men, and better apiarists.
Green Co., Wis.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

PUTTING PRODUCER'S NAME ON HONEY.

Let me offer a compromise in the matter of whose name shall go on the honey. Mark the white honey "Andrew Jackson," and the amber "Julius Cæsar." Are you sure this way would not be just as well? Consumer never eats the inscription, and rarely pays any attention to it, I reckon. However, if dealers would allow the producer's name on it, said producers would, in many cases, be quite a little bit more careful in putting it up. Few of us are so bad as to enjoy seeing our names on a swindle.

STORING IN SUPERS AND BELOW.

No matter how strong may have grown the habit of storing in supers, bees will put the honey below if there is room for it there—Dr. Miller thinks. I think he's wrong—in regard to some bees, in some cases. I think I have had bees, in quite a number of cases, get so interested storing in sections in August, that they kept on after there was room below, and after, in all reasonable prudence, they ought to put the honey below. I have not positive examinations and records to show for this, however. Their plan—if plan is a right name to use—was to form the winter cluster at the top of the brood-frames and eat on up into the sections. Plan is a good one, but the final removal of the sections makes it disastrous. But the general drift of Dr. Miller's article is right, I think. Page 358.

ROBBER-BEES AND THE ROBBED.

Having had one excellent reply, to the effect that robber-bees sometimes but rather rarely sting the bees of the colony which is defending against them, behold, now comes W. W. McNeal to tell us that they are bloated with poison and very ready to sting the bees which oppose. But, under my glasses, his article seems to be almost wholly made up of it-must-be-so arguments. That style of reaching conclusions looks a little out of place in the 20th Century. Let the previous centuries suffice for the reign of King It-must-be-so, and let us put Prince It-is-visibly-so on the throne. Page 359.

ITALIANIZING AT SWARMING-TIME.

At Italianizing swarms while they are being hived I am totally without experience, and so specially interested in the experience of Mr. Doolittle. Poor plan. A little better when you hive on the same old stand. But even then part of the bees are liable to ball the queen for awhile. Meantime, the rest of the bees are disgruntled at the balling, and at things in general, and many of them start out individually and find homes elsewhere, else get killed. Page 359.

PREVENTING SWARMING.

I eat a large grain of salt with the assertion that bees extra-well fed as larvæ will live very much longer than other bees. But, while this is the case, I am quite prepared to hear that bees almost starved to death in their development period might be found very short-lived, and perhaps poor workers while they did live. Until we know more about this we would do well to be shy of all manipulations (whether to prevent swarming or otherwise) that throw large amounts of open brood into a hive which most of the bees will quickly desert. Why such brood does not die very

much oftener than it actually does, is one of the minor wonders of apiculture. Practically, to throw brood away—or worse—would be a heavy price to pay even for non-swarming. But perhaps I am an alarmist seeing ghosts and things. This about the paragraph on preventing swarming, page 371.

CHEMICAL CONSTITUENTS OF BEESWAX.

The convenient definition that beeswax is chemically a varying mixture of three different waxes, seems to be upset by the report of Prof. Eaton, page 361. Mixture of two compounds with small quantities of two other compounds. Whether all the four are properly called waxes or not seems to be left a little "in nubibus." All right. Getting exact truths is bothersome, and comes high; but we can't do without it—not even if the next chemist finds five substances, and quarrels with previously reported proportions. But next time he must tell us what the "ester number" is.

HOW THINGS SEEM IN CANADA.

I smile—but not so broad a smile as might transpire in Canada. In that region, it seems by page 363, an object a foot across is a *little* larger than one's face.

AN EXTRACTING KINK.

From Aikin's paper to the Chicago convention I take this item: The bees of an extracting super, when an extracted super with honey-bedabbled combs is put beneath, stop persistently at the border of it, so that you can't smoke them out of the super you wish to clear. This is just what might be expected, and still what many of us would fail to foresee. Page 374.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Getting Rid of Burr-Combs.

This has been the best season I have ever had with my bees, and as a result there are great masses of burr-combs built between the tops of the frames and the supers, and also between the frames. What is the best plan to get rid of these next spring?

ALABAMA.

ANSWER.—I know of no other way but to scrape off the objectionable combs. For this purpose a knife of any kind may be used, the knife not sharp enough to cut the wood easily. Years ago the general space over top-bars was $\frac{3}{8}$ inch instead of $\frac{1}{4}$, and every year I cleaned off the burr-combs over top-bars at the time of putting on supers. I used a sharp garden-hoe. Bracing my foot against the top of the hive in front, I scraped the hoe toward me, while an assistant kept the bees smoked out of the way.

Plan for Working for Comb Honey.

Do you think it is a good plan to work for comb honey in the way E. E. Coveyou tells about on page 411?

SUBSCRIBER.

ANSWER.—The plan is an excellent one, being substantially the same as has been repeatedly given in this department. His communication, however, is not entirely without error. He says nothing about using a queen-excluder, although he seems to put on at once the super that has already been occupied. Whatever may have been his experience in this regard, others have found that in such case the queen is very likely to go up and lay in the super, if no excluder hinders, even if full sheets of foundation be in the brood-chamber. So the safe thing is to put the super on the swarm *after* the queen has established a brood-nest below, unless an excluder is used.

He says to move the old colony about a week after swarming so as to have the flying force united with the swarm, which is really the core of the whole matter; but he is a little confused when he says, "it is better to have the

flying bees from the parent colony enter with the swarm, as it gives the swarm wax-workers, which is very important at this time, and it gathers later." There will be a full quota of wax-workers with the issuing swarm, and the bees that join the swarm when the old colony is removed will be field-bees that are already gathering and will do little at wax-work. So instead of helping to have more wax-workers, the *proportion* of wax-workers will be less than it was before the accession of the flying force from the old colony. But this is simply a little matter of misunderstanding, and leaves the plan all right.

A Beginner's Questions.

On June 19 I had my hive open and counted the queen-cells, there were 4 capped, 7 or 8 ready to cap, and 19 in various stages of construction, nearly all with eggs or larva, each side of the brood-frame had one or more. Now I have had the drone-guard on since June 12; on that day I moved the hive to one side, and put an empty one in its place with a guard on it, and shook the bees off the comb in front of the trap. I found it impracticable to get all the bees off, but I cleared the combs sufficiently to expose the queen, if she was there (as I thought). After doing this I replaced the combs in the new body, and watched as the bees went in; there were lots of drones, but no queen could I find. Now that trap has been on ever since (that night I allowed drones to enter the hive). All this morning (June 24) the weather was wet and dark, but at 2 p.m. the sun came out brilliantly, and I was out feeding chickens when I saw the air was full of bees; they clustered in the forks of a little apple-tree, about 3 feet from the ground, and I left them there and went and took the trap off of the hive, as the bees were still issuing; then I took a frame from the hive with a little uncapped brood in it, some honey and the rest uncapped brood, with 3 capped queen-cells at the bottom, and held it among them. It would hold only a few, however, so I placed it in the hive with frames of foundation and shook the bees off into a box. It held 6 quarts and was filled once and three-quarters, or more than a peck of bees. They all went into the hive all right, but I do not know whether the queen is with them or not, and that is my trouble. I put the super they had been working in on their hive, but no honey-board. There is only a little honey in 3 or 4 sections.

1. Should I now cut the queen-cells out of the original hive, leaving but one?

2. In case the queen stayed behind, will the bees stay in the new hive and hatch queen-cells without trying to swarm out with the queen as they fly out? And if the queen is in the old hive will she kill off hatching queens?

3. Should I have put the honey-board under the super?

4. The bees clustered within 50 feet of the old hive. Can I move them back beside it?

5. I suppose the drone-trap must come off now, to allow young queens to take their wedding-flight. ILLINOIS.

ANSWERS.—1. Under ordinary circumstances, cutting out all cells but one would be all right. In this case it is not safe, because you did the very unwise thing to shake the combs. Please never do that again. If you shake combs with queen-cells you are likely to injure or destroy the young queen. So if you should now cut out all queen-cells but one, the one you left might contain a deed queen. The safer thing now is to put your ear to the hive each evening, and when you hear the young queen piping, go to the hive the next morning and cut out *all* queen-cells that are left. Of course it is now too late for this, but I am talking about what you ought to have done. When the swarm issued there was possibly a young queen with it (the old queen having been killed or lost), and in that case you would need to cut out *all* queen-cells that were left. You could tell whether a young queen had emerged by seeing whether there was a full-sized cell empty.

2. If I understand you rightly, the hive on the old stand is one you are talking about, it having most of the bees and brood, with a number of queen-cells. The great probability is that when the first queen emerges the bees will swarm. (The plan mentioned of listening for the piping queen would help out.)

3. If bees are put into a hive without empty frames or foundation, and sections upon which they have been working are at once put on, there is danger that the queen will go into the sections. Either wait a day or two before giving the super, or else use an excluder.

4. After bees have been flying even for a few hours, it is difficult to move them a short distance without loss of

bees. Fasten them in the hive for 24 hours, then pound on the hive before opening it. Look out that you don't smother them.

5. Yes, unless the young queen can fly out she will be a drone-layer, if she lays at all.

Size and Style of Hives—May be Lazy Bees—Bee-Sting Cure.

1. What size and style of hive would you use in Iowa, running chiefly for comb honey? I have 6 colonies of bees, 3 in American hives and 3 in Langstroth hives. Which do you think is the better?

2. I have a colony of bees that do not work as fast as the other colonies. What is the matter with them? The supers are not on, and the hives are light, but there are plenty of bees.

3. The best remedy for bee-stings I ever had is Chamberlain's Pain Balm, applied frequently.

IOWA.

ANSWERS.—1. You will probably find that the hive with the regular Langstroth frame (17 $\frac{5}{8}$ x 9 $\frac{1}{8}$) will suit you best; but as you have both kinds side by side, you can decide for yourself better than any one else what will best suit you. But try and decide before you have many more on hand, for you will find it a very troublesome thing to use more than one kind of frame in the same apiary, unless you treat them as box-hives. Whether you should have eight or ten frames is a question not easily answered. On the whole, the probability is that the larger hives may be better, unless you object to the weight. The smaller hives require a good deal closer attention.

2. It is hard to guess what is the trouble. It is barely possible the bees are queenless. The queen may be very old and poor. The bees may be of lazy stock.

3. After you have had stings enough you will probably not give a rap for any remedy, but will quickly give a slap on your leg to kill the bee and wipe the sting out of your hand, and then go right on with your work.

Rearing Queens Under Superseding Conditions.

I notice that some breeders say their queens are reared under the superseding condition of the colony.

1. How could they have enough colonies superseding to rear many queens?

2. When a colony wants to supersede a queen do they kill her and then build queen-cells, or do they build cells and make her lay in them?

3. If they build the cells after the egg is laid in it, why should the queens be any better than the one reared by removing the old queen from the hive?

4. How can I find out when a colony is going to supersede the queen? I should like to find one in this fix, as I want to rear a few good queens for my own use, but as I do not bother the brood-nests much this time of the year, I am afraid I should not find any superseding their queens?

5. I have only 25 colonies, and they were all Italianized last year. Do you think they would be apt to supersede a queen this year?

6. What do you think of queens reared from the cells formed when the bees swarm? I have an idea that I could next year force some of my best queens to lead out swarms early by stimulating, and giving them sealed brood so they would be strong colonies.

MISSISSIPPI.

ANSWERS.—1. A superseding colony can only rear one queen to completion, but it can start or continue a number of queen-cells at the same time, and one lot can be taken away and another lot given time after time.

2. They start queen-cells with the queen present, just as they do when they are preparing to swarm, only a smaller number.

3. The cell is built before the egg is laid in it; but I know no reason why a cell built for superseding should be any better than the best cells started under favorable circumstances when the queen is removed.

4. Look to see whether they have started queen-cells, and then guess whether it means superseding or swarming.

5. Sometimes a queen may be superseded before she is a year old, but in that case the superseded queen is poor. Usually queens are not superseded till three years old. Among 25 colonies you may expect about eight queens to be superseded every year.

6. Swarming cells are as good as can be had. If they are not of best stock you can inoculate them with larvae from your best queen.

Piping of the Queen—Nice-Looking Apiary—Bee-Paralysis, Etc.

1. Can a person hear the queen pipe when standing by the hive?

2. How can I make my apiary look very nice? Also, where can I get any kind of dwarf shrub or bush that does not grow to exceed four feet in height?

3. How long does a queen remain in the hive after she hatches? and suppose the weather is too cold for them to swarm after she is hatched, what then? I have heard that the bees kept the two queens apart until swarming-time.

4. What are the first symptom of bee-paralysis?

I have a colony that I have been watching, and sometimes I see bees that are hanging out, start hopping around, and then fall off the hive dead.

IOWA.

ANSWERS.—1. Generally speaking, no; but on a very still evening a queen may be heard when you are standing some little distance from the hive. The right way is to go to the colony after bees have stopped flying in the evening, and put your ear tight against the hive. You may then hear the free queen piping in a shrill voice, and the queens yet in their cells quacking in reply, in a coarser voice.

2. It is not well to have anything like a bush four feet high in an apiary. It would only be in the way, without giving a satisfactory shade. Perhaps nothing is nicer than to have spreading trees with a velvety sward beneath. If you do not care for expense, you might prefer a cement pavement to the sward, in which case there would be no grass growing up in front of the hives to trouble the bees. If you cannot have the trees, you can have the vines on a trellis overhead, the trellis being high enough so you can walk freely beneath. For immediate results you can have vines that grow from the ground in a single season, such as hops or wild cucumber, at the same time having something more permanent coming on, as grape, Virginia creeper, trumpet-vine, etc.

3. Don't take the hearsay of those that know little about bees, but get a good text-book, and it will enlighten you on this and many other questions. You seem to think a young queen comes out with the swarm. That is true only of after-swarms. The old queen comes out with the first or prime swarm, and perhaps eight days later the first young queen emerges. If the bees contemplate further swarming, they stand guard over the young queens in the cells, preventing the free queen from destroying them. A cold, wet spell may prolong this.

4. The bees you saw hopping about was perhaps the first symptom you might notice, unless it would be bees making a trembling motion with their wings, the other bees appearing to drive them out, some of the diseased bees being black and shiny.

Requeening—Bisulphide of Carbon.

1. In requeening would it be a safe way to place say 2 combs of brood and young bees on the old stand, and the young queen with them, placing the old colony on top, with a wire screen between, for say 36 hours? Then allow them to pass down through a bee-escape, after which place the balance of the brood below, and remove the old hive?

2. Would you allow a hybrid colony to escape general destruction whose bees have put up 120 Danz. sections of honey to date, about one super being apple or fruit bloom, the balance white clover?

3. I requeen to Italianize as the stock has run down, many too vicious little blacks. Here the surplus usually depends on buckwheat, and we have frequent swarms then. These are old queens and bees that usually die off at all events, in a few months. Why does not this method do the requeening, year after year, and what comb they make if taken care of is a help for the next season? Is not this method (of requeening) just as profitable as to bother with rearing queens, requeening, and all that? Of course new blood will have to be added year after year to meet the black stock and keep it in subjection.

4. In using bisulphide of carbon, do you stack up the supers and place the carbon on top? How long does it require?

5. How would it work to close up a cellar tight, and place it in there to destroy ants? or would the gas it generates remain in the corners thereof and wait for a lighted lamp to blow the house up?

PENNSYLVANIA.

ANSWERS.—1. You are hardly explicit enough. You do not say just what bees are on those two frames that are

with the queen. I suspect, however, that the supposition is that they are at least such that there is no question about the safety of the queen with them. I also take it for granted that the old queen has been removed from the colony placed over. In that case I should expect the plan to succeed, especially if honey was coming in freely. But I should expect a good many bees to perish during the 36 hours imprisonment. Having the queen all right with two frames of brood and bees, perhaps you might like better the following way: Let the colony to be requeened be queenless a day or two; then place over it a hive with two brood, bees, and queen, having between the stories a heavy piece of paper or two or three thickness of newspaper, with a hole large enough to allow just one bee to pass from one story to the other. If honey is yielding when this is done, you need have little fear as to the result.

2. I would respect a queen whose workers were doing exceptionally good work, no matter what her color or pedigree.

3. I have studied over this question quite a little, and I can't make out what you mean. I should understand it to mean the method of requeening mentioned in the first question, you buying the new queens, as you speak of its being as profitable as to bother with rearing queens; but right after that you say new blood would have to be added, and you wouldn't need to add new blood if you bought your queens. If you will tell me what method you mean, I'll try my best to answer.

4. In using bisulphide of carbon stack up the supers and place the drug on top, as you say, and the length of time is not very material. As a guess, I should say that the work might be done fairly well in an hour; but 24 would be better.

5. The gas evaporates and diffuses itself through the air very rapidly, so that after the cellar is opened and aired for a few hours there would be no danger of an explosion.

Swarming Questions.

1. I had a small colony of bees in a hive for about a week; I then had a large swarm come out, and hived it; it stayed in the hive over night, but in the morning came out and went in with the small colony. After they left the hive I looked to see whether they had any comb, and there were two queens, and two bunches of bees inside with a queen about dead. Do you think they had all of these queens with them when they swarmed? They went into this other hive and carried out another queen.

2. Yesterday I was watching a swarm work, and I saw a queen come out and fly away; she was gone about three minutes and came back again; it was a second swarm. What made her do this?

3. I had a second swarm yesterday, and this morning I saw a dead queen lying on the alighting-board. Why did this queen die? Was she an old or a young one? The dead queen was on the old alighting-board. NEW JERSEY.

ANSWERS.—1. It will not do to be too positive about such things, but this may be a fair guess: There was a plurality of queens in the strong swarm, and for some reason the bees divided into factions, and part swarmed out with one of the queens, going in with the small swarm. The small swarm had a queen before, and now two were in the hive, and you saw one of them carried out dead. Sometimes a half dozen queens may be in an after-swarm.

2. She was out on her bridal trip.

3. Two or more queens were in the swarm, and all but one were killed—not an uncommon thing with an after-swarm.

Why Dead Cells?—Separators—Races of Bees—Bitter-weed Honey.

1. I gave a colony young brood from which to rear a queen. They made as fine cells as I ever saw. After waiting some time I opened them and found both were dead. What caused them to die? We did not have weather below 56 degrees during that time.

2. Suppose I use drone-comb starters for extracting frames, will the bees be likely to build the whole comb drone-comb? If so, how wide should the starters be? If not, how can I get drone-comb built?

3. Suppose I use separators, would the bees be likely to build nice comb honey without starters? If not, how can I fasten the starters without a regular outfit?

4. Do you know anything about the Carniolans,

Syrians, Holy Land or Cyprian races of bees? If so, how do they work and sting compared with the full-blooded Italians? How do they do crossed with the blacks or Italians?

5. Would you advise me to have a few colonies of either or all four races with 75 colonies of blacks, hybrids and Italians?

6. Some times I see 3 or 4 bees around one bee; they don't seem to be trying to kill it, but act as if they were talking to it. What are they doing?

"Mississippi" asked you if bitter-weed honey was bitter; you told him you thought it was. You should try to eat some of it. I would like to see you when you try it. It is very pretty honey—looks as yellow as gold.

ALABAMA.

ANSWERS.—1. With weather at 56 degree there might be no danger of chilling brood, providing the weather continued at that or near that all the time. But if the weather were a good deal warmer than that for a good many days, and then a drop to 56 degrees there might be danger. For during the warm weather the circle of brood would expand, and then the cluster, shrinking on a cool night, the edges of the combs—the place where the queen-cells are most likely to be—would be exposed and cells killed.

2. With starters of drone-comb there will be more drone-comb built than with starters of worker-comb, but I should hardly expect bees to fill a whole story with drone-comb. The only sure way would be to have drone-foundation—a thing not easily obtained because there is no demand for it. Are you sure you want drone-combs?

3. You cannot depend upon the bees building in the right place without starters. Some who have no regular foundation-fastener use melted wax to fasten the foundation.

4. There are those who prefer each one of these different kinds, but the majority prefer Italians.

5. It would do no harm to try them, so long as your bees are not unmixed at present.

6. They act that way toward a strange bee, sometimes; just as a policeman might hold you up and question you if he should find you on his beat in the middle of the night in a strange city.

Virgin Queens Uniting with a Swarm.

When a swarm issues from a colony having a clipped queen, and a virgin queen comes out to mate, and goes among the swarm, will she return to the nucleus from which she came, or will she settle with the swarm?

Bees are about starving here (June 30); the weather has been so cold, and now it is so wet the bees cannot gather anything. PENNSYLVANIA.

ANSWER.—When a virgin issues from the nucleus to make her wedding-trip, she generally returns to the nucleus, but occasionally enters a wrong hive, and there is a possibility that she might be induced to unite with a swarm without any reference to the drones in that swarm.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

Pretty Hot

time to build fence, but our factory is running full time making your fall fencing.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white).....	\$.75	\$1.40	\$3.25	\$6.00
Sweet Clover (yellow)....	.90	1.70	4.00	7.50
Alsike Clover	1.00	1.80	4.25	8.00
White Clover	1.20	2.30	5.50	10.00
Alfalfa Clover80	1.40	3.25	6.00

Prices subject to market changes.
Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack.

Add 25 cents to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

GEORGE W. YORK & CO.
144 & 146 Erie Street, CHICAGO, ILL.

GENERAL ITEMS

Full Basswood Bloom.

EDITOR YORK:—The following little poem was suggested by the condition that now exists, I am happy to say, at our three apiaries. The basswood bloom is very full; only unfavorable weather will prevent a good crop being secured. The trees seem to be in a healthy condition, and free from insect pests.

LINDEN BLOSSOMS.

The linden blossoms hang to-day
Like little bells so creamy white;
Around each flower the bees will play,
From early morn till dewy night,
Making the sound we love to hear—
The sign of the bee-keeper's prosperous year.

The winds and rains have passed away,
The fleecy clouds float in the sky;
Soft breezes cool the sun's bright ray,
While busy workers swiftly fly;
The while the bee-man's heart is thrilled
To see the combs so quickly filled.

The toiler is gladdened at the sight,
Good cheer the flowers have quickly brought,
Each day that closes clear and bright,
With blessing sweet its hours fraught;
Chasing the anxious thoughts away,
In fairer promise day by day.

HARRY LATHROP,
Lafayette Co., Wis., July 8.

Good Prospect for Honey.

We have a good prospect for honey. If the weather is right, but it was too cool and then too wet, but now it is warm enough. I never saw so much white clover.
Trumbull Co., Ohio, July 7. J. S. BARN.

Pollen-Gathering.

On page 355, I read, "Bees have some discrimination in the matter of collecting pollen, and if there is an over-supply in the hive they will let up on the gathering, no matter whether they have a queen or not. When a colony loses its queen the workers keep right on gathering the pollen just the same, but when the combs begin to be well supplied with pollen, then they desist from gathering."

Well, if the above statement is true, and confirmed with bees in the State of Illinois, or in the city of Chicago, then our bees are the most ignorant critters to be found, for they don't possess such intelligence. For they do gather pollen as long as there is any to be had, unless they become queenless and the brood all sealed, then they will slacken up in gathering either pollen or honey. But they always prefer gathering honey, if they can get it, excepting such colonies as have a young queen just commencing to lay; those will gather pollen if they can get it, in spite of all the pollen in the hive, and no matter how good the honey-flow, for they do not know when they have enough. I have put four combs solid full of pollen in such colonies to stop them from gathering more, but those ignorant things did not stop, but kept right on at the usual rate until they got "pollen-bound" to such an extent that the queen could not lay any more for want of room, and the bees could not deposit the pollen; but in the effort of doing so they would lose it, and large quantities would drop on the bottom-board. If a colony of bees is being run for extracted honey, in a 4-story hive, they will get very strong, and by fall will store nearly all the lower story full of pollen, and enough in the second story to carry them through until the next spring, when the same thing is repeated over again. So I have to soak the combs and set them to fermenting, when the

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

extractor throws it out, and in quantities large enough to "paint the town brown," or green, if it happened to be that color.

Now, I suppose some of the readers will hallow, "What a greenhorn!" Yes, I suppose I am green yet, although I have kept bees for 10 years, and for the last four years I have made bee-keeping my principal business, keeping from 150 to 300 colonies, and producing large quantities of comb and extracted honey. If pollen were salable, I would have a wagon-load to sell every season. A colony of bees, in this locality, if run for extracted honey, will soon become so "pollen-bound" that something has to be done, for the bees gather so much of it that they can not consume it, and it is left in the combs and becomes a nuisance. Furthermore, if left in the combs, and honey be put on top of it and sealed over, and used for winter stores, it excites too much brood-rearing in the cellar, and the bees come out strong in bees and light in stores in the spring, some of them consuming all of their honey so they have to be fed in the spring. The same is true when all the combs are full of sealed honey. Bees winter best, in this locality, with about half of the combs empty, especially the center ones, and extremely poor fares a colony under such conditions, having a late-reared queen.

I lost 10 colonies last winter, having 10 sisters for queens of the choicest Italians this country produces.

So, for me, not too much pollen, and not depending on the bees to regulate the same.

A. C. BARTZ.

Chippewa Co., Wis., June 16.

Hiving a Swarm with a Colony.

In the "Editorial Comments" on page 403, it is requested that some one state "how long it may be necessary to wait after a colony has swarmed before a swarm can be given to it, without danger of having the swarm re-issue."

Time should be given for destruction of all queen-cells in the hive of the colony to which the swarm is to be introduced; or, the apiarist should go through the hive and remove them before introducing the swarm.

WM. M. WHITNEY.

Walworth Co., Wis., July 2.

A Swarming Experience.

Talk about swarming! It occurred in our apiary yesterday, and still at it to-day, but not so heavy. The young bees were out for a play; a swarm issued, and we covered the adjoining hives to avoid mixing. While we were watching for the queen we glanced down the row and saw two others coming out; we hurried there to cage the queens, when we looked back to where we had been a few minutes before, and saw the swarms coming out of the hives which we had covered. We uncovered them, and by that time about all in the row, some 30, had the fever, and were out. We glanced over to the row on "Easy Street;" they, too, had taken up the rumpus, and the whole string of them joined the others as fast as they could tumble out of the hives. We have the colonies all named—prefer names to numbers, as we never were very apt with figures. I am not going to give you the names of all, only a few that you are familiar with. "Rambler" swarmed about noon, and had been hived beside "C. C. Miller;" the latter behaved very nicely, and did not come out. I think the reason was, because "York" was not there to go along, as "York" had swarmed a week ago and was in the "hospital row." "E. E. Ilasty," as usual, did his part last by coming out after all the others were through. "Rambler" got crazy, as he had always wanted to go to some place, and swarmed again. "Mrs. Rambler" got lost in the fracas. A few queens came out, all black ones, and got their heads pinched.

There was a cluster on a tree as big as a barrel. We thought of the man who had fixed the clock, and had enough left to fix another one. We beat that, as we had three light swarms housed with division-boards, the returning bees being about as many as a corporal's guard, so we helped ourselves to the big pile and fixed the three in working

order, took out the division-boards, and think they will make a record-breaker.

The fracas lasted about two hours; we had one queen too many, but she is now in the sweat-box. I expected there would be some queens killed by returning bees, but on examination I find all in order.

The mix-up appeared agreeable, and about equally distributed, only "Miller" was fuller than a tick. It will be obliged to get out soon to get room according to its strength.

The fun of it was, they were tame—no stinging. If any of the readers can beat that record, at home or abroad, I would like to hear from them.

I have 55 colonies, all were out but those that had swarmed except the wizard ("Miller.") No super work is being done; the weather is wet and cool.

We are thankful all our queens were clipped; if they had not been it is quite likely our apiary would have been sick to-day—at least the manager would have been.

The swarms have behaved very badly this season; they do not care where they return—enter any hive, and usually make two or three attempts before the queen is willing to go with them.
J. P. BLUNK.

Webster Co., Iowa, June 27.

Long Drouth.

We had a very good flow of honey here during the early part of the season, but the last two weeks the bees have done nothing on account of the long drouth, and I am afraid they will not get any more surplus honey this year.
JOE S. WISE.

Copiah Co., Miss., July 5.

Bees Wintered Well.

I wintered 55 colonies of bees—all that I put into winter quarters. I disposed of 13 this spring, have had 7 swarms issue, have made one division, and 5 nuclei.

JOHN T. COBURN.

Middlesex Co., Mass., July 1.

Hard Weather on Bees.

The past few days have been very hard on the bees. I am feeding the most of mine. The most populous colonies seem to be the worst off for honey.
J. W. JOHNSON.

Stephenson Co., Ill., July 1.

Think It Was Starvation.

I rather think the case mentioned on page 419 is like many similar cases I have seen lately, which were complete starvation. The southern counties of Wisconsin, last summer, had severe dry weather, so that all clover was killed, with results as follows: Bees wintered well, were strong in April and May, 1902, gathered quite a little honey from fruit-bloom and dandelion, but it was all used up in the abundant amount of brood reared, so that by June 15 they were out of feed, and many colonies actually ate up the liquid portion of the brood, leaving the dry larva and grubs on the hive bottom-boards. Several colonies I found once that in May were strong colonies, and by June 27 were dead from starvation.

Basswood bloom is opened. Good weather on July 3, 4 and 5, and good colonies did well. July 6 it was rainy. I never knew or heard of such condition in Wisconsin before.

Grant Co., Wis., July 7. **N. E. FRANCE.**

Good Crop Expected—Swarming.

I have seen several reports from various sections of the country, some discouraging. While we in central Indiana have had cold, windy weather my bees are in a flourishing condition, and I look for a bountiful harvest. The majority of the bees surrounding me have the foul brood. I manage to visit those within reach and exterminate it. Some it puts out of business.

I notice that swarming puzzles a great many, as well as myself. I have had a number ask how to prevent swarming. To me there is but one way that will give satisfaction,

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Please Mention the Bee Journal when writing Advertisers *****

and that is: First get one or more text-books, such as Langstroth, Prof. Cook's, or "A B C of Bee-Culture," and study the nature and habits of the insects which you intend to handle. Either before or after, subscribe for one or more good bee-papers. The outlay will be but \$4.00 or \$5.00. I insist that this is the only way to become successful, and then you are ready to prevent swarming or reduce it to a minimum.

My bees average \$4.00 or \$5.00 per colony, which I think does pretty well for this locality. Then, others do not get anything, and their bees often die from starvation.

I will give one of the ways I have to hold swarming in check: First, a deep entrance, full width, and keep the bees in a grove with plenty of sunlight, cool to work with, then the heat does not irritate the bees. Clip the queen's wings and hive the swarm on 5 frames of starters, and put on the supers the second day; in about 10 days move the other 4 frames to the center of the brood-nest, or, I might say, when they have the 5 frames built clear down put the 4 frames in the center, and you have a nice colony and several pounds of surplus honey. R. L. HASKETT.
Tipton Co., Ind., June 29.

Very Little Honey.

There is very little honey from this (Riverside) County. I have 8 cases from 150 colonies.
JOHN C. WILMS.
July 6, 1902.

Too Much Rain.

Rain, rain. Basswood is in bloom, but the weather is inauspicious. EUGENE SECOR.
Winnebago Co., Iowa, July 8.

A Discouraging Season.

I am sorry to say the prospects are very discouraging here. Bees have to be fed to keep them alive. I found 2 colonies to-day starving out. It is so wet and cold, and no white clover is in bloom yet. It looks as if we would have a very poor year. If the bees live there may be a fall flow from heartsease. I had only 11 swarms out of over 200 colonies.
N. STAININGER.
Cedar Co., Iowa, June 28.

Poor Prospects in Southern Calif.

The prospects for honey are exceedingly poor. The sages are all dried up on the mountains, and an almost total absence of moisture from fogs or showers have about "done us up." Southern California will not be in it this year. J. M. HANBAUGH.
San Diego Co., Calif., June 21.

Bees Starving—No Honey-Flow.

Bees are actually starving here. June was wet and cold, with no honey-flow at all.
J. A. MCGOWAN.
Butler Co., Pa., July 2.

Bees Not Doing Much.

Bees are not doing much here. White clover was almost all killed by the drouth last summer, and there is not much bloom of any kind for the bees to gather honey from. Our only hope will be the fall honey crop. Last year, at this time (June 20), I had some colonies that had stored from 50 to 75 pounds.
Coffey Co., Kans. J. M. CHRISTIE.

A Very Poor Season.

This has been a very poor season in southwestern Wisconsin for the bee-business. Our bees wintered well, but it was very cold and windy, and the bees did not get any benefit from the soft maple, which we have in abundance.

It was rainy and cold all during the dandelion and fruit bloom, so it was worth very little to the bees. We all had to feed up to June 10, more or less. After that time the bees gathered enough to live on. June 17 I talked with two bee-men, one of whom had 40

colonies, and the other had 90; they said there was not a pound of surplus or new honey in a hive. My bees were the same.

We lost white and all other kinds of clover last year and through the winter. There is very little clover, and with so much cold weather and rain it is no good.

Our bees, in this section, are swarming to beat everything. I had several swarms the first part of June, with not over a half-pound of honey in the hive.

Basswood is heavily loaded, but we have so little of it, as there are so many stavo factories, excelsior mills, etc., that have cleared it off. We hope for enough honey to carry our bees through into the next season.

Grant Co., Wis., June 27. L. G. BLAIR.

May Get Fall Crop.

The bees are not doing very much good here. I have had only one swarm up to date. Basswood was in bloom last week, but we have had an old-fashioned June freshet of three days' rain, and no prospects of clearing up very soon; this means lots of fall honey, if the weather should prove favorable.

White Co., Ind., June 30. A. WORTMAN.

Poorest Season So Far.

This has been the poorest season for bees, so far, that I ever experienced. My 34 colonies came through the winter on the summer stands without any loss, and were in fine condition, but they are now almost destitute of honey, and a very poor prospect of getting any soon.

Warren Co., Iowa, June 30. H. G. WYKOFF.

Half as Much as Last Year.

My first extracting, last year, was June 25; at this time there is very little honey above the brood-nest, but the bees are very strong. If the weather remains favorable we will get at least one-half as much honey as last year, which was 130 pounds per hive. Farther back in the mountains the crop will be very nearly as good as last year, or, in other words, about one-half of the county will produce little or no honey, while the other half will get a full crop for an ordinary year.

L. C. NORTHRUP.
San Diego Co., Calif., June 24.

Honey Outlook Very Poor.

The weather has been cold, rainy and cloudy for a month. Colonies that did not have much honey and a prolific queen overflowing with bees must be fed. I have fed 6 colonies during the last week that did not have an ounce of honey—something I have not done since I have kept bees.

Blossoms of white and red clover have no bees on them. The outlook is very poor, though basswood buds are plentiful, and will be opened soon, if we have a few warm days.

N. A. KLUCK.
Stephenson Co., Ill., June 28.

\$9.25 to Cleveland, O. and Return \$9.25 on July 16th and 17th, via Nickel Plate Road, good returning to and including July 22, 1902. Three through daily trains. City Ticket Office, 111 Adams St., Chicago. Write John Y. Calahan, Gen'l Agent, Chicago, for particulars. 33—29A1t

The Home-Made Greenhouse.—There is scarcely a lover of plants who has not felt the need of some place other than the ordinary window for plant-growing, a place secure from dust, dry air and excessive heat that form the greatest obstacles to success. Many plants unable to survive the winter in open ground may be lifted and carried over in a dry cellar, well lighted; but many cellars are unsuited to the purpose, the extremes of furnace heat or over-dampness, with poor ventilation, proving fatal to all but the hardiest plants. Suitable plant rooms are highly desirable, and the amateur will be aided in his efforts to provide such, by the illustrated article in the August DELINEATOR on simple forms of plant quarters, which may be made at a comparatively small expense. Address, The Butterick Publishing Co., Ltd., 7 to 77 W. 13th St., New York, N. Y.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages, 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

WOOL MARKETS AND SHEEP, CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, July 7.—The honey market may be said to be on a vacation so far as actual business is concerned. Should the harvest of 1902 be practically a failure there will be no dearth of extracted honey, as there is more of it in storage than we have ever known at this season of the year. If the consumers are not too greatly impressed with the idea that the honey harvest is a failure this season it may be worked off at an advance in price. Beeswax is lower, yet sells well at 30 cents per pound.
R. A. BURNETT & Co.

KANSAS CITY, July 5.—Some new comb honey has arrived. We quote: New comb, 14@15c; old, 12@13c. Extracted, white, 6@6½c; amber, 5@6c. Beeswax, 25@30c. C. C. CLEMONS & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.
THE FRED W. MUTH Co.

ALBANY, N. Y., July 10.—Honey market not opened yet for this season, but we look for demand to begin in a couple weeks. No old crop in the way. Expect good demand and good prices for new crop, which is very light in this vicinity.
H. R. WRIGHT.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6¼@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

NEW YORK, July 7.—There is some fair demand for comb honey at 14c for strictly fancy white; 12@13c for No. 1, and 10@11c for amber. Extracted quiet at unchanging prices. Beeswax dull and declining at 29c.
HILDRETH & SROGREN.

CINCINNATI, July 7.—The shipments and offers on new comb honey are so little, besides the predictions for the yield of honey so uncertain, that I can give no figure for prices. Extracted is selling for the same price—Amber, in barrels, 5@5½c; alfalfa, 6@6½c; white clover, 6½c. Beeswax, 28c in cash.
C. H. W. WEBER.

SAN FRANCISCO, July 1.—White comb, 10@12 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4¼@—; amber, 4@—; Beeswax, good to choice, light, 27@29c; dark, 25@26c.

While offerings are light of both comb and extracted, buyers are not numerous at extreme current rates, nor do they show disposition to operate in a wholesale way at prices now generally asked. Most dealers are doing little else at present than awaiting developments, and producers, as a rule, are not crowding honey to sale.

WANTED!

Honey and Beeswax. Mail sample and state price delivered Cincinnati. C. H. W. WEBER, 2146-2148 Central Ave., CINCINNATI, OHIO.

AMERICAN

BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., JULY 24, 1902.

FORTY-SECOND YEAR
No. 30.

WEEKLY

CHAS. DADANT.

Born—May 22, 1817.

Died—July 16, 1902.

A STANDARD-BRED QUEEN-BEE FREE

To Our Regular Paid-in-Advance
Subscribers.

We have arranged with several of the best queen-breeders to supply us with **The Very Best Untested Italian Queens** that they can possibly rear—well worth \$1.00 each. We want every one of our present regular subscribers to have at least one of these Queens. And we propose to make it easy for you to get one or more of them.

In the first place, you must be a regular subscriber to the American Bee Journal, and your own subscription **must be paid in advance**. If it is not already paid up, you can send in the necessary amount to make it so when you order one of these fine Queens.

A Queen Free for Sending One New Subscriber

Send us \$1.00 and the name and address of one **NEW** reader for the American Bee Journal, and we will mail you one of the Queens free as a premium.

Now, go out among your bee-keeping neighbors and friends and invite them to subscribe for the old American Bee Journal. If you want some to show as samples, we will mail you, for the asking, as many copies of the American Bee Journal as you can use.

Should there be no other bee-keepers near you, and you desire one of these fine Queens any way, send us \$1.50 and we will credit your subscription for one year and also mail you a Queen. Of course, it is understood that the amount sent will pay your subscription at least one year in advance of the present time. So, if your subscription is in arrears, be sure to send enough more than the \$1.50 to pay all that is past due.

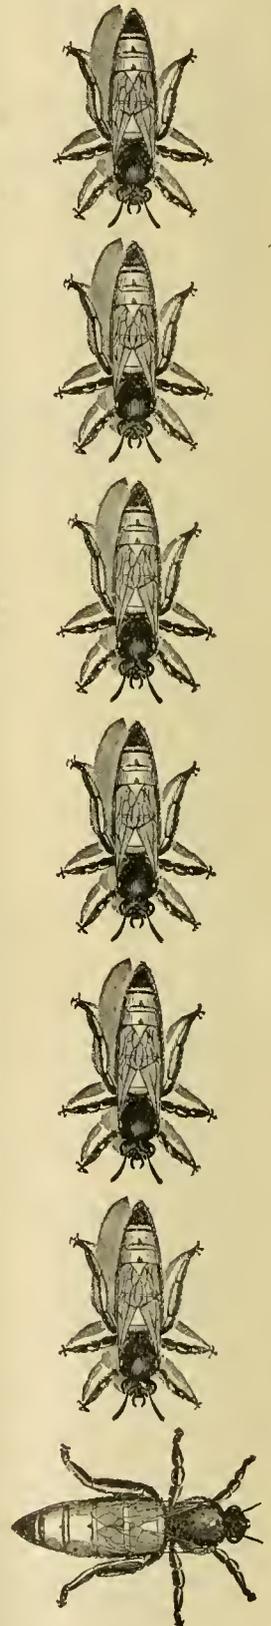

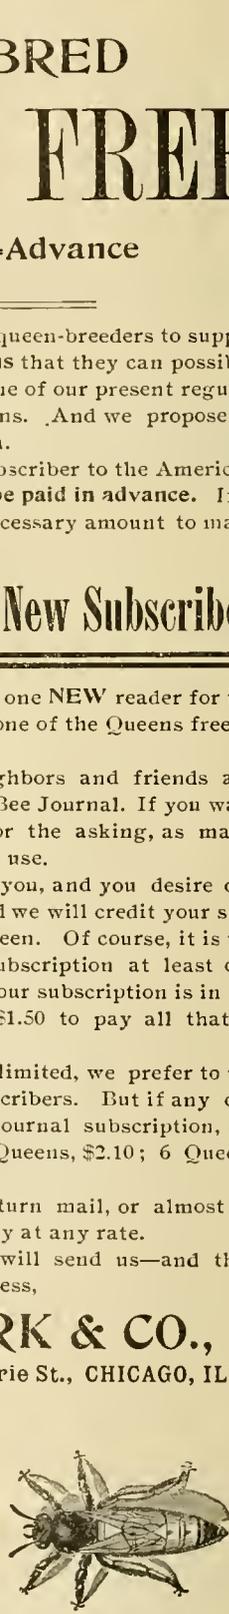

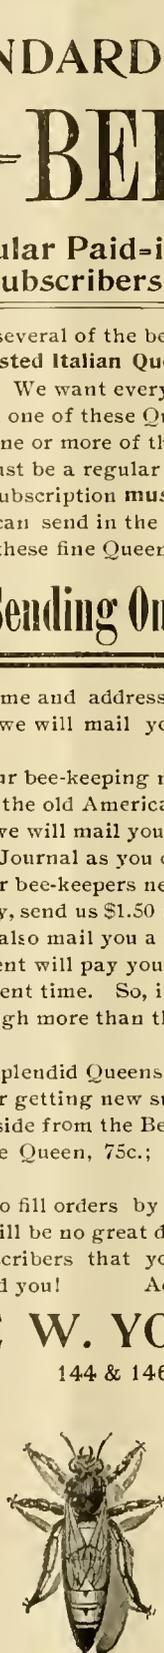

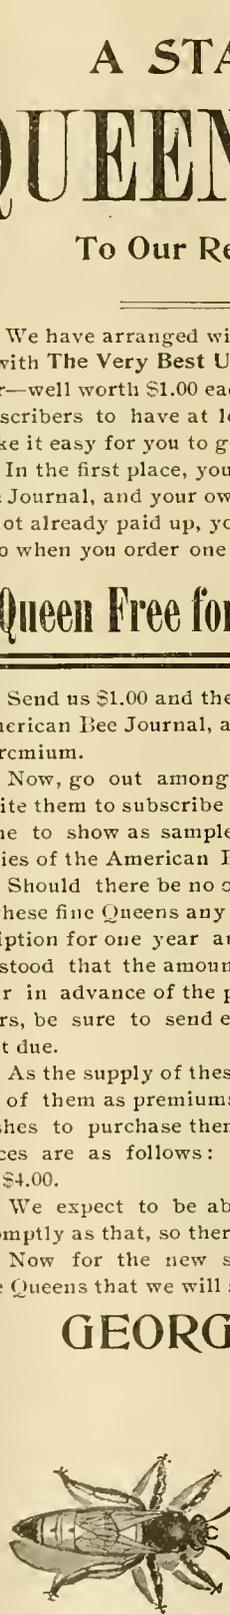

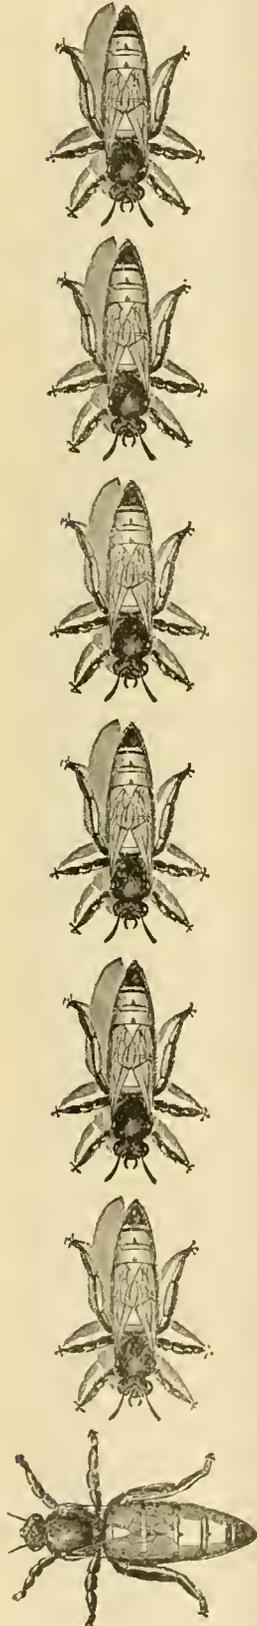

As the supply of these splendid Queens is limited, we prefer to use all of them as premiums for getting new subscribers. But if any one wishes to purchase them aside from the Bee Journal subscription, the prices are as follows: One Queen, 75c.; 3 Queens, \$2.10; 6 Queens for \$4.00.

We expect to be able to fill orders by return mail, or almost as promptly as that, so there will be no great delay at any rate.

Now for the new subscribers that you will send us—and then the Queens that we will send you! Address,

GEORGE W. YORK & CO.,

* Editorial. *

DEATH OF CHAS. DADANT.

We were startled by receiving the following telegram the afternoon of July 16:

"Father died this morning at 11:30, after short illness.
C. P. DADANT."

Bee-keepers everywhere will join with us in extending to the Dadant family sincerest sympathy in their bereavement.

We have had the pleasure of a personal acquaintance with Chas. Dadant for a number of years. It was his custom to spend a few weeks every fall in Wisconsin, and, passing through Chicago on his way, he called on us, and we thus enjoyed his friendship and acquaintance.

Mr. Dadant was one of the pioneers in bee-keeping in the United States, as all reading bee-keepers well know. Chas. Dadant & Son need no introduction wherever the literature of bee-culture is read, and that means in several countries and languages.

But we will let the departed Dadant himself tell something of his life, which he furnished to us nearly ten years ago, and which appeared in the American Bee Journal at that time. It is as follows:

I was born on May 22, 1817, in Vaux-sous-Aubigny, a French village of Champaign, near the confines of Burgundy. My father was a doctor of medicine. From the age of 6 to 17 I went to school, living with my grandfather, who was a locksmith in the city of Langres.

Then I entered as clerk in a wholesale dry-goods store, and ten years after I went into partnership with one of the owners of the store. We began successfully; we had earned some money when the French Revolution of 1848 came, followed by the Republic, which was destroyed by Napoleon III, and replaced by his Empire. For six years the trouble and the insecurity lasted, and determined us to quit the business. Then I succeeded to my father-in-law, who was a tanner, but bad luck continued to persecute me. The city of Langres, the ancient Audomatunum, which, several thousand years ago was the capital of a people named the "Lingones," is situated on a high mountain, which overlooks its vicinity nearly on every side. Caesar, and the other Roman emperors, at the time when the Roman Empire owned most of Western Europe, fortified Langres with strong walls, which were so well constructed that they are solid yet, after 2000 years. These walls affording a protection to the inhabitants, the city was densely peopled, and its com-

merce was facilitated by a quantity of good roads, laid with stones and cement, and directed to every point of the compass.

These Roman roads, as they are yet called, helped greatly the business of the city, which was very prosperous until the railroads came. Of course, these railroads refused to climb the high mountains, and built their depot two miles away, in the bottom of a deep valley. Then the city began to depopulate, and its buildings lost 90 percent of their value. Compelled to go elsewhere to get a living, I resolved to come to the United States.

It was 30 years ago I came, a poor man with a family. Unable to understand a word of English, I subscribed for a weekly paper, and began to translate it with the help of a pocket dictionary. But the greatest difficulty was the pronunciation. I was soon able to write so as to be understood, but my spoken English was not intelligible. The French language has very little accent; while the English has the accent on one syllable in each word, and the scholars themselves do not always agree on the syllable on which the accent ought to be placed. Then imagine the difficulty of a foreigner! A great many store-keepers were amazed to see me explain in writing what I wanted, when they had been unable to understand my language.

As I had already tried bee-keeping for pleasure in France, I began here with two colonies. What I knew of bees had satisfied me that a well-managed apiary would give enough profit to support a family, and the result proved that I was right.

Soon after I began to rear Italian queens. Being able to understand the Italian language, and having been elected an honorary member of the Italian society of bee-keepers, it was an easy matter for me to try the importation of bees. But the conditions indispensable to success were not yet known, so I lost some money in the undertaking. Then I went to Italy; but the trip was a failure. I had about resolved to quit the business of importing queens, when I began experimenting with Fiorini, and soon after all the queens arrived alive.

But the care of 400 colonies, with the comb foundation business, was then beginning to give us—my son and myself—as much work as we were able to do, so we resolved to quit the importing business.

We have since revised the book of our

friend Langstroth, and published a French edition, which has had the honor of being translated into the Russian language.

I am now 76 years old, and I have enjoyed, so far, good health, thanks to the care of my wife and of our children and grandchildren living with us, *en famille*.

CHAS. DADANT.

Such is the story Mr. Dadant wrote for us, and we are glad to place it again before our readers at this time, for since its first appearance thousands of new subscribers have been added to our list.

We need add but little further at this time. Later we hope to give sketches and incidents of his life and death, as they may be furnished to us by his devoted son and many intimate friends. Suffice it to say now that those who knew Father Dadant best will agree with us that his was a noble, honorable, upright, consistent, moral life, and, in his death, bee-keeping has lost one of its most faithful devotees—one who ever labored for its greatest development and highest progress.

Quoting the Honey Market.—Some time ago we promised to publish a symposium on this subject, and in this week's issue we give the first part of it. We think it is very interesting reading.

We may be pardoned for reprinting Rip Van Winkle's first letter, and also our comment thereon, as by thus doing it places the whole matter before the reader, and avoids the necessity of referring away back to see just what was said on page 195.

Of course, the commission men and other honey-dealers do not know it all. But we must give them credit for honesty of purpose in the conduct of their business, and in what they have written in response to our request that they help enlighten Rip Van Winkle, as well as all others who are inter-

BIRTHPLACE OF CHAS. DADANT—VAUX-SOUS-AUBIGNY, FRANCE.

ested in the subject of correct market quotations on honey.

We hope that our readers will suspend judgment until they have read what all the market quoters have to say. We expect to complete it next week.

Use Soft Water for Rendering Wax.

—This is a matter of considerable importance, as will be seen from the following by H. W. Brice, in the Bee-Keepers' Record:

In rendering wax in water containing lime or acids, either the cerotic acid or the myricine is dissolved out, and its composition becomes changed and forms a secondary product, as may be seen by the dirty-gray, spongy residue on the underside of a cake of wax after cooling. This residue has to be scraped away and wasted. Rain or distilled water should be used in the operation.

Blacks vs. Italians.—I venture to assert that a careful and unprejudiced examination will show things that will prove a decided surprise to many. I have in my apiaries some of the best strains of Italians to be obtained, also some pure blacks, and many shades of the crosses of the two races. According to the generally accepted view regarding Italians, such colonies should excel the others, but that has not proven to be the case. The black bees have bred up the fastest, have stored the most honey, and entered the supers most readily. Also, they have proved to be better tempered. The hybrids came next to the blacks in the possession of these virtues, and the Italians last. Such has been my experience this spring, and the contrast has been so marked that I have considered it worth recording.

The above by Arthur C. Miller, in the American Bee-Keeper, will, no doubt, be as he says, "a decided surprise to many." But does it prove that, as a rule, blacks are superior to Italians? Surely, all bee-keepers in this country are not deficient as observers who have testified to the superiority of Italians.

When Italians were new, it was charged that those who had them for sale had an ax to grind in recommending them. Now that Italians are common that can hardly be charged, especially against men who have no stock for sale, and are only interested in having the bees that will yield the best results.

It should not be forgotten, however, that in England and in Germany there are good men

who prefer blacks to Italians. Are there better blacks across the water, or do conditions make the difference?

Weekly Budget.

SECRETARY D. W. WORKING, who is pushing for a big attendance at the Denver convention, wrote us on July 14:

"There is nothing new to tell you yet about the coming meeting. We are hoping that there will be a large attendance from the other side of the Mississippi. In this State we expect to stir up a good deal of interest, and have our people out in good force."

We think "the other side of the Mississippi" will be well represented. We hear almost daily of more bee-keepers that are expecting to go. It looks now as if the Denver meeting might be almost as large as was the National when it met in Chicago in 1900! Even such a crowd would surprise Denver! Of course, Chicago is accustomed to such things!!

MRS. CHAS. BECKER, of Sangamon Co., Ill., after an illness of more than five months, passed away on May 2, 1902. This was learned just last week. We wish to extend our sympathy to our bereaved brother and his daughter who remain to mourn the departure of a beloved wife and mother.

THE APIARY OF A. HENTHORN & SON is shown on this page. When sending the photograph, they wrote as follows:

We send the picture of our home apiary. There are 96 colonies in this yard. We use the old standard Gallup hives, and run for extracted honey alone. Our average for 1901 was 72 pounds per colony.

We run one out-yard of 40 colonies, the average being 85 pounds per colony from white clover and basswood. We run on the non-swarmling plan of nuclei for increase, and kill the rest of the queens.

We have one colony that stored 40 pounds of red clover honey after the basswood flow was over last season.

Those trees seen in the picture are cherry-trees; we use them because they make fine

shade, and are nice, clean trees to work around, and on account of the fruit. The large tree on the left of the picture is a hickory: it is full of nuts every year.

We winter our bees in a cellar under the dwelling-house. The temperature was about 52 degrees all winter, until lately (March 3) we have been having very warm weather for this time of the winter, and had to open the outside door and let fresh air in at night. We wintered the bees last winter in the same cellar with a loss of 2 colonies; the temperature was down near 50 degrees all winter.

A. HENTHORN & SON.

MR. H. H. HYDE, of Wilson Co., Tex., writes us that he is planning to attend the National convention in Denver in September. Say, you hustling Denverites, get ready for bee-keepers from everywhere. They're coming.

PROF. COOK'S "BEE-KEEPERS' GUIDE, or Manual of the Apiary," is thus kindly referred to by Editor Root, in Gleanings in Bee-Culture for July 1:

The new revision of the nineteenth thousand of the "Bee-Keepers' Guide, or Manual of the Apiary," by Prof. A. J. Cook, published by George W. York & Co., of Chicago, is now out. It has been most thoroughly revised, and is enlarged by the addition of about 80 pages and 75 engravings. I have read over in a hurried way several of the chapters, and they all seem to bear the brand of 1902, and all of it orthodox, at least from my point of view. So skillfully has the old matter been blended with the new, that one would never suspect the book had not been written from beginning to end this year. The scientific, as well as the practical, part has been gone over completely; and while the book has always been a standard, both in Europe and America, it is now "clear at the front in bee-keeping science and practice." I congratulate the publishers as well as the author.

P. D. JONES, of this State, hived 48 swarms on a single day recently; again in a few days he hived 47 swarms on one day. Mr. Jones must have the swarming kind of bees.

MR. E. S. LOVESY, president of the Utah Bee-Keepers' Association, expects to attend the Denver convention. He should take a large delegation with him from his Association.

HOME APIARY OF A. HENTHORN & SON, OF RICHLAND COUNTY, WISCONSIN.

Contributed Articles.

Quoting the Honey Market.

On page 195, of the March 27th copy of this journal, there appeared the following on the subject of quoting the honey market in the bee-papers:

I have been interested in the honey market of Chicago, as I have been a Chicago bee-keeper for two summers past, and the article on page 121, by B. A. Hadsell, is timely and largely to the point, as tending to explain the low price of honey to-day as compared with the prices of 20 years ago. The commission man has the honey-producers in his grip in this market, more especially when he is a buyer as well as a commission man. A buyer is always a "bear" in the market, and when he also gives quotations of prices for the supposed guidance of honey-producers, it is beyond human nature, however honest he may be in general, not to try to buy low, when it is almost absolutely certain that his quotations will go to nearly all possible shippers.

I am certain there is this tendency here in Chicago, for I have time and time again investigated prices on South Water Street, inquiring of dealers in honey, as a possible buyer, and invariably had prices quoted me one cent higher per pound on comb honey than the regular "quotations" in the American Bee Journal.

Again, the prices quoted for Milwaukee, Wis., are almost invariably one cent per pound higher for comb honey of like grades than for Chicago. There seems no good reason why Milwaukee, located very much nearer the great basswood forests of the great honey-producing State of Wisconsin, should pay more than Chicago for the same grade of honey, unless the market reports are "fixed" to suit some one who is interested in buying honey low.

The bee-keepers of Cook Co., Ill., at least, ought to have organization and investigate just such things, and let the shippers honey know it, as I am trying to do. RIP VAN WINKLE.

In reply to the foregoing we had this editorial comment to offer:

Rip Van Winkle should go into the honey-dealing business a while, for by so doing he would soon learn some things that he will scarcely be able to see in any other way. Suppose the commission man did publish quotations a cent or two per pound higher (at the price he gets for a few single cases), how soon would it be before he would have his store flooded with honey which would be sent to him because of his high quotations? Then, of course, the market would drop, and the honey would have to be sold several cents below the quoted prices. How the shippers would howl then, when receiving their returns. That commission man would be called a fraud, a swindler, etc.

It is better to quote a cent lower rather than a cent above the market. If comb honey is quoted at 15 cents, and then sells at 16 cents, and a report is made at the latter price, no bee-keeper is going to kick. But quote the price at 16 cents, and then make returns at 15 cents (the best that could be obtained), and how high would the shipper kick? Well, he'd likely say, "That commission man quoted high so as to get the honey into his hands, then sold it so as to get his commission."

Any "Rip Van Winkle" who goes along the street inquiring the price of honey is easily "sized up" by the commission man, who is up to his business. He (the commission man) can tell very quickly that "Rip" is only "nosing around," and doesn't mean to buy, in nine cases out of ten. We have often been such a "Rip" ourselves, and we felt the commission men of whom we inquired knew that we were simply out "inquiring."

But we would like to have those who quote the honey market in our columns also help answer Rip Van Winkle. If all of us try, we think he ought to get what he is after—or something else equally satisfactory.

In response to our request in the last paragraph above, we have received the following from some of those who quote the honey market for the American Bee Journal:

CAN ADD NOTHING TO OUR COMMENT.

EDITOR YORK:—Replying to yours, wishing our views as to quoting honey market, we would say your answer to Rip Van Winkle in the American Bee Journal of March 27, so fairly and squarely explains the matter that we can not add anything to it.

Very respectfully,

BATTERSON & Co.,
Per N. D. B.

QUOTATIONS WILL NEVER BE ALIKE.

EDITOR YORK:—It is not to be expected that the market quotations are to be alike, not even in the same vicinity, as the different branches of business under different pressure are compelled to make different quotations to protect themselves.

The commission man will quote the article he sells at as low a price as he possibly can, so as to enable him to give his shipper better returns than he expected, and, therefore, securing for himself his shipper's future business.

On the contrary, the dealer will be governed by the supply and offerings, and stock he has on hand, also the demand and sale, to quote the highest and lowest sale he made to benefit his business.

I have made it all the time my practice to give the exact figures for "quotation" what I was able to sell for, and not prices that I would like to get. C. H. W. WEBER.

HONEY-DEALERS ARE THE PEOPLE.

EDITOR YORK:—We note Rip Van Winkle's article in reference to quoting the honey market, and we beg to say the commission men and the honey-dealers are directly responsible for the large demand there is for honey to-day. If left to the bee-keepers alone it would be impossible for them to find buyers and consumers for the vast amount of honey that is produced. Business is business, and a good business man is of necessity a good buyer. We ask here, Who is it that creates the demand for honey? The bee-keepers, the bee-papers, the commission men, or the honey-dealers? To be sure it is none other than the dealers. Their business is to buy and sell honey; while it is to the credit of bee-keepers to produce the right kind of honey in salable shape.

Supply and demand regulate the price of all commodities, any fair-minded individual will acknowledge. Honey is governed also in like manner, and because Milwaukee markets will pay one cent per pound more than Chicago is no criterion for all honey and prices. Very frequently in one grocery you can see comb honey posted at 20 cents per pound, and in the next block priced at 18 cents, apparently the same kind; this I have observed in Cincinnati, many times.

Rip Van Winkle is apparently looking from his selfish standpoint alone; I would suggest a broader range. The dealer seeks the market for the consumption of his ware, while the producer yields the supply. Bee-papers, as a rule, reach only the producer; the public in general is not concerned in bee-literature, market quotations, etc., therefore, it devolves upon the vender, in a great measure, to distribute the production; and necessity regulates the price. Periodicals do not always give correct estimates of amount produced and consumed, and are at fault many times in giving the producer the wrong information as to yield and prospective price.

Rip Van Winkle should hold his peace until he has thoroughly gone over the territory and considered all points, conditions, etc.

Yours truly,

THE FRED W. MUTH CO.

FRED W. MUTH, Pres.

QUOTE THREE GRADES OF PRICES.

EDITOR YORK:—The writer, in entering a store of one of the large seed-men of Ogden, Utah, who handles a great many car-loads of honey, was greeted with rather a cool reception, and found out immediately the cause of it was the damage that he felt our Philadelphia market quotations had done his market repeatedly, and the writer had impressed upon his mind very forcibly how much quotations could damage such large car-load shipments of the West, and on reaching Chicago found the whole subject of quotations was in general discussion.

We have always understood that the quotations in the bee-papers were for the small bee-keepers scattered throughout the country; that is, parties who produce from one to five cases of comb honey and a few cases of extracted honey, in order for them to know what they might reasonably expect as returns if their honey was shipped to commission men in the various cities.

Now, then, if such a honey-shipper would ship to Philadelphia to-day to a commission man, a few cases of fancy white clover extracted honey, such commission man should get, if he sold it to a grocer, 9 cents per pound. Such a grocer would only buy one or two cans at a time.

On the other hand, should California or Utah ship to Philadelphia to-day a car-load of extracted honey in cases, the market price would be, in car-loads, 5½ cents. Now, the seed-man at once says that we quote the price of 9 cents, and if he shipped he would not get over 5½ cents. You can see the reasons are very clear. On the other hand, should we quote car-lot prices, we would want to give very correct what a shipper might expect spot cash for same. Now, then, if said shipper would ship a car-load of extracted honey to Philadelphia to-day, and would urge the receiver

to sell it out quick, 4½ to 5 cents might be all that would be realized on it.

Again, we have had repeated calls from a customer out of town, who saw quotations intended only in a wholesale way, and he thought that was the price at which he could buy a single can of it; he would send the money, which would have to be returned to him.

There are a great many things to be considered in quoting prices, and prices vary according to so many different circumstances. If a car is unloaded at a depot and carted into a store and held from 30 to 60 days, the cost of carting, storage and insurance would have to be added to the price over and above what the car could have been sold at spot cash at the depot and carted away by the purchaser.

The writer would suggest that a possible way out of this difficulty, which is a very serious one, would be to quote three grades of prices. 1st—car-lot prices. 2d—wholesale prices. 3d—retail prices. And then quote only for fancy or best grades of both extracted and comb honey, and let those who are looking for quotations make their own average of the lower grades.

We repeatedly say at the end of our quotations that we are producers of honey, and not dealers, and do not handle on commission.

WM. A. SELSER.

(Concluded next week.)

Bisulphide of Carbon—Its Value to Bee-Keepers.

BY C. DAVENPORT.

The article by Prof. A. J. Cook, entitled, "CS" which appeared on page 390, I read with much interest. Before commencing to use this drug moth-worms were one of the most difficult problems I had to contend with, for they have always been very numerous here. I have had sets of combs, and even hives themselves, almost cut to pieces by moth-worms in cases where the bees deserted their hives, and it was not discovered until some time afterward. When comb honey is removed from the hive a close watch must be kept, for moth-worms are sure to develop on some of it, and if their depredations are not checked a large part of it will soon be ruined.

Some persons seem to think these moth-worms appear only on comb honey that contains more or less bee-bread, but I regret to say that this is far from being the case here. They are much more apt to appear on combs that contain a few cells of pollen, but I have had hundreds of sections of comb honey that did not contain a cell of bee-bread badly cut up and damaged by moth-larvæ.

A number of years ago I sold 2000 pounds of white clover comb honey to a large retail grocery concern in Minneapolis. The honey was shipped about the middle of August, by express. (I got a special rate, and went along with the shipment, as it had to be transferred twice, and I wanted to see that it was handled as it should be.) It was not crated, simply cased in 24-pound cases, two of which were fastened together. Not a comb was broken *en route*. The firm was much pleased with the honey, and contracted for more to be delivered later.

About three weeks after I returned home I received a letter from them, saying the honey was being all cut to pieces by worms, and that they would hold me fully responsible for not only the price of the honey, but for damages to them in loss of time, customers, and numerous other things, for, they said, they could prove the worms were in the honey when I delivered it; they had kept it in a place free from worms, and there were no other worms of that kind in the city.

I had been afraid the moth-worms might damage it before they were able to sell it all, for it was shipped soon after being removed from the hives, and had not been sulphured, sulphur being then the only remedy I knew of. It would have done no good, for the honey was free from worms at the time it was shipped, but contained moth-eggs, which developed into larvæ soon afterwards. The fumes of the sulphur have no effect whatever on these eggs, at least not what we can subject them to without discoloring the honey.

The fumes of bisulphide of carbon not only kill moth-worms, but utterly destroys the vitality of all eggs that the comb may contain. A good many seem to question whether it does kill the eggs as well as hatched larvæ. I know, from a large amount of actual experience, that it does.

Last year I sold to a large grocery house, in a near-by city, nearly 7000 pounds of honey. This firm had consider-

able experience with, and loss from, moth-worms developing in honey after they bought it, and on this account would not buy any very large amount at one time, although besides a large retail trade they had quite a jobbing trade from the Dakotas. Last season one of the firm was at my place to buy honey; if it were not for worms they could handle a large amount. He was very skeptical about my assertion, that the worms would not appear on it. In order to get him to buy the amount which he did, I had to get the bank in our town to guarantee him the full amount he paid for the honey, on all that the moth-worms appeared upon.

The reason I have mentioned this incident is on account of a curious, and possibly important, incident connected with it. This firm expected to need about 2000 pounds or more for their retail trade, and this amount I put up in "T" supers. The honey was all hauled to them by team, and by using supers it saved me the price on shipping-cases for this amount.

*Last spring I went to that city to gather up a load of empty supers, cases and cans, and found that this firm still had considerable of the honey I sold to them. I helped take out what was left in the supers and pack it in boxes. While one of the firm and I were doing this he spoke about my honey keeping so much better than the other they had. He said that was why they had so much of mine left. They had bought a number of small lots from different bee-keepers around there, and towards spring it all commenced to granulate or candy in the comb, and they wanted to get rid of that first. I was unable to find a trace of granulation in any of that I sold them. Now, this honey I sold them was all subjected to the fumes of bisulphide of carbon for 3½ hours, or longer. Did this prevent granulation, or have anything to do with its not granulating? If I live I shall know in a year from now, or less, for this season I shall subject samples of both comb and extracted honey to these fumes and keep them over winter, besides similar lots that have not been treated.

Some may remember that I described how, last fall, I had subjected the winter stores of a number of colonies to these fumes in order to find out whether honey so treated was affected or rendered unfit for winter food. I have not space here to go over the matter, but in a former article I explained why it was very important for me to know whether honey so treated was safe for winter food, and I am glad to say that it is. The colonies on these stores wintered in good shape, and this proves, also, I believe, that honey so treated is perfectly wholesome, for if trace enough of these deadly fumes remained in to make it injurious to health, it would surely have affected the bees during the long confinement of winter.

Before closing I will say a few words about the manner of using this drug. I have described this before, but I still see it recommended by many to pile up hive-bodies containing combs, and treat them by putting some bisulphide in the upper stories. Such a method may kill moth-worms and eggs all right, or it may have no effect on them—it all depends on how tight the bottom cover and hive-bodies fit, how much of the drug is used, and the length of time the combs are exposed to the fumes. I have a tight box made out of matched lumber that is large enough so that a number of supers of section honey or hive-bodies containing combs can be placed in and treated at one time. When this box is closed up it is nearly air-tight, and I know pretty nearly to a minute how long it takes to kill moth-worms in it, but whether the vitality of the eggs are destroyed as soon as the worms themselves, I do not know. For this reason I have always treated the combs much longer than was necessary to kill the worms. Southern Minnesota.

No. 8.—Rearing Long-Lived Queens and Bee.

BY DR. E. GALLUP.

A few years ago I received a circular and price-list from a queen-breeder "away down South in Dixie," which read something like this; "We have 300 colonies and our queens are reared in those strong colonies under the swarming or superseding impulse." And this is about the way I wrote to him:

"DEAR SIR:—Enclosed find money order for and untested queen, as I like the ring of your circular."

In due time I received a queen, and she turned out to be a good one in every respect. I ordered others from him and received satisfaction, that is, they were as good the second

season as the first. I then sold out and did not keep track of them any further.

In article No.1, page 342, I left out something of importance. After saying, "we should not be disappointed," I should have added, "providing we succeed in getting them reared under the superseding or swarming impulse, one can rear very fair queens in a very strong colony from eggs or larvae from worker-cells. But they will lack the missing link, therefore they fail the second season." I was in the same boat with the rest of the queen-breeders, but I jumped out and allowed my bees to swarm naturally, was not satisfied with forced or unnatural queens, and am not yet. They are only a make-shift for the bees in case of emergency, or until they can do better. I cannot see the propriety of confining a queen that will fully occupy 16 Langstroth combs to an 8 comb or frame hive. Some say if you breed her up to her full capacity she will fail so much the sooner, but I have not found it so, where the queens are properly reared.

With your degenerate queens I think possibly it may be so, but I am not positive, as they fail the second season. Why need we care, as we do not want them anyhow? A large proportion fail the first season, especially the first winter. Now we will suppose you start in on the fad of rearing extra-yellow bees, extra-golden-colored, extra-five-banders, Adels, albinos, etc. You rear them by the hundreds, all on the nucleus plan, as I call it; and you keep it up for a good many generations. What kind of queens did you finally send out? Why, some queens that will not lay an egg after they are received, some that only occupy a piece of comb as large as your hand, some that will occupy 2, 3 or perhaps 4 combs, in a scattering manner; that is, all among the brood there are cells filled with pollen or honey, no regularity about her laying at all, and if there comes a flush of honey-gathering we will find every cell filled with honey. The queen is so slow about her laying that the bees keep ahead of her. We have tried to remedy this by extracting, putting in foundation, and even empty frames, but it was no go. Then by the first of March in all these colonies, even the best of them, the bees have dwindled until the colonies cannot be brought up to take advantage of the orange-blossom honey, which this season was extra-fine here.

The queens are short on laying, there workers have no longevity, etc.; finally, they are short on every good quality.

Now, I have not exaggerated the facts one particle; in fact, it is rather a hard matter to picture the facts as bad as they are.

Do naturally-reared queens get driven out of their brood-nest in the above manner? Do their bees die off with old age, and leave the queen destitute of subjects before spring? Why, the queen is in a condition to compel the bees to take possession of the super and store orange-blossom honey. Orange blossoming commences here the first of March, and continues up to the 1st or 15th of June. While in bloom the whole atmosphere is scented with perfume, which accounts for the hundreds of tramp swarms flocking into the vicinity of orange-orchards this season; outside there was nothing for them to gather.

By the way, I was up to the orange-packing house one day when they had just loaded a car, and a swarm flew inside, and the agent closed up the car; the engine hooked on, and they started on the road for Chicago.

The valley here would be an ideal place to rear queens. If it were not for the difficulty of getting them purely mated, one could rear the very best of queens for business. The first good yield is orange-blossom, the next is alfalfa, then comes the Lima beans, all three extra-good, with any quantity of other blossoms switched in between. One hundred acres of alfalfa in blossom now for seed, two miles south. June 18, Italians storing, but blacks not quite holding their own.

The very best conditions for rearing first-class queens are at natural swarming time. The bees are active, and keep a loud hum at night while evaporating the nectar they gather through the day, and there is a moist heat in the hive, instead of dry. Moisture and heat are promotive of growth—why not in bees as well as vegetables? Of course we can stimulate with diluted sweet to promote natural swarming, but we can hardly come up to the natural gathering. When bees are gathering stores they manufacture a larger amount of electricity or magnetism, which is life itself. This is all lacking in your small nucleus. Therefore, do not transfer your cells as soon as sealed to a nucleus; keep them in the strong colony as long as possible. This accounts for the fact that queens reared in extraordinarily large hives and extra-strong colonies are so long-lived, extra prolific, and have such extra vitality, and rear

extra-long-lived workers. On the other hand, an opposite extreme accounts for the fact that by rearing our queens in such an unnatural condition, and contrary to nature, we have deteriorated or degenerated our queens and their progeny to the very lowest stage of vitality, longevity, productiveness, etc. Who knows but many of our new diseases of bees are generated through this low type of vitality, caused by bad breeding?

A number of years ago Mr. Aaron Benedict, of Ohio, sent out a circular, and advertised extensively that he was going to supply the demand, and warrant his queens to be purely mated, etc. He moved on Kelly's Island in Lake Erie, with an imported queen and about 100 small nucleus boxes stocked with bees, and went into the business on a wholesale plan, but he made an entire failure, and published in the American Bee Journal that his queen was not pure. The queens reared from her were as black as crows, etc. You can readily see that he failed on account of the worst kind of management. The climate was cold and windy; everything about the management was contrary to nature. I wrote to him and told him that he was the one to blame, and he afterward acknowledged that the queen turned out all right.

When I first began the nucleus plan I reared them small, inferior, and as Mr. Benedict said, as black as crows, but I jumped out of that boat long ago.

Well, I think I would better submit the above argument to the jury. Now, gentlemen of the jury, what are you going to do about it? Let us hear your side of the story.

Orange Co., Calif.

Convention Proceedings.

The Colorado State Bee-Keepers' Association.

Its Moral, Social, Scientific, Business and Financial Interests.

Read at the Convention held in Denver, in November, 1901.

BY R. C. AIKIN.

Every man owes to every other man duties. The greater part of the things we know, and the blessings and privileges we enjoy, are obtained from others. There is a great debt hanging upon us—a debt we owe to others because by and through them we are made to enjoy many things. We have government, the comforts and enjoyments of inventions, business relations, and all social privileges. Not only because of being recipients from others, but as well because of divine commands, do we have obligations upon us to do for others. Cain said to God, "Am I my brother's keeper?" and at the same time he had but recently proved by his act of murder that he at least was *trying* to be his brother's keeper, when he forcibly came between him and the enjoyments and privileges of life. If men are to live in social relations, then they *must*, of necessity, aid and foster each other's interests. A pauper is no help to the community in general, therefore we must not make paupers of our brethren. Neither are the vicious, the immoral, and criminally inclined, a help to you and me or to the social compact; hence, to make a brother such is to injure ourselves. In no way can we so surely protect and promote our own interests as by promoting the interests of our brethren. To shirk or avoid the duties we owe to each other is to injure self more than him toward whom we fail to perform obligations.

It follows, then, that we as brethren and members of this Association, should strive to build up each other in every moral relation. Morality pertains to our duties to one another—of man to man. If a brother is weak, strengthen him. If he is down, help him up. Let not a member of this Association do anything that is against the interests of a brother. We can rejoice that in all the history of our Association there has never been anything degrading in its conduct, though we may have come short of our whole duty, not doing all we might have done. Members have not always been as brotherly as they should be—it is human to err; but, with all our weakness there has been a spirit of brotherly love that surely must have made

better men and women of all who come under the society's influence.

THE SOCIAL SIDE.

I feel that I speak the sentiment of every member when I say that from year to year I look forward to our conventions with a joyous anticipation. I am glad to be here to-day, to meet with you and grasp the hand in a brotherly greeting. I rejoice to be able to give, as well as receive, the enjoyments that come to us when we meet after months of separation. I have labored with many of you for years working for the interests of each other, and to-day a blow given to you would hurt me perhaps as much as you. Because of longer acquaintance and closer intimacy in our work, some of us seem bound by a closer bond of love and sympathy; and, brethren, to meet in these annual gatherings, to labor together for the common good and upbuilding of all will knit us into a richer, nobler, and better life. Our Association is not all hard business; there is a social side that we do exceedingly well to cultivate, and I shall be happy indeed if I may be able to help you all to a better and more full social life. May I not be disappointed in realizing in each countenance, and in every word and act, that hearty good-will and enjoyment that is ours to have if we but will it.

SCIENTIFIC RESEARCH.

Our constitution says of this Association, "Its object shall be the promotion of apiculture in all its interests." That is short, but broad and comprehensive. As indicated hereinbefore, we can not escape responsibilities to others, nor can we honestly engage in our pursuit without helping others. I know, brethren, that some of you will say this is not sound doctrine, that there are too many in our ranks now; but a full investigation will prove to you that I state no false doctrine when I say that apiculture is *not* overdone. I will repeat and emphasize that an honest and intelligent conduct of apiculture by not only those now in our ranks, but by others who may see fit to enter the business, can not, and will not of itself, injure us.

However, admitting and believing the foregoing to be true, it makes my heart sad to see many people rushing into apiculture without a knowledge of the first principles of scientific bee-keeping. I will plainly say it is not honesty to self, nor to those already in the business, for any one to put money and time into the bee and honey business not knowing how properly to handle it to meet the requirements of the times and conditions. Look at the nice, fancy honey in our markets, and you see the results of science. Is it far amiss to say that science is Nature comprehended? An intelligent application of the laws of Nature in obtaining results is applied science. It is, then, self-evident that one should, before becoming possessed of much of a stock of bees, or entering the pursuit as a business, have gained a reasonable knowledge of the science of apiculture. Note, I do not say he shall be an expert in the science, but have a reasonable knowledge of it—none of us know it all.

If, then, we are all students in this science, it becomes one of the duties of this Association to make scientific research, but especially to add to each other's knowledge by an interchange of thought and experiences. By so doing we become a mutual help, we spread knowledge, and help each other to better produce and market, and that which betters or puts the business on a higher plane helps all. I do rejoice in the fact that the Colorado State Bee-Keepers' Association has stood well up to her privileges and duties in the line of science. There has been in our annual meetings an intense interest by the members in bringing out a true knowledge of the laws governing the bee and its labors, the most scientific application obtainable. Except in rare cases the spirit of helpfulness has been displayed, and in a degree not excelled by any similar association.

Remember, however, that having reached these heights, to neglect our opportunity to push forward and protect our increasing numbers and foster that which we have built up will be a very great wrong to ourselves and to the pursuit in general. This Association has not only fostered and very materially aided in a spread of scientific knowledge, but it has in no small degree protected its members and others in their

BUSINESS INTERESTS.

This is shown by the obtaining of legislation favorable to the industry; by the obtaining, year by year, lower prices on supplies used by us, and by advertising our product, and in many ways fostering the industry. In this con-

nection I will call your attention to the fact that after years of effort we have at last obtained a show-case in which to display apiarian products in the State House, where so much is already on exhibition showing other resources of the State, and it is now our duty to make a proper and creditable display, of which we shall not be ashamed, and which shall do justice to our rapidly growing industry.

There was a time when apiculture in Colorado was but an infant, when the product of the bee did not begin to meet the home demand; while to-day our home needs are not only supplied, but a large export trade has sprung up to take our surplus. Our people consume immense quantities of honey that is not excelled in quality in any State, and we send hundreds of tons to other States. And, brethren, the very fact that we must export is a *very*, *VERY* great reason why we must continue to work in harmony, co-operate and unite in our efforts. Co-operation has been one of the outgrowths of the work of this Association, and to relinquish this work in the least we can not afford, we *must* go on. To stop or go back means a death-blow to the business and financial interests of very many apiarists in Colorado. Yea, more than this, the pursuit in other States would suffer injury with us. Cut off your hand, your foot, or any member of your body, and you injure the whole body. Let this Association, or the Colorado Honey-Producers' Association, or any of the co-operative interests of the State fail, and our business in Colorado, as well as outside interests, will surely suffer.

There are many apiarists in the State who have never been to a single one of our conventions, yet much good comes to such because of the work and influence of the organization. The absent ones miss the social contact, the side discussions that we have between sessions at hotels, restaurants, and wherever two or more of us meet, but they do reap something from the published reports, and in the general moral influences that can not be enumerated. There is not an apiarist of any consequence in the State who has not received directly or indirectly more benefit from our organized and co-operative work than the annual membership fees. So closely connected and sympathetic is the whole social compact as one body, that these influences are felt in many ways and places of which those affected are entirely unconscious of the influence. Brethren, let not your interest flag; be firm in your faith and interest in your own and others' welfare. Be not deceived with the selfish and greedy methods commonly practiced, they partake much of un wisdom and anarchy. Scorn all methods and practices that tear down others, remembering that to build up self at a sacrifice of others is a sin that will surely react, it will prove a boomerang, coming back to bring you sorrow. Let your motto be, "The greatest good to the greatest number." This is wisdom in a nutshell.

And to the general public a few words: We are glad to have you with us—we be brethren. What I have said to our bee-brethren applies to you; we all have an influence upon one another, we can not escape it, no matter how hard we try. Are you a merchant? Then if we prosper you reap a benefit in our increased ability to purchase your goods. Are your interests in railroads? We pay you freights on supplies shipped in, on our products sent out, and passenger traffic to and from these conventions, and in other ways. If you are a farmer do not worry because our bees feed upon your alfalfa; they fertilize the bloom by the distribution of pollen, thereby increasing your seed crop.

And to the fruit-growers I also have a word: If it were not for insects visiting the blossoms of nearly all kinds of fruit, where would be your fruitage? The bee is the most important of all insects in transmitting pollen from bloom to bloom for its fertilization, and you can not much better do without the bee than can we do without your bloom. I have a neighbor who has said that the honey my bees gathered was so much stolen from my neighbors. Let me tell you that it is a common belief that he who so charges me with theft is himself a thief, and enjoys (or at least possesses) plunder. No, no, my friends; there is altogether too much jealousy, too much selfishness, too much greed. Jealousy and selfishness tend to poverty and ruin; but a spirit of good-will and kind liberality will come back to be with us, but in a way that causes rejoicing and love, a spirit of peace and joy.

In conclusion, I want to say again to all, "We be brethren." Our prosperity is yours, and yours is ours. We can not afford to fight and antagonize; we must harmonize. If you believe otherwise, I will just point you to the former condition of this country when inhabited by the selfish and cruel Indian, contrasted with the present. Then, no progress, no love and happiness, nothing that helped up; now,

under co-operation and mutual help we grow in wealth and luxury, in peace and wonderful attainments. Brethren, I warn and exhort you, for the sake of all that is good and just, curb the spirit of greed and selfishness, and work for the greatest good to the greatest number. It is the true road to prosperity, the only safe, right, and commendable way.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

LONG-LIVED QUEENS AND BEES.

Lengthening the lives of our bees won't shorten their tongues or their tails, eh? I guess that's so, Dr. Gallup. And another thing you hint at is probably so: If we can add an average of even two days to bee-life, that extra time will not have to be divided between indoor and outdoor life, but will be all honey-gathering time. As to long-lived queens producing long-lived workers, that's very possible—and especially possible that queens such as are superseded in one year may produce short-lived workers. But all that is in urgent need of some more verifying. To shout "Long-Lived Bees!" when there is nothing back of it but desire to sell queens, and to shout, "Long-Tongued Bees!" in the same unproven but thrifty way—what's the difference? So, Doctor, I entreat *not* to have either made exactly a fad. Both far too important. Page 374.

SWARMING AND SUPERING.

And he didn't even tell the fellow how to prevent the first and most provoking item (bees boomed and forced for the greatest number of swarms refusing to swarm at all), so I guess we have here another chapter from the big book of what none of us know yet. He's level-headed in saying to put on the supers betimes; for then, if the anticipated swarms fail to come, only *part* of the honey crop will be lost. Doolittle, page 375.

TELEGONY.

And so it's Telegony. Glad I know now what it is. We need some such word so badly that it will not be so hard to make us remember and use it—and so, happily, it won't superinduce any more "bug" and "worm" unpleasantness between us and the scientific folk.

Believed in by many of the very highest authorities. Apparently proved by some striking cases. Doubted, perhaps doubted increasingly, because divers and sundry extensive and careful efforts to produce it fail so utterly. The influence *must* be small, and one of the strong evidences on the books provokes doubt because it seems to show *great* influence. The horse kind furnishes a great share of the evidence, and very young colts often show faint stripes without any Telegony. Very distant Atavism it seems to be. And so, and so, and so another fine case of nobody knows yet, and believe just what you like—about the drones from mismatched mothers being slightly impure. Pages 375, 376.

BOGUS FLOWERS.

C. C. Parsons, page 377, is wrong in calling the showy part of the dogwood blossom a "calyx." The calyx is a part of a true flower, while the flaunting imitation referred to is not one of the essential floral parts at all, but an "involute" of whitened leaves—technically called "bracts." Queer that we should have bogus flowers in Nature as well as genuine ones. The sunflower is also a bogus flower, of a somewhat different sort, many real flowers so arranged as to simulate a still larger flower which is not real.

THAT CORNCOB FEEDER.

The bunch-of-corncobs bee-feeder, page 380, I should lay to give tolerable satisfaction *for a while*—an indefinite while—until it gets soaked and sour once. Perhaps waste some of the feed by soaking before that time.

A POINT IN QUEEN-INTRODUCTION.

The main queen-introduction point which Pridgen furnishes, page 381, is not by any means universally familiar. Introduce in a bran new cage, and first scent it

by keeping the old queen in it for an hour. To add to the scent, and also to secure other good ends, put in a new escort of her future subjects. I think this likely to be valuable. Very likely we do not consider enough the provocative scents bees get in the mails. Rules ought to work both ways. Bees are undeniably liable to kill their own queen if caged an hour where she gets a provocative scent: why should they not then accept an alien when she comes with the right scent? The main rub is, I suspect, that she has an individual scent which, while it may be overlaid somewhat, can not be entirely gotten rid of. Colony must take her scent, she can not take theirs, except partially and temporarily.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Dragging Out Brood.

1. Why do my bees drag their brood out of the hive? I first noticed it in a nucleus to which I had given frames of brood and bees, giving them an Italian queen, and thought perhaps it might be owing to mismanagement of my own in some way; but I find this morning (July 2) it is going on in all of my colonies. The brood is fully developed, can crawl about, and upon my attempt to replace them in the hives it is either lugged out again by the bees or come out themselves, seemingly bent upon staying anywhere but in the hives.

As the weather has turned quite cool and cloudy, with a chilling wind blowing, the young bees are dying by the hundreds from exposure. The trouble affects the strong as well as the weak colonies, and all are perfectly free from moths. I am at a loss to account for it.

The honey-flow is on the wane in my locality, but about 4 miles from here at the apiary of an acquaintance it is about at its height, but he is having the same trouble, so it cannot be from lack of stores. CALIFORNIA.

ANSWER.—I confess I do not understand the case. You speak of brood being dragged out, but again say that it is fully developed and can crawl about, so it seems it is bees rather than brood. It is just possible that the trouble may be paralysis, in which case you will see the diseased bees making a tremulous movement of the wings, some of them being black and shiny, and other bees are inclined to worry them much as they do when a strange bee is caught in the hive. If it is paralysis, there is no certain cure known. There is also the possibility of poisoning.

A Swarming Experience.

I have just had an experience with bees that I can't find duplicated in any of the books and papers, and I thought you might be interested or perhaps had had a like experience.

One very full colony had several queen-cells two weeks ago when I clipped their queen, and I have been expecting them to swarm, but they did a little work in the super and then loafed. I ventilated the hive well but they would come out and cluster on the currant bushes, that is, about $\frac{1}{3}$ of the colony, and one night they stayed out so late, and I saw it was going to storm so I put them back into the hive. Next day they came out again and went into an empty hive and went to work like nailers. On opening the old hive yesterday, I found plenty of capped brood but no eggs or unsealed brood, and 12 queen-cells, one of them evidently just opened, but on account of so many bees (for I could hardly miss the loafers that had gone into the other hive) no queen was to be seen.

I gave the loafers a frame of capped brood and 2 queen-cells, and cutting 2 more out of the old hive I found a queen just ready to come out, so I gave her to the loafers, and they have 5 or 6 brood-frames drawn out from foundation, and are also working in the supers.

Now, as I said before, this is out of line with anything I ever heard of or read about, and I would like to know whether you have ever had bees come out and loaf away from the hive entirely, and then hide themselves. They have actually put in 3 or 4 pounds of honey already, and were 2 days without a queen. I had hoped the old colony would swarm, and then I would have put them all back together, but I concluded to give them a queen, as I had a good chance to do so, and call them a colony, for there are enough left in the old hive to make a good, strong colony.

I had another colony swarm without a queen, but after loafing out all afternoon they went back. MINNESOTA.

ANSWER.—If I understand the matter rightly, the unusual thing in the case is that that a smaller number than usual of the bees came out with the swarm. Why that was I don't know, and I don't know that their is any rule determining the number of bees that should issue with a swarm. Probably matters occurred a little after this fashion: When you found queen-cells started the bees were preparing to swarm. About the time the cells were capped the bees considered the matter of swarming and did some loafing—it is a common thing for bees to do more or less loafing a day or two before swarming. Then the bees swarmed, although not so many bees as you expected issued, and as the clipped queen could not go with them they returned to the hive, repeating the swarming, and probably staying out a little longer each time. Then when the first young queen emerged and was strong enough to fly, the swarm issued with her and went into the empty hive. The cells and the young queen that you gave to "the loafers" did no good, as a young queen was already with them or they would not be working like nailers but would have returned to the old hive. (By the way, do you think it fair to continue to call them "loafers" after they "went to work like nailers?") You found no eggs or unsealed brood in the old hive, because the old queen was lost when she swarmed out or was later put out of the way. It is just a little to be feared that you meddled too much by so freely giving cells to the "loafers." for if you left neither virgin queen nor queen-cell in the old hive you may count the chances are in favor of a queenless colony. Under the same circumstances you may expect a repetition of the program, except that usually more than a third of the bees will issue with the swarm.

A Beginner's Report on Queens.

I have just been through the hives, the ones I bought queens for. In one I found a quantity of brood, and what I take to be eggs. These, however, are not lying on the bottom of the cell, but are stuck half way up the back of the cell. Are they eggs?

In the second I find more bees than there were before, but no sign of young brood. There is a little brood which I think is dead, being old stuff laid by a former queen that died. I gave them a frame of brood from another hive and this may account for the increase. The dead brood is in a frame near the side, and all the center frames are filled with honey. Bees are working well, but no sign of queen, eggs or young brood. I wish I had an expert here to look at them for five minutes.

The third colony is dwindling—no queen, no brood. I saw the queen in this hive 4 or 5 days after she was put in, but cannot find her now; I feel sure that she is dead. I will give them a second frame of brood to-morrow. The three queens were put in 14 days ago, so there ought to be brood now. I wish you could give me a hint or a clipping.

BRITISH COLUMBIA.

ANSWER.—Those are eggs that you found on the sides of the cells. It sometimes happens that a queen lays an egg in that way while in general she places her eggs all right. I once had an imported queen which for a time laid all her eggs in that objectionable way, and afterward laid them properly. It is likely that rough handling in the mails may have something to do with the matter. It is to be feared that no queen is in the second or third hive, although it is barely possible that there may be one. Sometimes a queen will not lay for a week after being introduced, and if the weather has been very bad it might be longer. If the weather has been as bad during the last half of June as it has been here, it is not to be wondered that the queens are not kindly received, especially after being roughly handled in the mails. I had a fine queen killed by strange bees in circumstances in which heretofore there never had been any loss. That was two weeks ago, but if it had oc-

cured during the present hot weather there would have been no loss.

There seems something wrong in one colony that I can hardly understand. The bees have allowed the brood in that comb to die when there seemed to have been no other brood in the hive. It looks at least as if the colony must have been very weak.

The first-named queen will likely put her eggs in the bottom of the cell after she is fairly settled down. I have, however, a little fear that there is no queen in the hive, as you say nothing of seeing her, which leaves the suspicion that there may be laying workers in the case, for when they have only worker-comb they sometimes lay eggs on the sides of the cells, although at other times they are placed all right. By this time the brood will be sealed, and if sealing is flat it is work of a queen. If, however it is raised, so that it presents the appearance of a lot of little marbles, you have laying workers, and will do well to break up the colony and distribute the combs among other colonies.

Wants Honey, Not Increase—Supers from Foul-Broody Colonies.

The greatest problem confronting me in bee-keeping is how to produce the greatest amount of honey with what bees I have—some 25 or 30 colonies. When I get the 9 frames full of brood, and the super of 30 pounds ready to cap, or if I tier up to 60, and the 9 brood-frames full, as G. M. Doolittle recommends, out comes a swarm, and it is all spoiled. Now, then, can I at that stage, when the hive is full of bees, take 4 frames of brood out of the center of the brood-nest and put in frames with starters, and keep my bees at home and at work successfully?

2. Will sections or supers that have been on foul-broody colonies be safe to put in with a healthy colony, when they have not drawn out the foundation, and have been exposed to the air for some time?

INDIANA.

ANSWERS.—1. Your problem is the great problem with a great many, how to produce comb honey without the interference of swarming. Taking away all brood and leaving the colony on foundation or starters will effectually stop the swarming foolishness, and taking away four frames of brood will answer sometimes, and sometimes it will not.

2. The fact that so good an authority as Wm. McEvoy says it is safe to use hives that have been occupied by foul-broody colonies makes it seem that it ought to be equally safe to use supers and sections, if no drop of honey has ever been in the sections.

Fastening Queen Below on Foundation.

I will give the desired report of my efforts this year. As mentioned in my previous letter, in building up my one-story hives to "double deckers"—I work for extracted honey and run hives 2 or 3 stories, using full-sized hives for all stories—I took brood and bees from one hive, and placed another, with queen-excluder between, leaving the old queens and two frames of hatching brood, on the old stands, filling up with empty frames and dummies. The hatching brood and returning bees make good nuclei, and immediately commenced building worker-comb, and are now fairly good colonies for wintering. But unless the sumac yields a good fall flow, feeding may be necessary. I think if foundation had been used I might have been able to get better results. I am so well pleased with this method that I shall practice it next year. By taking brood from the hybrid queens, it entirely prevented rearing impure drones. The colonies topped out with brood and bees, went to work at once as though they had always been one family, and stored more honey than those that had two stories during the winter. The season being a "record-breaker" for not producing honey, the two-story colonies did not build up fast enough in the spring to be ready for a honey harvest, if there had been one. I extracted a little from those built up strong, but I wish I had not, as I may have to feed it all back.

After reading your advice to "California," I tried 2 more colonies that way. Not having foundation, I put one empty comb and empty frames below, and confined the queen on them with excluder and put the brood on top. The bees built queen-cells above, but did not build comb below. I do not think the queen "sulked," I think it was the "sulky bees."

In the case of the "shook" swarms, they have done just as well as natural swarms, but not taking bees from them the brood alone would not build up the other colonies as quickly as the other way. CALIFORNIA.

ANSWER.—I thank you for the further trial of fastening the queen on foundation in a lower story, and it seems to be thoroughly settled that the plan is not a success with you. Of course you are right in using the plans that are successful, and I think your plans will be generally successful, as others have used them with success.

You do not say specifically just what you do with the brood when you shake off all the bees, except that you put it over other colonies. Do you put all the brood over one colony, or do you give it to more than one colony? It has been claimed that when it has all been put over one colony, that colony with its double load of brood would not afterward swarm. How has that been in your experience? Another thing: When all the brood is taken from a colony, leaving empty frames or foundation, does such colony never swarm out?

Using a Mothy Hive.

Did you ever have a colony thrive in a hive which has been cleaned of webs, moths, etc. MICHIGAN.

ANSWER.—Don't you think you're pretty hard on me to ask a question that will bring out whether I have been so very careless as to allow combs to be filled with "webs, moths, etc.?" Well, since you insist upon it, I may as well own that I have had all degrees from the mildest to the severest cases. If you mean did I ever have a colony thrive in a hive in which the colony had allowed the moth to get the upperhand so that most of the combs were filled with webs and cocoons, I must answer no. If you mean did I ever have a colony thrive in a hive that was given to them in that condition, yes. Take a very bad case, only that some parts of the comb are still left, dig out the worst bunches of webs, place the hive under or over a strong colony, and see how nicely they will clean it out so as to be habitable. Even a swarm put upon wormy combs, if the case is not too bad, will make things all right. If the moth has made too much headway the swarm will be likely to evacuate.

Queenless Colony.

I have a queenless colony, and I am fearful of losing them; they are quite yellow or a hybrid strain, I should judge; they have been queenless for 4 weeks. I got them out of a bee-tree, and there is where I lost the queen. I put in a frame of larvæ but they did not build a queen-cell on the frame I put in, but on another frame. Do they transfer larvæ themselves, or is it on an old cell that they built out of the brood that I put in the frame when I felled the tree? It seems to me that it ought to be hatched out before this time. I put the frame in about a week ago to supply themselves with a young queen, and when I looked a week later I found this queen-cell started on another frame, so I am puzzled to know what to do about it. WASHINGTON.

ANSWER.—It is not likely that the bees transferred a larva, and there would be nothing strange in their starting a queen-cell from brood taken from the bee-tree. But as the cell has not yet hatched out four weeks after the loss of the queen, you may count that the queen in the cell is dead. Having had brood given them at two different times, it is not impossible that a young queen may be in the hive (a queen-cell is sometimes so inconspicuous as to be missed), and in that case any queen you give them will almost certainly be killed, so look out. Before giving them a queen it will be well to give them frames of brood to see if they start cells. If they start none they have a queen.

Selling Honey—Having Bee-Hives all Alike—Electric Hive-Heater.

1. Enclosed I send you an account of sale, and may the bee-papers find and advertise a honey-dealer that can give higher prices. Bees increase here very fast, about 300 to 1000 percent per year, but hardly any sales for queens or colonies of bees.

2. I think it would be an advantage, or desirable, to have the inside of the bee-hives all alike. I have some Langstroth-Hoffman frames that where the top-bar rests

on the tin rabbets some of them are thicker than others, and the one above smaller. The bees glue them together and kill the bees between them. Bee-keepers should agree on a certain size frame and a manufacturer that makes them, otherwise bee-keepers should refuse to buy them.

3. I think with the Electric Heater virgin queens and drones can be made to come out. Glass and tar-paper work about as well in the sunshine. CALIFORNIA.

ANSWERS.—1. The account of sale dated June 27 shows that the honey was sold at $3\frac{3}{4}$ cents, certainly a discouraging price if the honey was of prime quality, as to which no mention is made. The advertising columns of the bee-papers are always open for placing of advertisements of reputable dealers. That is about all that ought to be asked of them.

2. You are quite right. Having two dimensions such as you mention is an unmitigated nuisance. There is more or less uniformity among the leading manufacturers, and where there is fear of undesirable variation it is only the right thing for the man who orders to stipulate as to dimensions, and then refuse the goods if they are not of the desired dimensions. The difficulty in such cases is that there is no particular tribunal to settle just what dimensions should be used, and it is quite possible that manufacturers would be glad of there being some authority to tell them just what dimensions should be used. Every one, however, has the right in any and every case to order explicitly just what he wants, whether it be in accord or not with that which is most in vogue. Only in most cases it will cost a little more for goods that are not standard.

3. I suppose your idea is to excite the queen and drones to fly earlier in the day than the usual time, a thing which is recommended by Dzierzon. Will you please tell us explicitly just what you mean as to Electric Heater, glass and tar-paper.

Bees Eating Foundation—Other Questions.

I have been keeping from 10 to 15 colonies of bees for several years, just for the pleasure they give me in looking after them. I live in the buckwheat belt, and hundreds of acres are being sowed now which will begin to bloom by August 10. It always produces an abundant flow of dark honey which sells readily at 16 cents per pound. My bees last year averaged 40 sections from buckwheat alone. This year I sowed the buckwheat June 10. It is now almost a foot high (July 8), and will bloom in a few days, which will make the season much longer. Please answer the following:

1. Why do some colonies go into sections and just literally eat the foundation?

2. Would you advise feeding at night at this time of the year? I use Boardman feeders, and if I use them in the daytime it starts a rumpus.

3. I have all my queens clipped, so when a swarm issues I simply let it go back. What will be the result when a young queen is hatched?

4. Bees here will need no sections for two or three weeks, but will it do any harm to put supers on now to be ready for the honey-flow when it does come?

5. In making 2 colonies from one, should the queen be left on the old stand or taken to the new place?

PENNSYLVANIA.

ANSWERS.—1. You will not likely find this to occur when the bees are very busy storing. When bees have nothing to do they are a little like mischievous puppies. Better not leave sections on after the flow stops. The thinner the foundation the worse the bees are about gnawing it.

2. Yes, if you are obliged to feed this time of year, it is better to feed at night if you use an entrance-feeder like the Boardman. If you use a top feeder, like the Miller, it makes little difference.

3. When it comes time for the young queen to fly, a swarm will issue with the young queen, and must be hived or it will abscond.

4. It will do no great harm, but the sections will not be quite so nice and white. In some cases the foundation may be gnawed.

5. Nearly all the field-bees will go to the old stand, and they will do better work at storing if the old queen is with them. Very little storing will be done at first at the new stand, and by the time there is a good force of field-workers there the young queen ought to be ready to encourage them.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

GENERAL ITEMS

No Honey Worth Mentioning.

Let me state the results of my visit with the brethren: The counties of Ventura, Los Angeles, Riverside and San Diego are the leading honey sections of California, and notwithstanding the many newspaper reports of the "record-breaking" year for honey in Southern California, put in circulation by buyers and speculators (including a so-called bee-journal, whose editor and proprietor is a speculator, but has two or three colonies of bees in a city back-yard, so he can say "us bee-keepers") there is no honey in these counties worth mentioning.

Mr. Mendleson with about 800 colonies reports no honey, and is moving his bees into the bean-fields, hoping for a little bean-honey. Mr. McIntyre with his 800 or 1,000 reports some honey, but is not going to extract any. Others report no surplus.

Southern California will not produce more than enough for home use, in place of the boasted 500 car-loads. The honey season is practically over. DELOS WOOD.

Santa Barbara Co., Calif., June 28.

Hiving Back Swarms.

I notice on page 403 a request to those who have had experience in hiving back swarms into colonies that have previously cast swarms. I have had quite a large experience along this line, having practiced this plan of preventing increase for three or four years on hundreds of colonies. How long is it necessary to wait after a colony has swarmed before a swarm can be given it without danger of having the swarm re-issue? If it is at the beginning or during the first half of the regular swarming season, wait at least 8 days, and then it may be necessary to take away about 2 frames of brood, and give frames of empty comb or foundation. If it is toward the end of the swarming season, put in a swarm in 7 days, as they are not so liable to re-issue at this time. The cells should be cut on the fifth day after the swarm has issued, then again the seventh or eighth, just before running in the new swarm. It will not do at all to hive a swarm into a colony that has unsealed brood young enough to make larvae for queen-cells, as they will do nothing but build cells and swarm out. But it is fairly safe after all larvae are 4 days old or over. I have had only a very few cases where the queen laid a few eggs and the bees swarmed out with cells just started. W. C. GATKRIGHT.
Donna Ana Co., New Mex., June 29.

Vetch as a Honey-Producer.

I have seen at different times letters regarding the vetch as a honey-producer, and I think I am now in a position to speak with certainty on the subject.

There are in my immediate neighborhood this year between 20 and 30 acres sown to vetches; they are sown in the fall, mostly mixed with wheat, and are the best thing I know of for feeding green to horses, cows and pigs. They also make first-class hay, and we had a heavy crop. During the past week they were in full flower, and humming with bees all over, and a colony I have on scales increased 28 pounds in 6 days. There is not a large amount of white clover around here; on the other hand, some colonies I have at a place some distance off, where there are no vetches but great quantities of white clover, have not put up as much. The honey is as light as white clover, and of good flavor. British Columbia, June 24. W. FISHER.

[The following, on the same subject, was sent us quite awhile ago, but with the request that we do not publish it lest "it bring a flood of letters of inquiry" which the writer said he had "not the time to answer." (That is one of the nuisances resulting from pub-

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us their stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

So we will omit the correspondent's name as well as post-office, and publish his letter, believing he will not object by such use of it for the benefit of our readers:—
EDITOR.]

There is a variety of vetch here, the seed having been first sown about 4 years ago. It continues to grow on the same ground, I suppose, from seeds that are scattered when the hay is made. The bees work very busily upon it from March until July, but not upon the blossoms. At the base of each stipule is a little brown spot or gland from which a sweet sap is secreted. If the plant is not visited by bees for a few minutes, enough of this sap will accumulate to form a drop as large as the head of a common pin. The blossoms appear in June, but I have never seen a bee upon them. I think the flower-tubes are too deep for the bees to reach the nectar.

The vetch is not plentiful here; but since the bees work upon it whenever the weather is warm enough for them to fly, if raised in large quantities, it certainly would be of great importance in getting the bees in good condition for the white clover flow, which begins late in June.

The opportunities for bee-keeping here are good. The amount of clover is increasing rapidly; we have a good home market, and at a fair price.

A good many bees are kept by farmers, and do quite well; but real live, up-to-date bee-keepers are very few indeed.

Only 15 miles away are the burnt timber regions of the Cascade Mountains, where fireweed, salal, vine-maple, and other honey-plants abound. The quality of the honey produced there is of the best, but the territory is unoccupied except by the millions of wild bees that are everywhere found. I visited this region twice last summer, and found the salal yielding nectar in quantities that surpassed even the most extravagant reports of the basswood.

Here are thousands of acres of unclaimed land, good mountain water, and only 20 to 25 miles from the railroad—surely, a bee-keepers' paradise, unknown and undeveloped.

Not many years ago a man kept an apiary of 90 colonies in the mountains 12 miles from here, and cleared an average of \$600 per year. This man died, and the apiary passed into the hands of others, who were not bee-keepers, and the business soon went to ruin. No one has tried bees on an extensive scale there since, but most of the settlers keep a few (one man whom I visited had over 40) colonies at a good profit. I am now studying conditions, hives best adapted to moving, location, and other matters, with a determination to take 20 colonies there in July and give the pasturage a trial. I shall employ my spare time in hunting bee-trees, and may decide to locate a homestead if I find the enterprise a promising one.

Marion Co., Oreg.

Unfavorable Weather for Bees.

The spring and summer, so far, have been the most unfavorable for bees of any during my experience—too much wind, cold and wet weather, and now, at the end of June, with abundance of flora there is no weather to handle it. The thermometer has been bubbling around 50 degrees nearly all this month; sometimes below 40, and only a few times above 60, and rain, rain. To produce a good flow of nectar the thermometer should register from 80 to 90, and even 100 would not hurt.

The bees in anticipation of a good flow made ample preparations for swarming, building queen-cells by the dozen, but have been so retarded in their desires, have swarmed with the least possible outbursts of sunshine, and in many cases before the swarm could get fairly on wing a dark cloud would obscure the sun, and the air become so cold, and with the strong winds continually blowing, the

7A26t

bees would be driven down upon the tops of hives, and upon the grass, and would have to remain there until the cloud passed over and they got warmed up so they could return to the hive. In most cases I was able to capture the queen on the alighting-board and adjust a new hive on the old stand before the bees were able to return: in several cases they took refuge in other hives, and in one case the cold was so intense that day and for several days following, that they remained there, that is, the major part of the swarm.

This season is my first real experience with clipped queens: I have about $\frac{3}{4}$ of them clipped, leaving one row of about 20 unclipped, as I failed to get such practical help as I needed, when the weather was suitable. Of the clipped ones I think fully 10 percent have been superseded, while not one of the unclipped, so far as I know, have been disposed of. This would seem to be some evidence that clipping causes supersedure. I find, however, that I can manage swarms much more easily with clipped than unclipped queens, and notwithstanding the tendency it seems to have with me to supersedure I may become an advocate of clipping.

Swarming having been delayed, the swarms are coming off very large, and if the weather should clear up and become warm we may yet get some honey, but the prospects are for a very short crop. A. BOOMER.
Ontario, Canada, July 2.

Loss in Wintering—Swarming.

Last winter was the worst on record for the bees for many years; losses from 50 to 100 percent, and the average loss at least 60 percent. Backward spring—in fact, the same old story you read in the bee-papers almost every week. My loss touched 40 percent; the bees died and left from 58 to 75 pounds of honey in the hives (10-frame). I cleaned the hives out and stored them away and put early swarms right in on the honey, and as a result I have some 400 fancy sections from my swarms that otherwise I would not have had.

While I have had such bad luck in winter losses, never saving over 60 percent, still I have never lost a swarm; I never clipped a queen's wing, and have never had to hive a swarm a second time.

I have had 20 swarms, the first on May 17; there is lots of complaint of swarms leaving, and they frequently pass over. Will some of the "bruddering" tell me how to stop a swarm that is passing over? I have tried to stop them, but always fail. I have a boy to watch the bees, and just as soon as they get clustered I go after them. If the queen has failed to come out, and is not with the swarm, they will not go into the new hive, but return to the parent colony on the attempt to put them in.

There seems to be a good flow of white clover and basswood, but the weather is so windy, cool and wet that bees can not do much. J. M. WEST.
Pike Co., Ohio, July 3.

Plenty of Bloom, but Little Honey.

Bees are humming, but nectar is slow in showing up, as there is plenty of bloom. Cold nights and afternoon winds are killing off the field forces at a terrific rate. I am afraid that the yield from first crop of alfalfa will be light, as the mowing machines will be out shortly, and that means quit in short order, in this valley.

Bee-keepers that are running for extracted honey say that all colonies that are strong enough are storing pretty lively; none extracted yet.

I had only 5 swarms from 100 colonies and all had queen-cells. How is that? They did not lose much time, either, while the fever was on. Ninety-eight colonies working in the supers and almost ready to be reinforced, or supers doubled. Two are rearing queens.

A bee-keeper told me yesterday that he expected to average 3 cases of comb honey per colony, from 150 colonies, and his bees are not yet up in the supers, and not more than 30 on as yet. I hope he succeeds, for I will do quite as well. I think, for I have the start of him.

I think if C. Davenport will try using one or two brood-frames (or frames of brood)

when driving below an excluder, he will have no further trouble with the bees swarming out. It is almost impossible with us here to keep them at home when transferring the second time for foul brood (McEvoy method), without using entrance-guards or brood.

I think the convention must either elect all officers at the regular meetings, or make nominations so the members will have some idea who to vote for. I am lost when it comes to voting, as the matter now stands. Our conventions should come a little later in the season to benefit us Nevada bee-keepers, as all our heaviest work comes about the first of September, and all who try to do the most of their own work, like myself, cannot get away at that time. I would like ever so much to attend the Denver convention, but I'm afraid it's no go for me. I expect, too, that it will be some time before we will have another chance at it so far west.

JOHN W. LYEEL.

Washoe Co., Nev., June 28.

Poplar Honey—Short Crop.

All my life I have heard that a "good beginning makes a bad ending." Although we had a bad, discouraging beginning, we have not had a very good ending. The bad weather lasted until April 14; the 15th opened up bright and warm, and continued very warm and dry all of poplar-bloom time, which gave us one of the finest flows we ever had, and it was the finest honey I ever saw. It was so thick before it was sealed that it would hardly run through a strainer-cloth, but on account of the cold, late spring bees were very weak and in a sad shape to take care of the crop. The best colonies stored from 5 to 8 gallons; the rest from 2 to 3 gallons.

On account of the dry, hot month (and it was awful hot), our June flow from sourwood has been almost a complete failure. Bees usually store some honey from cotton and bitterweed, but our surplus crop is over now. I think that I can safely say that the crop is from $\frac{1}{3}$ to $\frac{2}{3}$ less than it should be. Out of 70 colonies only two colonies in box-hives and two, and maybe three or four, in frame hives, swarmed. I did not do anything to prevent swarming, only gave them plenty of room. I have found out that the road to success lies through a rich hive in the winter and a good queen. Some writers say that it is best to re-queen every year; I do not think that would work every time. I bought an untested Italian queen in 1900, and that colony has stored more honey than any other one here.

I see that C. C. Parsons wrote Dr. Miller that bees store honey from dogwood in some parts of Alabama. I do not think I ever saw a bee on a dogwood bloom here.
Hale Co., Ala., June 30. J. S. PATTON.

Fastening Brood Foundation.

Bees in this locality are not doing very well this season; there have been only 6 swarms in the whole country, to my knowledge. We have had only two weeks of good honey-flow, and that is the last two weeks. This section of the country has been visited with heavy rains, and constant winds (that we could not say were only breezes), and some very cool nights. But we live in hopes of better weather. White clover and basswood are in bloom.

I saw in the American Bee Journal some time ago something about fastening comb-foundation in brood-frames. I have tried all the ways that have been told of in text-books, and I come with something new—at least I have never seen it in any text-books. I want to say right here that the first text-book should be the "hive of bees" you get, and if you get it "hived" successfully, try some bees, and see how much pleasanter it will be.

Now for the faster: Take a board 2 feet long and one foot wide, planed on one side; nail a small cleat on top of the board on the side you want next to you. This is to keep the frame from slipping away from the foundation; tack a light strip under the bottom of the frame on the board to hold the frame level, then take a piece or strip that will go in the frame easily; this piece should be just one-half as thick as the top-bar. Push the frame up tight against the cleat, and lay this one on the inside of the frame. Bring it up

until the beveled edge almost comes in contact with it; this piece must come up to the bevel of the frame so as to keep the foundation level. Then you want a small cleat on this one so as to keep your foundation from slipping away from you. Take the foundation as wide as you want it, allow $\frac{1}{4}$ of an inch to rest on brood-frame, then slip the little cleats up against the foundation and tack them to the board, that is, the cleats. I use a half roller for fastening foundation and find it more satisfactory than the roller, for the roller pushes too much. I take a firm piece of wood 3-16 of an inch thick, 3 inches long, and $2\frac{1}{2}$ inches wide. Take a compass and make a circle on one end, trim off nice and round, with a very smooth edge, leaving one end square; lay down a damp cloth, when it is convenient, and roll over on this once for every frame, and it will not stick to your roller. Keep a constant, firm pressure on the roller. I have put 10 frames in a few minutes, and that is fast enough for anyone.

I have explained this device as clear as I could, and if there is any one who wants to know more, I would be only too glad to explain further.

How about keeping bees in an attic? Is it a success? There is a man here who wants to put bees in his attic, but would like to know more about it. *A. M. HOOVER, Vermillion Co., Ill., June 20.

[We will have to call on Rev. W. S. Sly, of Michigan, who has an attic apiary. How about it, Mr. Sly? Is it a success?—EDITOR.]

Keeping Down Increase by Uniting Swarms.

I see on page 403, under "Prevention of Increase," what I call uniting swarms or doubling them up. It says when the first colony swarms hive the swarm in the usual way. When the second colony swarms hive in No. 1, that is, in the hive of the colony that first swarmed, and so on. My plan is to have boxes to put bees in that I wish to double up. When the first colony swarms hive in a box; when No. 2 swarms put it into a hive or shake off in front of the hive; then take No. 1 in the box and dump them out on swarm No. 2, and they will all go in together in perfect peace. I have thrown 7 weak swarms together in that way, and got a good colony, whereas, if they had each been hived in separate hives, they would have been of no account. Reno Co., Kans. WM. F. CARSON.

Prize = Winning Stock

Daughters of Moore's famous long-tongued red clover Italian Queen, which won the \$25.00 prize offered by The A. I. Root Co. for the longest-tongued bees; and also daughters of other choice long-tongued red-clover breeders whose bees "just roll in the honey," as Mr. Henry Schmidt, of Hutto, Tex., puts it, now ready to go by return mail. HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, July 7.—The honey market may be said to be on a vacation so far as actual business is concerned. Should the harvest of 1902 be practically a failure there will be no dearth of extracted honey, as there is more of it in storage than we have ever known at this season of the year. If the consumers are not too greatly impressed with the idea that the honey harvest is a failure this season it may be worked off at an advance in price. Beeswax is lower, yet sells well at 30 cents per pound.

R. A. BURNETT & Co. KANSAS CITY, July 5.—Some new comb honey has arrived. We quote: New, 14@15c; old, 12@13c. Extracted, white, 6@6½c; amber, 5@6c. Beeswax, 25@30c. C. C. CLEMONS & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c. THE FRED W. MUTH Co.

ALBANY, N. Y., July 10.—Honey market not opened yet for this season, but we look for demand to begin in a couple weeks. No old crop in the way. Expect good demand and good prices for new crop, which is very light in this vicinity. H. R. WRIGHT.

DETROIT, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c. M. H. HUNT & SON.

NEW YORK, July 7.—There is some fair demand for comb honey at 14c for strictly fancy white; 12@13c for No. 1, and 10@11c for amber. Extracted quiet at unchanging prices. Beeswax dull and declining at 29c. HILDRETH & SEGELKEN.

CINCINNATI, July 7.—The shipments and offers on the new comb honey are so little, besides the predictions for the yield of honey so uncertain, that I can give no figure for prices. Extracted is selling for the same price—Amber, in barrels, 5@5½c; alfalfa, 6@6½c; white clover, 6½c. Beeswax, 28c in cash. C. H. W. WEBER.

SAN FRANCISCO, July 9.—White comb, 10@12 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4½@—; amber, 4@—; Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Stocks are of light volume and market cannot be termed favorable to buyers, but demand is not brisk at prices now generally asked, dealers waiting as a rule for offerings to be presented to them. If pressure to realize were exerted, the material shading of rates to buyers would be necessary to effect noteworthy wholesale transfers.

WANTED!

Honey and Beeswax. Mail sample and state price delivered Cincinnati. C. H. W. WEBER, 2146-2148 Central Ave., CINCINNATI, OHIO. 21Atf Mention the American Bee Journal.

WE can place a few cars of COMB AND EXTRACTED HONEY. Will be glad to correspond with parties having some to offer. We also solicit local consignments. C. C. CLEMONS & CO., 29A9t 306 Grand Ave., KANSAS CITY, Mo.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

A New Edition. 19th Thousand.

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all), and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

Untested Queens.—We find that there are quite a number of bee-keepers (beginners, of course) who seem to think that the untested queens offered for sale are also unfertilized. We are frequently asked by letter whether untested queens are fertilized. It seems such a useless question to ask. What good would be an unfertilized queen? No honest queen-breeder would send out virgin queens.

An untested queen is simply one that is fertilized, but has not been kept in a colony or nucleus long enough for her eggs to hatch, so as to see the kind and color of her bees.

A tested queen is one that has been kept by the queen-breeder long enough to see first what kind of bees she produces.

The Use of Smoke On Opening a Hive is a thing subject to abuse. If a colony is deluged with smoke there is an unnecessary loss of time in the work of the colony, supposing, of course, that the time is one when the bees are gathering. If too little is used upon a cross colony, or at a time of day or under any circumstances when the colony may be temporarily cross, a lot of cross bees will be in the air, and in the long run more smoke will be necessary than if the bees had been kept under subjection from the first. Experience is needed to know just what is best.

The beginner is likely to be confused by the contradictory advice sometimes given. In a late exchange the beginner is told that before opening the hive he must puff smoke into the entrance and wait three or four minutes for the bees to fill themselves with honey. That would be a time-robbing performance in a case where fifty or a hundred hives are to be opened in the course of a day. Suppose we take the medium ground, and say that 75 hives are to be opened, and that 3½ minutes are allowed in each case for the bees to fill

themselves with honey. Seventy-five times 3½ minutes make 4 hours and 22 minutes—a length of time that a busy bee-keeper could not well afford.

Another writer tells him that only in rare cases is it necessary to blow any smoke into the entrance. That may be going to the other extreme. In many cases it would be all right, for in many cases bees are so gentle that no smoke whatever is needed from the time the hive is opened until it is closed, but if smoke is to be used at all during the operation it is well to give at least a preliminary puff at the entrance, so as to give the guards notice that they are not to rush out when they feel the hive jarred by the prying open of the cover.

The beginner should have in mind that if a queen is to be found, especial care should be used to give no more smoke than is absolutely necessary, for if the bees are set to running it is a very hard thing to find the queen.

Rambler's Jouncer was seen in operation by the editor of *Gleanings in Bee-Culture* while he was in California, and he commends it as a good thing to jar bees out of supers, especially where the modern escape is not used, and can not be used at out-yards. He says:

It consists of a framework, or four table-legs, as it were, without a top, thoroughly braced together. It stands about two feet high; is just wide enough and long enough to take in a regular hive-super between the four legs. Beneath the super is put a trap of cloth, and this is supported at such a height as will bring the super up flush with the top of the legs. Now, to get the bees out: Lift the super and jouncer off the ground a few inches, and give it a sharp "jounce" downward. Repeat these jounces till the bees are all jarred out on the tray, which can be dumped in front of the entrance.

Quoting the Honey Market has another "whirl" this week, as will be seen by referring to page 485. Mr. S. A. Niver, of New York, sends us the following:

MR. EDITOR:—I am glad to see you stir up the subject of quoting the honey market, for it needs attention in many ways. It is the most interesting—if not the most valuable—column in the "Old Reliable" to the bee-keeper. That is the first thing I read. But w. at a "tired feeling" comes over me when I read a finely written and encouraging market quotation, in the July 24th number, which is dated "March 6." "It hath an ancient and fish-like smell."
S. A. NIVER.

Of course, in one way, we are to blame for not removing from our market column any old quotations. But we have an understanding with those who quote, that they will change quotations whenever any changes in prices or conditions in their several cities occur. But some of those who quote don't seem to appreciate the privilege they have of

being represented in the market column of the American Bee Journal. If they were to pay full value for it they would find it would cost them a good many dollars every year. If dealing in honey is a profitable part of their business, they should see to it that their quotations are fresh and up-to-date. We stand ready to change them every week, if they will only send them in.

We are glad to have the bee-keepers "get after" those who quote prices on honey. Some of them need a good poking up.

Weekly Budget.

SECRETARY D. W. WORKING, of the Colorado State Bee-Keepers' Association, has sent us the following, dated July 18:

DEAR MR. YORK:—I enclose a copy of a set of resolutions adopted yesterday by our Executive Committee.

We have appointed a Reception Committee to look after the comfort and convenience of our guests at the National convention. Mr. Herman Raufchfuss is chairman; and among the other well-known members are Mr. Gill, Mr. Morehouse, and Mr. Aikin.

Pres. Harris came over from Grand Junction yesterday, and is in the city to-day looking after business connected with the big meeting.

Yours truly,

D. W. WORKING.

The resolutions mentioned by Mr. Working refer to the death of Mr. Chas. Dadant, which was noted last week, and read as follows:

WHEREAS, We have this day received notice of the death of the venerable Charles Dadant, of Hamilton, Ill., at the ripe old age of 85 years;

WHEREAS, The services of Mr. Dadant to the science and art of bee-keeping have been of the first order, and his life has been a benediction to all who have been associated with him in business and social ways; therefore, be it

Resolved, That we, the members of the Executive Committee of the Colorado State Bee-Keepers' Association, hereby express our appreciation of his character and worth as a man and a friend, and that we unite with his friends and admirers everywhere in testifying to his worth;

Resolved, That the Secretary of this Committee be directed to transmit a copy of these resolutions to Mr. C. P. Dadant with the condolence of the Committee.

JAMES C. HARRIS, } Executive
FRANK RAUFCHFUSS, } Committee.
D. W. WORKING, }

ON THE GENERAL MANAGERSHIP MATTER, Mr. Abbott sends us the following letter for publication in answer to Acting Chairman E. R. Root's, as given on page 418:

ST. JOSEPH, Mo., July 14, 1902.

Permit me to reply to the communication of Mr. Root in a late number of the American Bee Journal.

I desire to say that the Board have declared that they have authority to act in this matter. My contention is that they did act, and that seven out of eight votes were cast for me. The question of a quorum can not be sprung. The entire Board were notified and were constructively present. Seven of the eight who voted, voted for me.

Now, as to the vote cast for E. M. Abbott: There is no use for any fair-minded man to quibble over that. Dr. Mason knows who cast that vote, and it would not take very long to find out what the voter intended, if one wanted to deal fairly and honorably with a fellow-worker. However, it does not re-

quire a majority of the Board to constitute an election, if the constitution is to be taken for a guide, but a majority of those voting. Six votes are, however, a majority of eleven, and there were only that many of the Board to vote, leaving out myself.

You know, perhaps, that this whole thing is a mere quibble and a subterfuge, and is not the real reason of all this trouble, and none of the parties who started this diffidently dare say that it is. This whole thing grew out of the attitude of Mr. York and myself toward Mr. Benton, a matter that has been adjusted by the parties interested long since.

I contend, further, that every man who cast a vote for a successor to Mr. Secor, voted to accept his resignation at the same time, and that let him out. You wink at this, simply because it is unanswerable. There was no occasion for Mr. Secor to send his resignation to you—he was *already out*—if the Board had power to act—and *I was in*. It seems to me folly to talk of appealing from my decision. I had not made any decision, but the majority of the Board of Directors had.

After every bee-journal in the United States and Canada had made the announcement of my election, you had notified Mr. Secor, and I had taken up the work of the office, then these gentlemen began to look around for a way to dispose of me, and I was asked to resign. Why resign if never elected? Drowning men cling to straws.

You say, "Mr. Secor's resignation has been returned to him marked not accepted." By whom? Surely not by the eight people who voted to let him out, seven of whom elected another man to serve in his place. Does not the man elected have some rights?

You say you are for the Association. So am I; and I think I am safe in saying that I have done as much hard work, and spent as much cash to promote its interests, as any other man in it. I did not want to be General Manager, neither do I want to be kicked out of the Board simply because I am not willing to see the affairs of the Association mismanaged. I openly charge that its business has been neglected, and, further, that Mr. Secor himself was placed in office at least once when he was not legally elected. At the last election he received only 172 votes out of over 900 members, which would show that the membership is not overly enthusiastic, to say the least, about having him for General Manager. At an election before this he received a less number of votes than another man, and yet he was declared General Manager. I was Chairman of the Board and said nothing about this, simply for the sake of harmony, hoping that the time might come when the affairs of the Association would be conducted on different lines. However, I do not have to base my contention of mismanagement on anything but his own statement. He has said over his own signature, that owing to the press of other business he neglected the work of the Association, and I say without any hesitancy, as a member of the Association who has its welfare at heart, that the time has come for this neglect to stop.

I am for the Association, but I am, also, for right, justice, and fair dealing. I am not asking any favors of the Association; I never asked any. It was not my will that I be elected General Manager. It was none of my seeking. I am not one who is given to wink at what he believes to be wrong, simply to get the good-will of a few individuals, even though this might promote the interests of the Association. I do not hesitate to say that if the life of the Association hinges on the unfair treatment of any individual, then it would be better that it *die now*; for no institution which openly defies the rights of one of its officers and active members, let it be ever so meritorious at the start, can live very long.

I am ready to meet these gentlemen at any time and discuss this matter in a fair and candid way. I, too, was a member of the Board, and was elected by the same constituency that elected them, and as I see things I am now a member of the Board, and its Chairman, if I am not the legal General Manager. You do not place before the membership the real reason for this trouble; neither do you tell them that all of this was worked up *after* the Board had voted and the vote

had been declared. I am at a loss to see how the Association is to be benefitted by such a procedure as you suggest. Yet it may be perfectly clear to you.

I have no personal grievance against any member of the Board, and I can co-operate with any of them, but I do object to being held up before the public by you, or any one else, as trying to elect myself General Manager. If we want to be fair and just, let us hear from the man who voted for "E. M. Abbott;" let us hear from any man on the Board who thinks his rights have been infringed upon, and perhaps we can get at the real facts in the case.

Here is what a member of the Association says in regard to the matter:

STANISLAUS CO., CALIF., July 9, 1902.
MR. E. T. ABBOTT, St. Joseph, Mo.

Dear Sir:—In the marked Modern Farmer you sent, the members of the National Bee-Keepers' Association are requested to give their views on the miserable smash-up of the Association. As the latest Gleanings is at hand, and I should desire the information, if in your position, I now comply with your request.

In my opinion the Directors had the authority to accept the resignation of Mr. Secor, and elect his successor, which they did at one and the same time. Their easiest way now to get rid of you is to declare your election valid, which it certainly is.

Your offer to leave the matter to the membership is certainly fair, but I doubt very much if the Directors will leave it to a vote. The Executive Committee would probably stand with the "push." If left to the members at a special election, I fear you would be defeated by a strict party vote.

Of course, you can do little for the Association, as things now stand. Were I in your place I should endeavor to hold all funds in my hands until a successor should be elected. I see no opposition to the Colorado Director keeping your old seat warm—all legal, I guess.

This letter is not founded on personal grounds in the least. Why men usually so fair, as are the most of your present opponents, should take the contradictory and absurd positions they have, staggers my comprehension.

You have my consent to use this letter any way you please, provided the entire letter is used.

Yours truly,

W. A. H. GILSTRAP.

Another member says in the name of a half dozen others:

"We recognize no General Manager except you, and will never pay a cent of dues to any other but you, and your properly-elected successor. So hold your ground, and contend for your rights. If much of such doings is kept up by the leaders, our Association will be busted, and no mistake, sooner or later."

I hold that I am the only legal General Manager in existence. I want to say to all of those who have sent their dues to me, that they need have no anxiety about them. I will see that their rights are protected. I have receipted for all dues sent me the day they were received, and I shall continue to do so until the Association elects another General Manager. When it does, I shall make a report to him, and give him a check in full for the amount due the Association.

In conclusion, I desire to say that I am perfectly willing to leave this entire matter to three disinterested men. If they say I was not legally elected, that ends all opposition on my part.

Yours for justice and right,

EMERSON T. ABBOTT.

In order that this controversy might be ended this week (so far as the American Bee Journal is concerned), we requested Mr. Root to forward his reply so that both might appear in the same issue. Here it is:

EDITOR AMERICAN BEE JOURNAL:—I am sure your readers must be tired of this thing, as it is a matter that concerns the Association alone, and not the general public; and I, for my part, do not feel like inflicting on your readers a further discussion, any more than

to say I championed Mr. Abbott at the beginning of this trouble, and hoped that the matter might be dropped, and that he (Abbott) might be permitted to fill out the unexpired term of Mr. Secor. When I was convinced, after a conference with some of our best men, that the proceedings respecting his supposed election was wholly illegal, and out of order, and how Mr. Abbott was attempting to "force things" irrespective of the consequences to the Association at the very zenith of its success—just when it was getting to be a power for good—I felt that I could no longer support him.

Six members of the Board voted for him for General Manager in the first place; but when they came in possession of the same facts as myself, twelve of them unanimously voted not to accept Mr. Secor's resignation; and a good majority of them voted also to declare Mr. Abbott's election illegal and void. A further reply to Mr. Abbott's points will doubtless be made to the membership direct.

But I can not forbear noticing his reference to Mr. Secor. I have probably criticised him privately as much as any member of the Board, and Mr. Abbott knows this; but unless it be to prejudice his readers I do not see why this public attack should be made on him (Secor) when the question is not whether Mr. Secor has been *negligent or incompetent*, but whether *Mr. Abbott* has the right to lay claim to the office of General Manager. Mr. Abbott says that "at the last election Mr. Secor received only 172 votes out of over 900," and then goes on to say, "The membership is not overly enthusiastic, to say the least, about having him as General Manager."

Is he grasping at straws? The implied assumption from the above quotation is that there were 900 votes cast, and Mr. Secor received 172, or less than a fifth of them. The fact is, there were only 338 votes cast, and Mr. Secor received 172, the other ballots having been "cast for 109 different members." The constitution plainly says:

"The General Manager . . . shall be elected by ballot during the month of December, during each year, by a majority vote of the members voting." (Italics mine.)

Mr. Abbott probably didn't intend to misrepresent the facts; but the general public would be misled. The fact was, Mr. Secor received a majority of all the votes cast, and therefore was duly elected. But it is a wonder he received any votes when there were 109 other men voted for, and when he plainly stated, when calling for votes for a new Manager, that he did not wish to serve any longer. Mr. Abbott's statement, that "the membership is not overly enthusiastic, to say the least, about having Mr. Secor as General Manager," is as ungenerous as it is unfair.

Regarding the Benton matter, while I once thought it might have had an influence, I am now in possession of facts that show conclusively that it had nothing to do with the case. If any of the members were prejudiced at all, it was because of the treatment Mr. Abbott, as Chairman of the Board, exhibited toward Mr. Secor.

Mr. Gilstrap—and a most excellent man he is—apparently saw only one side or a part of the other side. If he will withhold judgment until he receives a full statement, I think he will see the matter in a different light.

E. R. ROOR.

And thus endeth this controversy in these columns. We believe we have given both sides a fair and sufficient hearing. For us to use more space would be a waste; and the majority of our readers, not being members of the Association, care little about the trouble, anyway. Personally, we have refrained from taking sides in the public discussion, preferring not to meddle with either the Board of Managers or Mr. Abbott in the settlement of their difficulties. We still hope that everything may be amicably adjusted, and that all may continue to be friends and brothers as heretofore.

Mr. R. A. BURNETT, of R. A. Burnett & Co., is expecting to attend the Denver convention. Things will likely get warm when the question of selling comb honey by the case or pound comes up for discussion. "R. A." may be able to help "Burn-ett" into some of those conceited alfalfa boys, that "there are others."

Say, reader, if you want to see "A Hot Time" in Old Denver the first week in September, you'd better arrange for yourself and wife (or best girl, if so unfortunate as to have no wife) to "get aboard the train," and run up to Denver and help "liquefy" some of those candied apiarian Coloradoans!

Contributed Articles.

Does Not Think the Bees Were Poisoned.

BY C. P. DADANT.

The inquiry of a reader, on page 419, about the possibility of the poisoning of bees from spraying, attracts my attention.

It seems to me that the suspicions of the writer of this inquiry are based upon an erroneous impression. Fruit-bloom takes place early in May, and the loss of bees from bee-poisoning would be immediate. Even if the poison was fed to the brood, the bees would have shown the effects at once. The brood would have perished in its earliest stages, and the depopulation of the hive would have taken place more than a month earlier than the time reported.

The ragged-looking bees with frayed wings and shiny bodies are only old bees that have worn themselves out by continuous hard work. It is quite probable that in a wet season like the present, the labor of the field tells more upon the bees than in a dry summer. The worker-bee's life is short—exceedingly short—during the long summer days. The most practical method of testing this is by changing the breed—Italianizing, for instance. If an Italian queen is given to a colony of common bees and the black queen removed on May 1, there are ten chances to one that not a single black or common bee will be left in the hive by Aug. 1. In many instances it takes even less time. Yet, when the black queen is removed on the first of May, she leaves in the hive brood in all stages, and fresh-laid eggs which will require some 22 days to hatch. So the last black bees will have hatched May 22, and yet those bees will all have died by Aug. 1. When we reflect that those same bees, if they had been born Sept. 1, would have lasted till the following May—a part of them, at least—we must look for a cause of this short life. The cause is hard work.

After 8 to 10 days of sedentary life in May and June, the young bee begins its active work, and is constantly on the go from early daylight till long after sunset. At first it is covered with a thick down of hairs. Its wings are perfect. Slowly and steadily, by repeated flights among the grasses, in the calyx of flowers, it loses its downy fleece, and its body begins to shine, bald looking, the wings become worn, frayed and short, and some evening after a hard day's work the poor laborer is unable to reach its

home. Or, if it happens to get home with the last load, a light breeze on the next trip will force it down in the dust from which it will never rise. Thus, do our bees die out during the summer days. Nature is a harsh and inexorable mother.

If the queen is healthy, and there is room in plenty in the breeding combs, the numbers are not too much depleted by the natural wearing out of the old bees; but if the queen becomes tired, or is getting old, the laying may be reduced, and the colony will soon show a decrease of activity.

In some cases it may be that the colony has swarmed unknown to its owner, and not until the young queen has been fertilized, and her first-laid eggs begin to hatch, will the numbers increase in the hive.

I believe it is to these causes, and not to spraying poison, that your correspondent must ascribe the condition of the bees mentioned. "The sick bees have flown away." Yes, just so. The poor worker, when her wings get so frayed and so short from overwork that they can no longer carry her, does not seem to realize what is wrong, and still insists on going to work, and does fly away and drag herself till she falls exhausted in a ditch. She dies in the harness. She is to be praised, and yet pitied. There ought to be a time for bees, or for men, when the days of hard labor should be crowned with a few days of rest and enjoyment; but the bees, like some men, enjoy nothing but hard work, to the last minute of their life. Hancock Co., Ill.

Quoting the Honey Market.

(Continued from page 470.)

SELL HONEY THROUGH COMMISSION MEN.

EDITOR YORK:—I have sold honey extensively for the past 30 years on commission. From my knowledge of the business, and observation of the marketing of honey, if I were a bee-keeper I would place my product in the hands of a commission merchant to sell in preference to trying to sell to the "bargain hunters."

First, I would find a responsible commission merchant in a city of not less than 100,000 inhabitants—one who understood the grading and handling of honey, and had been engaged in it for a number of years, thereby having worked up a trade of regular customers that relied upon him for their yearly supplies.

Commission merchants in general lines of produce generally include honey in their price quotations, not so much expecting consignments of honey as to give general mar-

ket quotations on all kinds of country produce, which are not specific enough.

In every large city there are at least one or two commission merchants that make a specialty of honey-selling, who have a money-trade, and know how to handle, who know what grades their customers want, and can generally place honey at good prices; while some dealer next door, not generally known as a honey-dealer, can't sell unless at a slaughter price.

Commission merchants in honey are as indispensable to the honey-producer as commission merchants are to the manufacturer of cotton or woolen, and about all manufacturing industries. For their goods are nearly all sold by commission merchants that know the trade and the wants of it better than the manufacturers do.

As in all lines of business, there are irresponsible commission merchants that should be avoided, but it is a very easy matter to find out the responsibility after you have found a practical honey commission merchant. Go to any bank and ask them to give you the financial rating, which they can do in the mercantile agency book. There is no excuse in these days for shipping to irresponsible commission merchants.

It behooves a responsible commission merchant to do his best for a consignment, for it is on his consignments he has to depend for his supply of honey. It is quite impracticable for the commission merchant to-day to buy his needed supply of honey. He can not afford to spend his time traveling the country over to buy, and to buy by sample is generally unsatisfactory.

The honey-producer should not begrudge the commission merchant his small commission of 5 percent, which is usually well earned by the risk of credit the commission merchant has to give; the risk of delivery to his trade safely; the risk of turning out as represented or shown, and coming back after he has made account of sale to the owner, etc.

Regarding quotations being always reliable and sure, that is impossible, for quotations, although based on actual past sales, are somewhat problematical. Selling honey, like all other produce, is governed more or less by circumstances. Some buyers are more bearish than others. It is not always possible or practicable to hold to a rigid price, but many times a small concession is advisable rather than let a hard buyer go.

It is not wise to quote honey too high, nor too low; better err on the side of too high, for quotations are seen by the buyer as well as the producer, and it is extremely difficult to sell above quotations.

I would avoid consigning honey to any commission merchant not strictly commission, or who bought honey more or less, for it is quite according to nature for such to sell their own purchased honey to the most favorable customer and best-price-paying customer, to the exclusion of consignments on which they make only a small commission compared with the profit they are making on their purchased honey.

It is quite the custom for bee-keepers, and they take a natural pride in selling the finest selection of their honey at home, or to some "finicky" groceryman that sells but little at best. The bee-keeper often in this way lowers the average grade or quality of honey. He sends the balance of his crop to commission merchants late in the season, and is oftentimes disappointed in his returns.

In selling honey, unless you sell at home for cash before shipping, you take much more risk than by consigning. If you sell your honey delivered at a distant city, the buyer is apt to be fastidious, and if he sees the least sign of drip, or leaking, or out of condition, will refuse to accept it and pay for it; and if he doesn't pay you at all he can go into bankruptcy and pay you nothing. While, on the other hand, if you consign the honey, and the commission merchant doesn't pay, you can send him to jail for conversion of property. When you consign honey a good plan is to write promptly and ask the commission merchant to write you on receipt of the honey, the condition it arrives in, and what he thinks it will sell at; also to send you two-thirds to three-fourths of its market value as an advance on the consignment, which any responsible commission merchant will readily do.

There should be a better understanding prevailing between the honey-producer and the commission merchant than there is. I do not understand why any party would want you to quote markets incorrectly or under price, unless they want to use the quotation to help them buy cheap in the country.

The quotations of honey in the various markets that

you publish in the American Bee Journal must be a guide, and of great value to the many bee-beepers, in helping them to get a fair price from the home or country buyer. The fact that these quotations are made and signed by reliable dealers is more or less of a guaranty. Of course, the quotations must necessarily be somewhat expectant or prospective, and the prices governed by the supply and demand.

It would be a gross injustice, and entirely against the usage of trade, to quote honey less than market. Your market quotations signed by those who furnish them is evidence with the witness furnished, while quotations without the authors' names is evidence without the witness.

H. R. WRIGHT.

MARKET QUOTATIONS ARE FOR WHOLESALE.

EDITOR YORK:—We notice that in the closing paragraph of your editorial on page 195, that you invite some of us who quote the honey market in the columns of the American Bee Journal to help enlighten "Rip Van Winkle." It would seem that there is little for us to do, for you have made about as complete a setting forth of the other side of the question as can well be done. We think that by the time "Rip Van Winkle" has been 20 summers instead of two summers bee-keeping in Cook County he may change some of his ideas; if not, he might as well "take another sleep," and that, of course, might be considered selfish, as it would tend to give the commission man a rest. But there is just about as much rest for the commission man as there is for the honey-bee when the flow of nectar is on. He must be "up and doing," or the labors of all concerned will fail to bear the fruitage that they should.

We do not know that that side of our life has been presented of late in any of the bee-papers, so we will call the attention of those who send goods to be cared for, that the commission merchant in the summer-time is at his place of business at 5 o'clock, and he does well to get away by 6 or 7 o'clock in the evening. For many years the writer kept up this pace, but now is not to be found on duty quite so early, nor always quite so late, still some one else has to represent him who has reached the maturer years. We find that the old do not run as many miles in a day in rounding up the affairs intrusted to him, but he often accomplishes as much by the short cuts that he has learned by careful attention to each day's experience, and thus he may be able to work out in 10 hours quite as good results as he did formerly in 18, by aiding others younger with counsel, so that in 9 or 10 hours he has accomplished a full day's work, and is entitled to the rest and recreation that a fairly well-spent life deserves.

Beginning with November the hours of the labor day gradually shorten until about 6:30 or 7 is as early as most of the stores open, but with April they begin to open at 5 to 6 o'clock in the morning for continuance during the summer.

The prices given at the request of the editors of the various bee-papers are for the figures obtainable for honey in the wholesale way, and not for honey retailed by the case or single package. There is in the Chicago market, as in all other cities, wholesale dealers, some known as receivers and others as jobbers; the receiver is supposed, in selling to a jobber, to get the market value of goods in lots, the jobber or wholesaler, on the other hand, varies his profits by the amounts taken by the purchaser, as a man buying a case of honey would not buy it quite as cheap as a man buying 25 or 100 cases would—there would be a difference of anywhere from $\frac{1}{4}$ cent to 1 cent per pound, according to the nature of the goods and trade.

Now, there are quite a number of so-called wholesalers who buy from receivers in the manner already described, and peddle it out as best they can from $\frac{1}{4}$ to 1 cent per pound profit, and their asking price is hardly ever their selling price, so that any one going along the market and pricing stuff is almost certain to get the extreme figures given in reply to his question; but if he is a bonafide buyer he will soon impress the salesman with that fact, and by practicing the usual diplomacy will succeed in purchasing for a little less than the original figure given (especially if the would-be buyer and the salesman are strangers to each other), for the day of bartering and haggling over prices has not yet become obsolete in the produce markets, while to a large extent it has done so on the more permanent articles of trade, or those that are less liable to perish if not sold within a very short time after they have been placed on the market. A great many people find fault and say that the price asked should be the price that the seller is willing to take. In the abstract we quite agree with this proposition, but if we wish to live in the practical, every-

day world we must conform somewhat to the customs that prevail in our surroundings.

You give utterance to a well demonstrated fact, that it is better to be a little lower in the quotations given than a little higher than the actual conditions warrant, for these quotations are supposed to be given as a guide for those who have produce to place upon the market. It is the desire always of the commission merchant to quote as high as he dares (and sometimes he dares a little too much), for it is only natural, as society is now organized, that he should seek to get the goods to sell. It is much pleasanter to receive a letter from a consignor which reads: "You got for us the full market price for what we sent you," or, "You got us more than the market price," than it is to get a letter saying, "You did not get us even the market price, but a good deal less, and we don't think you have treated us right; we shall write to the bee-papers and tell them just what you are doing."

Now, the commission merchant's skin is not thicker than that on the alligator's back; therefore, an impression of a painful nature is sometimes made upon it, and by experience he learns (that is, if he wishes to become wise) to avoid as many of the disagreeable things as possible. For ourselves, we may say that we frequently discourage would-be consignors from sending us their product when we find that they think their goods should bring a little more than the quotations.

Very truly yours,

R. A. BURNETT & Co.

THE FACTS AS THEY ARE.

On page 195, we note the article from Rip Van Winkle, on "Quoting the Honey Market." Even if we are outside of the Chicago market we take exceptions to his statements, simply for the sake of truth and justice. The writer of that article certainly selected a fit name, when he signed himself "Rip Van Winkle," admitting thereby that he has been asleep for years, and is utterly ignorant of present conditions of commerce and trade. Furthermore, the man who is afraid to attach his name to any statement he makes, lacks the courage of his own convictions, and can hardly be taken seriously.

We endorse most emphatically every word of Editor York's reply, and especially where he says, "*It is better to quote a cent lower rather than a cent above the market.*" Exactly *this* has been our rule ever since we have been in the business, and the same has been generally appreciated by shippers.

The quotations we give in the journals are the market value, or, in other words, the selling price in quantity lots. In a small way, single cases or so, here and there, a better price is obtained, while, in a jobbing way, the price quoted is sometimes shaded in order to effect sale. This must be left to the seller's discretion and judgment. He is on the spot and must size up his customers, take into consideration the condition of the market, demand, supply, stocks on hand, etc.

If the market is well stocked, with more supply to follow, demand not brisk, and indications pointing towards a decline in price, the commission man is justified in making concessions; in fact, it is his *duty* to close out at a fair value, rather than to hold the honey and take still less later on.

We have had shippers write us that other parties had quoted better prices than ourselves, and wanted to know why we, being in the honey-business, could not do as well, or even better. We would answer that we could not conscientiously quote higher prices than we felt safe we could realize, and if they could do better elsewhere *that* was the place to ship to. Thus, we lost some shippers for a season or two, but invariably they would come back to us, and oftentimes admitted that they had made a mistake.

Again, if the market is overstocked with a certain grade, and no demand, we advise NOT TO SHIP; that we could not see our way clear to meet the shipper's expectations, and, rather than have complaints afterwards, we preferred not to handle the goods. If we quote, for instance, fancy white honey at 14 cents a pound, we feel confident that we can realize that price, and shippers can depend that returns will be made accordingly, provided, however, that the shipment comes up to the standard rules of grading. Quite often we receive honey marked fancy and No. 1, which is really no more than No. 2, or amber, to say nothing of the careless and slovenly way in which the honey is put up.

Only recently we received 14 cases of honey packed in two large dry-goods cases, no caution marks, and, consequently, they were handled rather roughly in transit.

They appeared to be in good order, and we signed for them that way when we received them from the railroad company. In opening the cases there was not a whole comb in the lot. The straw had absorbed part of the leakage, and the heavy wood prevented it from oozing through the case. In notifying and explaining to the shipper, our trouble began, though it was wholly his own fault. Such cases are a tedious and thankless job, but we are glad to say that they are few with us.

Rip Van Winkle further says: "The commission man has the honey-producers in his grip, more especially when he is a buyer as well as a commission man;" and, "A buyer is always a 'bear' on the market." Rip Van Winkle does not seem to be aware of the fact that most bee keepers prefer to sell rather than to consign, which is but natural. If a bee-keeper sells his crop he knows exactly what he gets, and if the buyers are not willing to pay his price he is not compelled to take their offer. If he sells his honey his responsibility ends, and his chances end at once, whereas the buyer takes all the chances himself, and it is also but natural that he should want to buy as low as possible; but even if he thinks he has made a good purchase he is far from being sure of a profit.

Of all the honey we handle the most of it we buy outright. We know the shippers know how to grade their honey, and how they put it up, and we have no trouble in agreeing on prices.

Rip Van Winkle is absolutely wrong when he says commission men have the producers in their grip. The bee-keeper who has his honey in good shape will find no trouble in selling it. If one buyer will not pay him what he considers fair value, others will. The buyer knows he can not buy his honey for a song, and will not dare to make him any ridiculously low offer, for fear that some of his competitors will pay a better price; and, if he wants the honey he will pay fair market value for it. We have bee-keepers in New York State whose crop we have bought ever since we have been in business without a break. They are not "small fry," either, but generally come down with a good-sized crop, and one year brought to New York over 4000 cases. *They never even try another market*, knowing that they will always find us willing to pay fair value, and evidently they are well satisfied for us to have them "*in our grip.*"

On the other hand, there are some producers who are laboring under the delusion that *no other* honey is as good as *theirs*, no matter how inferior their own may be, and these are rather hard customers to deal with, especially so when they want to buy a few cases *themselves*. *These* are the ones who want to buy a single case or can at the *lowest quotations*, and even *less*, because they are *bee-keepers themselves*.

A bee-keeper wrote us the other day (seeing that we had new crop Cuban comb honey), that he would like to have a few cases, and offered us 10 cents (which was all he could pay), or 9½ cents for a full carrier; that he was an apiarist who was not going to pay Cuban apiarists fancy prices to the detriment of home apiculture. We refused his liberal (!) offer, having no intention of slaughtering the honey for his benefit.

No doubt some bee-keepers will disagree with us, but, their opinion to the contrary notwithstanding, we have given the facts as they actually are.

HV. SEGELKEN, of Hildreth & Segelken.

Only One Night to Denver.—By going over the Chicago & North-Western and Union Pacific railways, you will need to spend only one night on the road from Chicago to Denver. There is a daily train leaving Chicago at 10 a.m. on the C. & N. W., and leaving Omaha, Nebr., over the Union Pacific at 11:30 p.m. of the same day. This train arrives in Denver at 2 p.m. the following day. That is, by starting from Chicago at 10 a.m. on Tuesday, Sept. 2, you will arrive in Denver at 2 p.m. the next day, or Wednesday, Sept. 3, in ample time for the first session of the National Bee-Keepers' convention, which begins that evening.

Now as to rates: The round-trip price at that time from Chicago to Denver will be \$25. By going over the route mentioned, the regular sleeping-car rate would be only \$3.00, because of being only one night on the way.

There is also another saving by taking the C. & N. W. and Union Pacific. There is a Pullman tourist car on this train from Omaha, in which the charge for a double berth is only \$1.50 to Denver. As no sleeping-car accommodations are required on this train east of Omaha, it will be seen that one can go comfortably by this route for a very small sum.

We may say that Dr. C. C. Miller and the Editor of the American Bee Journal expect to go over the route indicated, starting at 10 a.m. on Tuesday, Sept. 2. Who will join us?

Questions and Answers.

CONDUCTED BY

DR. O. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Cross Colony of Bees.

I have a colony of bees that are so cross that I cannot handle them. They seem to be very lawless in other respects, such as building comb on top of the frames, and will not go up into the super. What is the best way to fix them?
ILLINOIS.

ANSWER.—Change the queen. One would think that would only make the bees good-natured after all the bees of the old queen had died off, but I have found that when the queen of a very cross colony was replaced, there seemed to be a change in the temper of the colony in a very few days.

Saving Virgin Queens for Future Use.

I am just a beginner in the bee-business and would like to know how to save queens for the future, and keep them alive and have them fertilized at the same time. I had two nice queens from one I got last summer, but I could not save them, so if there is any way I wish you would tell me.
MICHIGAN.

ANSWER.—The only way to save virgin queens and have them fertilized is to keep them in separate nuclei quite small by having division-boards in a hive, and keeping two or more nuclei in the same hive, so they can be mutually helpful in keeping up the heat. I have had as many as six nuclei in a 10-frame hive.

Why So Many Bachelor Bee-Keepers?

I have been greatly interested in reading the "Questions and Answers" in the American Bee Journal, but there is one question I would like to have answered, namely: Why are there so many bachelor bee-keepers? IOWA.

ANSWER.—Are there any more among bee-keepers than among other people? Perhaps bee-keeping is such an interesting pursuit that a young man is too much taken up with it to give attention to the little matter of looking for a wife, and then after he gets old enough to be on the list of old bachelors the law does not allow him to be killed. After all, I don't know that I'd want them killed off; there are some first-rate fellows among them.—[We thought it was because they were so taken up with their queens!—EDITOR.]

Did Well for a Backward Spring—Balling Queens.

1. I have run across something in handling bees that puzzles me. I set 5 colonies out in April, and they did splendidly, and by May 15 were strong enough to make 3 more new colonies, so I sent and got 2 golden and one red clover queen. All proved to be fine queens. The bees of one of the golden queens have stored about two 10 frame, shallow extracting supers up to the present date. The red clover queen's bees have stored one shallow super full and one comb-honey super one-half full. Now I would like to know what you think about this for this backward spring? Is that doing well, or just fair?

2. When I opened the hive of one of the golden queens last week I found the bees balling her. I took her away from them and caged her, and took 2 frames of brood and bees from the hive and started a nucleus with her. Did I do right or not?

I found one of the old colonies with the old queen doing the same, and when I smoked the ball they stung the queen and she died. What made the bees ball the queen? and why did they sting the queen? They had not started any queen-cells when they balled her.
MINNESOTA.

ANSWERS.—1. For a backward spring that is doing remarkably well.

2. If I understand correctly, the queen had been in the colony a good many days, in which case you went to unnecessary trouble. When I have opened a hive I have in a number of cases had the bees ball their own queen. In every case I have closed up the hive as quickly and quietly as possible, and when I have opened it on a later day have found the queen all right. When you opened the hive the bees were alarmed and balled the queen to protect her; at least that is the way it seems. When you smoked the ball, the probability is that you blew hot smoke upon them. Hot smoke will make a ball of bees sting a queen, whereas if let alone it is a very rare thing for a queen to be stung. Even when the bees feel the most bitter against a queen they do not sting her, but keep her in the ball till she dies of exhaustion or starvation.

Requeening.

In clipping my queen's wings I lost one; I have twice given the colony a frame containing eggs, larva and brood, hoping that they would rear a queen, but they have not met my wishes. The colony has been queenless a month. Can I requeen that colony? and, if that can be done, how shall I proceed to accomplish it?
IDAHO.

ANSWER.—Perhaps the best thing is to break up the colony, dividing the brood and bees among weaker colonies. If, however, you are anxious to continue the existence of that particular colony, give it some brood and bees from other colonies and then give it a caged queen.

Moving Bees on a Wagon.

I have 40 colonies of bees that I must move this fall a distance of 20 miles. Please advise me how to prepare them for the journey, over an ordinary wagon-road, about what time to start, and how I should fix the wagon on which I move them.
IOWA.

ANSWER.—Better wait till the weather is pretty cold, but the weather should not be freezing very hard lest the combs become brittle and break. Close the hives bee-tight, but provide for plenty of ventilation. If your bottom-boards give an entrance two inches deep, all the ventilation needed in cool weather is to have the entrance closed with wire-cloth. If the entrance to your hive is very small, it is better to have the top of each hive entirely covered with wire cloth, a frame to fit the top of the hive being covered with it. The easiest available thing for you, in the absence of something specially made for the purpose, is to use a wagon with a common hay-rack. Put a foot or so of straw or hay on the bottom of the rack to break the force of the hard jolts. Possibly you can borrow a pair of heavy springs that can be put under a hay-rack.

Swarming Difficulties.

I have some bees that have knocked all the theories that I can find in two bee-books into a cocked hat, and I want to know if you will put a little of your bee-philosophy on it through the columns of the American Bee Journal.

Wednesday, July 2, a prime swarm issued from hive No. 4, and settled where we had to let it go. Monday, July 7 (5 days after) a second swarm issued but returned to the hive; 6:30 a.m. Tuesday it issued again, and again returned; 10:30 a.m. Tuesday it issued the third time and settled. I got them well hived and contented all but a "hat full," which I supposed would go back to the new hive on the old stand. But they fooled me. Tuesday night there was a hard wind and rain. Wednesday, more rain, and hat full still in tree. Thursday, rain and bees still in tree. I concluded to capture them (thinking they must have a queen also), and put them in an observation hive. I fixed this with an empty brood-comb into which I poured some honey-syrup for bait. I shook apparently all the bees into a bag and thence into the hive; but no queen. Some clustered again and were shaken off a second time, and into the hive. At this point I got tired and have left them alone to do as they wish.

The present state (12 m. Friday, July 11) is: Main swarm—contented in hive; in observation hive—handful left and very restless; no queen. In tree—(75 hours)—same old hat full in same old place.

Now what I want to know is:

1. Why did this second swarm issue in five and six days

after the prime swarm, when, according to text-books, no well-brought-up bees should have a queen for at least seven days?

2. Do second swarms ever have two queens? and does that account for those remaining in the tree?

3. What is the record of time for bees hanging in a cluster?

I intend to give the bees in the observation hive a comb of brood with a queen-cell, but—

4. In case I didn't, what would the bees do? and what are they staying for, anyway, without a queen?

ILLINOIS.

ANSWERS.—1. A second swarm issues about eight days after the issuing of the prime swarm, because about that time the young queen is mature enough to leave. If, however, for any reason the issuing of the prime swarm is delayed, then the time between first and second swarm will be shorter. The first swarm may be delayed by the weather two or three days, possibly by some other cause, and in that case the second swarm will issue at just the same time it would have issued if there had been no delay on the part of the first swarm. Of course, that will reduce the length of time between the two swarms. Indeed, it is possible that there might be an interval of only a day or two between the issuing of the first and second swarms. The old queen might be too heavy to fly at first, or she might be utterly unable to fly, as in the case of a clipped queen. So the swarm could only return when it issued, and come out again, and if you did not happen to see it issue except the last time, you might think there was only a day or two between the prime and second swarms.

2. Yes, second swarms sometimes have a good deal more than two queens, and it would not be a hard thing for part of the swarm to be separated from the rest with one of the queens.

3. I don't know. I never knew a cluster to hang more than two weeks, and that was a very small cluster without a queen. A stray swarm was hanging on a tree one day when I was driving to an out-apiary. The swarm was small and of no great value, but the owner of the tree was rather insistent that we should take the swarm away. My assistant took it in her bee-hat to the out-apiary. On our return home we found a small cluster still on the limb. They had probably been out foraging when we took the swarm away. I think the little cluster staid and dwindled away.

4. Those bees on the tree may have a queen, and having been kept there by stress of weather so long, they may have become reconciled to the situation, and if left alone they may remain there all summer.

When to Sow Sweet Clover Seed.

When is the best time to sow sweet clover as a honey-plant for 1903? MICHIGAN.

ANSWER.—Sow sweet clover when other clover is sowed in your locality. Probably most sweet clover is sown in early spring, at about the time for sowing oats, but if convenient it might be well to sow in the fall and have it well tramped in. But if you want sweet clover to yield nectar in 1903, you must sow it right away, immediately, quick, so as to have it grow this year. Doubtful whether you can get it to do that. It does not blossom till the second year of its growth, and the winter after blossoming it dies root and branch.

A Vermonter's Seven Questions.

1. Do you prefer golden, leather-colored, red clover, or honey queens, for honey-production?

2. Do you prefer Danzenbaker or Langstroth hives for comb-honey production?

3. Would a queen bred in Texas do as well in northern Vermont as a northern bred queen?

4. Which do you think would be more profitable here, comb or extracted honey?

5. Is it necessary to put on perforated-zinc honey-boards between the super and the hive for comb honey?

6. Do you clip your queen?

7. How do you get your bees ready for winter?

VERMONT.

ANSWERS.—1. I prefer the queens that will assure me the greatest profit, under whatever name or garb they may appear. It is not easy to answer your question categorically, for what may be best in one place may not be the best

in every other place. I like much the appearance of the goldens, but the ones I have had have not excelled others in storing. All goldens, however, may not be alike. Leather-colored and their grades have given excellent satisfaction. The term "red-clover queen" has been used as applying to different strains, and I am not sure I can say very definitely just how much bees have ever done for me on red clover. Honey-queens, as already intimated, are my preference, if by that term is meant bees that give best results in the long run. But between you and me, I suppose there is a lot I haven't yet learned about such things.

2. I prefer the Langstroth.

3. I think the general testimony is that she will do just as well, although one might naturally expect a little more hardiness in bees bred for a long time in the severer climate.

4. As a rule, probably comb, although the right man and the right management might make the most out of extracted.

5. It is not necessary in this locality when separators are used and full sheets of foundation in sections.

6. Always.

7. I don't get them ready. They are carried into the cellar, cover, bottom and all, just as they were on the summer stand. Some time, however, before it is time to take in cellar, the false bottom has been removed from each hive, leaving a space two inches deep under the bottom-bars.

Bees Visiting Out-Houses and a Planing-Mill.

1. What will keep the bees from visiting out-houses? and what do they go there for? I keep the weeds and grass from the hive fronts by sowing salt, but still a few bees visit the out-house; I do not know why they go.

2. My bees in early spring made trouble at the planing-mill, which is some 4 or 5 blocks away. What can be used or done to cause them to stay away? IOWA.

ANSWERS.—1. It is generally supposed that they go for the salts to be found in such places, but it is not certain that such is the right view. It is not disproved, however, by the fact that all the salt needed lies in front of the hive. Set a dish of water at the entrance, and you will still find some bees going off a distance to get water. Perhaps you might try giving the bees a watering-place where they could at all times find water somewhat salty. You see, the salt in front of the hives is wet only part of the time, and dry salt would hardly answer.

2. In early spring, bees quite often gather sawdust as a substitute for pollen. Give them something better to work on, as ground corn and oats or other feed.

White-Eyed Drones—Queen-Excluders on in Winter.

1. To what race of bees do white-eyed drones belong? I have never seen any drones with white eyes before. I saw the first one about 5 weeks ago—found him in the yard, then I watched every hive but could not find any more, but in a few days I noticed two in front of one hive, then more and more, but only in the one hive. This colony is extra-strong, and is storing lots of honey in the third story, keeping ahead of 18 other colonies.

2. Can I leave a queen-excluder over an 8-frame lower brood-chamber all winter? or must it be taken away? My hives are all two-story 16-frame during the winter, and I would like to leave the queen-excluder on during the winter, if possible. KANSAS.

ANSWERS.—1. To no particular race. Drones with heads of unusual coloring may occasionally be found among bees of any kind. Just why drones should be tricked out in fantastic colors, and never workers, seems to have no satisfactory explanation.

2. Certainly, there is no reason why you can not leave excluders on all winter. Don't be afraid to ask all the questions you like. That's what this department is for.

Trouble in Introducing a Queen—Feeding Bees.

1. I received a red clover queen but the bees do not want to accept her. They started a lot of queen-cells, and when the candy was taken out they wanted to kill the queen. What can I do with her?

2. I am taking care of bees of a man 5 miles from here, and the grass-hoppers have taken all the bloom from the

alfalfa so that the bees must be fed. While I can't get honey what shall I feed them? and how? SOUTH DAKOTA.

ANSWERS.—1. Keep the queen caged; take two frames of brood and bees from the queenless colony and put them in an empty hive on a new stand; after they have stood there 24 hours give them the caged queen and at the end of another 24 hours free her, when you will probably find that the bees will treat her kindly. In the meantime all the queens-cells should have been destroyed in the colony and in the nucleus. As soon as the queen is kindly received by the nucleus, return nucleus, queen and all to the colony. Another way, a little more troublesome, is absolutely safe. Take frames of sealed brood with young bees just emerging, shut them in a hive bee-tight, first putting the queen on the brood. Keep the hive in the house where it is warm if the weather is at all cool, or else place the hive over a colony of bees with wire-cloth between, so that there is no possibility of a bee getting from one hive to the other. In five days

the hive may be set on a stand of its own and the entrance opened, and then you can strengthen it gradually from the queenless colony or from other colonies, the same as you would strengthen any weak colony. It is possible that when you first gave the queen to the queenless colony it was at a time when no honey was coming in. If so, it would have helped matters to have fed the colony.

Feed them granulated sugar. The most convenient way is perhaps with a Miller feeder, taking equal parts of sugar and water (either by weight or by measure). If you have no feeder, use the crock-and-plate plan. Take a gallon stone crock and put into it equal parts of sugar and water stirred together. Lay over the crock a woolen cloth of five or six thicknesses of cheese-cloth. On this put a dinner-plate upside down. With one hand on the plate and the other under the crock, quickly turn the whole thing over. Set it on top of the frames, put over it an empty hive-body, covering it up so no bee can get in except through the colony, and the bees will do the rest.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy... 3.00			

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Quirin the Queen-Breeder,

PARKERTOWN, OHIO.

Transferring Bees.

To transfer bees in midsummer I don't think a better method can be devised than to drum the bees into a box, set the new hive, filled with worker-combs, or full sheets of foundation, on the old stand; place a queen-excluding zinc on the new hive; over this place the old box, in three-week's time slip a bee-escape board under the box, and when the bees have all gone down, take the box off. It will then have nothing but the combs and what honey may be in the comb, no bees to mash, no brood to kill, and all the brood hatched out and added to the hive's army of workers.

The foregoing is given by E. H. Schaeffe in the American Bee-Keeper. There is a possibility of misunderstanding on account of the repetition of the word "box" which after the first time has reference to the old hive. The understanding is that after the old hive has been placed on the top of the new one, the bees are run from the drumming-box into the new hive.

Bee-Keeping in the Sandwich Islands.

On the island of Oahu, the greater part of the honey is produced. There are two large corporations there; one is incorporated for \$65,000 paid up capital, with a bee-privilege of 75,000 acres. They produce a large amount of honey and ship mostly to London. The other is not quite so large, but they produce and handle a lot. There are quite a number of persons, both white and Japanese, also in the business. The bees are imported Italians and, of course, hybrids, as well. The wild bees (of which there are a large quantity on the islands) are black or German brown bees.

Our honey-source, that is, the best quality (light amber) comes from the kauvi or algeroba, which blooms more or less nine months in the year, and the honey is fine-flavored. There are also a great many weeds and much lantana, which gives a dark honey at certain seasons.

On Hawaii, 150 miles, a little south of east, from Oahu, the principal honey district is Koua, situated on the southern or lee side of the island, sheltered from the strong north-east trades, but having a cool land-breeze at night, while during the daytime the breeze comes from the sea. There are lots of Japs in the business and they make 10-frame hive out of anything that comes along, from a coal-oil box to a 2-inch plank, and also use Hoffman frames.

The Japs thought all they had to do was to get a hive of bees, put a super on, and when

the super was full ent the honey out and squeeze out by hand, then sit down and eat and smoke till the super was full again; but most of them found to their sorrow that that was a losing game; and now there are only a few who have stayed with it and got extractors, etc. I know of two who run 200 colonies and understand the business quite well; although one cannot impress upon them the necessity of getting good queens—any queen is good enough for them.—H. H. SMYTH, in the American Bee-Keeper.

Fastening Foundation in Sections.

For this purpose it is a paying investment to have a good machine such as the Daisy foundation fastener; but some with a very small number of sections may care to know the plan given by G. F. Herman, in the American Bee-Keeper:

For this purpose we use a board with four blocks nailed on it, 1/4 of an inch thick by 3 3/4 inches square. This size is for the standard section which holds about one pound of honey. When we pick up four sections at one time and place them over the four blocks. The sections being on their edge, lay in the one-inch starters, or full sheets, just as preferred. The blocks bring the starters just midway in the sections.

We next dip the piece of tin into the heated wax and touch the starter and sections at the uniting point, holding the starter in place with the left hand, withdrawing the piece of tin instantly, as it only requires a touch and the work is done. If full sheets are used we dip twice, touching the top and one side and leaving one side and the bottom loose for expansion.

The size of the piece of tin used in the operation is 3 3/8 by 5 inches with a perfectly straight edge. The receptacle to hold the heated wax is a small sardine-box 2 3/4 by 4 inches, kept about one-third full of wax and placed over a small hand lamp with a tin chimney, having the top nipped in a little and then bent out to form a crown which will give vent to the burning lamp when the pan of wax is placed on top.

Comb Honey and Excluders.

Some say that in producing section honey excluders are unnecessary; others say that without them the queen is sure to lay in the sections. M. F. Reeve having said in the American Bee-Keeper that excluders were indispensable, Dr. Miller replies in that journal:

For a long time it puzzled me to understand how there could be the difference, but I think I have solved the mystery. Nowadays there is little or no drone-comb left in the brood-chamber, and the bees make desperate efforts to secure drone-brood. More than once, when using 10-frame hives, I have known the queen to go outside the brood-nest and lay eggs in a patch of drone-comb, leaving one or two combs without any brood between this patch of drone-brood and the worker-brood of the brood-nest. You will notice that Mr. Reeve especially mentions that in his supers he found "the nicest lot of capped drone-cells." I am not certain whether this was in working for comb or extracted honey, and it doesn't matter; he says at the outset that excluders are necessary for either. If I am not greatly mistaken the queen goes into the super to lay because the workers have there prepared drone-cells for her.

If they go up into his supers to rear drone-brood, why don't they do the same thing for me? Simply because there are no drone-cells in mine to bait the queen up. I use top and bottom starters of worker foundation, filling the sections entirely full. If I should use small starters I would consider excluders indispensable.

I would not think of working for extracted honey without excluders, for even if only worker-comb should be in the supers there would be at least part of the time empty comb there, and whenever the queen should be a little crowded for room she might find her way up. When working for comb honey, I

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

—BEST—

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

Queens Now Ready to Supply by Return Mail

should want excluders, unless there was so much drone-comb in the brood-chamber that there would be no desire to have any elsewhere, or unless the sections were so filled with worker foundation that there was no chance for drone-comb above.

Pretty Good Sweet Clover Flow.

We have had bad weather throughout June. The bees were starving the last part of June, and the first part of July I fed 360 pounds of honey to my bees. The last 10 days there has been a pretty good honey-flow from sweet clover.

JOHN EENIGENBURG.

Cook Co., Ill., July 18.

Thinks Minnesota all Right.

Bees are doing well in my locality. I have 2 hives with about 150 pounds on each, and others with from 100 pounds down to 25 pounds, and lots to come yet, as we have a good honey-yield in this locality in the fall.

I am sorry to hear of so many failures in other States. I think Minnesota is all right.

P. H. DAVIS.

Hennepin Co., Minn., July 17.

An Old Beginner's Report.

I am a beginner in the bee-business. I found a colony in a tree last October and wintered them; they were Italians. This spring I traded and got 6 colonies of blacks, and in old hives with racks, but the combs were in every shape. I transferred them into new hives which I made, and in 3 weeks I divided 2 of the colonies, and put 3 frames of brood and adhering bees into a hive and 3 frames of brood foundation, on May 28, and on July 9 they cast a nice swarm, and I hived them on brood foundation. The Italians cast their first swarm July 4, and to-day, when they swarmed out the air was alive with them for about 20 minutes, then they returned to the old hive that they issued from, and went to work as usual.

My bees are doing well this month, so far: white clover is in profusion here, the most for a great many years. It has been very warm for 2 weeks or so, with occasional rains. One of the old colonies that I divided cast a swarm July 11, so now I have 10 colonies, and I sold one.

To-day I hived 2 more swarms; one was a second from the Italians, and they came out again yesterday about 3 o'clock, and after a while they returned to the old colony from which they issued; this morning they came out and settled on a small birch and I hived them.

D. B. BOYNTON.

Oxford Co., Maine, July 14.

Too Much Wet Weather.

My bees are doing fairly well. There is an abundance of white clover this year, but the weather has been unfavorable, too many dark, wet and windy days, but when we do have a nice day the bees fairly make things hum.

Last year I got 825 pounds of honey, mostly extracted, from 5 colonies, spring count, and increased to 8 colonies. I thought that was doing pretty well for a greenhorn.

I will send you a report of this year's crop later on.

G. GLESTEN.

Sioux Co., Iowa, July 19.

Heavy Rainfalls and Washouts.

During July, so far, we have had a little good weather, and so our bees have secured a small amount of surplus honey. But now the season has closed.

Within 10 miles of us some of the friends have secured a large crop, so I hear. Basswood was not frozen in these localities.

□ I established a small yard about 14 miles

north of me, for an experiment. If I had been there with my home yard I undoubtedly would have made a nice thing, but as it is I did not know just what was going on, and lost some by neglect in this yard of 15 colonies.

The quality of our honey is very good, in fact it is better than I have ever had, in this section, except during 1881.

We still have a deal of rain, more than we have sunshine, but it is warm.

You have probably heard of the immense waterfalls in New York State. We have suffered greatly from washouts here, some of our crops being seriously damaged; roads have been torn out, and bridges washed away. Between my home and the out yard north of me (mentioned above), 8 or 10 bridges were washed out; the roads last Monday (July 7) were almost impassable, in some places entirely so. Our little town is damaged in roads and bridges not less than \$6,000. A few farms have been completely ruined; some stock and a few lives were lost. F. GREINER.
Ontario Co., N. Y., July 12.

Report of White Honey Crop.

As I am anxious to know how the honey crop is in other places, I thought best to report for this location. I had 78 colonies in the spring, increased to 112, have taken off 2,500 pounds of honey and think there is 1,500 pounds on the hives now.

The season was cold up to the first of July, except during apple-blossom, when we had a few warm days. White clover is the main honey-plant here, as the basswood has been nearly all cut down. D. L. FILES.
Monroe Co., New York, July 21.

Poorest Prospects in Years.

The prospects for a honey crop in San Diego County are the poorest they have been for a number of years, but I think the bees will go through the winter without feeding.

We have had cold and dry, and hot and dry, so the results of honey-secretion are bad, although the flowers were in a fine, healthy condition. MAYNARD D. NICHOLS.
San Diego Co., Calif., July 17.

Hot and Dry in Texas.

Bees in this section are not doing very much. We have had hot, dry winds that have dried up all the nectar. I have been feeding my bees for two months, but since the rains all vegetation has commenced growing, and bees will store until frost.

Mrs. C. R. WEST.
Ellis Co., Texas, July 14.

A Handshake for Dr. Gallup.

Dr. Gallup, here is my hand—shake. You have voiced my sentiments in full, and to the letter. I have read your series of articles on queen-rearing with great interest, and they are so closely in touch with my experience that I fully endorse every word.

I have bought many queens that I well know were reared by small swarms or nuclei, as they were of no value whatever, and some were superseded within two months after being received.

I would like to hear your impressions of some of the other fads, as long tongues, for instance; also as to the exactness of spreading frames to 1 3/4 inches from center to center; but more particularly the long tongues.

Give me queens reared at home, in full, strong colonies, under the swarming impulse, and I will compare notes with any and all, both long-tongued men and bees. This may look a little strong to some of the queen-breeders, but perhaps the "truth should be spoken at all times."

All my short-tongued bees did nothing until July 2, and were starving June 25 and 27. Why? Because there was nothing in the flowers to get, and if there had been they could not get out to get it, as it rained almost every day and night, and was so cold the entire month of June. On July 2 they commenced to roar, and have kept it up to the present time, and are now commencing in the

QUEENS!

Please mention Bee Journal when writing advertisers.

supers. I am inclined to believe the long-tongued bees have not done much better.

I had four swarms in May, and nothing since. A. Y. BALDWIN.

DeKalb Co., Ill., July 14.

Cold, Wet, and Windy.

I have said that nothing short of an earthquake swallowing up all of Sioux County would keep my family and me away from Denver, in September; but too much cold, too much wet, too much wind, and a whole lot of other "too muches" may make me change my mind yet, though I will not give up until the last minute.

May was cold, but the bees built up fairly well; June was windy, cool, cold, colder, and fairly dry, for the first half, and the remainder was wet, wet, wet, and it appears to be getting wetter all the time. The bees work well when a few hours of suitable weather shows up. Pasturage could not be better, but the weather—O my!

You should have seen me "spreading" myself early June 26, after the tornado had spread itself, and somewhat, well, considerably, spread the bees and bee-hives. The bees got such a "jouncing" (and it wasn't any of Rambler's make-up, either) and soaking that they made very little trouble while I was straightening things up. Broken trees, chimneys, windmills, and an occasional building, were common. F. W. HALL.
Sioux Co., Iowa, July 8.

Bees Hustling.

Bees are booming now and swarming at a fearful rate. We are getting from 10 to 15 swarms a day, and no stop to it. Some of the colonies gained from 5 to 10 pounds in weight per day, so prospects are grand at present. If the weather would keep hot and dry for about two weeks we would have 100 pounds per colony. I hope it will be so.

Cook Co., Ill., July 12. A. WICHERTS.

Hard Year on Bees.

This is a hard year on the bees; such unfavorable weather, all of the earliest young queens lost in mating. Honey will be a very light crop in this section, although there has been an abundance of nectar.

I have 92 colonies, and about one-half the amount of honey I had last year with 80 colonies. C. H. HARLAN.
Kanabec Co., Minn., July 15.

Average Crop of Honey.

My bees have stored an average surplus up this date. The white honey harvest is completed in this locality.

I use a horizontally divisible brood-chamber, and shall, as usual, put the supers containing unfinished sections between the upper and lower parts of the brood-chamber. The bees will, in most years, finish them from the fall honey-flow.

I suppose all the "covention" that we small fry bee-keepers will enjoy this year is the talk we may indulge in near the honey exhibits at State and County fairs.

P. O. WESTRUM.
Hamilton Co., Iowa, July 21.

Expected Crop Failed to Appear.

They say in California the unexpected is ever popping up, like Banquo's ghost. This is exemplified in the present season's honey crop. I have often praised California as a honey State, or the paradise of the bee-keeper, because he could divine at the beginning of each season, knowing the rainfall, whether or not a honey harvest would be realized, and thus make, or not make, all due preparation. I must say now that this, like all rules, has its exception. From the rainfall, we had every reason to expect a splendid honey harvest this season. The early promise was fine, and I made what I thought was a safe prediction of a very generous harvest. The results are severely disappointing.

About here we have done better than in

144 & 146 Erie Street, CHICAGO, ILL.

most places, but even here the crop is light, not more, surely, than one-third or one-half that of last year. In some of our best honey sections, like parts of Riverside County, or about Perris, there is no crop at all. I think the cause of this is in the cold weather. An overcoat has been in demand all the spring. A little fire in the house each morning has been relished most of the time. The same cold, I think, is making the oranges drop badly. Thus, while our friends in the East are mourning the dearth of honey because of excessive rain, we will join in the lament, and charge up our misfortune to the cool weather, which has been very delightful.

A. J. COOK.
Los Angeles Co., Calif., July 8.

Will Plan for Fall Flow.

The rain seems over; 4 inches fell on Friday night. The ground is full of water. No sections completed.

We have had only three warm days, and not a warm night; it is 55 degrees at 7 a.m. To-day it seems as if it would be warmer.

Clover is in full bloom, and may give 24 sections of honey per colony. I shall begin to plan for a good fall honey-flow.

JOHN C. STEWART.
Nodaway Co., Mo., July 21.

Yellow Sweet Clover—Sainfoin.

Bees here are behaving splendidly, gathering in plenty of nectar. Yellow sweet clover came into bloom June 8, here this year, and is still in blossom, just meeting the white sweet clover, the two making a constant bloom of over three months; and if the white clover is cut just as it comes into bloom, a much longer period.

Yellow sweet clover does not grow nearly so tall as the white sweet clover, and is of a finer nature. It is not so thrifty on very poor soil as the white sweet clover, but perhaps after it has been in the ground some time it would improve. Every day I see evidence that cattle will eat sweet clover when they have learned to eat it.

This year I put in a small plat of sainfoin clover seed; the plants came up and some of them blossomed; it is quite a thrifty plant, making a heavier growth for the first season than red clover, and the stalks are not nearly so coarse as the red clover, but seem to carry a greater amount of leaves. Of the few blossoms that came out I did not notice any bees on them, but they have such a feast here this season that it would be hard to get them to look at small things.

I got a farmer friend of mine to try some of this clover seed this spring, and he thinks it is a good fodder-plant; however, we will know more about it next year, if all goes well, as I shall try to put in a larger piece of ground. It is altogether unlike any other clover in appearance that I have ever seen.

I notice the Ontario Agricultural College, at Guelph, reports on it this year, and it seems to be as good as any of the clovers. Give it a trial, in a small way at first, and see what you can make of it. You will need to plant the seed deeper than other clover seeds, as it is very large.

W. D. HARRIS.
Ontario, Canada, July 14.

Superseding Queens—Starved Bees.

We have been having a honey-flow from some source for about 15 days. This was unexpected. It is less than 10 days ago that I was feeding some starving colonies, but at the time I was feeding these the strong colonies in the yard were storing quite rapidly without my knowledge, as I was then unable to give them the attention demanded. Swarming from these strong colonies commenced about a week ago, and has kept up until now. I had to hustle in order to hive the swarms, and keep the bees provided with storage-room. This I have done without help, but I have had to work and think all day, and then think all night, with the exception of a few cat-naps, in order to do it. Fortunately, I was provided with a good deal of storage in the shape of drawn comb, both brood-combs

Tested Adel Queens.

Reared by a New Method. Queens very large, prolific and handsome. One Queen, \$1.00; three Queens, \$2.75; six Queens, \$5.00; twelve Queens, \$9.00. Everything guaranteed.

and unfinished sections, and so I have been able to handle the crop so far.

Storing is interrupted now on account of the heavy rains. This will probably insure a full flow of more than usual magnitude.

I lost quite a number of colonies, but the most of these left hives with a good deal of sealed honey in them. I think only one colony starved. Two were lost because the hive-entrances were not kept clear of dead bees. I had directed that all entrances should be cleared by means of a bent wire, but it was not faithfully attended to. The most of the losses were due to the loss of queens.

I had been taught by many writers that it is best to let the bees attend to the matter of superseding the queen. I am tolerably certain that following this advice has resulted in great loss to me. Had I made use of queens reared in my own yard in strong colonies under the swarming impulse, and then allowed no queen to live more than three years, I think I would be better off. I have some good purchased queens, and have had a good many purchased queens that were good for nothing. I have one queen introduced Aug. 3, 1897, which has done as good work this season as ever before, and she has always done well. This is a York State queen. While one can get a good many good queens by purchase, he has the trouble of experimenting a great while in order to find out which are the good ones; hence, I believe it safest for the ordinary bee-keeper to rear his own queens from the best queens in his own yard in the swarming season.

It is stated in some of the papers that many colonies in Iowa and Illinois have been allowed to perish in the past month from starvation, owing to the lack of bloom, or the weather being so bad that the bees could not work. A few dimes expended for sugar at a critical time may be returned in a good many dollars later on. To let bees starve in June is poor economy. Shall such a man be called an apiarist? He is only a bee-bugler. If the flowers yield nectar from July to November they yield it in vain for him.

EDWIN BEVINS.

Decatur Co., Iowa, July 9.

Pretty Well for Beginners.

In February, 1892, we bought 4 colonies of bees; now we have 10 colonies. I have hived 6 swarms, one June 19, 22, 24, 30, and July 4 and 7.

On Saturday afternoon my wife was at home alone, and being quite anxious to know what the bees were doing, she took the smoker and looked through all the hives, and found all the brood-frames well built down, and enough stores ahead so they will not need to be fed just yet.

The colony we hived June 19 has the super well filled and nearly all capped. It is the only one that has done much in the super.

We thought we were doing pretty well for greenhorns; many others are losing their colonies.

R. A. MARSHALL.

Wright Co., Iowa, July 21.

Worst Season—Foul-Brood Cure.

This is the worst season ever known in this section. It rained 28 days in June, and every day in July up to the 5th, which was cold and cloudy. It rained July 9, 10 and 11, and a cold northwest wind. This morning it is cool, but it looks as if it would be a honey-day.

I never saw such a large crop of white clover.

Yesterday was the first day in about 20 that the farmers have been able to plow the ground, it being too wet. That will make the buckwheat at least 50 percent less. Our outlook for this season seems to be very slim, as the white clover is on the decline.

I think I have found a sure cure for foul brood, at least it has made it disappear in one yard. I will be able to report in a short time, as the second lot of brood will be hatching in about 12 days. The 3 colonies I have treated are as healthy as any bees I ever saw since the treatment; but I want to make sure before I report. Facts are what we want in our practice.

J. W. TUCKER.

Jefferson Co., Pa., July 12.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, July 19.—Not any comb honey of the new crop yet on the market, but advices of this week would indicate that some sections of the country are now prepared to ship as soon as any demand appears, and beginning with August there has in past seasons been more or less of a market, and it is looked for to begin this year on time. This for several reasons, one being that we are going to have some choice white clover and basswood to offer, which has not been over plentiful during the past three or four seasons. Prices are nominally the same as during the past 90 days. Beeswax sells at 30c.
R. A. BURNETT & Co.

KANSAS CITY, July 5.—Some new comb honey has arrived. We quote: New, 14@15c; old, 12@13c. Extracted, white, 6@6½c; amber, 5@6c. Beeswax, 25@30c.
C. C. CLEMONS & Co.

ALBANY, N. Y., July 10.—HONEY market not opened yet for this season, but we look for demand to begin in a couple weeks. No old crop in the way. Expect good demand and good prices for new crop, which is very light in this vicinity.
H. R. WRIGHT.

NEW YORK, July 7.—There is some fair demand for comb honey at 14c for strictly fancy white; 12@13c for No. 1, and 10@11c for amber. Extracted quiet at unchanging prices. Beeswax dull and declining at 29c.
HILDRETH & SEIGLER.

CINCINNATI, July 7.—The shipments and offers on new comb honey are so little, besides the predictions for the yield of honey so uncertain, that I can give no figure for prices. Extracted is selling for the same price—Amber, in barrels, 5@5½c; alfalfa, 6@6½c; white clover, 6½c. Beeswax, 28c in cash.
C. H. W. WEBER.

SAN FRANCISCO, July 9.—White comb, 10@12 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4¼@—; amber, 4@—; Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Stocks are of light volume and market cannot be termed favorable to buyers, but demand is not brisk at prices now generally asked, dealers waiting as a rule for offerings to be presented to them. If pressure to realize were exerted, the material shading of rates to buyers would be necessary to effect noteworthy wholesale transfers.

WANTED!

Honey and Beeswax. Mail sample and state price delivered Cincinnati. C. H. W. WEBER, 2146-2148 Central Ave., CINCINNATI, OHIO.

\$300,000,000.00 A YEAR and you may have part of it if you work for us. Uncle Sam's poultry product pays that sum. Send 10c for samples and particulars. We furnish capital to start you in business. Draper Publishing Co., Chicago, Ill.

A New Bee-Keeper's Song—

“Buckwheat Cakes and Honey”

Words by EUGENE SECOR.

Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

“THE HUM OF THE BEES in the APPLE-TREE BLOOM”

Written by

EUGENE SECOR and DR. C. C. MILLER.

PRICES—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for \$1.00 *strictly in advance* payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

GEORGE W. YORK & CO.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

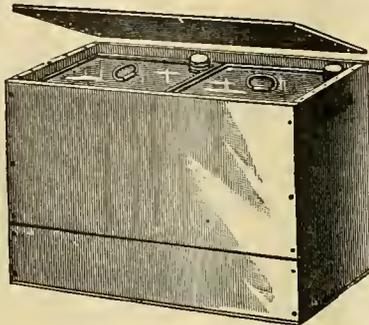

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., AUG. 7, 1902.

No. 32.

Editorial.

We invite you to subscribe for the American Bee Journal.

This invitation is extended to the thousands who will get this copy as a sample. We only wish those who know and appreciate the value of the American Bee Journal could visit all who will receive this number and who are not now subscribers, and tell them just what they think of it. If that could be done, we believe that our subscription list would be doubled in a month.

But, of course, it won't do for us to "blow our own horn" too hard. We will simply ask you to examine this number carefully, and see if you don't think it is worth all of two cents. That is just what it costs when you pay us \$1.00 for a whole year's subscription, or 52 numbers.

Shall we not have your name and address for our list right away?

Supersede the Invariable Rule.—It seems hard for some to believe that supersede is anything but exceptional, and when a queen is superseded it is considered something out of the usual. The beginner should have it impressed upon his mind that in the ordinary course of events every queen at the termination of her life is superseded. It is the invariable, the inevitable thing. Lately a correspondent wrote:

"Of the clipped ones I think fully 10 percent have been superseded, while not one of the unclipped, so far as I know, have been disposed of."

If only 10 percent of his clipped queens are annually superseded then he has no reason to find fault with clipping, for that means that the average life of his queens is 10 years, and 10 years is a longer term of life for a queen than has ever before been reported. The reason that he has not observed much superseding among his unclipped queens is that the superseding queen looks so much like the old queen that he does not recognize any superseding. If he will observe carefully, he will probably find that about a third of his queens, whether clipped or unclipped, are superseded annually. In other words, the average life of a queen does not exceed three years.

The Reputation of Extracted Honey is a very varying quantity; that is, it varies greatly in different localities. Some bee-keepers say they can get as much for extracted as for comb, while others can scarcely

dispose of extracted at any price. Whatever other reasons there may be for this, one all-sufficient reason is the varying character of the product itself. In some cases extracted honey is so well ripened, so rich, and of such fine body, that some prefer it to comb honey at the same price, especially for some uses.

As there are always new comers on the field, the advice to be scrupulously careful as to the character of extracted honey is always timely. Small wonder that people do not care for honey that is thin, raw, and inclined to sour. Some extract when a part of the honey is little more than nectar, because they will get more pounds than if they wait till the honey is thick. They will have more pounds of honey and water, but not more pounds of honey, and although they may get more pounds, they will not have so much money in the long run.

There is a difference of opinion as to whether honey may be ripened artificially to equal that ripened by the bees. In any case it is well for the beginner to be on the safe side, extracting only that which is sealed. The practice of some is to extract only at the close of the season. It is a safe plan.

Let the beginner remember that a single sale of honey that is not thoroughly ripened, of good flavor, and scrupulously clean, can have its evil effects neutralized only by many subsequent sales of the proper article, if indeed such subsequent sales can be made at all.

Vinegar for Bee-Stings.—A Canadian subscriber writes:

"Rub on a little good vinegar. You will find almost instant relief. Try it."

May be honey-vinegar would be best to subdue the pain caused by a bee-sting!

Prevention of Swarming.—Editor Root says "the bee-keeping world would give thousands of dollars to get hold of a plan by which it could put strong colonies with small brood-nests at out-yards and leave them there with a reasonable assurance that those colonies would not swarm;" and he thinks that two plans offered by Dr. Miller do not fill the bill. Dr. Miller says:

One is to take away all brood about swarming-time, and the other is to get the bees to rear a young queen about swarming-time. Giving a young queen reared elsewhere will not answer. I've had a swarm issue with a young queen that I had given not a week before, she having just begun to lay; but when a colony has itself reared a young queen, and that queen has begun to lay, I never knew or heard of such a colony swarming till the next year. Gravenhorst gave this as reliable without being able to explain why the young queen must be reared in the hive itself.

Bleaching Honey.—Mr. J. E. Crane, in *Gleanings in Bee-Culture*, gives his experience in bleaching honey so as to change No. 2 honey into No. 1, and No. 1 into fancy. His success has been such that he has added to his honey-house a permanent structure 10x13 feet, with gable roof, and mostly glass sides. He says:

I ran some 6500 combs the past year through the bleaching process with very satisfactory results. Combs that are only a little off would come out almost as white as snow, while those a little darker would be greatly improved. A few hundred, however, had so much propolis mixed with the cappings that no amount of bleaching would make them white, as I held some of them to it for three months, and finally concluded I might as well try to change the skin of an Ethiopian. It takes more time at best than one would expect. Even those combs that are but slightly stained usually require several days to make them look bright.

In closing, he wisely suggests that it would be much better to produce comb honey without stains.

"Pollen-Clogged Combs in wired frames cleaned, 4s. per doz., standard frames." So runs the beginning of an unusual advertisement in the British Bee Journal. A dollar a dozen seems a pretty good price, but the work is done at least promptly, as the advertiser says he will send back the cleaned combs by return mail. It is much better, however, to try to have pollen used by the bees, in some cases pollen being worth more than an equal weight of honey.

Uniformity of Hives and Fixtures is a thing whose importance is keenly felt by the experienced bee-keeper. Not always—perhaps not often—by the beginner. Indeed, one of the first things with a large number of beginners is to try to make some change in hives or fixtures, later on to find that what was supposed to be an improvement was anything but that. It is safe to give to the average beginner the advice: Don't invent.

After some experience the bee-keeper becomes aware of the nuisance of different measurements when perhaps he finds himself in possession of frames of two kinds so that they can not both be used in the same hive. Then he falls to belaboring the manufacturer. In some cases the manufacturer may be to blame for encouraging changes, but generally it is money in his pocket to have as few changes as possible. If all the bee-keepers in the country would agree upon one kind of hive, one kind of frame, one kind of everything, the manufacturer would never need to have on his hands dead stock out of style. As matters now stand, a set of bee-keepers in one locality insist on a certain kind of goods, a

set in some different locality want something different, the real need for something different perhaps being real, perhaps fancied. It costs more for the manufacturer to make two kinds than to make one kind; and when the need for one of the kinds turns out to have so little foundation, in fact, that the goods are no longer called for, then the manufacturer is left with more or less of the stock on hand; and so it is that from time to time remnants of odd goods are advertised at ruinous prices. In the final analysis the loss must fall more or less upon the bee-keeper, for manufacturers are not in the business entirely for their health, and must make themselves good for losses upon odd goods by prices on regular articles.

The moral for all this is for each bee-keeper to be as conservative as possible, using only such fixtures as are standard, unless there seems an imperative need for something different, in which case he must be willing to pay the price for odd goods.

Competition of Cuban Honey is a thing that is not to be feared by bee-keepers of the United States, in the judgment of W. K. Morrison. He says in *Gleanings in Bee-Culture*:

Cuba bulks largely in the mind's eye of some Northern bee-men just now. They forget that the land is comparatively small. Texas is ten times as big, and a good deal of Cuba will be rendered unfit for bee-keeping by the advance of the sugar industry. But even if it produces all the honey that its most sanguine admirers think it will, it is certain very little of it will be consumed in the United States. Honey sells for more money in Europe than it does in America; hence, for a long time Cuban honey will gravitate toward Europe, as is the case at present.

I do not think the present tariff of a cent or so a pound on honey sent to the United States avails very much. It only tends to discourage trade. If honey were on the free list the dealers in New York would buy the whole Cuban and West Indian crop and re-export it to Europe. The American bee-keeper would lose nothing by the operation; on the contrary, a market would be created which, in times of plenty, would be a valuable asset to the United States.

Weekly Budget.

THE BUTTERFLY APIARIES of Maynard D. Nichols are shown on the first page this week. He wrote as follows when sending the picture:

EDITOR AMERICAN BEE JOURNAL:—I have been trying for some time to get a suitable picture of my bee-keeping investment, and have not been very successful, but will offer the enclosed. If the whole of the wings could have been taken it would have suited my idea. I have named my apiaries "Butterfly Apiaries," and the arrangement of the pictures forms one.

This is my fourth season with the bees on a large scale—all short-crop years—and during these years, with the great help of the "old reliable" American Bee Journal, one other leading paper, and one of my neighbors, I have acquired some of the rudiments of bee-keeping as managed now-a-days.

In the "Butterfly" the two upper pictures represent my increase of last year, nearly all caught in decoy hives placed in trees, then transferred to standard hives. The picture with the wheelbarrow scene is my queen-

rearing stock exhibit near my house, and the other is my main apiary with 100 colonies in it. They are according to Dr. Miller's plan, except there are three twos on each 16-foot rack up from the ground, so that big skunks can not molest them so badly. I have adopted the 9-frame "Jumbo" hive, and am getting very strong proof that a large hive is the best for this canyon. The 9-frame hive is being used more from year to year in this county.

In the body of the "Butterfly" is the picture of the members of my family.

I run every colony for extracting, and have the honey-house arranged so that I can wheel the honey in on a slight incline, uncup it, put through the extractor, then it runs on a cheese-cloth strainer held by a hoop over a tank large enough to hold two cases if necessary. My honey-house is 8x20 feet, with part two story, so I am not obliged to handle the honey very much; then the tank is proof from dirt, bees or ants, and I feel that with queen-excluders I am able to put my crop up for the market as clean and pure as is required.

To those bothered with ants I would suggest that they try putting a tin pan over their hole with a bit of bisulphide of carbon under it, and put dirt around the edge so it will be air-tight. It is the best and cheapest way we have found yet.

I wish to say "Amen" to the Editor's advice some time ago, not to remove the old queen until the new one has been received.

MAYNARD D. NICHOLS.

San Diego Co., Calif.

THE COLORADO ASSOCIATION is to hold a joint session with the National in Denver in September. The program of their 23d annual session, held Sept. 3, is as follows:

WEDNESDAY, SEPT. 3, 1902.

10 o'clock.

Invocation.

Reading Minutes.

President's Address.

(After the President's address ten minutes will be given for members to offer suggestions or give notice of any business or discussion that they wish to bring before the convention. Come prepared.)

11 o'clock.

A four-cornered discussion, by four prominent apiarists, speakers limited to 10 minutes each.

1st subject, "Association Work and Influence—If Good or Bad, and Why."

2d, "Comb Honey Production—Best Hive and System, and Why."

3d, "Extracted Honey Production—Best Hive and System, and Why."

4th, "The Most Pressing Need of Our Pursuit."

General debate on the foregoing subjects, speakers limited to three minutes except by consent of the convention.

Appointment of Temporary Committees.

Dinner.

AFTERNOON SESSION.

1 o'clock.

Question-Box.

1:30 o'clock.

Unfinished Business.

Report of Committees.

New Business.

2:30 o'clock.

Election of Officers.

3 o'clock.

Paper: "The Bee in Literature"—F. L. Thompson.

Miscellaneous Business.

The Program of the National.

FIRST DAY—WEDNESDAY—EVENING SESSION.

7:30 o'clock.

Invocation.

Music.

Addresses of Welcome by Pres. Harris, Mayor Wright, and Gov. Orman.

Responses by Pres. Hutchinson, Sec. Mason, and Director Miller.

8:30 o'clock.

"Bee-Keeping from the Atlantic to the Pacific, as Seen Through the Camera and Stereopticon"—E. R. Root, of Ohio.

SECOND DAY—THURSDAY—MORNING SESSION.

9:30 o'clock.

Music.

President's Address—"The Future of Bee-Keeping"—W. Z. Hutchinson.

Discussion.

10 o'clock.

"Which is the Most Hopeful Field for the National Association?"—Dr. C. C. Miller, of Illinois.

Response by Rev. E. T. Abbott, of Missouri.

Discussion.

11 o'clock.

Question-Box.

SECOND DAY—THURSDAY—AFTERNOON SESSION.

1:30 o'clock.

Music.

"Reporting of the Honey Crop; When and How it Should Be Done"—C. A. Hatch, of Wisconsin.

Response by Frank Rauchfuss, of Colorado.

Discussion.

2:30 o'clock.

"Bee-Keeping Lessons that May be Learned from the Word 'Locality'"—H. C. Morehouse, of Colorado.

Response by E. R. Root, of Ohio.

Discussion.

3:30 o'clock.

Question-Box.

SECOND DAY—THURSDAY—EVENING SESSION.

7:30 o'clock.

Music.

"The Outside and Inside of a Honey-Bee" (Illustrated by the Stereopticon)—Prof. C. P. Gillette, of Colorado.

THIRD DAY—FRIDAY—MORNING SESSION.

9 o'clock.

Music.

"Selling Extracted Honey at Wholesale—How to Get the Best Prices"—J. F. McIntyre, of California.

Response by T. Lytle, of Colorado.

Discussion.

10 o'clock.

"Putting Up Extracted Honey for the Retail Trade"—R. C. Aikin, of Colorado.

Response by George W. York, of Illinois.

Discussion.

11 o'clock.

Question-Box.

THIRD DAY—FRIDAY—AFTERNOON SESSION.

1:30 o'clock.

Music.

"Managing Out-Apiaries for Comb Honey"—W. L. Porter, of Colorado.

Response by M. A. Gill, of Colorado.

Discussion.

2:30 o'clock.

Question-Box.

3:30 o'clock.

THIRD DAY—FRIDAY—EVENING SESSION.

9 o'clock.

Banquet.

A. B. MASON, Sec.

Sta. B, Toledo, Ohio.

Remember it is less than a month from this date when the Denver convention will be in full blast. We hope that as many bee-keepers as possible are planning to be there. It promises to be the biggest and best of all the meetings of the National Association. It ought to be. Colorado is a great honey-producing State. It has within its borders some of the greatest bee-keepers in the world. And they, with many from all over the United States, will be at the convention.

It's in Denver. And Sept. 3, 4 and 5 is the time.

Contributed Articles.

Two Queens with a Swarm—Mysteries of Swarming.

BY G. M. DOOLITTLE.

QUESTION.—“Does a colony of bees ever have two queens? I hived a swarm of bees the other day that had two queens, I am pretty sure. I have kept bees only a short time, but I think I know what a queen is. My bee-keeping neighbor tells me that there were two swarms which I hived, and says there is never more than one queen in a colony. Which of us is right? Please tell us through the columns of the American Bee Journal, as we both take that paper.”

ANSWER.—Very likely both your neighbor and yourself may be right in this case, but you have things a little mixed. I think such a thing was never known as a prime swarm of bees coming from a colony in a normal condition, having two queens with it. To be sure, we do sometimes have two laying queens in a hive at the same time, although such is a rare exception; but so far as I am aware no colony was ever known to swarm at such a time, and both of these laying queens go with the swarm. With a prime swarm, or what is often erroneously called a first swarm, there always accompanies it a laying queen. All swarms having a young or virgin queen can be properly classed as after-swarms. When a prime swarm issues it generally leaves maturing queen-cells in the old hive, from which, when matured, a young queen leads out all after-swarms.

The only exception to this is that hinted at above, where, from some cause, the old queen dies near the swarming season, when several queen-cells will be formed on the brood left, so that young or virgin queens may lead out what appears to be a prime swarm.

For convenience, all swarms except the one having the old or laying queen are called “after-swarms” by beekeepers, and from this explanation the readers may know what the term “after-swarms” means. As a rule, about six to eight days after the prime swarm has issued the first young queen emerges from her cell, and if after-swarming is considered by the bees to be the best economy for the colony, the other young queens are kept in their cells by a little knot of bees clustering on them at all times after said queens are heard to be gnawing at their cell-covers, so the lid of the cell can not be removed to let the queen out, her majesty being fed all the time through an aperture made by the gnawing of the imprisoned inmate in the royal cell. If further swarming is not considered “economy” by the bees, then all the other queen-cells are torn down after the young queens have been destroyed, so that the first which emerged is the only queen in the hive.

If the cells are protected as above, the first emerged queen seems to get into a rage, and utters shrill notes at intervals, sounding something like tee—tee—tee-tee, te, t, t, t, would sound uttered in this way, and called the “piping of the queen,” which is kept up for about two days, when the second swarm, or the first of the after-swarms issues. This piping of the queen is always heard if listened for before all after-swarms, or any case of a plurality of queens in a colony intending to send out a swarm. The queens kept back in their cells by the bees are growing in age and strength, the same as is the one having her liberty, they telling this by their trying to pipe the same as the one does that is out of her cell, which noise is termed “quanking;” and so it happens that, during the hurry and bustle of second swarming, one or two of these queens hastily finishes biting the cover off the cell and gets out with the swarm, in which case two or more queens are found with the swarm, as was the case with our querist, although it is a rare thing to see more than two or three queens with a second swarm, unless said swarm has been long delayed on account of bad weather.

If a third swarm is to issue, the bees now cluster about the remaining royal cells having queens in them, the same as before, keeping all queens prisoners except one, which liberated queen scolds and pipes away, as did the one before, the others in the cells showing their anger back again by a chorus of quanking immediately after the first ceases piping, when, after the lapse of two days, or such a matter, the third swarm issues.

As there are less bees in number at this issue than there were when the second swarm issued, and more mature queens held as prisoners, the queen-cells are quite generally

vacated by the guard-bees; and queens, bees, and all rush out, and in such cases I have often counted as many as from 8 to 15 queens with one such swarm, though from one to five is the usual number.

Occasionally a colony will send out a fourth, and sometimes a fifth swarm, though the latter is of very rare occurrence; and sometimes all of the young queens will leave their cells and go out with the last swarm, in which case the parent colony is hopelessly queenless, and dies from their inability to procure a queen, when, as soon as the bees are gone, the larvæ of the wax-moth take possession of and destroy the combs, and the owner declares that the worms was what destroyed his bees.

In the above I have tried to give a short insight into the mysteries of the swarming of bees, many points of which do not seem to be fully understood, even by those who have kept bees for several years. Onondaga Co., N. Y.

Importance of Good Stores for Bees in Winter.

BY C. P. DADANT.

I believe it is necessary that we should report failures as well as successes, in order to enable the producers to judge of the possibilities of the business and take advantage of the experience of others, whether for good or for bad.

Last year was probably the driest season that we have ever seen, and the apiary conditions were anything but favorable. But in spite of the drouth the bees stored some honey. Those that were located on the lowlands near the Mississippi River gathered quite a crop from the fall blossoms that grow there in abundance. Those on the hills had, in this locality, a heavy flow of honey-dew, the honey-dew of plant-lice, a very unusual occurrence in the month of September, for I do not remember having ever seen honey-dew later than the month of July.

When our apiarist reported to me that the hives were getting fairly good stores from honey-dew, I had some misgivings as to the probable success of wintering on such food, but as he reported also that they already had some honey from other sources, though in small amount—and as I had noticed the bees at work in the fall bloom, which was rather scanty, it is true—I concluded we would best risk wintering on that food rather than going to the very considerable trouble of extracting all the honey and feeding. But I felt uneasy, and wrote to a friend who asked me about the condition of the bees, that I was afraid there might be considerable loss, owing to the bad supply of winter food. He reminded me of this after he was informed of the result.

Well, the beginning of winter was very favorable. The bees had a flight every few days, and everything looked prosperous. But after Jan. 15, we had about five weeks of confining weather, during which the bees could not fly, and when a warm day came it was plain that the bad food was doing the havoc anticipated, and worse, too. Nearly every colony suffered from diarrhea, and a few colonies were found dead. Then dwindling began, and slowly and steadily we lost one colony after another till one-third of the apiary had gone, here at the home place.

Two other apiaries were equally decimated, both having been within reach of the unhealthy supply, while the bees that had harvested a crop of fall honey wintered as well as any. Never had we seen such poor food in the hives, and never had we lost so many bees during the winter. It was practically a disaster, and until May the bees kept falling away. But at the opening of the fruit-bloom they began picking up, and now the hives are full (June 27), artificial divisions have refilled the greater number of empty hives, and our apiary is itself again, though still we have a few hives full of combs waiting for a little better weather. For the season is not at all favorable, the white clover bloom is missing almost entirely, though there is plenty of it coming up, but this will not bloom so as to give us any crop this year. The wet weather is filling the corn-fields with knot-weeds and Spanish-needles, and we look for a fair fall crop.

This loss, it seems to me, carries a good lesson. We knew, by former experience, that winter food was of great importance, but this evidences the fact that it is probably the most important item in successful wintering. Not only can not the bees be wintered safely out-of-doors with such food as honey-dew, when the confinement is to extend beyond a few days, but even cellar confinement is dangerous.

We had put 20 of our weakest colonies, in an out-apiary, in the cellar, and out of these only four came out alive. With good, healthy food it is not probable that we should

have lost more than one or two of these. So we must emphasize the need of good stores for winter.

It is not probable that an accident of this kind will occur very often, because honey-dew may not appear for years at the end of the season, but it is very clear that it would be better to extract all such honey, when it is present in the hives, rather than run the risk of its pernicious influence on the health of the bees.

But the beginner should remember, when he meets such a disaster, that it is a mistake to get discouraged; first, because such things do not happen very often; and, secondly, because an apiary can very soon be recuperated when you have the hives, the combs, and a few good colonies left to breed from. With a number of hives full of combs and partly full of honey, the most insignificant swarms can be turned into strong colonies in a few weeks of warm weather.

Hancock Co., Ill.

What Determines Sex?—A Big Question.

BY PROF. A. J. COOK.

When we stop to think, the fact of the approximate equality of the sexes numerically, not only among our own species but among most organisms, can but awaken surprise. It would seem that the determining factor must be some fortuitous event that is just as liable to turn one way as the other. It also speaks of a Planner who controls in the physical world, and has planned that the best—equality of the sexes in number—shall always hold.

Cattle-breeders have often argued that each alternate egg that passes from the ovaries will produce males, and the others will develop into females. While there is enough evidence to give this position some standing, and to effect results in auction sales of fine cattle, yet the numerous exceptions seem to negate its reliability, and I think now it has no hold at all among scientists.

The theory most advocated to-day is that the quantity of nourishment which the embryo at the time of sex-determination governs in fixing the trend. It is a well-known fact that the sexes are indistinguishable for some time. The sex-organs are present long before they are differentiated so that the sex can be determined even by closest examination. Even the keenest, best microscope can not tell whether male or female is to result. I doubt if there is any difference at first. Just when the difference commences, or what determines it, are interesting questions. The view now being explained is that the vigor of female just at the crucial time effects the trend of development. If the female is strong, and all her organs in healthy condition so that the egg or embryo will receive a maximum of nourishment, then a female results. If the reverse is true, then a male is produced. This theory has much to sustain it, else it would not receive the support and advocacy of our most advanced scientists.

THE ARGUMENT.

The animals and plants that first peopled the world, when Time was young, as also similar simple life today, are sexless, and only produced by division. These organisms are single-celled. They produce by simple dividing. After a time, that is, after they have divided again and again, they conjugate, that is, two cells unite in close apposition. After remaining together for a season they separate, when division goes on as before, each organism dividing and becoming two. That this conjugation in some way gives new vigor and strength cannot be doubted. This is surely a precursor in purpose and reality of real sexes among plants and animals.

BEEES IN THE ARGUMENT.

The Dzierzon theory of agamic reproduction, or parthenogenesis, in the production of drone-bees, it seems to me offers a substantial argument in favor of the new theory, I truly believe, notwithstanding the note of criticism that ever and anon is being sounded forth by doubters, that no truth in science is better founded than this, that the drone-bee is the result of reproduction from unimpregnated eggs. A few in early summer, and later, at the volition of the queen, have the sperm-cells withheld. These invariably produce drones. Old queens whose sperm-sacs, or spermathecas, have become emptied of the sperm-cells received at the time of mating, produce only drones. We call such, as also unmated queens, that lay eggs that develop, "drone-layers;" such can lay unimpregnated eggs, and so such can produce only drones, and are worthless.

We have seen how conjugation vivifies the lower organism. The giving of its substance, or exchange of substance, adds vigor and enhances vitality. Can we doubt that in the incorporation of the sperm within the egg of both plants and animals also gives new vigor, and that this is a principal purpose of sexuality in all organisms? It follows that the impregnated egg would have an added vigor, and if it is true that added vigor determines female structure and function, then, in case all eggs develop, those that have received the sperm will produce females, while the others will result in males. Usually, unimpregnated eggs have not vigor sufficient to develop at all. Prof. Loeb has shown that in some cases the addition of certain chemicals can induce this development of eggs without sperm, that else would have been infertile. Thus I believe the production of drone-bees from unimpregnated eggs, and females from impregnated ones, among ants, bees and wasps, is a real argument in favor of our theory.

There are other arguments. In the plant kingdom we find some cases where the reproductive cells are better fed and developed, and these always produce eggs, and are females. Plants and animals are alike in their basic structure, and such a phenomenon in one can be safely used as an argument in regard to the other.

If this theory is true, then if a female is kept in maximum vigor during gestation, the progeny will be female; if at a certain indeterminate time there is lack of vigor then a male will result. It is possible that an indigestible meal, a hard task, or a bitter disappointment, may have been parents of many a male, while the opposite gives us our females.

Los Angeles Co., Calif.

Methods of Rearing Good Queen-Bees.

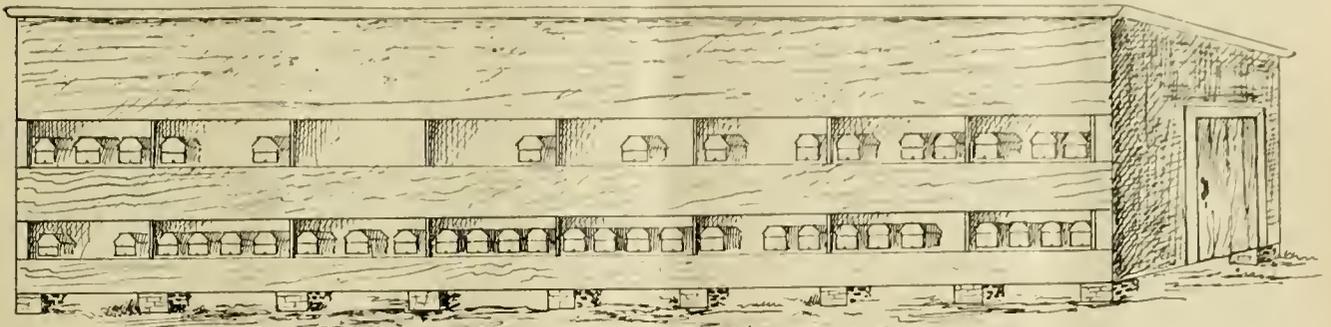

BY F. GREINER.

The cool and rainy weather of late has been unfavorable for honey-gathering here, and extremely so for queen-rearing. I am very anxious to put to test some of the newer and cheaper methods of keeping young queens in very small nuclei for the purpose of having them mated; but the weather we have had all during June has not permitted of any such work. At least it did not appear to me that mere handfuls of bees could be depended upon for it. If queen-rearing is at all practicable here during such times, good, strong, three-frame nuclei are to be preferred. Warmth—a certain degree of it—is essential for the development of brood, and I would as soon think of running an incubator 10 degrees below the proper temperature, as to mature bee-nymphs at a low temperature.

Of course, we do not know just in what manner, or to what extent, bee-brood is injured by letting it become cold or chilled. It is difficult to ascertain this. Capped brood may be exposed to a low temperature for a time and not be harmed, so far as I can see; but to be on the safe side, developing queens should be kept at the proper temperature all the time. This, however, is no higher in a doubled-up colony than in a single one when in full strength, and I can, therefore, see no advantage in using two colonies united for the purpose of rearing queens in that respect. If there was, one might reason thus:

If a single colony rears queens living three years, and a doubled-up colony queens living six years—about what Dr. Gallup claims—then ten colonies united into one giant colony must rear queens living 30 years. By continuing this doubling-up plan we would finally produce queens reaching the age of Methuselah, etc., *ad infinitum*. I can not think that Nature should have made a mistake in limiting the powers of a queen, the life of a queen, or that of the workers.

I suppose one might assert that two colonies united would be able to prepare a greater quantity of royal food, and in order to dispose of it would provide it for the baby queens more lavishly. It could be supposed that there was a limit to the production of this food. One colony, for instance, might be able to feed a dozen queen-larvæ properly, but no more. A doubled-up colony would have to feed each of the 12 larvæ a double portion; the same would result if but six cells were allowed to be built in the single colony. The superiority of queens would thus be governed to a great extent by the number of cells built in each colony. If but few cells were built they would be very large in order to hold this greater quantity of food. But this is not so. Only recently one of my best colonies built but a single queen-cell. It is exceptionally small. Another colony by its side built 12 or 15, all of which were large and long, indicating a large amount of food under the developing insect.

WINTER AND SUMMER BEE-HOUSE OF F. R. WEBSTER, OF CHESHIRE CO., N. H.

If the theory was sound, a colony robbed of all its brood would be in the best condition to feed queen-larvæ. But it seems that a colony in normal condition, with lots of brood of all ages, does the best work. Even after a colony has been robbed of the greater part of the bees, in the shape of a young swarm, it is still in a condition to keep warm and properly feed a large number of growing mother-bees.

I agree with Dr. Gallup in his closing remark on page 408: To rear long-lived, healthy queens we must rear them in a natural manner. It shall be my aim in the future, more than it has been during the past three or four years, to rear my queens from normally-stocked-up cells. However, we should not ignore the fact that Doolittle and others are just as successful since practicing queen-rearing according to the new methods, as they were before when queens were reared naturally.

The great majority of honey-producers have always reared their queens according to nature, and do so now, but it has not been discovered that the powers of the queens have materially changed or increased. I don't anticipate that we will accomplish wonders. It must have been an exceptional case when it was necessary to provide a hive of the capacity of three full Langstroth brood-chambers to hold the bees of one young swarm, as Dr. Gallup says in a previous article. If it was possible, and we should succeed in changing the nature of the honey-bee to such an extent our bee-supply dealers would have to get up different patterns for the hives to be used in the future.

Mr. Frank Benton suggested, some years ago, that the queen-lymph might absorb nourishment through her abdomen, or the part which rests upon the food. Dr. Gallup claims this process takes place through the umbilical cord. It can not be said in the true sense that the nymph rests upon the food, for the food is above the insect, from which it would fall if it were not held in its position in some manner. The umbilical cord may serve this purpose. It looks highly improbable to me that the queen-bee in its nymph stage should take nourishment in any fashion. Other insects pass this stage of their lives without taking food or having access to it; why should the queen-bee be an exception? On the other hand, it would seem like wasting material if this—what seems like an accumulation—which is found at the base of each queen-cell after the insect has emerged—should not have served a purpose.

There are a great many things connected with our pursuit still hidden in mystery. Many will remain so for all time. However, this should not hinder us, but rather urge us on—to work trying to solve some of them. All who engage in such work are deserving credit, although they may fail to find the real truth.

Ontario Co., N. Y., June 27.

A Bee-House for Winter and Summer.

BY F. R. WEBSTER.

I speak of wintering bees not only because I feel that I have been successful in my plan, but because I am convinced that others have failed to meet with success by other methods, or I might say because they had no method at all. Neither do they try to form one. If you have 20 head of cattle to winter you must prepare to have a suitable place to keep them; you must also have from 20 to 30 tons of hay, grain, etc. You are not expected to be to this great outlay to winter your bees, for if in a suitable place they will supply the necessary food for wintering themselves. But according to my way of thinking this is not all that is required of you.

You must provide a suitable winter shelter to protect them from the elements of our long, cold and stormy winters. For this purpose I build a bee-house, and it is for bees only. The accompanying rough drawing will give a fair idea of its construction. It is 8 feet between each space, double-deck, and intended to hold 4 hives between each space. It is 6 feet wide, with 2 platforms 30 inches wide for holding hives, with a slant to the front of 1½ inches; leaving the balance of space behind the hives for a walk.

My bees are kept in this house in winter as well as summer. The hives are always dry, which, in my opinion, is much better for wintering than one that is cold and frosty.

As soon as stormy weather begins I close the two open spaces with heavy canvas, which keeps it so dark that the bees never leave the hives. The warm sun warms the air through this canvas, and the air is always pure.

This house faces the south-east, while in the rear a high, uneven bank furnishes the best shelter from the northwest. My building standing to the northeast is another shelter from that direction.

Two or three times during the winter I raise the canvas curtain and allow the bees a good flight; at the same time I tip back the hives and brush off all dead bees from the bottom-boards.

I do not advise others to do as I do, but I will say that while others in this locality have lost nearly all their bees I have met with small reverses, and shall continue as I began until I have proven to myself that I am following the wrong trail.

The wise man profits by experience, while the otherwise spend their time in experimenting. What the foolish man does in the end the wise man should do in the beginning.

I am a subscriber to the American Bee Journal, and find in it many items of merit which are of great interest and profit to every bee-keeper of our great country.

Cheshire Co., N. H.

Bees Dying from Spraying While in Bloom.

BY C. H. LAKE.

EDITOR AMERICAN BEE JOURNAL:—

The first paragraph that caught my eye in the July 3rd edition of the American Bee Journal was the Richland Co., Wisconsin, case of "Poisoning from Spraying," and I take the liberty of being one of the many who will probably comply with your invitation to answer the questions there put forth.

1. The effect of spraying with any of the arsenical solutions, the trees or any kind of plants the bees work on, will be death to the bee that works on the flowers in quest of honey.

2. Would it affect the working bees? Yes, it would kill them.

3. Would it affect the brood, etc.? It would kill every larva fed with the honey gathered from sprayed fruit-trees.

4. Would the brood hatch? No, it would die within 24 hours after the nurse-bees fed it to any hatching brood, besides killing the nurse-bees.

5. Would it produce healthy bees if it should hatch? This I cannot answer, as in the case I am about to relate but few bees hatched at all, after the trees began to blossom.

I base these replies upon my own experience of 4 years ago. I had a small apiary of 39 colonies of as fine Italians, and in as fine condition, as I ever saw, when the spring opened. I had wintered them under a covered shed, with plenty of protection all about them, even leaves packed snug beneath the stands and between the hives, with a we

filled bag over the brood-combs. They were strong enough to swarm on the opening of the first blossoms.

The plums were the first to blossom, and a goodly number of trees were in close proximity to my bees. I then discovered in front of the hives quite a number of dead bees with pollen on their legs, and on opening several hives I found the bottoms covered with dead and dying. I remember picking up quite a number and sending them to various authorities asking their opinion of what was the trouble. A. I. Root, I remember, answered that he was unable to surmise the cause, and, you, Mr. Editor, may have received a box of the dead. At the time I had not thought of any one spraying.

Ten days later I visited the apiary again, and I could have filled a barrel with dead bees in front of the hives; thousands were dead with pellets of pollen on their legs, showing how quickly death came. I began then to look about for the cause, and in conversation with the gardener of an adjoining farm he made the statement, that "he must go and see about the men spraying."

"Spraying what?" was my inquiry. "Why, the orchards," he replied. "We have been at it for two weeks, to kill the codling-moth, etc."

"The cat was out of the bag," and he was the ruin of my bees.

It is useless for me to add anything further, but the result was, that every colony but two dwindled to a handful, and the moth soon made their appearance and I was compelled to break up the apiary entirely, by uniting the best I could.

If your correspondent will visit some of his near-by friends and make inquiries respecting the spraying while the trees are in blossom, he will find the cause, and also what poison they used.

One main point before I close: The cause of his "hatching young being healthy," was from the fact that plenty of the old stores were in his hives, while in my case they had but little, when the trees began to flower, and the young were fed the poisoned honey as fast as it was gathered.

I sincerely hope others, if there were such, will give their experience along this line, and that fruit-growers will get their eyes open one of these days and learn that they destroy thousands upon thousands of their best friends, not only the honey-bees, but all classes of insects that our Great Master has given to fertilize the blossoms to give them a bountiful crop.

If the same labor were expended in going over the orchards and gathering up and destroying all the "wind-falls" and defective fruit, which is the breeding-pen of the codling-moth, that is put into the task of spraying, I will guarantee the codling-moth will be a stranger in such orchards.

I was born and reared among fruit, and it was part of my daily task to destroy all fruit that dropped. The result was our fruit always maintained a high reputation, and no spraying was thought of. Baltimore Co., Md., July 8.

Do Robber-Bees Sting?—Other Questions.

BY ALLEN LATHAM.

This question is raised on page 115, and having had some experience in the matter I will venture to offer an opinion. I say that they do. I would suggest here that there should be a distinction made between thieves and robbers. Some bees get a thieving habit and will sneak about the apiary seeking an entrance here or there, always watchful and alert to keep out of a struggle with the entrance guards. These bees are sneak-thieves. There are other bees which get stirred up over some exposed honey, or the poorly guarded stores of a weak colony, so that they sally forth in conquest. Will they sting? Well, I should say so! They will sting both bee-keeper and the home bees.

Last fall I had a colony which, swarming late and possessing an exceedingly prolific queen, bred heavily, and had to hustle to get a living. A drop of honey could not be exposed a minute before that colony would be in an uproar. Sallying forth by thousands they would try to force every entrance in the yard, and would *kill* and be killed by the hundred. These bees were a bright yellow, and the dead bees left by the entrances were by no means all yellow ones. Many a time I watched these bees, and it was no infrequent sight to see one of them turn on its captor. Being an exceedingly active bee it often got its sting into action first. In more than one instance I saw the two bees sting simul-

taneously and both die. These are facts. This is not the only instance I have known, though I think that it is the exception rather than the rule for robber-bees to sting the home bees.

AMOUNT OF HONEY CONSUMED BY A COLONY IN A YEAR.

On page 263 is an excellent article by Adrian Getaz, but in it is the statement that a colony consumes 200 pounds of honey in a year. By my figures, allowing most generously, a strong colony will use only 165 pounds in a year. I doubt if average colonies consume more than 120 pounds in a year. If the matter seems of sufficient importance I will later submit my figuring, but not now, for it would take up a great deal of space.

MOVING BEES A SHORT DISTANCE.

I had occasion, last fall, to move several colonies a short distance. For distances less than 20 or 30 feet this plan worked well: The colony was moved about 10 inches; two days later two feet; two or three days later a yard; and so on till the full distance was reached. The bees seemed to get the habit soon of easily finding their hive, though it was changed as much as four feet.

For distances more than 30 feet I found this to work well: I have portico hives, and I fitted over the portico a board with four $\frac{3}{8}$ -inch holes in it. Few bees returned.

BREEDING FOR LONG TONGUES.

I would not discourage this worthy effort, but would cry out against too great expectations. Though a bee with a long tongue can thereby reach into a few deep blossoms, a tongue too long will hinder the work on the shallow blossoms. At present the legs, tongue and other parts of the bee are in perfect harmony. Give the bee too long a tongue and the harmony is destroyed. Too long a tongue will probably be a disadvantage in the domestic duties of the hive.

We can at best, then, seek to lengthen the tongue only slightly. Shall we gain more than the red clover by a lengthening? Let him who knows answer. If not, then it would be far better to seek red clover with short corolla. I am strongly of the opinion that we already possess bees with as long a tongue as their bodies will profitably utilize. Let us breed for larger bees with the longer tongues.

LONG-LIVED BEES.

Too much can not be said concerning longevity of bees. I shall continue to harp on this strain. A few years ago I had a colony with a 4-year-old queen. The queen could keep only four or five frames filled with brood, while other colonies kept eight or nine. The colony stored twice the amount (75 pounds) that I got from any other colony. The season was a poor one.

THE FATHERLESS DRONE.

Though I do not question that the drone is fatherless in the ordinary sense of the term, I do think that he has a father in the sense of looking like the drone which was the father of his sisters. Last summer I reared several queens from a mother whose workers are yellow and whose sons are well marked with yellow. Out of four of the young queens two mated with yellow stock, the other two with impure stock. The first two throw as yellow sons as their mother, the second two throw as many black drones as they do yellow ones. So that it is a mere accident, if you wish. It may be. I do not know. I will, however, show the progeny of these queens to any visitor. I have frequently had queens throw blacker drones than their mother furnished, and explained it by saying that the grandfather was dark. But when some queens throw yellow grandsons to a drone, and others black ones to the same drone, then we have a puzzle.

THE FATHER OF GREATER IMPORTANCE THAN THE MOTHER.

How often are we disappointed while breeding from a fine queen that we get queens uniformly inferior to the mother. Until we control mating this will remain true. I am more and more convinced that the drone makes up for his sonlessness by transmitting his character to his daughters, and that the queen throws her peculiarities into her sons. Allow me to offer facts. A few years ago I bred from a fine queen at a season when the drones flying were mostly from colonies of a neighbor whose bees were very vicious. The progeny of the young queens proved vicious. Again, last fall I bred queens from a dark Italian queen whose workers are rather cross. I had drones flying freely at the time from a colony of most gentle yellow bees. The

two queens which I have saved from that lot have beautiful yellow workers which are as gentle as one could desire. (By the way, the drones are much more yellow than those of the old mother-queen.) I believe, therefore, that the worker takes more strongly after the father, and that we shall have to control mating if we ever get the results that are possible.

WORKING FOR NO INCREASE.

I should like to get the composite opinion of bee-keepers on this plan: Clip the queen; let the colony swarm if it wills, allowing the queen to get lost, or take care of her in any way one may wish; let the bees return to the hive; six days later cut out all but one good cell, and then push the colony for section-work.
Worcester Co., Mass.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

The Use of the Queen's Sting.

On page 409, "Ohio" asked whether the chief use of the queen's sting is in ovipositing, and my reply leaned strongly to the negative. My attention has been called to a different view expressed by no less an authority than T. W. Cowan. In his excellent work, "The Honey-Bee," he says in speaking of the queen's sting, page 81, "Dewitz, Vogel, and others, have pointed out that it is not only analogous to an ovipositor, but is actually used for this purpose by the queen-bee." (See also Grimshaw, B. B. J., 1889, p. 514.) I take pleasure in recording my change of belief. C. C. M.

A Case of Laying Worker.

What is the cause 5 or 6 eggs in a cell? My husband and I have looked over this colony for 3 hours and cannot find a queen, and we are quite positive there is no queen, but the cells are laid with eggs, and there are lots of bees, in some of the cells there are two young bees formed. Is there any danger of foul brood in a case of that kind. Should we try to throw the brood out with the extractor? Where there is more than one bee in a cell would they decay?
ONTARIO.

ANSWER.—You have on hand a case of laying workers. The best thing to do is to break up the colony and give combs and bees to other colonies. The brood that is present will produce only drones. You will find it cheaper to break up the colony and make a new one than to straighten up this one.

Requeening—Extracting—Yellow Sweet Clover.

1. I subscribed for the American Bee Journal for 3 months, and my time expired, I think, but I would like to have the paper continued. Would I be entitled to an Italian queen as a new subscriber, if I sent \$1.00?

2. I have 3 colonies in which I cannot find the queen, and that will not accept a queen-cell, will cut it out, but they won't draw a cell. They go on storing the honey same as the others. One of them draws out some cells about 1/2-inch long, caps them over, and in a few days cuts them out. I have tried everything I know, and would like some advice as I do not like to exterminate them.

3. I think I shall have more than a ton of honey in my apiary that I could extract. Shall I do it, and then let the bees build up for winter? I have sown buckwheat, and we have a good deal of goldenrod in the fall, so I am undecided what to do, whether to let them work in the supers or to extract.

4. Will sweet clover seed grow from the first bloom, or does it have to be cut and gathered the second crop like other clover?

5. Is the yellow sweet clover earlier than the white? and does it produce white honey? I would like something

that would give work for the bees about the first of June, for that is the most critical time for us here, for we want our little workers strong when the basswood comes.

NEBRASKA.

ANSWERS.—1. By the terms of the advertisement it will be seen that to secure a premium queen one already a subscriber must send in a subscription of another who has not been a subscriber; it is not your own subscription that counts, but that of a new subscriber whom you have secured. You are not barred out, however, even if you do not secure a new subscriber, for, according to one clause, you will see that not being in arrears, if you send in \$1.50 you will get the premium queen and the American Bee Journal for one year.

2. Try giving them from another colony a frame of brood with adhering bees, of course being careful to see that you do not take the queen along.

3. Better be on the safe side. You can extract later, if necessary, but make a sure thing of winter stores.

4. Seed from the first crop of red clover is not obtained because at that time bumble-bees are too scarce to fertilize it. Sweet clover being fertilized by hive-bees, the first crop is all right.

5. It is earlier, and it makes light honey.

Removing Granulated Honey from Combs.

I have about 40 Hoffman frames with as beautiful comb as one could wish to see, but during winter the honey granulated. I wish to know if there is any safe way of taking the granulated honey out, without melting the combs.

NEW BRUNSWICK.

ANSWER.—M. M. Baldrige gives this plan: Sprinkle the frames with water and give to the bees. As often as the bees lick them dry, sprinkle again.

Dark-Colored Wax and Foundation.

Do bees that feed on buckwheat honey produce dark-colored wax? If not, what is the cause of dark-brown-colored comb foundation?
ONTARIO. □

ANSWER.—Foundation is not dark-colored because the wax was made from buckwheat honey, but because in some way the wax became dark after the bees were through with their part, such as having it melted in an iron kettle.

A Beginner's Troubles and Questions.

I cannot tell queen-cells from any other. We have had bees for 3 summers, and I never saw a queen that I know of. I am very much afraid of them. My husband is in California this summer, and I am the only one to care for the bees. I thought I had done something to boast of when I got courage enough to put on supers. We had only 3 colonies when they were put into the cellar. A good many died, and we did not know the cause, whether for lack of food or not, we did not dare to look.

1. Two of the colonies sent forth 2 swarms apiece in June, and the other one, a small colony, has not swarmed; they seem to be working the best. The last two swarms gave me trouble, and that is the reason I sought information. When No. 1 came out it settled in two different trees; I shook the smallest number until I got it to go over on the other tree with the rest. I then hived them. In about a half hour they were out again and settled on a grapevine all together, and I got them in once more.

2. This time they stayed in 9 days. I had set it beside the old hive; the fourth day when at daybreak I went to put on a super I saw a great tumult going on in it, and in the old one that it came out of, and it was kept up until the ninth day, when I noticed there were no bees going in and out, as there had been, but they had done quite a little work in making comb and laying eggs. The foundation comb had loosened, or they had gnawed it until the most of it lay on the floor of the hive, and the work they had done was without foundation comb.

3. There has been more noise in the 3 old hives, until 3 days ago. I supposed by the racket that was kept up in the old hives they must have gone back to the old hive they came out of, and that the queen would not receive them all, but made them divide up and some go in the other old hives; the hives were side by side, still the first 2 new

swarms were not troubled. Did they fly away, or go back into the hive in which they were reared?

The last swarm, No. 2, came out of another hive two days afterward, on a very sultry day, there was scarcely any air. I could not get them to stay in after chasing them in from three different trees; they finally flew away so far I could not carry the hive, so I lost them.

I find by the Bee Journal that it was as I thought—because it was too warm, and they preferred hanging on the trees to being in a hive.

Our bees are small brown ones, and I have been told by persons who know, that they are Italians; they are great workers.

MINNESOTA.

ANSWERS.—1. The dead bees you found in the cellar may have been nothing more than the usual number of bees that died from old age.

2. It is an unusual thing for a swarm to desert a hive after nine days; yet too great heat may have caused the bees to leave then—a view that has some confirmation in the fact that the foundation broke down.

3. The queen would not object to the return of the bees, but it is by no means certain that there was such return if you did not actually see it. The issuing of a swarm from the same hive a second time may have been nothing more than the issuing of an after-swarm that is likely to be a part of the regular program with a strong colony.

You will no doubt find plenty of information in future numbers of this journal equally as valuable as those already found, and the study of a text-book would be a matter of the greatest profit.

Bee-Keeping in Oscoda Co., Mich.

1. How about the climate and honey-plants of Oscoda Co., Mich.?

2. Would bees do well in a basswood location in Oscoda County?

3. Could I winter bees by packing in a shed that climate without much loss from freezing?

4. Is the season too short for the bee-business in that county?

OHIO.

ANSWERS.—1. As the counties of the different States run up into the thousands it would be difficult to have a knowledge of all, and if any possessed such knowledge it would not be of sufficient general interest to occupy the large amount of necessary space with it. Some acquaintance living in that county can probably set you on the way to find out what you want.

2. You may count safely on basswood anywhere, although even so good a honey-plant as basswood has its years of failure.

3. Most likely, as it is less than 45 degrees north, and between two of the great lakes.

4. No.

Changing Queens for Bee-Paralysis.

I wrote you some time ago in regard to a colony of bees that was suffering from disease which you pronounced "bee-paralysis." I acted on your advice and let them alone for about 3 weeks, during which time the mortality increased very much, to the extent that perhaps 150 to 250 bees fluttered around the alighting-board each day and died before night. The queen all this time was doing her duty nobly, keeping the combs pretty well filled with eggs; she was a fine looking queen but I did not know her age as she was in a colony I bought in the spring of 1901. I thought possibly she might be very old, and I had about made up my mind I might as well break up the colony, as the death-rate about equaled the number of young bees produced, and the colony was not getting any stronger. About this time there was an article in the American Bee Journal by Dr. Gallup, in which he said, "If you have bee-paralysis take a sharp ax and cut off the head of the queen and give the colony another queen, and you will have no bee-paralysis, provided the queen you give is healthy." It was June 27 when I read that article, and I destroyed the queen and gave a queen-cell about ready to hatch; in a little more than a week she was depositing eggs. This is perhaps two weeks ago, and the disease seems to have disappeared.

Now, Doctor, was this a happen so, or is there some connection between the facts and the results?

The books seem to give no cure for this disease, indicating that not much is known about the disease, and I quote these facts to you in the hope that yourself or some one else,

by putting facts together from different sources, may eventually work out the cause and a cure.

OHIO.

ANSWER.—It is not an easy thing to prove that when a cure occurs after the administration of a certain remedy the cure was the result of the remedy, and perhaps equally difficult to prove that there was no relation between the two. Changing the queen of a colony is one of the many remedies put forth as a certain cure, only to prove a failure when tried by another person. Root's "A B C of Bee Culture" has this to say about it:

"In many cases destroying the queen of the infected colony, and introducing another from a healthy stock, effects a cure. This would seem to indicate that the disease is constitutional, coming from the queen; but in the South, where the disease is much more prevalent and destructive, destroying the queen seems to have but little effect."

That statement, together with the fact that in the North it is a common thing for the disease to disappear when no remedy is attempted, makes it at least not certain that the change of queen had any thing to do with the cure.

Changing Queens Now—Keeping Queens.

1. I would like to know whether it will do to change queens at this time of year or not? I have a colony of bees that were transferred about 2 weeks ago, and they have 13 queen-cells started, and I cannot find the queen; I suppose she was lost in transferring, by having so many cells started. I have a new colony of hybrid bees, which were found on a bush June 27. I would like to have the good queen in this hive, but they have a queen-cell started, and a very nice-looking queen. Can I take the queen from this colony and give it to the queenless one, and give the new queen to a good colony?

2. How long can I keep a queen before I introduce her?

ILLINOIS.

ANSWERS.—1. Yes, this is a good time of the year to change queens, or at any time when honey is freely coming in, and you can make the desired change if you observe the precautions advised in your text-book.

2. With a sufficient escort of workers and plenty to eat and drink, there is no trouble in keeping a queen a number of days while the weather is warm, possibly a month.

Transferring and Perhaps Robbing.

We lost the colony of bees transferred from the old box-hive to a new Danzenbaker hive. The bees were all, apparently, driven into the new hive, and the old hive, which contained but little honey or brood, and a lot of old dark-colored comb broken up and the pieces left lying near the stand. They seemed gradually to leave the new hive and to merge with another colony in the hive alongside, until the new hive is now empty, except a few dead bees. These bees in the two hives had not worked much all summer, and we are in doubt whether to risk transferring the other colony to the new Danzenbaker or not.

ILLINOIS.

ANSWER.—Without full particulars it is not easy to make a diagnosis. You do not say whether you left the new hive on the old stand, but it is supposed that you did. The fact that the old hive which contained some honey was broken up and the pieces left lying near the stand awakens suspicion that you left lying on the ground near the transferred colony the remains of their old residence, there being in the scattered combs some honey. It might not be a very wild guess, in such case, to say that other bees commenced promptly to work on the unprotected honey, and when that was cleaned up the marauders would turn their attention to the transferred colony, as yet in a somewhat demoralized condition, and then the robbed colony would join the robbers. This would be likely if in your locality, as in some other parts of the State, there has been something of a dearth in the harvest. It is not a safe thing to transfer when bees are not gathering.

Swarming—Italianizing—Rearing Queens—Dividing—Keeping Bees in a Building.

1. On July 8 I had a swarm come from a colony that had not swarmed for two years. About seven o'clock they came out and alighted in the top of a tall maple tree. At 9 o'clock I went to hive them; I sawed the limb off but be-

fore it reached the hive the rope broke and they fell about 4 feet from the hive, but they all went in. At noon, when I came in from the field, they had swarmed again in the hedge a block away. At one o'clock I took the same hive and tried it again and they all went in. At 3:30 o'clock I went to look at them and they were all out in front, not one inside. It was very hot and clear until 4 o'clock, when I got a sheet and set a new hive on it and shook the bees on the sheet in front of the new hive; they all went in but a few that hung to the front of the hive. At 5 it was raining; after the rain I poked them off of the front of the hive and they went in, and have been in ever since then and are doing well. Can you tell me why they did not stay the first time?

2. I am just starting, and have 2 colonies of black and 2 colonies of Italians. I would like to have all Italians. Do you think it too late to try to change now?

3. Can you tell me how to rear queens?

4. The 2 colonies of Italians are very strong and would swarm if more honey was coming in. Do you think it is too late to divide them now, or would you leave them this year?

5. I have an old building that has a vacant upstairs. Do you think it advisable to cut holes around the side and put the hives up there next spring?

ILLINOIS.

ANSWERS.—1. The heat was almost certainly the whole cause of the trouble. Next time try to keep the swarm cool. Leave the cover partly off for a day or two, and if the entrance is not large raise the hive an inch or so on blocks. If the hive is not in the shade, it will help to put an armful of hay or cut grass on top and keep it sprinkled with water.

2. Plenty of time yet.

3. You ought to find pretty full instructions in your text-book, and if you want to have fullest information on the subject you can hardly do better than to get Doolittle's excellent book on queen-rearing. See also the answer to Connecticut, page 312 of this journal.

4. It is not too late to divide, but you will have to feed if necessary.

5. Such a course is advisable only as a matter of necessity. If you have room enough to set the hives on good old Mother Earth, don't bother with any vacant up-stairs.

Changing Location of an Apiary—Crossing Blacks and Cyprians.

I send you a drawing of the location of our apiary. You will see by it that our bees have to cross one-half mile over an open bleak field. I have favored the removal of the bees to the main woods where the most of the honey is gathered, believing that the bees would gather $\frac{1}{4}$ more honey if they did not have to cross a bleak field in the face of strong southern wind. Our yield this year was 6,000 pounds of section honey from 130 colonies, spring count.

1. My partner, who is half owner, is opposed to the removal, claiming that he does not think it would pay us. I would like your opinion on the matter.

2. We are introducing Cyprian queens this season, and Cyprian queens mated to Carniolan drones. Our bees are blacks and hybrids except a few colonies of Italian 5-band, and I must say after 5 years' experience with 5-band Italians that I would not have them as a gift. They are cross, and will not store in supers even if they have full-drawn empty sections, except in a very few colonies. I find the first cross between blacks and Italians are all right. What do you think of a cross between blacks and Cyprians?

NORTH CAROLINA.

ANSWERS.—1. One of the very difficult things is to make a fair estimate as to the relative value of two different locations. One should know about the honey-plants in range of each, and even with that there will be more or less guessing. A flight of half a mile is no great thing for a bee, still it is desirable to have a pasturage as close as possible. Why not compromise matters by putting part in each place and making a comparative trial? Indeed it is quite likely that the bees will do better divided than all in one place. At any rate it would help a little toward deciding the question.

2. I don't know the character of a cross between blacks and Cyprians. Some strains of Cyprians are said to be cross, and it is possible the cross might be crosser.

The Premiums offered this week are well worth working for. Look at them.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Quirin the Queen-Breeder,

PARKERTOWN, OHIO.

[Parkertown is a P. O. Money Order office.]

15A26t Please mention the Bee Journal.

SHEEP MONEY IS GOOD MONEY if you work for us. We will start you in business and furnish the capital. Work light and easy. Send 10 cents for full line of samples and particulars.
DRAPER PUBLISHING CO., Chicago, Ills.

Please mention Bee Journal when writing.

GENERAL ITEMS

A Nebraska Report.

It looks so queer to read the reports of some of our brother bee-keepers, what discouraging reports from old bee-States, and we are having such a rush of honey and bees out here in Nebraska. I have been handling bees for over 50 years; I bought one of the first patent hives that was sold in that part of New York State; it had doors on behind, and drawers with boxes with glass in them, so we could sit and see the bees work. How many hours I have sat and watched them work, and how much I learned from it. I remember very well, though it has been over 50 years, what my old grandma said when I bought my hive, "You will never have any more luck with bees," because she did not think we should speculate in bees, for she was of the old Puritan stock that landed at Plymouth Rock. But, God bless the man that first invented the patent hives, for before that we had to rob and kill the most industrious and wisest insects that God ever made.

In all the 50 years this is one of the best of them all. This is the first year that I have taken care of my bees as I should. I started in the winter with 28 colonies, the mice destroyed 8 of them, and I bought 2 in the spring, so I had 22 to start with last spring, all good ones. I increased to 30 during plum and fruit blossom. Most of our fruit is wild, such as gooseberries, black raspberries and plums. Our bees commence on elm first, then the box-elder. In June, this year, I fed 100 pounds of granulated sugar, and kept the bees rushing so that when basswood and sweet clover came I had almost all of my 30 colonies in the boxes. When they swarmed I would

put them back, until last week, and then I had to begin to put them into hives. The swarms are so large that they fill the old Langstroth hive, that is, the most of them. I have some colonies that I hived June 28, that have their second super almost full, and everything full below. I have two and three supers on almost all of my colonies, and one and two on the new ones.

I have 38 colonies now, and all well filled. To-day is the first day in three weeks that I have had time to write. My daughter and I have been busy almost day and night; not expecting such a rush we were not prepared for it. A. C. BUTLER.

Dixon Co., Nebr., July 15.

Poisoned by Spraying—The Gulls.

We had the same experience, some years ago, as our Wisconsin friend, mentioned on page 419, and our loss was caused by being poisoned by the blossom-spraying method. There are several causes that may vary the results—if the spraying mixture is very strong, or if used in large quantities, or if the bees are working exclusively on that class of bloom it will soon use up the colony by killing off the worker-bees; but if the solution is weak, or spread on a limited area, or if the bees in the colony go to different points of the compass, or to different localities, these conditions will sometimes produce the results as our friend complains of.

If the trouble is only temporary it may be relieved sometimes by feeding the bees to keep them in the hive for a few days.

This spraying question is a wearisome one; if we are ever going to succeed we must catch the moth with its 90 to 125 eggs at the same time. The 2 to 5 percent we are catching now is little if any better than nothing.

On spraying to thin fruit (see page 436), there is a point that the writer and ye editor seemed to have missed. It does not require a poison spray for this work; clear water will produce the same effect. Practice or judgment is the only necessary qualification, as by a big drenching at the right time the whole crop can sometimes be washed off. Nature often proves this by a heavy downpour on trees when in full blossom, sometimes destroying all, or nearly all, of the entire crop. I know whereof I speak in this matter, and I know that while a poison spray may answer the same purpose, water is better because it will not injure the fruit, which the poison may do.

While we have our share of difficulties to cope with, some drouth, smelter-smoke, grasshoppers, etc., on the whole our State is doing fairly well in the different localities. We are getting from a few pounds to a full crop, even here in smoke-smothered Salt Lake County. Our old "saviors," the gulls, are devouring the grasshoppers by the wholesale, and I think we will be able to produce a sample of our product. While I don't feel cruel, I look with gratification on the many thousands of the big white birds as they devour this miserable pest; these birds are protected by law in Utah, and they seem to know it, for they are as tame as chickens. If it were not for these gulls sometimes we would have neither crops nor honey. E. S. LOVESY.

Salt Lake Co., Utah, July 12.

Mulberries for Bees.

Don't you wish you had about 100 white mulberry trees in full bearing just now?

Most of you will agree that for reasons wiser bee-keepers than I may explain, bees, this season, have certainly "been backward about coming forward" with the usual supplies of pollen or nectar. Mine had just about existed up to two weeks ago.

For some unaccountable reasons the white mulberry fruited much earlier this season than usual by nearly a month. Ordinarily it is the first week in July before any fruit ripens, but here it is now the middle of the month, and the fruiting season is practically over.

I suppose the fact is due to so much rain. The berries were exceptionally large, but not up to their standard of sweetness. I began early to gather them, mash them to a pulp, and put on the alighting-boards. It is real

fun to see the bees swarm all over the crushed berries, and extract every particle of substance, leaving the bare seeds as clean as if actually washed.

The weight of the hive is a certain evidence of what they did with the juice.

The more I reflect and observe, the more impressed I am with the usefulness of the white mulberry as a bee-provender, also as a beautiful shade-tree—a tree so hardy as almost to leave the conviction that it would thrive on an iceberg!

But apparent trouble comes with all good things. Before I began to feed the bees on mulberries no one desired more than to taste them. "Ach! too sweet!" Now that I wish them for the specific purpose, boys come around daily to nibble at them; but they don't stop at nibbling. I, too, have acquired a decided taste for them, and my "better half" remarked naively enough the other day, that "one felt like having just one more." Indeed, after eating a bowlful! And, too, the robins, and even a few cat-birds, have been lured by the fruit, until what I had set apart for the bees has become a coveted morsel for two-legged animals, with and without wings.

Only one way out of the difficulty—plant more of the trees. This I am prepared to do by rooting cuttings, and sowing the seed. I now have plants growing from both processes, and hope soon to be well stocked and able to make some of the most interested readers of the American Bee Journal a present of a plant to each (none for sale). Exception was taken to a previous article on the value of white mulberries for bee-feeding, that the bees could not extract the juice from the fruit. But bear in mind that I specifically stated that the berries must first be crushed before the pulp is fed to them.

DR. PEIRO.

78 State St., Chicago, Ill., July 10.

Bees Not Doing Well.

My bees are not doing very well this season. I started in the spring with 21 colonies, and now have 38 by natural swarming. I had one swarm issue at 5:15 in the morning of July 3, and at 7 o'clock there were 7 swarms flying. Four swarms clustered on one bunch, and 3 on another. I lived the 3 in another hive. I use the Langstroth hives. I got 17½ pounds of honey in 4½ sections from one swarm in 20 days after being in the hive. I have one colony I put in a hive on July 7; they cast a large swarm, and I examined the old hive when the bees were flying, and found it filled with brood and about a dozen queen-cells. I returned them to the old hive again, and they are doing very well now.

CHAS. HEITCHLER.

Henry Co., Ohio, July 21.

One Way to Improve Stock.

A good thing is the plan Doolittle offers, to graft cells in a colony with a queen that the bees are trying to supersede. As beginners are not likely to have many such queens, but are likely to have plenty of colonies preparing for swarming, why not graft swarming-cells? They could be cut out two or three days before time for the queens to emerge, and quite a batch might be secured—[The best time in the world for the honey-producer to rear queens, and a very choice lot of them, too, is during the swarming season. He can well afford to take the time to graft some of his swarming cells with larva or eggs from a choice breeder; then when those cells are capped cut them out and put them in nuclei. This is a very simple and easy way to rear queens, and is, in fact, if I mistake not, the one practiced by some of our most successful honey-producers who have become convinced that such queens are remarkably strong and vigorous. The next best colony, according to

our experience, is the one that is trying to supersede queens. Indeed, we consider such a colony a prize, and set it apart and keep it breeding and filling out cells.—[EDITOR.]—(Gleanings in Bee-Culture.

Moisture in Cellars.

"A York County Bee-Keeper" says in the Canadian Bee Journal:

So Mr. Alpaugh thinks that a perfectly dry cellar is not an ideal place to winter bees in! There are others who hold the same opinion. Just a short time ago a bee-keeper friend was telling me that the past winter he had part of his bees in his cellar, which is very dry. The bees were quite noisy and restless, temperature 44 degrees till along towards spring; during a heavy rain, water contrived somehow to fill up the drain around the cellar, when the bees at once quieted down and remained quiet as long as the water was there. Looks as if Doolittle's idea, that bees need moisture more than fresh air, is about right after all.

Our Nomination as a Candidate for General Manager.

In Gleanings in Bee-Culture for July 15 appeared the following, which was written entirely unbeknown to us, and consequently without our consent:

GEORGE W. YORK FOR GENERAL MANAGER.

I consider Mr. George W. York, editor and owner of the American Bee Journal, as the logical candidate for General Manager of the National Bee-Keepers' Association at the election to be held in December, 1902. It is common knowledge that Mr. York stands in the foremost rank of bee-men in America, and that he has always had the interest of the National and of bee-keepers in general at heart. Mr. York is ex-President of the National, and right in the line for promotion.

It is probably not generally known that Mr. York received the next highest number of votes for General Manager after Mr. Secor at the last election. Mr. York has declared repeatedly that he is not a candidate for any office, but I believe he would obey a unanimous call, and sacrifice his personal feelings to the good of the greatest number. He is in position to do great good in the way of publicity and promotion, and his journal has always been ready to forward the interests of the National.
HERMAN F. MOORE.

In a foot-note comment on the foregoing, Editor E. R. Root wrote this:

It is true that Mr. York has repeatedly declared he is not a candidate for the office of General Manager. I once broached the subject to him, and he very positively declined to be considered a candidate. He based his refusal on the ground that no bee-editor should take the office. But if he were to get the unanimous support he might reconsider. Personally I know he would make a good General Manager; and I do not see why the fact of his being an editor of a bee-paper should stand in the way of his considering the office. Mr. Secor has said he wished to be relieved. Just what his future action will be I do not know. There are a dozen good men whom I could support as candidates, and Mr. York, Mr. Hutchinson, Mr. France, and Mr. Secor are some of them.

Now, when I say I do not believe that the position of editor bars one from being General Manager, I wish to say emphatically there are other reasons why I, as one of them, can not and will not be considered as a candidate; but I can give my support most cordially to any other bee-editors.

I suspect the publication of this letter from Mr. Moore will raise a breeze with Bro. York. Well, let him raise the wind, Mr. Moore and I can stand a good deal—these hot days. The Association needs some men who can cool things off a little.

Certainly, all the above is very pleasant, and appreciated, but we really do not care to have the office of General Manager. We have often said that we did not think that an edi-

tor of a bee-paper should hold the position of General Manager. We are still of that opinion. And yet we realize that we have a duty to perform to our friends as well as to the cause we represent and are so deeply interested in. We are here to serve wherever best we can; and, as Mr. Root suggests, were the support on the part of the membership practically unanimous for us as General Manager, we would in duty bound feel that we should reconsider, and work where the majority wanted us to be. That would simply be in the line of duty, as we see it.

Whether or not a bee-paper editor be General Manager of the National Bee-Keepers' Association is not a matter of right or wrong. If it were, and we felt that it would be a wrong thing for us or any other editor to hold the position, we would oppose it as strongly as we could, no matter how hot or how cool the weather.

Personally, we would not do a single thing to win the position. It is no easy job. It is of no financial advantage to any one, as both Mr. Newman and Mr. Secor can easily testify. It means a lot of careful, conscientious work, but work that needs to be done, and done well, for the good of bee-keepers and the pursuit in which they are vitally interested.

So, all we can say now is, that if elected to the position of General Manager we would simply endeavor to fulfill its requirements to the best of our ability. If not elected, there will be nothing to regret on our part. We would expect to continue to labor for the good of bee-keepers and the Association just the same as we have done heretofore, counting it a privilege to have been permitted to aid so worthy a band of the world's workers.

Against Liquor and Tobacco.

Prohibitive rules against the use of liquor and tobacco have become now so nearly universal among railway and other large corporations that the recent action in this direction taken by the Chicago & North-Western Company did not receive the attention it deserved. It established far more rigid rules than ordinary, inasmuch as the company not only forbids the use of intoxicants, but forbids its men frequenting places where they are sold. An employee who does either is liable to get a curt note of dismissal from the general superintendent or the general manager. The operation of trains in this day of high speed and congested traffic requires every ounce of brain and nerve force an employee can bring into action, and for this reason the management of the North-Western does not purpose having the brains of its passenger-men befogged with whisky and tobacco. Regarding the new rule prohibiting the use of tobacco an official of the company said:

"Cleanliness and neatness are important factors in the railroading of to-day, and these considerations alone are sufficient warrant for a prohibition of the use of tobacco by employees when on duty. We desire that employees shall not make our property disgusting to travelers by the use of tobacco, and themselves steeped by tobacco-poison while on duty. I believe, however, that the use of tobacco by railroad men engaged in train operations is fast decreasing, and the time will come when a tobacco-user will be as unwelcome in the transportation departments of the railroads as a drunkard is now."

Young men who are contracting the tobacco habit in any form, or who take liquor of any kind as a beverage, or associate with those who do, may as well give up all hope of entering business life. They are not wanted. The door of success is shut before they approach its threshold.—Ram's Horn.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, July 19.—Not any comb honey of the new crop yet on the market, but advices of this week would indicate that some sections of the country are now prepared to ship as soon as any demand appears, and beginning with August there has in past seasons been more or less of a market, and it is looked for to begin this year on time. This for several reasons, one being that we are going to have some choice white clover and basswood to offer, which has not been over plentiful during the past three or four seasons. Prices are nominally the same as during the past 90 days. Beeswax sells at 30c. R. A. BURNETT & Co. □

KANSAS CITY, Aug. 2.—Receipts of comb honey increasing; fairly good demand. New fancy white, 14@15c; No. 1, 13@14c; amber, 12@13c. Extracted, white, 6c; amber, 5@5 1/2c. Beeswax, 22@25c. C. C. CLEMONS & Co.

CINCINNATI, July 26.—Considerable stock of 1901 crop fancy comb on the market and sells at 14@15c; there is a call for new comb honey, as yet none on the market; this market demands fancy comb; all other grades discourage trade. Extracted is in fair demand at 5 1/2@6c for amber and 7@8c for clover. Beeswax, 28@30c. THE FRED W. MUTH Co.

ALBANY, N. Y., July 10.—Honey market not opened yet for this season, but we look for demand to begin in a couple weeks. No old crop in the way. Expect good demand and good prices for new crop, which is very light in this vicinity. H. R. WRIGHT.

NEW YORK, July 7.—There is some fair demand for comb honey at 14c for strictly fancy white; 12@13c for No. 1, and 10@11c for amber. Extracted quiet at unchanging prices. Beeswax dull and declining at 29c. HILDRETH & SEELKEN.

CINCINNATI, Aug. 2.—Some small lots of new comb honey have been coming in, but as the weather is so warm there is very little demand. That sold to stores brought 15c for fancy.

The market for extracted was more lively, brings as follows: Amber, 5@5 1/2c; alfalfa water white, 6@6 1/2c; and white clover, 7@7 1/2c. Beeswax, 30c cash. C. H. W. WEBER.

SAN FRANCISCO, July 23.—White comb, 10@12 1/2 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4 1/2@—; amber, 4@—.

Beeswax, good to choice, light, 27@29c; dark, 25@26c. There are moderate quantities arriving, with asking figures in the main above the views of wholesale operators. Business doing at present in this center is principally of a small jobbing or retail character, and in this way transfers are being made at an advance on any figures which would be warranted as quotations based on values for round lots.

WEEKLY

APIARY OF DANIEL WHITMER, OF ST. JOSEPH CO., IND.
(See page 516.)

A STANDARD-BRED QUEEN-BEE FREE

To Our Regular Paid-in-Advance
Subscribers.

We have arranged with several of the best queen-breeders to supply us with **The Very Best Untested Italian Queens** that they can possibly rear—well worth \$1.00 each. We want every one of our present regular subscribers to have at least one of these Queens. And we propose to make it easy for you to get one or more of them.

In the first place, you must be a regular subscriber to the American Bee Journal, and your own subscription **must be paid in advance**. If it is not already paid up, you can send in the necessary amount to make it so when you order one of these fine Queens.

A Queen Free for Sending One New Subscriber

Send us \$1.00 and the name and address of one **NEW** reader for the American Bee Journal, and we will mail you one of the Queens free as a premium.

Now, go out among your bee-keeping neighbors and friends and invite them to subscribe for the old American Bee Journal. If you want some to show as samples, we will mail you, for the asking, as many copies of the American Bee Journal as you can use.

Should there be no other bee-keepers near you, and you desire one of these fine Queens any way, send us \$1.50 and we will credit your subscription for one year and also mail you a Queen. Of course, it is understood that the amount sent will pay your subscription at least one year in advance of the present time. So, if your subscription is in arrears, be sure to send enough more than the \$1.50 to pay all that is past due.

As the supply of these splendid Queens is limited, we prefer to use all of them as premiums for getting new subscribers. But if any one wishes to purchase them aside from the Bee Journal subscription, the prices are as follows: One Queen, 75c.; 3 Queens, \$2.10; 6 Queens for \$4.00.

We expect to be able to fill orders by return mail, or almost as promptly as that, so there will be no great delay at any rate.

Now for the new subscribers that you will send us—and then the Queens that we will send you! Address,

GEORGE W. YORK & CO.,

144 & 146 Erie St., CHICAGO, ILL.

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., AUG. 14, 1902.

No. 33.

Editorial.

White Clover has an unusual history this year, at least over a considerable extent of country. The unusually cold and wet weather of June, while destroying all hope of the usual June clover yield, kept the clover plants in an increasingly luxuriant condition, so that instead of becoming exhausted in June, the plants were actually blooming more profusely the last of July than the first of June. One correspondent in northern Illinois wrote us Aug. 4:

"I fed throughout the entire month of June to prevent starvation. With July came pasturage enough to supply the daily needs of the bees, but only with the coming in of August has it appeared that there may possibly be some surplus from white clover, although it is too early to tell yet. There has been no time without white clover blossoms since the first week in June, but the number of blossoms has been constantly on the increase up to the present time."

This is certainly remarkable, considering that it is not often that white clover continues to yield much beyond the middle of July. If it should turn out that clover, having given no surplus whatever previous to the first of August, should then yield a surplus, it will be something contrary to the memory of that distinguished individual—"the oldest inhabitant."

Shallow Hives.—W. K. Morrison says in *Gleanings in Bee-Culture* that when shallow hives are used it is better to use drawn combs than starters in hiving a swarm, so as to prevent pollen in sections. "The section-super in the case of an older colony should be placed on the hive earlier in the season than is the case with ordinary hives." "Full sheets of foundation must be used in the sections, otherwise there is trouble," probably because of the queen going up.

Profits of Bee-Keeping.—The *Saint Joseph Daily News* contains an article of more than a column relating to the bee-industry, in which many good things are said, the article apparently resulting from an interview with our well-known friend, Rev. Emerson T. Abbott. It is a good thing that the daily press can be interested in our pursuit, but there is always danger from misleading statements like the following:

The profits in bee-keeping are larger in proportion, according to the money invested, than of any other rural pursuit. Starting in the spring with one colony, costing \$6.00, the

yield will be 50 pounds of honey and a good swarm. The honey should bring on the open market 15 cents per pound, or a total of \$7.50, and the swarm would be worth as much the following spring as the original colony. It is a fact that small quantities are a more paying investment than the handling of many colonies, as when grouped they can not be handled so well, and contingencies arise which materially reduce the profits.

Pity that Mr. Abbott had not censored the article before it went to press, for reporters seem to have a special aptitude for getting a little "off" when it comes to matters pertaining to bee-keeping. The average reader will plainly understand from the statement quoted that he may count on a profit of \$13.50 a colony—\$7.50 for the honey and \$6.00 for the swarm. Most bee-keepers would be willing to pay a good premium to be insured the half of \$13.50 per colony annually.

Wintering Bees in Canada.—The Ontario Association called for reports as to wintering, and 55 members with 4303 colonies responded. The average losses are given in the *Canadian Bee Journal* as follows: In pit, 3.3 percent; in bee-house, 3.9; in cellar, 7.2; packed outside, 7.3; in dug-out, 12.5 percent.

"**A Tale of Blasted Hopes**" is the heading to a collection of crop reports from the different quarters of Colorado in the *Rocky Mountain Bee Journal*. Of the 29 reports quoted, nearly all warrant the heading given, and only two report a good crop.

Editor Root says that after reading hundreds of letters he thinks some regions will have a crop, others none. Readers of this journal will have noted that reports in general have not been of the most favorable character. Late flows may, however, be better than anticipated. Ours is a large country, and likely it will average up to fairly well.

The British Bee-Keepers' Guide-Book, by the well-known authority, Thomas William Cowan, has passed through 16 editions, comprising in all about 40,000 copies, and the 17th edition has now made its appearance. That others besides our British cousins appreciate the work is evidenced by the fact that no other text-book on bees has been translated into so many languages. What many have felt to be a lack in the book has now been supplied by a fine likeness of the author.

The American reader will be struck by the fact that locality, fashion, or something else, makes no little difference in the implements and plans described in this book as compared with those in vogue in this country. The British, for example, have a standard frame,

14x8 $\frac{1}{2}$ inches. In this country there is no standard frame, the one most in use being probably the Langstroth, 17 $\frac{1}{2}$ x9 $\frac{1}{4}$. Ten or eleven frames are generally used in the British hive, ten giving nearly the same comb surface as eight Langstroth frames.

Don't Put Honey in the Cellar.—In the *Rocky Mountain Bee Journal* the advice is given, "Do not store honey of any character in the cellar." If that is sound advice in one of the driest States in the Union—so dry that in the cellar is a good place to keep bread—it is eminently sound advice in places where cellars are so damp that great drops of moisture are frequently seen standing on the wall. Of course, not many bee-keepers are likely to make a mistake in this regard, but it is well to keep it constantly in mind so as to caution consumers, for the average housewife is pretty sure to consider the cellar just the place to keep honey.

Formalin and Foul Brood.—Those who have any personal experience with foul brood will be interested to know particularly about the experiments of Prof. Harrison, in Canada. It must not be understood that formalin is a drug that can be administered to a colony to cure it of foul brood any more than the fumes of sulphur could be administered to a colony to rid it of the larvæ of the bee-moth. The fumes of the formalin will kill the bacilli and the spores of foul brood, and an agent powerful enough to kill the spores could not be expected to be without effect on bees and brood; as a matter of fact, all forms of bee-life will be promptly killed by the fumes, so the drug works merely as a disinfectant. It is much, however, if the combs can be saved to be used again.

The exact manner in which Prof. Harrison proceeded is thus given in the *Canadian Bee Journal*:

Sections of comb were taken out and placed in a box the same size as an ordinary hive. The exit at the bottom was plugged up, with the exception of a small hole, and a small opening about half an inch in diameter was left at the top. To the lower hole was affixed a formalin apparatus consisting of a small alcohol lamp at the bottom, with a reservoir at the top which contains formalin.

Formalin, I might say, is the trade name given to a 40 percent solution of formaldehyde gas in water. A small portion of this is put in the reservoir over the alcohol heater, and then the top is screwed down. The top connects with a small hose-pipe, and it is placed in the lower hole of the hive. Directly after the apparatus is attached the alcohol lamp is lit and the formalin is vaporized and spreads throughout the hive. This means of disinfecting the hives was used; and the wax of the comb that was placed in it was several years old, judging from the looks of it, and contained dead larvæ, foul brood,

and also a certain number of capped cells, so that probably all the conditions were present which would be met with in a bad case of foul brood.

After the gas had spread through the hive, and the smell of the gas could be noticed issuing at the hole at the top, this top hole was closed, and almost immediately afterwards the formalin apparatus was disconnected and that lower opening plugged up, and it was kept there from one to four hours. At the end of that time the hive or box was opened and the combs taken out and a careful examination made, not only of the capped cells but all of the foul-broody cells and also certain marked cells which contained honey and also spores of the foul-brood bacillus.

In not a single instance did foul-brood germs grow from these combs after they were treated. And since then I have performed the experiment three separate times with three other distinct combs and with the same success, and in each case the germs were killed, whether they were in dead larvæ, whether they were in honey, or whether they were in capped cells.

Pure Queen-Fertilization.—Among several plans given by Mr. Doolittle in *Gleanings in Bee-Culture*, he prefers the following, adding that for securing honey the mismated queens will give just as good results as those purely mated:

Give to all colonies which have good Italian queens one or two frames of drone-comb, so that large numbers of drones will be reared in these Italian colonies, which will be very likely to secure the pure mating of from one-fourth to one-half of your young queens; and when one is found that is impurely mated, kill her and give the colony a queen-cell from your best pure breeder, and try again. As your colonies increase, your drones will increase also; and the more drones reared in your Italian colonies the better will be your chances of having all purely mated.

Weekly Budget.

MR. J. T. CALVERT, of the A. I. Root Co., passed through Chicago last week on a western trip with stop-offs in Colorado, Utah, California, Oregon, Washington, and then back through Minnesota. It will be quite a "swing around" among the bee-supply dealers. He expects to be home again about the middle of September. He reports a good season's business for 1902 at the Root factory.

QUESTIONS FOR THE CONVENTION.—Secretary Mason, of the National Bee-Keepers' Association, requests us to publish the following:

STA. B, TOLEDO, OHIO, July 30, 1902.
EDITOR AMERICAN BEE JOURNAL—

Please say to your readers that if any of them who have any questions to ask that they would like to have answered at the Denver convention, will send them to me soon, I will present them for replies.

Very truly yours,
A. B. MASON, Sec.

QUOTING THE HONEY MARKET.—A subscriber sends us the following in reference to this subject, which was discussed by the commission men in these columns recently:

MR. EDITOR:—In that interesting symposium giving views of the middlemen as to quotations, part of them think it better to quote the market a little too high than too low, while another part think it better to

On the Way to Denver

SCENE NEAR KEARNEY, NEBR., ON THE UNION PACIFIC RAILROAD.

thau high. That makes us producers suspect that part of the quotations are a little up and part a little down. As we want to get nothing but the truth from the "Old Reliable," what are we to do? Couldn't you stick a tag on the end of the high fellows, saying, "Shave these figures down a little." And another for the low fellows, reading, "Boost these figures a trifle?"

PRODUCER.

Look here, do you want to get us into trouble, and perhaps be the cause of a murder? The idea of wanting us to "stick a tag on the end of the high fellows?" Which end? And what if we couldn't reach up? And another on the low fellows! Isn't that awful?

Then, what kind of "figure" do you suppose the market-quoting "fellows" would cut after they had been "shaved" or "boosted?" No, sir, we'll not "play tag" with them, nor allow any shaving or boosting of their "figures." Why, it might disfigure them, and perhaps get us into a peek of trouble. Excuse us, please!

DANIEL WHITMER'S OAK LEAF APIARY.—When sending the picture of his apiary (shown on the first page) Mr. Whitmer wrote us as follows:

This apiary was established about 1880, and has never known a failure in a crop of good honey. Neither has it ever been diseased in any way whatever. It has never been infested with the bee-moth except in a limited degree. I have never fumigated a particle of the honey, neither do I think it is necessary if the apiarist is on duty and observing.

I have kept the Italian bees almost exclusively, believing them to be the most desirable, although I have manipulated other races in a limited way.

The "Oak Leaf Apiary" started with 2 colonies, and the maximum number consisted of 247 colonies, and were manipulated successfully in one yard by myself when at home, otherwise my wife and daughter did the work.

I produce both comb and extracted honey, and have never taken less than 10 cents per pound for the extracted, and have had as high as 18 cents; and for comb honey I have received from 10 to 22 cents per pound.

It will be noticed in the front row, just north of the tub of water, an observatory hive

upon a stand one foot high. This colony I denominate my "Missionary Hive," the entire proceeds of which I appropriate to the missionary work of the church. One year I secured \$8.00 from it for that purpose.

I have my hives placed 4 feet apart each way, and do not experience any difficulty in running my apiary.

The picture does not show nearly all of the hives in the apiary.

Last fall, after the first zero weather, I brought 20 colonies from an out-apiary in a wagon-bed on a stoneboat, and hauled them 6 miles with the hives open, and but one bee escaped and took wing that I saw. I placed them in the cellar without a flight, and they wintered finely.

DANIEL WHITMER.

ON THE WAY TO DENVER.—Here are a few questions from a Wisconsin reader that may interest all who are preparing to go to the Denver convention, Sept. 3, 4 and 5:

EDITOR YORK:—I am thinking of taking in the Denver meeting, and would like to know—

1. If the rates will be low from all points, or just from central points like Chicago?
2. For how long a time are those excursion tickets good?
3. Can a person stop off in going to or coming from Denver?
4. Can a person go one way and return another?

Please post us up a little more fully.

B. T. DAVENPORT.

We reply as follows, after interviewing a representative of the Chicago & North-Western Railroad Company:

1. Low rates cover all points.
2. By having the time on the tickets extended at Denver, they will be good until Oct. 31.
3. Yes; at points west of the Missouri River.
4. No—not at the low rates.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

Contributed Articles.

No. 4.—Improving the Race of Bees—Queen Pointers.

BY ADRIAN GETAZ.

(Continued from page 264.)

Summing up the preceding pages, we may say :

1st. In breeding stock of higher animals, close parentage can be allowed, provided defective individuals are rejected. Close parentage or inbreeding has the advantage of surely perpetuating and increasing the qualities already acquired. There is no reason to think that it would be otherwise with bees.

2d. The nurse-bees have no influence except what may arise from insufficient feeding, lack of warmth or other physical conditions.

3d. The drones have at least as much influence on the workers as the queens, and probably more.

Since the preceding numbers were written, Mr. Doolittle has published some of his experiences on the subject. When he first introduced Italian queens in his locality there were none but pure blacks in the whole neighborhood. The first mismated queens were necessarily a first cross between blacks and Italians. He says that in nine cases out of ten the hybrid workers exhibited the characteristics of the drone-stock. The workers from the Italian queens mated to black drones would show the disposition to sting, running from the combs, capping the honey white, which belong to the German race of bees. On the other hand, the hybrids from a black queen mated to an Italian queen would have all the traits peculiar to the Italian bees. He does not say anything about the color. The experiment could not be repeated now. The two races are so much intermingled that we never know certainly whether we have an absolutely pure queen of any race, and still less about the drones.

4th. The mating of the queen has no influence on the drones she produces.

Now let us go to work.

THE NURSING COLONY.

The colony in which the young queens are to be reared must, of course, be made queenless, and must be very strong in nurse-bees so as to insure sufficient warmth and generous feeding. Plenty of feed should come either from the field or from the sugar-barrel. Somebody lately claimed that some colonies or strains of bees feed their brood more generously than others. That may be, but I doubt it. I think the honey-flow, and, above everything else, the number of nurse-bees in proportion to the amount of brood to be fed, are the factors in the case.

THE TIME OF YEAR.

After the honey-flow, even when the apiarist does not especially work in view of improvement of the stock.

For several reasons. It does not interfere with the surplus-gathering. The apiarist has comparatively little to do. The drones can be controlled. In the South there is no difficulty in rearing queens at that time of the year. Simply by feeding abundantly, I can get all the worker-brood, drone-brood and queen-cells I want; and occasionally some swarms, that I don't want. In the Northern States the weather is already cool at that time of the year, and it is sometimes difficult to induce the bees to rear drone-brood.

RE-QUEENING EVERY YEAR.

Excepting the queens that are reserved for breeders, that the apiarist wishes to test a second year, I am more and more inclined to think that it is best to re-queen every year.

1st. It prevents swarming to a great extent. A young queen being more active and more vigorous will, somehow or other, induce the bees to empty and prepare the cells for brood-rearing; and probably more honey stored in the surplus apartments and less in the brood-nest. It is a well-known fact that the failure of the queen to lay a sufficient quantity of eggs is the chief cause of swarming or superseding, whether the failure is due to the queen or to the want of empty comb. And it is well known that the colonies with young queens are less apt to swarm than those with old queens.

2d. There will be less drones reared. Somebody here will say, "Why don't you cut out all drone-comb from your hives?" Well, I used to do it much more closely than now, and I thought there were only a very few drones in my whole apiary. In fact, I saw only a few now and then. When I began using queen-traps, I found that there were a great many more than I thought, and I discovered, also, that a great many were undersized and had been reared in worker-cells.

The fact is that a queen will lay but very few drone-eggs the first year (if she has no drone-comb); but their quantity will increase every year, and if no drone-cells are there they will be laid in worker-cells.

BUYING OR REARING QUEENS.

For the one who is not interested in "improving the races of bees," and who owns hundreds and perhaps thousands of colonies, the question might be asked: Would it not be cheaper for me to buy my queens than to rear them, having already more work than I can do?

I think it would be cheaper, and besides, that the queens reared by an experienced and well-equipped queen-breeder are probably better than those reared by an ordinary bee-keeper.

But there is a "but" in this case. That is, the queens are sometimes more or less injured by the transportation, and their laying faculties thereby impaired. It seems to be due to rough handling through the mails. And there seems to be a difference according to the line of transportation they come. At least it is so in my locality. Those coming from a certain direction are very often injured.

Often, apiarists think that the queens they buy are impure or mismated. But they must remember that the bees of an apiary mix considerably more than is suspected. I have several five-banded queens, and in their colonies three-banded hybrids and even black bees can be seen in small numbers. But when I look close I find that the very young bees are invariably five-banded, showing conclusively that the other strains come from the other hives of the apiary.

THE BREEDING COLONIES.

As stated above, the colony that is to rear the queen must be queenless, strong in bees, especially young bees, and well fed.

The one that is to rear the drones should be supplied with drone-comb, and also well fed. In order to prevent any interruption or delay this should be all ready at the end of the flow. The drones driven from the other hives are apt to take refuge in the ones that are fed. A judicious use of the queen-trap will dispose of the intruders.

The colony that is to furnish the brood (it may be the same that furnishes the drones or it may not), has also to be fed.

THE PROCESS.

There is no need of artificial queen-cells, transfer of larvæ, etc., for one who rears queens only for his own use. Besides that, the one who is not experienced in the business may fail. He may injure the larvæ during the "transfer," or choose some too old, or do it so awkwardly that the bees will have to remove the jelly and replace it. This will necessarily check, to some extent, the growth of the larvæ. Whether the delay is injurious or not, I don't know. Better avoid it.

We will simply take a comb of eggs and very young larvæ, cut under the eggs and larvæ holes wide enough to accommodate good cells, and as long as convenient, and put the comb thus prepared in the nursing colony. As soon as the cells are started an examination is made, and if some are built too close together, a few are destroyed so as to give sufficient room to the others. We want none but good, big cells—they give the best queens. Exactly why, I don't know. Perhaps big cells and plenty of room go together.

As soon as these cells are capped, or thereabout, we can give another comb and start the next batch of cells.

Two or three days after the cells are capped they are put in cages. The cages are either left in the nursing hive or put where the queens are to be introduced. In that last case the queen must be removed.

QUEEN-CAGES.

I make my own queen-cages for sake of cheapness. The West cages are all that can be desired, but they cost too much. I make them of wire-cloth; the two edges are sewn together with foundation wire. They are made over a round stick of wood. A few small saw-cuts across one side of the stick helps to pass the wire under. At the top end I put a ring of thick wire, one end of it projecting as a handle to fasten the cage to the comb. The wire-cloth is simply turned over the ring. The other end is closed permanently, by pinching the sides together. The top end can be closed by any kind of suitable stopper.

The queen-cells are cut with a small piece of comb forming a tail-piece. They are introduced in the cage at the top, and the tail-piece pressed into the wire-cloth so as to hold the cell, and the stopper put in.

Care must be taken in constructing the cage that no wire should protrude inside so as to injure the queen.

As far as I know, it will not do to cage queen-cells just after they are sealed. At that time the end is very thick. As soon as the queen has spun her cocoon, the bees remove the surplus wax; the end of the cell is then smoother, somewhat darker, and of a leathery appearance. If the surplus wax is not removed, the queen cannot cut her way through, and dies in the cell. At least I had a few that I thought were lost that way.

The cages should be placed at least two inches apart, that is, after the young queens have emerged. I did once put a number of them close together, and lost nearly all the queens. I suppose that they worried themselves to death trying to destroy each other.

No feed is needed. The bees will feed the caged queens provided the cages are within the cluster, that is, where the bees are constantly.

Knox Co., Tenn.

(Continued next week.)

What Caused the Bees to Die?—Was it Spraying?

BY PROF. A. J. COOK.

The following letter from Mr. J. Luther Bowers is of great interest, and I am glad to send it for publication in its entirety:

PROF. COOK:—I want to give you an account of my bees. Something like six or seven weeks ago I noticed by getting

out early, say before sunrise, a great many young bees, just hatched, on the alighting-board in the last struggles of death; and from that time until the present I find the same thing, and at this writing, in front of each hive, there are from one pint to half a gallon of dead bees.

The bees are close to the house and part of the garden which is always free of weeds. Now this ground has been, each morning, literally covered with bees crawling in every direction, and, when I irrigate, the little ditch gets clogged with bees. Some of my hives are almost depopulated. I have examined hive after hive. The young bees seem to gnaw out all right, but do not seem to be perfect. This morning, in my rounds, I found one of the best queens dead on the alighting-board with other dead bees. This queen I received April 10, 1902. I opened some of the hives of the strongest colonies and found only a few just-hatched brood (but no eggs), and those were scattered, none together, in all cases from five to eight cells apart. One hive was well filled with bees, and most of the brood-nest cells partly filled with a very light honey. There was no sealed brood in this hive, and no eggs found; I did not look for a queen, as I concluded she was dead, too.

I have tried three times to get a very strong colony to build queen-cells; in fact, I have tried three different colonies during the period named. On June 3 I took away the queens; on the seventh day I destroyed all queen-cells and inserted in each a nice frame of brood and eggs in all stages; on June 21 I opened each of these hives, but not a queen-cell did I find. I again gave each a frame of brood and eggs; I did not open the hives again until July 4, and to my astonishment no queen-cells had been built. I again gave them each a nice, new comb with fresh eggs, not over five days since they were laid, and to my surprise no queen-cells, but this comb was filled with honey and no brood whatever.

I have reared many queens—made a business of it prior to 1882. I never ran up against a case like this before. My hives have no smell. I never saw a case of foul brood in the East or in California.

I have been so situated that I could not keep bees until the last two years. When I first came to California, in 1883, I had charge of John Bidwell's bees in Butte County. There were some 300 colonies. Since that time I have been superintendent of five large fruit-ranches, and at the present time I am manager of the Fisher Lake Packing Co., and have here quite a little apiary.

February 1, 1901, I got two colonies in soap-boxes, and had 7 swarms. In the fall I began the winter with 9 colonies, and secured 110 sections of nice, white honey. I wintered 9 strong colonies, have secured about 200 sections of honey this season, and have 27 colonies; but the way things look now I do not know how many I will have in another month.

My bees have had for flora, mustard, hoarhound and black sage since fruit-bloom; and at this time a field of 60 acres of radishes, and also a field of lettuce of 110 acres, are in full bloom, to which they have free access. During the last six or seven weeks the buckeye has been in bloom, and at our county convention, July 5, it was suggested that the buckeye bloom was the cause. I have visited other apiaries and find them as bad as mine. I have tried to give you the facts. Can you give me the solution, or a remedy, or tell the cause?

J. LUTHER BOWERS.

Santa Clara Co., Calif., July 15.

ANSWER.—I have never known but one case at all like the foregoing, and that was a case of wholesale poisoning by spraying fruit-bloom. A large apple-orchard at Grand Rapids, Mich., was sprayed while in full bloom. The season was propitious, and the bees swarmed on the trees eager for the tempting nectar. The result was great loss of bees in all stages—brood, young bees, old bees, and even queens died. If it was earlier when the orchards were in bloom, and the orchards being sprayed for codling-moth or canker-worm, I should feel pretty sure of the cause of the alarming mortality.

Can it be possible that poisoned honey was stored weeks ago, and is now being used to the destruction of the bees? In case no such poisoning can be explained, or made to harmonize with the facts, then I should look to the nectar. Such immense acreage of lettuce and radish is rare. Can the bloom furnish poisonous nectar? It is not to be believed that buckeye furnishes poisonous nectar. I have

always doubted if any nectar or honey is ever poisonous. I believe a close study will prove that the arsenites are the cause of this mortality. I have suggested that the honey in the worst colonies be analyzed. A detection of arsenic would explain all.

BEES IN THE MOUNTAINS.

It will be remembered that on my visit two years ago at Yosemite, I found no bees on the highest peaks, and great quantities of aphid honey-dew was going to waste. Now I am in the San Bernardino Mountains, and have just made the top of "Old Gray Back," 11,600 feet high, yet we saw bees on Yerba Santa and Potentilla, away up at the top. The yellow and brown lilies are beautiful. It is a glad pleasure to live in the mountains and to breathe the blessed air.
Los Angeles Co., Calif., July 24.

No. 1.—How to Rear the Best Queen-Bees.

BY HENRY ALLEY.

I have read the articles of Dr. Gallup on queen-rearing with a good deal of interest. In the main the Doctor is about right.

I do believe that fully 90 percent of all the queens reared are as worthless as so many house-flies. Such queens are not reared by Nature's plans; in fact, the means used by many queen-breeders are just the opposite to those ways suggested by Nature and used by the bees themselves. Did you ever know bees to use sticks to form cell-cups first? Do bees ever go into the chamber above the brood-nest to build queen-cells unless about to supersede an old queen, or to prepare to swarm? Now, I have experimented a good deal in trying to get bees to rear queens in a hive above the main brood-nest. When the honey-flow is at its height good queens can be reared by the above method; but that part of the queen-rearing season is very short in many parts of the United States; particularly was it so this season, and if queens are to be reared they must be reared, so to speak, out of season.

Now, what are the conditions under which bees usually rear queens? Natural swarming, superseding an old queen, and when a queen is killed by accident. Of course this last condition comes more properly under a forced condition. Nearly all queens are reared under a forced condition, but bees even then comply with natural laws in producing another queen, or others. What do the bees do under these last conditions? Do they loaf about the hive, waiting until some one has furnished them artificial cell-cups? By no means; they just select an egg, or several eggs, in some convenient place, and at once commence to construct a cell-cup; in due time a lot of fine queens are reared and appear. As a rule, a queen-bee so reared is in any way the equal, and often the superior, of any queens reared under the swarming impulse. I say superior. And why are such queens superior? Now, this question brings me to a point I wish to dwell upon:

I have always claimed, and still claim, that I can rear better queens by the forced method than can be produced under the swarming impulse. I have the queens in my apiary to-day to prove this assertion. And, by the way, let me say here, that I am using an entirely new method for rearing queens. Although good queens can be reared by methods I have given, I can rear much better queens by the method now being used in my apiary.

I have found by actual experiments that a colony of bees will not rear good queens while there is a fertile queen present. I don't want any one to tell me it can be done, for I assert that it can not be done by any person. 'Tis contrary to Nature's laws. Even at swarming-time the bees do not rear as good queens as they will under queenless

conditions, and this is why I claim that I can beat Nature in the way of rearing queens. I have thought that queens from cells made at swarming-time were superior to any I could produce by the forced method. They are not, and I do not now save such cells.

As queens are now reared they are short-lived and unprolific. *All* queens reared in hives while a fertile queen is present are short-lived. The bees appear to understand, when they are given cell-cups over their brood-nest, that they are not in want of another queen. But this is not the case with queenless bees. Bees in a queenless condition feel the need of a queen, and they will bend all their energies to produce one or more. Does the reader see the point?

Again, queens reared while a fertile queen is present are not nearly as large as those reared by queenless bees. I can show larger and better-developed queens than any ever reared under the swarming influence. Come and see them.

Now, let any one come forward and dispute the statements here made. I stand ready to back them up. One may "beat around the bush" forever in trying to prove that the artificial methods employed now will produce first-class queens, but the fact remains, all the same, that it can not be done.

There is quite a difference between artificial and forced methods for rearing queens. In the artificial method it is, "Do it as you please;" in the forced plan it is a case of, "We must have a queen or the colony is destroyed." Isn't this so?

If I had time, and Editor York would allow me the space, I would show how man can undo Nature, not only in producing queen-bees, but in many other things. All the same, it is only Nature's ways under the direction of experiment and common sense.

Let this do for this time.

Essex Co., Mass.

[Come on with your proofs and methods. "Editor York" will "allow" you all the space necessary to do the thing up in a proper manner.—EDITOR.]

Marketing—Taking Orders for Honey.

BY S. E. MILLER.

If you have never tried canvassing, allow me to give you a few instructions, not that I am perfect in the art, but my experience may be helpful to others. In the first place, dress yourself in respectable clothing. With some people you might have more success if dressed somewhat shabbily, as they will be the more likely to take you for a producer if you appear in that garb; but, on the whole, I consider it best to appear respectably dressed when appearing before strangers.

Take a small pail, say one-half gallon of honey. The pail should have a lid that is easily removed and replaced, and for this purpose I find nothing neater than the friction-top pails. The sample should be a fair average of what you intend to deliver when sold, and, it is needless to say, should be thick, well ripened, and perfectly clean. As to the color, I do not find any objection raised to amber or slightly dark-colored honey. However, we should sell only one kind of honey in a town, for the average person does not know that there is a great variety of honey from various sources, and should neighbors where you have sold two kinds happen to compare the two, they are quite likely to imagine that one of the other is not a pure article, or, more likely still, they will conclude quite frequently that you are a mixer, and that it is all impure. Should you be obliged to supply honey of a kind different from what you have sold in the place before, it will be best to explain to the pur-

chaser at the time you deliver it. I allude to this because many bee-keepers are likely situated like myself. Here I nearly always get two crops, one from clover blossoms and other sources, and later another from autumn flowers, the former being almost clear, and the later amber colored.

Now, having entered a town or village, if you are acquainted with any of good standing and influence, try to secure their orders first, which is practically a recommendation. Having done this, proceed to canvass the town from house to house. Step up to the door in a business-like manner, and ring the bell or knock. When your call is answered, take off your hat and say, "Good morning, Madam" (Miss or Sir, as the case may be). "My name is Smith. I am a bee-keeper. I live over at Smithton. I am in town to-day taking orders for honey. Do you use honey in the house? I should be pleased to show you a sample of what I have."

At about this point they are likely to reply that they hardly ever use honey, or they always buy their honey from the country, and the reply will likely be accompanied by a suspicious look that indicates that they think you are offering a mixture that is put up in some city. In fact, some people will tell you as much. Do not be discouraged, however, but come at them like this:

"Madam, I am a bee-keeper, and this honey is gathered by my own bees. I am willing to stake my reputation on every pound of it. I suppose you know Dr. Jones?"

"I am well acquainted with him."

"He has known me for years, and will tell you that I would not offer you a spurious article. I have just taken his order for a gallon. Here it is" (showing your order book). "Here is Mr. Brown, also. I suppose you are acquainted with him. I have his order for one-half gallon. Would you kindly bring me a spoon and a saucer? I shall be pleased to leave you a small sample, even though you do not purchase, and it shall not cost you a cent."

At this request the spoon and saucer will generally be promptly produced. Remove the cover from the pail, dip the spoon in and give it a twist, draw it out and lay it in the saucer, and say, "There is as fine honey as was ever gathered by any bees."

If they bring a tablespoon, and your honey is as thick as it should be, this will be a good taste for a small family at the next meal. You can well afford to give a liberal sample, for a customer once gained, if properly treated, is quite likely to remain permanent.

About this time the one addressed will probably say to another member of the family, or a lady who may be visiting, "Well, Jane, I believe this is genuine honey; taste it once. Isn't it nice?" And addressing you, will say, "How do you sell it?"

By this time you should have your book and pencil in hand, and after quoting the price, say, "How much can you use? I put it up in quarts, half-gallons and gallons. Can you use a gallon?" Try to sell all you can, but if a party decides to take only a quart, do not annoy her by insisting on taking more, but say, "Thank you. I will deliver the honey in two or three days, if nothing happens to prevent." Step to the door, and as you turn to close it, say, "Would you please tell me who lives next door?" On being informed, say, "Thank you; good day."

There is some advantage in knowing the name of the person you are calling on, and, therefore, it is well to inquire as you go along. Call at every house where any one lives, unless you have good reasons for believing that there is no prospect of making a sale. Do not judge the occupants of a house from the outside appearances of the house, for though it looks dilapidated, there may be within it good

people who have good money with which to buy your honey. Canvass the town street by street, or as most convenient.

Do not plod along on the street as if you were lost, but step in a business-like manner, and when you approach a house, step up as if you were going there to sell honey, and intended doing so. Talk business. Talk honey to all with whom you have occasion to converse. If you happen to meet some one who keeps bees, and he plies you with questions, answer him kindly, explain to him what a honey-extractor is, and how it works; how extracted honey is produced. Do not appear overly wise, but let him understand that you are posted and up-to-date in the production of honey. More than likely he will talk to others about you, and tell them that you know a whole lot about bees and the production of honey.

Deliver the honey on or as near the day you have named, and you will find that most of your customers have the money waiting, and quite likely you will find a few extra orders waiting for you.

I have not named all of the obstacles that you will meet with, but all can be overcome if you are determined and energetic. Do not fail to be polite and gentlemanly in address and action.—Progressive Bee-Keeper.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Introducing a Queen to a Colony with Paralysis.

Would it be safe to introduce a new queen to a colony of bees that is troubled with paralysis? WASHINGTON.

ANSWER.—Yes. Indeed, one of the cures confidently put forward every now and then is giving a new queen to the diseased colony. The trouble is that when a new queen is given and the disease disappears, you can not be certain that the disease would not have disappeared if there had been no change of queen.

Moving Bees—Danzenbaker Hive.

I began 3 years ago by purchasing 6 Danzenbaker hives; then I bought a colony of bees in an American hive and transferred them to a Danzenbaker hive, and they did not do very well the first year, but last year I got a swarm and about 20 plain sections filled from them and from another colony which I found that was queenless. I sold the honey for 15 cents a pound in cartons.

I have been cutting out the queen-cells this year, but one colony swarmed, nevertheless. I purchased two colonies from a neighbor 2½ miles from my home, so I have all my new hives filled with good, strong colonies, and have about 150 nicely-filled sections, in spite of this poor year, as there has been so much rain.

I am 25 years of age, and to say I enjoy handling bees does not express it. I wish to increase my apiary as fast as I can, and as my knowledge will allow.

1. Could I not move home the 2 colonies I purchased, 2½ miles, by tacking a screen over the entrance at this time of the year?

2. Is the Danzenbaker hive as good as the dovetailed with Hoffman frames for comb honey?

3. Is the Danzenbaker hive good for extracted honey?

4. As I hope some time to produce both comb and extracted honey, and will have to purchase all my new hives, and of course want them all alike, what kind of hive would you advise me to buy? I like the Danzenbaker brood-nest, as the bees fill the brood-frames straight with only starters;

and I have fine success wintering them, by placing them together in a low shed and packing with chaff.

5. Is the Danzenbaker comb-honey super as easy to handle and operate as the dovetailed super with slotted section-holders, with old-style sections having bee-ways.

6. Can the dovetailed super, with slotted section-holders for old-style sections, be used on a Danzenbaker brood-chamber?
OHIO.

ANSWERS.—1. Yes, providing the entrance is large enough or the weather cool enough. It will be safer in the evening when it is cooler. If it is hot and the entrance is not more than six square inches, better have a screen to cover the top. For so short a distance two thicknesses of mosquito-netting might do. Sprinkling with water will help keep the bees cool.

2. That's a matter on which there are differences of opinion.

3. It can be used for one as well as the other, but is not very generally used for extracting.

4. Your safe plan may be to try a few of each side by side, so as to see which does best for you, and that will be better than the opinion of some one else.

5. That depends somewhat on what kind of supers you mean in the latter, and also upon the facility one has in handling the different kinds. I can handle the T super easier than either of them, while others would not have T supers.

6. With some little adaptation they can be used interchangeably.

Winter Repository—Sugar vs. Honey.

1. I have a shop 16 by 36, 7-foot studding, shingled on the outside; now I intend to partition it off to make it 16 by 16, board it up inside of the studdings, fill with sawdust, ceil it, and have a stove in the adjoining room, with a pipe running into the room described. Will that do to keep bees in during winter?

2. Which is the cheaper for cooking and general use, honey at 12½ cents per pound or sugar at 19 pounds for a dollar?
WISCONSIN.

ANSWERS.—1. You will probably find it not so successful as an underground cellar, although some are successful with a house-apiary.

2. Sugar.

Comb Foundation in Sections.

How large a piece of foundation should be put in a section?
WISCONSIN.

ANSWER.—I fill my sections, using all the foundation I can get in without having it sag. Some prefer to use small starters. "You pay your money and take your choice."

Colony with Laying Workers—Uniting Bees.

1. I have one colony of bees that is queenless. I have put frames with larvæ and eggs in three times, and they would not start a queen-cell. On July 11 I looked them over and found evidence of laying workers, so I took all of the frames and scattered them among three colonies, and took unsealed brood from those colonies that were the strongest, and put in place of the ones I took out. So on the 15th I looked them over and saw they still had not started a queen-cell. What is the reason they do not start a queen-cell? and what am I to do to save them?

2. When I exchanged the frames they fought like mad; smoking would not pacify them, and they killed each other frightfully. Do they always fight so when exchanging the frames with adhering bees? I am a beginner and do not understand much about these things yet.
WASHINGTON.

ANSWERS.—1. A colony with laying workers is generally so perverse that the best thing is to break it up entirely, for it is cheaper to make a new colony than to doctor up a colony of laying workers, in which, as a rule, all the bees

have lived so long as to be set in their ways and unwilling to do what the bee-keeper wants.

2. The fighting was probably made worse by the fact that little honey was coming in at the time, for the bees are likely to be good to each other when there is no scarcity. A plentiful sprinkling with thin sugar syrup might have been a help. As already said, the best thing is to break up the colony. If, however, you have a special affection for that colony, and want to preserve its identity, give it sealed brood from other colonies (not taking bees with the brood if they still keep up their ill temper), and after young bees hatch out from the brood you will find them ready to rear a queen from brood, or to accept a queen or cell offered them.

Queenless Colony—Quit Robbing.

I had just one colony queenless, and that for a great while, as it seemed. It was a strange case—I never had such a one. One day in June a new swarm issued, and everything seemed all right. The hives were about two rods apart. The second day both colonies commenced flying to and fro from early morning until late at night, in and out of their respective hives; that is, one to the other. That lasted over a week, and at last they gave it up. Now I see the old colony has lost its queen. I gave a queen to the new colony at that time, but the bees killed her. Does that happen often?
MICHIGAN.

ANSWER.—The case is an unusual one, but such cases have been reported under the head of quiet robbing, the swarm quietly carrying off the stores of the mother colony. The swarm having their old queen would naturally kill any other queen given them.

Bees Eating Wired Comb Foundation.

My bees have done well. I run 12 colonies for extracted honey, of which I took 88 gallons. They did not do as well in the sections. I divided the strongest colonies and used wired frames with whole sheets of comb foundation; they ate the most of them off at the lower and second lower wire. What causes the bees to eat comb foundation along the wire? Above that they build out very nicely.
PENNSYLVANIA.

ANSWER.—Perhaps the lower wire was too close to the bottom-bar. Bees are quite inclined to leave a passage-way between the comb and the bottom-bar, and if the wire was less than half an inch from the bottom-bar they would be likely to cut up to the wire. If the wire was not imbedded they would be more likely to gnaw away the foundation; and they will do more gnawing if no honey is coming in.

A Swarming and Queen Experience—Painting Hives.

1. As I hived a swarm of bees yesterday, when nearly all the workers were in the hive, the queen left them without going into the hive at all, and did not come back as long as I was watching. What could be the reason?

2. How can I find out whether there is a queen in the hive?

3. What would I better do if there is no queen in the hive?

4. How would it do to take a frame with a queen-cell and place it in the hive?

5. Would it do the bees any harm to paint the hives while they are working in them?

6. Is there any way by which I can get what bees are flying around in the air after a swarm is taken down and hived from a high tree?
MINNESOTA.

ANSWERS.—1. It is possible it was a virgin queen taking her bridal trip.

2. You may be able to see the queen by looking over the frames. Not always, however. Give a frame of brood, some of the brood at least being quite young. If you find no queen-cells started on the brood a day or so later, you may count on the presence of a queen. But you hardly need

wait for this, for if you give them no brood the swarm will return to the mother colony if no queen is present. If the queen is a laying queen, you will find eggs laid by her.

3. If you give them a frame containing eggs and young brood, they may rear a young queen, or as soon as you find they are starting queen-cells, you may give them a mature cell or a laying queen.

4. That would work all right.

5. It would be all right except the danger of having the bees daubed with the paint at the entrance. With plenty of drier in the paint, at least in the paint used in the entrance, there ought to be no trouble.

6. Unless they should have an extra queen with them, there is no need to pay any attention to them. What bees do not join the swarm will return to the old hive. If they have a queen, you must capture them the same as a separate swarm, and then unite them with the rest of the swarm.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

The Premiums offered this week are well worth working for. Look at them.

Bees Did Well, Considering.

Last spring I bought 19 colonies of bees from a neighbor in box-hives, at \$4.00 per colony. One was robbed, but the rest have done well, considering the weather. They have increased to 40 colonies. I have taken off 263 pounds of comb honey already.

V. A. HANSEN.

Polk Co., Wis., July 21.

At Least One Good Colony.

I took off 84 sections of white honey from one hive the other day, and every section was completed fancy comb; but in taking out I broke five sections by their having burr-combs. Every section on the hive was completed; I do not know how many they would have stored if they had been properly taken care of.

I have no other colony in the 20 that is storing white honey, and no other one storing half as much, and not one doing such a nice, clean job.

We had no basswood honey, and I did not think they were crowded for room.

This is my fourth year, and I have never failed to get some honey, thanks to the American Bee Journal.

LEWIS LAMKIN.

Woodbury Co., Iowa, July 31.

Fastening Brood Foundation.

Seeing the letter that A. M. Hoover wrote about fastening foundation in brood-frames, on page 487, I thought I would give my way. When I get the top-bar sawed out I set the saw to cut just so deep, so that it will cut out one-fourth of the top-bar; that is to say, cut two ways, one from the bottom and one from the side; that takes out a piece (say one-quarter) of the top-bar from the underside. Save this piece. Now, when the frame is nailed together lay it on the work-bench (or any place that is strong enough to nail on), and cut a board that will go inside of the frame, and just one-half as thick as the top-bar. Lay the foundation on

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-purified, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-GOLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy ..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white)....	\$.75	\$1.40	\$3.25	\$6.00
Sweet Clover (yellow)....	.90	1.70	4.00	7.50
Alsike Clover	1.00	1.80	4.25	8.00
White Clover	1.20	2.30	5.50	10.50
Alfalfa Clover80	1.40	3.25	6.00

Prices subject to market changes.

Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack.

Add 25 cents to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

this board and on the top-bar, where the piece is sawed out, take the piece that is sawed out and nail it back just as it was before it was sawed. The foundation is straight and firm, and can not drop out. This is the kind of frame I make and use.

Bees have done nothing in storing honey in supers yet—too much rain; it rained 26 days in June. How is that for rainy weather? D. COOLBY.

Van Buren Co., Mich., July 26.

Blue Vervain.

I enclose a flower and some leaves, and would like to have it named. It grows very extensively here in pastures, and is a great nectar-yielder.

A. C. BUTLER.

Genesee Co., Mich.

The plant is the blue vervain, *Verbena hastata*, and is, as you say, an excellent honey-plant. It is very widely distributed over the Northern States, and is of vast service to bee-keepers. (See Bee-Keepers' Guide, page 444, 17th edition.)—C. L. WALTON.

Short Honey Crop.

Our honey crop has been short, and prices low this year. The season was very wet in the early spring, and was followed by very dry weather.

Our bees came out booming this spring, but stored only 21 barrels of honey so far, and the prospects are very poor for getting any more. I had 83 colonies, and increased to 93.

B. F. BATEMAN.

Liberty Co., Fla., July 30.

Poor Season Until July 25th.

I have increased from 19 colonies to 42 this year, by natural swarming, and will have a few more; still, the season was very poor here until about July 25. White clover is just in full bloom, and the bees have been doing very good work for the last few days. Before the 25th of this month it rained on an average of four days each week, but my bees are very industrious, and some of them would go out in spite of the rain.

F. E. CASTLE.

Oueida Co., N. Y., July 30.

Quinine Honey—A Bee-Hat.

I have 18 colonies of Italian bees; they have filled, up-to-date, about 300 sections and 50 Langstroth frames with honey. About this time of year a weed that resembles "dog-fennel," except the bloom is yellow instead of white, comes into bloom, and if the bees work on it, which they do in dry weather, it makes honey as bitter as quinine, and spoils all the honey in unfinished sections or frames. It grows along streets and highways and on vacant city lots, and is a great drawback in the production of good honey.

I will give you my way of making a good bee-hat:

Take a strip of wire-cloth about 6 inches wide, and long enough to go around the head loosely, preferably having a selvedge running lengthwise on one edge. Sew the two ends together, and sow the raw edge to an old straw hat that will not leak bees; and sew to the bottom edge (the selvedge) a

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

Thousands of Hives, Millions of Sections, ready for Prompt Shipment.

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all), and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.

piece of cheese-cloth to make a kind of curtain at the bottom—and there you are. The two ends must be joined at the back, so that when you put the hat on, the place where these edges join will come at the back of the head. This makes a good protection, and a cool and comfortable veil that does not catch on to every limb or brush. I have worn one for three years, and would not swap it for the finest silk one.

G. W. FAGAN.

Arkansas Co., Ark., July 7.

A Swarming Time.

I never saw bees swarm like my bees this year. I had the new swarm on the old stand, yet the old colonies would swarm the same. Some three or four weeks later each of the new colonies swarmed. I did not have hives to put them in, so I tried everything I could hear of, but of no avail. I had the best results in caging the queen, and keeping the queen-cells cut out. I also had trouble with queens laying in the super. I think my queens are too prolific, or it may be too warm. They surely have plenty of room and ventilation—more than they ever had.

JONAS WOLF.

Howell Co., Mo., July 14.

Experience of a Minnesota Bee-Keeper.

I have been keeping bees for the last seven years. Before I took the American Bee Journal I was not much of a bee-keeper; then I commenced to learn some things. I have 102 colonies, and they are doing very well. You will think it is hard to keep bees so far north, but we do not get 300 to 400 pounds of honey as some of the Southern boys claim, but we can get some good honey this far north. Four years ago I got 1920 pounds of fine comb honey from 17 colonies, spring count, and I had 50 colonies in the fall. Last year I had 65 pounds of comb honey per colony. One colony gave me 149 pounds of extracted honey.

I was the first one to have bees in this place, and now there is one bee-keeper who has 200 colonies in this county.

I sold all my honey right here—2200 pounds to the same house last year at 14 cents a pound.

I wish I could meet some good old bee-keeper, so we could have a good bee-talk, and have him teach me some things about bees, as all I know I got out of books and from the American Bee Journal.

I have to use my left hand in all my work, as I lost my right hand five years ago.

OLIVER CARSON.

Red Lake Co., Minn., July 10.

A Wet Time in Iowa.

As has probably been noticed in the newspapers, we are having a wet season here in Iowa, as well as in the adjoining States.

Bees wintered well here, and what clover was left from last year's drouth came through so that things looked fairly promising for honey at the winter's end.

But the spring was dry and cool up to the last of May, and windy. Well, windy hardly expresses the idea—it simply kept things on the move, espe-

cially dirt. Why, dirt drifted off the fall plowing like snow, and piled in drifts 2 or 3 feet deep. Then it began to rain the latter part of May, which was what we wanted, of course, bad enough at that time, but it gradually got wetter and wetter until now it rains about half the time, and such rains! almost floods; it simply pours. The bees, of course, starved through clover bloom. that is, they all but starved, though a few of the best colonies made a good living, but mostly from mustard, I think. Since basswood began to bloom—about 10 days ago—they have stored a little surplus between rains; the most of them have one super nearly full, but whether they will finish any section honey looks extremely doubtful just now. There have been a good many swarms here this season. The bees would swarm when the hive was so bare of honey that the parent colony, when put on a new stand, not only ran off the drones before the young queen hatched, but actually pulled and carried out the drone-brood—something I never saw before, and did not suppose they ever did.

I find, as I work with bees, that there is only one sure rule in regard to them, and that is, there is no telling what bees won't do.

With fair weather in the fall there might be some fall honey; but will it stop raining?

Farm crops are at a critical stage, and unless it "fairs off" very soon small grain is doomed.

E. S. MILES.

Crawford Co., Iowa, July 8.

Introducing Queens.

I had a colony of bees this summer which mocked all treatment that I knew or ever read or heard of. It would positively accept no queen or queen-cell, under no conditions, until it finally became drone-broody. I had given up all hope, and intended to unite it as soon as I had time, when one more chance, and, to me, a seemingly good one, occurred. A large swarm issued from the hive standing next to the queenless colony, and having, besides its old queen, a virgin with it. So I left the old queen with the swarm, but the virgin I introduced in the queenless drone-breeder as follows:

First, I took about a pint of bees from the swarm and started them to run into the queenless hive; then I let the queen run in with them, when I took two or three handfuls more and threw in after them. The bees were very cross on that day, for robbers bothered lots. I did not use one whiff of smoke, and did the job in the most reckless manner, because I was very busy and felt vexed because a swarm issued so late in the season, and then having a virgin queen with them, so I had to go after them and get them. To-day she is in nice shape.

I introduce a laying queen by simply taking the old queen from the comb she is on and putting the new one in her place, by letting her run out of a round wire-cage, holding the cage over the comb, and watching when she becomes perfectly quiet, then carefully remove the cage, and very, very carefully lower the comb down into the hive; and just as carefully, without

PAGE

—BEST—

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound; 4 cans or more, 7½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Honey Season Not Encouraging.

Young white clover is everywhere now. It looks as if we would have a fine flow from it next season. I expect an immense crop of apples and pears this year. I have the finest crop I have ever seen on the trees. I think we will have hardly any surplus honey here this season, but I will have quite a crop at another apiary.

A. N. DRAPER.
Madison Co., Ill., July 28.

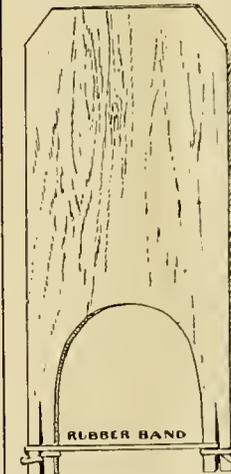

A Device for Holding a Queen While Being Clipped.

This has been sent to the editor of Gleanings in Bee-Culture, who says concerning it:

This I regard as an exceedingly simple and practical device. It consists of a piece of broken section cut in the shape of a fork, as shown. A small rubber band is stretched moderately across the two prongs, being secured at either end in the manner illustrated. Some care should be exercised in getting a rubber band light enough, and then drawing said band to such a point of tension that it will hold the queen down nicely on the

comb. To determine whether that point is reached, try the device after it is made, on a few of the worker-bees. If you can succeed in holding any one of these down, then you can with reasonable safety try it on a queen.

While she is standing still on a comb, receiving the attention of her admirers, clap it down across her back. She will wiggle and squirm; but if the rubber band is adjusted to the right point it will hold her firmly without doing any damage. Now, then, deliberately pick out one of the large wings,

WILLIS' QUEEN-CLIPPING DEVICE.

pass it between the points of the scissors and clip. Lift the little tool, and all is over.

Horn's Plan with Bee-Escapes.

Bee-escapes are now in use, or soon will be, and it is an appropriate time for me to tell my readers of a little item sent me some time ago by Mr. Henry E. Horn, of California. He says that he has obtained the best results by putting the escape in the center, and then have four strips of wood tacked to the top of the escape-board, each strip extending diagonally, from the escape to the corner of the board. Then when the bees begin racing around the edge of the board, looking for an outlet, these strips lead the bees to the center where the escape is located.—An editorial in the Bee-Keepers' Review.

Editor Root in a Scrimmage.

The editor of Gleanings in Bee-Culture had a slight difference of opinion with his bees on the occasion of trying to put on some supers

In the evening, after a thunderstorm. Others may be reminded of like experiences that they have taken the precaution to keep quiet about. Here's the story in Mr. Root's own words:

With my usual caution after such a storm I blew smoke into the entrance of one hive, removed the cover, and was about to pull out a frame from the brood-nest. It was toward dusk or I should, perhaps, have noticed that a lot of bees were standing high up on their legs, nervously twisting this way and that, ready for an onslaught. At all events, the onslaught came. It being very warm, as before stated, I had nothing on but one thickness of clothing, and linen trousers at that—a fact that those bees were not slow to discover. Unfortunately, I had hung the smoker on one side of the hive, and that was the only smoker in the yard. I reached for the weapon. Oh, no! they had possession. I retreated a few paces, and waited for them to calm down. The minute I showed myself again, out they came like hot shot, up my sleeves, and wherever my thin clothing touched me they were sure to find the spot. I retreated again, and waited for them to "cool off." Again I showed myself, with the same result.

"Well, now," said I, "I have never been conquered by a colony yet. If I can get hold of that smoker I will see who is boss." But the minute I got anywhere near the hive to get my weapon, that moment they would rush out. I finally got behind a big apple-tree which was conveniently near, and with a long screw-driver I reached the point of it into the nozzle of the smoker, and quietly lifted it off the hive.

Didn't I work up a big smudge? and didn't I give 'em fits? I smoked them at the entrance. I smoked them at the top, I made them fairly howl for mercy, and then I was boss.

Say—I was rubbing stings out of my arms all night. I was stung so much I did not really know where I had been hit until an itchy spot would remind me there was, may be, a sting located thereon.

Honey in Oil-Cans.

The Rocky Mountain Bee Journal endorses the position of this journal after the following fashion:

We hope none of our readers will risk putting extracted honey in cans that have once been used for oil. It is well-nigh impossible to remove the taint and smell of the kerosene, and the honey will quickly absorb it, rendering it unfit for use. The Editor of the American Bee Journal recently received a consignment of honey in second-hand oil-cans, much to his disgust and loss. He comes down pretty hard on the thoughtless consignor in an editorial. None too hard, however, when one considers not only the financial loss, but the incalculable damage done to the extracted honey market by such worthless stuff reaching the consumer's table.

Tennessee Queens

Daughters of Select Imported Italian. Select long-tongued (Moore's), and Select, Straight 5-banded Queens. Bred 3/4 miles apart, and mated to select drones. No bees owned within 2 1/2 miles; none impure within 3, and but few within 5 miles. No disease. 29 years' experience. **WARRANTED QUEENS**, 75 cents each; **TESTED**, \$1.50 each. Discount on large orders. Contracts with dealers especially. Discount after July 1st

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, July 19.—Not any comb honey of this week would indicate that some sections of the country are now prepared to ship as soon as any demand appears, and beginning with August there has in past seasons been more or less of a market, and it is looked for to begin this year on time. This for several reasons, one being that we are going to have some choice white clover and basswood to offer, which has not been over plentiful during the past three or four seasons. Prices are nominally the same as during the past 90 days. Beeswax sells at 30c.
R. A. BURNETT & Co.

KANSAS CITY, Aug. 2.—Receipts of comb honey increasing; fairly good demand. New fancy white, 14@15c; No. 1, 13@14c; amber, 12@13c. Extracted, white, 6c; amber, 5@5 1/2c. Beeswax, 22@25c.
C. C. CLEMONS & Co.

CINCINNATI, July 26.—Considerable stock of 1901 crop fancy comb on the market and sells at 14@15c; there is a call for new comb honey, as yet none on the market; this market demands fancy comb; all other grades discourages trade. Extracted is in fair demand at 5 1/2@6c for amber and 7@8c for clover. Beeswax, 28@30c.
THE FRED W. MUTH Co.

ALBANY, N. Y., Aug. 1.—We are having some calls for new comb honey, but no receipts to speak of yet. No price established yet, but think can get 15@16c for good white comb. Extracted, demand light.

The crop of honey near here is light, owing to so many colonies of bees having been destroyed.
H. R. WRIGHT.

NEW YORK, July 7.—There is some fair demand for comb honey at 14c for strictly fancy white; 12@13c for No. 1, and 10@11c for amber. Extracted quiet at unchanging prices. Beeswax dull and declining at 29c.
HILDRETH & SEIGELKEN.

CINCINNATI, Aug. 2.—Some small lots of new comb honey have been coming in, but as the weather is so warm there is very little demand. That sold to stores brought 15c for fancy.

The market for extracted was more lively, brings as follows: Amber, 5@5 1/2c; alfalfa water white, 6@6 1/2c; and white clover, 7@7 1/2c. Beeswax, 30c cash.
C. H. W. WESER.

SAN FRANCISCO, July 23.—White comb, 10@12 1/2 cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4 1/2@—; amber, 4@—; Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There are moderate quantities arriving, with asking figures in the main above the views of wholesale operators. Business doing at present in this center is principally of a small jobbing or retail character, and in this way transfers are being made at an advance on any figures which would be warranted as quotations based on values for round lots.

WANTED!

Honey and Beeswax. Mail sample and state price delivered Cincinnati. **C. H. W. WEBER,** 2146-2148 Central Ave., CINCINNATI, OHIO.

Please mention Bee Journal when writing

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Please mention Bee Journal when writing Advertisers.

FORTY-SECOND YEAR
No. 34

WEEKLY

D. W. WORKING,
Secretary of the Colorado Bee-Keepers' Association.—See page 532.

A STANDARD-BRED QUEEN-BEE FREE

To Our Regular Paid-in-Advance
Subscribers.

We have arranged with several of the best queen-breeders to supply us with **The Very Best Untested Italian Queens** that they can possibly rear—well worth \$1.00 each. We want every one of our present regular subscribers to have at least one of these Queens. And we propose to make it easy for you to get one or more of them.

In the first place, you must be a regular subscriber to the American Bee Journal, and your own subscription **must be paid in advance**. If it is not already paid up, you can send in the necessary amount to make it so when you order one of these fine Queens.

A Queen Free for Sending One New Subscriber

Send us \$1.00 and the name and address of one **NEW** reader for the American Bee Journal, and we will mail you one of the Queens free as a premium.

Now, go out among your bee-keeping neighbors and friends and invite them to subscribe for the old American Bee Journal. If you want some to show as samples, we will mail you, for the asking, as many copies of the American Bee Journal as you can use.

Should there be no other bee-keepers near you, and you desire one of these fine Queens any way, send us \$1.50 and we will credit your subscription for one year and also mail you a Queen. Of course, it is understood that the amount sent will pay your subscription at least one year in advance of the present time. So, if your subscription is in arrears, be sure to send enough more than the \$1.50 to pay all that is past due.

As the supply of these splendid Queens is limited, we prefer to use all of them as premiums for getting new subscribers. But if any one wishes to purchase them aside from the Bee Journal subscription, the prices are as follows: One Queen, 75c.; 3 Queens, \$2.10; 6 Queens for \$4.00.

We expect to be able to fill orders by return mail, or almost as promptly as that, so there will be no great delay at any rate.

Now for the new subscribers that you will send us—and then the Queens that we will send you! Address,

GEORGE W. YORK & CO.,

No. 34.

* Editorial Comments. *

Formalin for Foul Brood.—Editor Root is very skeptical about believing that formalin, or indeed any drug, may be successfully used in killing the *spores* of foul brood. But those Canadian professors say that beyond a doubt they *have* killed spores with formalin, and they seem to think it not so very difficult. Let us hope that Editor Root, rather than our more northern friends, is mistaken.

European vs. American Conventions.—Mr. C. P. Dadant has an article on another page contrasting the bee-keepers' conventions of continental Europe with those of America. No other man is more competent to write on this subject, for he has attended conventions on both sides of the Atlantic.

Undoubtedly the fact of greater distances in this country militates against great conventions here. The only way we can hope to gather a large crowd is to hold our meetings when low railroad rates are in force for some other and more important occasion. We have had the largest and best bee-keepers' conventions when taking advantage of the railroad rates granted on account of the meetings of the Grand Army of the Republic. This year the Denver convention will likely be well attended for the same reason—that of low rates.

And, then, another matter that may induce bee-keepers to "go again" may be that of having a jolly time rather than so much "shop talk." A convention should be as far removed as possible from being like sitting down and reading a bee-paper. This latter can be done at home, and at far less expense. The meeting and greeting of old-time as well as new-time apiarian friends should be one of the greatest incentives to attending any convention, and especially the meeting of the National.

If we may judge from the published program of the Denver convention, it will be a leader in the way of providing a variety of entertainment for those fortunate enough to be there. We hope that aside from the indoor sessions it will indeed be the best meeting ever held by the bee-keepers of this country.

We Americans have much to learn from our European brethren in many ways, and in no way more than in the convention line. Why not begin at Denver to strike out on this new line for our bee-keepers, and have such a good time that not only will all who attend this year be sure to attend next year (if alive and well), but cause those who remain at home this year to feel that they have missed about five years out of their lives by not being at the Denver convention? If Colorado bee-keepers can't succeed in doing that, they're not nearly up to the grade of their fine alfalfa honey. We are just "Aikin" to begin "Working"

up such a glorious convention here in Chicago in the fall as will simply "Harris" those Denverites into "Rauchfussing" around and putting up "the real thing" in the convention line in September.

However, we are willing that Denver shall be first. But look out for Chicago later on!

Foundation and Foul Brood.—H. W. Brice, in the Bee-keepers' Record, insists that it is not safe to use for foundation wax from foul-broody combs, while all authorities in this country seem to agree that it is safe. Which is right?

Legislation Against Foul Brood.—Although no new thought upon the subject may be given, its great importance makes it advisable to keep it warm so long as the States that have proper laws to protect the interests of bee-keepers are so very few in number. It seems a little strange that so little should be said or done by bee-keepers in States without any legislation. Now and then a solitary voice is heard, then all is again silent.

Possibly the matter stands a little in this shape: Those bee-keepers who are especially suffering from foul brood because of the lack of legislation are somewhat inclined to be discouraged, and those who are yet safe from the scourge feel no personal need of any legislation. An earnest plea to this latter class may not be amiss.

Let us suppose that you are living in a part of the State where there is no disease near you. Why should you trouble yourself about legislation? But those who are in the most distant part of the State need your help to secure legislation, and you ought not to be so selfish that you will stand idly by and see them suffer without making any effort to help.

Neither are you so safe, perhaps, as you may think. The disease may be brought into your neighborhood at any time, and it will be a great deal better for you if there is legislation in advance of the appearance of the disease. With proper laws, if you learn that your neighbor has a diseased colony, you may take steps to secure the stamping out of the disease before any colony of your own is affected; whereas, if there is no law, you are utterly helpless against having the disease spread through all the colonies surrounding you, if indeed you can do anything to prevent its appearance in your own apiary.

The fact is, that every State that secures proper laws against the disease makes you that much safer, and it is of interest to the fraternity at large that every bee-keeper in the land should do his part toward securing legislation in his own State. The entire wiping out of the disease in California will make it safer for Maine, and *vice versa*.

In the article of Hon. J. M. Hambaugh, on page 406—which article may be worth a re-perusal—he takes the ground that all hives but those with movable combs should be outlawed. At first it might seem that such a thing would be arbitrary and unjust, and the box-hive man might say, "Isn't this a free country? And haven't I a right to

keep my own bees in any kind of a hive I please?" On the same principle one might say, "Haven't I a right to carry a pistol in my pocket if it's my own pistol and my own pocket? Haven't I a right to sell poison or whiskey to any one I please?" No, you haven't the right to do these and many other things that would be a menace to the public safety or a detriment to the public good. If you have a colony in a box-hive, and the disease starts in it, you can not determine whether there is any disease until the scourge has advanced to a severe stage. In other words, the inspector can not tell whether there is any disease present or not. You have no right so to jeopardize others.

There should be earnest action everywhere; organization and combined effort everywhere. It ought to be made a difficult thing for an ignorant, careless, or pig-headed bee-keeper to harbor the disease; and it ought to be made an easy thing for others to rid him of the disease, will he will be. Shall there be such combined action everywhere, or shall it be confined to a few States?

* The Weekly Budget. *

MR. THADDEUS SMITH, of Pelee Island, Ont., Canada, died on June 11, 1902. He wrote several articles for the American Bee Journal the past year.

DR. C. C. MILLER stopped off in Chicago over night on his way home from Winona Lake Assembly, in Indiana, where he gave a talk on "The Story of the Bees, or Secrets of the Hive." His own bees (some 200 colonies) are not telling a very good story this year, on account of the unfavorable season. He fears having to feed them for winter stores.

SPECIAL RATES TO DENVER.—Pres. Hutchinson sends us the following for publication:

Special rates on the railroads were expected all over the United States when the National Letter Carriers' Association held their annual convention in Denver, but I can not learn, by the most persistent correspondence, that any rate has been made for the far West. If there is any one going from any part of the country, and there are no reduced rates given from his part of the country, let him write to me, and if any rates are eventually secured, I will at once write to him.

W. Z. HUTCHINSON.

LATER.—I have just received notice from the Santa Fe Railroad that they will sell tickets from California to Denver and return at the rate of \$55.00, for accredited delegates of the National convention of bee-keepers. Date of sale is Aug. 28, and final limit 60 days.

W. Z. H.
Flint, Mich.

MR. D. W. WORKING, whose phiz decorates the front page of this issue of the American Bee Journal, sent the following sketch with the photograph, written "By Himself":

I was born in Belle Plaine Township, Scott Co., Minn., if I may trust the records. In my short career, I have lived in three Minnesota counties, one county in Missouri, five in Kansas, one in Nebraska, and three in Colorado. My first experience with honey-bees was in Minnesota, where my grandfather kept a few colonies that knew how to sting as well as to make honey. I was stung. My latest experience with the little honey-makers has been in Colorado. My own bees sting and make honey, too. They have done neither this year; but it isn't my fault.

I have written this sketch at the earnest and frequently repeated request of Editor York, who has also asked me for a photograph of myself. I have had the picture made es-

pecially for use in connection with the coming convention of the National Bee-Keepers' Association; it flatters me, though Brother York's engraving may not. I confess that I don't like to write this stuff. It is all true enough, no doubt; but somehow my modesty and my vanity both protest that some one else ought to have written me up. Probably no honest man could be persuaded to do it.

* * * * *

P. S.—If you are coming to the big Denver convention, I wish you would let me know at once. I want to tell our daily papers about the crowds of bee-keepers who are going to be with us on that occasion. We are to have a real poet at our banquet. I don't mean York, or Secor, or Myself.

Box 432, Denver, Colo. D. W. WORKING.

A BEE-KEEPERS' PICNIC.—Mr. F. Greiner, of Ontario Co., N. Y., wrote us Aug. 7:

"We had a bee-keepers' picnic Aug. 1, along the shores of Canandaigua Lake. We had a good time. The most of our bee-keepers have harvested a fair honey crop."

So far as we know, this is the only bee-keepers' picnic in the United States. It's a good idea. The only trouble is, that many who would like to join in an affair of that kind live too far away.

A DELUGE OF ORDERS.—It seems the American Bee Journal is a pretty good advertising medium, if we may judge by the following:

DEAR BRO. YORK:—Please take my advertisement out of the American Bee Journal. It has caused such a "deluge" of orders that I am now three weeks behind orders, instead of being able to send by "return mail," as that "little, lying old man" is telling your readers.

If this is any criterion to go by, the American Bee Journal is the best advertising medium out.

Hastily,

G. M. DOOLITTLE.

And yet there are a lot of breeders of good queens who do not have their advertisements in the American Bee Journal. Some seem to think that our advertising rates are too high. But when returns are compared with the amount invested, we think there will be no cause to complain, that is, provided the prices of queens or goods offered are reasonable, and that all comes up to the claims made by the advertiser.

"IMPORTED" A "SUPERIOR QUEEN."—A Wisconsin ex-bachelor, who, of course, is no longer "queenless," sends us the following:

I would say to "Iowa," who asks, "Why are there so many bachelor bee-keepers?" that I was one for a good many years, and in the summer season was too busy with bees and bee-queens to think of much else, but finally devoted one winter (while my bees were in the cellar) to a more worthy enterprise, and the next spring I was no longer a bachelor, for I had found and imported a "queen" of "superior stock."

B. T. D.

[Now, that's good. Only don't let any lonesome bachelor get discouraged if he should not be able to import his "queen." The home-bred ones are just as likely to be of the "superior stock" as the best imported. We have been rather observing "along this line," and have also found, from personal experience as well, that, should the prospective home queen not be of such tender years, it is no perceptible detriment, so far as we have been able to determine. (Of course, it wouldn't do for a certain "queen" to see this copy of the American Bee Journal, or a certain "old drone" might wish he hadn't buzzed so loud.)—ED]

DR. ANGELO DUBINI, one of the most prominent bee-keepers of all Europe, who lived in Italy, passed away recently, at the age of 89, the result of a fall in his house. Editor Bertrand says of him:

He had been for about 38 years attached to the Grand Hospital of Milan; and after a brilliant and useful medical career, in the course of which he published several impor-

tant works which established his reputation, he retired at the age of 65 years. But he had too much activity of spirit to remain idle. An amateur experimenter with bees, he devoted his robust old age to the advancement of apiculture.

He became, in 1868, one of the founders of *L'Apicoltore*, and worked for that journal assiduously till his death. Understanding several languages, he kept abreast with apicultural literature, and published monthly, under the name of *Spigolare Apistiche*, an analytical review of foreign journals, which was greatly appreciated, as were all the rest of his contributions to the journal. He left a very complete treatise, "The Bee and Its Management," which has gone through two editions.

The loss of this gifted man and untiring worker, one of vast erudition which he devoted to the service of others, will be keenly felt in Italy, and by all outside of Italy, who, like ourselves, have had the privilege of knowing personally the man, or who have been able to appreciate his works.

Bee-Keepers' Associations and Conventions.

BY C. P. DADANT.

I have often wondered at the greater success of the bee-keepers' associations in Europe than in this country, and especially at the greater attendance at conventions, whether local or national, and I have tried to explain the thing in several ways. We feel ahead of the Old World bee-keepers in practice and pecuniary success in bee-culture, but it is only accidentally that we can have a bee-keepers' meeting that is well attended; and whether our associations are local or represent entire States, we can readily see that it is only exceptional that the bee-keeper belongs to them or attends them. The greater distances, also the higher railroad fares, in this part of the world, would partly explain the lack of attendance; but money is more plentiful here, and our citizens spend a dollar as easily as a European spends a franc. So this is not the whole explanation.

I have been reading, lately, some of the programs and reports of meetings, and it strikes me that there is a congeniality and unconventionality about *their* meetings which are absent from many of ours. It seems to me that we are too stiff, too matter-of-fact; we are too fond of parliamentary rules, essays, and addresses; we do not put enough free, neighborly intercourse into our meetings. We do too much bee-keeping and do not mix in enough pleasant social intercourse, which enables the members to get acquainted.

Let me read to you the program of the Societe Romande d'Apiculture, of Switzerland, which was to meet May 12 and 13, as I find it in the *Revue Internationale*:

Official meeting at 10 o'clock, a.m.

At 12:30, dinner at Hotel de l'Ange; price, 40 cents.

At 2:15, departure in carriages (20 cents) to visit the apiaries of Messrs. Sautter and Odier.

At 5:45, lunch at the apiary of LaRippe.

Return to Nyon in the evening, unconventional meeting.

Rooms at the Hotel de l'Ange, 30 cents; breakfast, 20 cents.

The 13th, at 7:15, if the weather is good, excursion to the Jura mountains. Upon the return, visit and lunch with Mr. Bertrand.

In the evening, adjournment.

Now for the report of the meeting of Feb. 17: It appears that this Romande Society is divided into sections, each section being expected to make regular reports of the condition of the bees, and in each section some bee-keepers are provided with scales at the expense of the Society and are expected to make monthly reports of the weights of hives, with meteorological observations, and all remarks that may be of interest to the apiarian public. At this meet-

ing in February, one apiarist is reported as failing to make his reports regularly, and it is decided to take away his scale and give it to some one who will be more prompt. It appears also from the reports that the Romande Association is a member of the Federation of Agricultural Associations of Switzerland and that this latter national body allows the Romande a certain sum each year for experiments, etc., requiring a condensed annual report.

The statement of the treasurer shows that the Association is in debt, but that the receipts for 1901 have been 1656 francs. It appears also from the report that the annual membership fee is only one franc—20 cents.

We see, also, that the Association appoints a member each year to visit apiaries, give instructions or suggestions, and deliver lectures when desired.

All the foregoing, although showing that there is more social intercourse among the members of an European Association than in this country, also shows that more pains are taken to diffuse information in different ways. But the important point that I wish to notice is the more steady condition and better attendance at these local meetings than is usually found in the United States. The Germans are, if anything, still more enthusiastic in their meetings, and their National Congresses are attended by hundreds upon hundreds of jovial and happy members.

If our apiarists will look back upon our experience in bee-keepers' associations in this country, they will see that we have been successful in proportion as we have made our meetings attractive, not only by some practical discussions in the meeting, but also by social and familiar intercourse between members, visits to apiaries, exhibitions, banquets, and, in fact, by such enjoyable performances as would make the absent member wish that he had been there, when he reads the report.

I know that some of my friends will say, as I have heard them say: "I do not care for all this visiting; what I want is bee-knowledge, and I want to put in ten solid hours each day, to get all the information I can." This is well and good if everybody thought as he does, but for ten who feel thus, there are hundreds who want a little pleasure mixed in with their attendance at a convention. Besides, some of you have probably experienced what I did. I have learned more, at conventions, from a private talk with an individual whom I had singled out of the mass, than I have learned from discussions where we often hear a man make a long talk about something that you and I learned perhaps long before he did.

In my opinion, Mr. Editor, the Chicago meeting last fall, which was so pleasant, derived as much of its popularity from the humble banquet in the evening, as from any and all of its discussions. Hancock Co., Ill.

No. 2.—How to Rear the Best Queen-Bees.

BY HENRY ALLEY.

(Continued from page 519).

I have looked over Dr. Gallup's article on page 470. They are good articles, interesting, and to the point. I want to take up a few points in one of Dr. Gallup's article. He says:

"When I first began the nucleus plan I reared them small, inferior, and, as Mr. Benedict said, as black as crows, but I jumped out of that boat long ago." I never reared queens by any nucleus plan, always using the strongest colonies in my apiary for that purpose. But I want to tell Dr. Gallup, and all others, that the best queens I ever saw were reared in a small box 5x5x6 inches, and on 4 small combs. Not only do I make the above assertion, but I now have a dozen queens in my apiary that were so reared. Now

these boxes have been used by me more than 30 years. I do not rear queens in them, but merely use them for fertilizing-hives. I have always found these small hives more convenient, and easy to manipulate, and superior in every way to full-size frames. "Well," some one says, "how came you with those fine queens if you didn't rear them in those little hives?"

When the young queens have filled their little combs with brood, they are sent out to a customer. In some cases I fail to introduce queens to them, or they are in some way lost, and the result is the bees rear several queens. Although none of these hives contains over one pint of bees, they never fail to rear the best queens that are produced by any method used for rearing queens. Now, the "proof of the pudding is in eating it," and I want to say here that I will mail Dr. Gallup, or any other man of his standing, several queens that were reared in these small boxes, and if these queens can be equalled by queens reared at swarming-time I am ready to "throw up the sponge," and drop this question. Conditions, and not circumstances, are what produce good queens.

Taking a hint from the above experience, I am now rearing all my queens by a method that has never appeared in print.

The poorest queens I ever saw were reared at swarming-time, and as Dr. Gallup says, "I jumped out of that boat long ago." I don't want any such queens. I can rear better ones. Why, a queen that was reared in the above way (nucleus) was kept in my apiary 4 years and 2 months, and she was the mother of more than 400,000 bees.

A few years ago, as many readers will remember, I had a hundred-dollar queen. Thousands of the readers of this Journal had received queens from this particular queen, and nearly every customer sent me a testimonial of the queens received.

This hundred-dollar queen was a come-by-chance, and reared in one of the little hives described above. I now have several queens that are promising duplicates of the hundred-dollar queen.

I don't believe queen-rearing begins to be understood. When it is, no queens will be reared in colonies that have fertile queens. First-class queens cannot be reared by that process, and the sooner queen-breeders give it up the better the queens will be. 'Tis unnatural, unscientific, and not an up-to-date method.

I sometimes purchase a queen or two to see what some people are rearing for queens. In all my experience in this line I never have as yet gotten a queen that was worth the two-cent postage stamp that was on the cage. Last season I paid a man \$8.00 for two queens. One of them was half fair; and the other was worthless.

Experiment, gentlemen, and get down to a method for rearing queens that will beat Nature out of sight. It can be done. It has been done. My experience in rearing queens over the brood-nest has been that more than half of the queens so reared are worthless; and out of one lot of 35 queen-cells only 2 queens appeared to be worth saving. Other people claim that they can rear good queens in this way. Why can't I? My colonies are as strong, and I feed to stimulate as much as anybody. I had to give up the system several years ago.

I rather like this queen-rearing subject. I have given nearly 40 years of my life to rearing queens, and I shall probably continue in this business as long as I am on earth.

Queens whose colonies fill 100 one-pound sections cannot be considered cheap queens.

Finally, I have shown that a few bees, in a small hive, without a stimulant of any kind, save for the want and necessity of a queen, will produce much better queens than

can be produced under the most favorable conditions. One thing is peculiar with the small colony, and that is, I have found the queens they rear are always good—first-class in all respects.

Dr. Gallup is good authority on almost any subject connected with bees, but I believe that I have had very much more experience in this line than he has, or, in fact, any other man living.

No. 5.—Improving the Races of Bees—Queen Pointers.

BY ADRIAN GETAZ.

(Continued from page 518.)

INTRODUCING QUEENS.

You don't want any nuclei. Nuclei are a necessary evil with which the professional queen-breeders have to put up to get their queens mated. The apiarist rearing only his own queens can just as well have them mated in the colonies which they occupy.

One or two days after the old queen has been removed, the virgin queen will be accepted, and could be as well turned in loose. Still it is safer to introduce her caged, and release her the following day.

The trouble will come later, if it does come. If there is any unsealed brood the bees may start queen-cells, and, when they are ready to seal, kill the virgin queen. At least they have done it a few times for me; and since then I never release the virgin until all the brood is sealed. Needless to say that the queen-cells which may be there are removed.

Under such circumstances, a laying queen would go out with a swarm. Why should a virgin queen be killed? When the queen-cells are ready to seal, the queen, whether virgin or laying, will try to destroy them. The bees on the other hand, will try to protect the cells against the attack of the queen.

Now, bees have a great respect for a laying queen and will avoid hurting her. But they may not be so particular about a virgin; and she may get worsted in the scuffle. That would be my explanation.

TO PREVENT SWARMING.

In working for comb honey, it is not possible to avoid swarming entirely. If swarming is allowed, both the swarm and the parent colony are too weak to do much good in the majority of localities. The question comes to keep all together. Some re-queen throughout; and where the majority of the colonies are expected to swarm, it is probably the best. If not, I would treat only those that do swarm.

In the first place, the old queen must be removed or caged as soon as possible. Otherwise there would be a daily swarming and no work done. Furthermore, as long as there are eggs and larvæ present the bees will construct queen-cells as fast as you destroy them. So it is imperative that the egg-laying is stopped as soon as possible.

Later on you can release the old queen, if she is caged, or introduce another one, or let the bees have one from their own queen-cells.

The advice to destroy all queen-cells but one is not good. Cage several of the cells and pick out the best-looking of the queens after they have emerged. I am partial to color, and also to a long and well-shaped abdomen, taking for granted that such a one contains the best developed generative organs.

Here is the chief point, and the key to success: Be sure that the bees are at least four days without unsealed brood. During these days the bees lose their disposition to

build queen-cells. How it is, I do not know. But I suppose that the majority of the nurses take to the field-work, and that when the egg-laying is resumed, those remaining have all they can do to feed the young brood, and have no time to fool away constructing queen-cells.

CATCHING AND CARRYING QUEENS.

A trick of my own to catch a queen is to throw a cup of water on her, whether she is on a comb or in a queen-trap, or before an entrance-guard.

I frequently carry queens from one apiary to another simply by putting them in the cages described above, and the cages in my pocket. A few hours of fasting does not hurt them.

FINDING THE QUEENS.

Perhaps the most disagreeable part of the operation is to find the queen to be replaced. After trying nearly all the methods of which I read, and almost all those I could think of, I finally settled on the following :

Smoke the colony ; take out the combs as rapidly as possible, putting them into a comb-basket. Look into the hive ; the queen may be on the walls or on the floor. As there are but few bees left she can easily be seen if there. Cover the hive, closing also the entrance. Now shake the bees from the combs on a sheet or some boards two or three feet away from the entrance, replacing the combs in the basket. Cover the basket. Now, uncover the entrance of the hive (not the top), put on an entrance-guard, and start the bees in. You will see the queen readily if she is among them. If not, you will find her on the combs. Do not uncover the hive and return the combs until the queen is found.

Some details need a few more explanations. Do not smoke the bees more than necessary, yet enough so there will be no danger of having to do it again. Smoke first at the entrance, not much, or you might drive the queen in the super or on the under side of the cover. Then smoke from above, not too much, either, chiefly between the combs and the walls of the hive. Then again a little at the entrance so as to drive the queen back on the combs, if she happens to be on the floor of the hive. If supers are on, it is well to first smoke through them, as the queen might be in the sections. The whole is done in little time. The object is to drive the queen among the combs or rather on the combs, instead of driving her off the combs and perhaps clear out of the hive.

It is not necessary to shake off the bees clean from the combs ; only enough so the queen can easily be seen. A virgin queen will be almost always found on the combs ; a laying queen being heavy with eggs will, on the other hand, fall easily from the combs.

In looking over the combs watch especially the space between the comb and the end-bars and bottom-bar. Sometimes the queen is near the bottom opposite you, and when you turn the comb to look on the other side she passes under and is on the "other side, too." I suppose she does that to avoid the sun or the light, as the apiarist inspecting a comb invariably turns it so the light strikes it.

The covering of the hive is to prevent the shaken bees from climbing in (queen and all) before the operator is ready. It also prevents a virgin queen from alighting unbeknown to the apiarist. Virgin queens do often take wing and come back a few minutes later.

If there are some queen-cells on the comb that are to be saved, they should be cut off and caged before shaking, otherwise their occupants might be injured. Often when ripe cells are on the comb, a number of virgins emerge while the combs are in the basket. Be sure to get them all.

In taking the combs out of the hive, I take one or two

on one side, and then begin on the other side. This still diminishes the chances of leaving the queen on the walls of the hive.

QUEEN-TRAPS.

When the apiarist is not present all the time during the swarming season, the best is to have the queen-traps attached to the hives. Then if a swarm comes out during his absence the queen will be caught in the trap, and he then knows which colonies have swarmed, and saves his swarm.

That is all right so far as the saving of the swarms is concerned, but the queens do not remain in the traps. In the course of a few hours they invariably succeed in getting back through the cones. The drones are not quite so smart. Still, a number of them do go back. There is room right here for improvement.

As originally constructed the queen-traps (and entrance-guards) are a considerable help to the bees against robbers. But the present traps are just the reverse. The robbers learn to get in, and come out through the upper story while the home bees are vainly watching in front of the lower entrance. This should also be corrected.

LONGEVITY OF BEES.

Some writers have lately insisted on having strains of long-lived bees. I do not see the point. Bees in the working season do not die of old age, but from accidents and actual wearing out of the body, especially of the wings. If you look at those which leave the hive to die, you will almost invariably see them with ragged wings, unable to fly any more. But for the accidents and wearing out, the workers might live perhaps as long as the queens.

It has been said also that the rearing of brood is what shortens the life of the bees the most. I just don't believe it. It is true that bees die faster when the most brood is reared. But the bees rear brood when they gather nectar. And it is the gathering, with its exposure to accident and wearing out, that kills the bees. Knox Co., Tenn.

Working for Beeswax in Australia.

In Australia, with honey at a very low price, and with some kinds of honey not readily marketable, there is live interest in the question whether it may be a profitable thing to work chiefly for wax, and the matter has been discussed no little. Opinions vary greatly. R. Beuhne expresses himself thus in the Australian Bee-Bulletin :

The editor of the Australian Bee-Keeper thinks that 13 pounds of honey (the amount which, according to Cowan and Siumins, is necessary) is an excessively high estimate.

In my opinion it is a very low one, and I have never been able to get below 20 in my wholesale attempts some years ago to convert inferior honey into wax ; notwithstanding that the attempts were made under the most favorable conditions of strength of colonies and of temperature, and a dogged determination on my part to succeed, I finally gave it up and got rid of the inferior honey by shifting away from it.

Unless we feed back the honey, which is a ruinous proceeding, we can not get more than one pound of wax to every 25 pounds of honey in running bees for wax. Box-hives produce as high as 1 to 20, when they have been allowed to become choked up, resulting in endless swarming.

The amount of wax asserted to be wasted when bees have no opportunity to build combs is greatly over-estimated. Has any one ever found a half-ounce on the bottom-board of a hive in which a swarm was hived on sheets or combs ? Let it be wasted ; it is paid for many times over by the honey stored if combs are given, and after a few days it will take all the wax they produce for sealing cells.

"Loyalstone," on the other hand, considers the cost in honey only about a fifth as much. His plan of procedure

will be of interest to any who may be situated so as to have practical interest in the matter. He says in the same journal:

I have not tried the method on a large scale, because my locality is not suited for it; but I have tried it year after year for four years, on various colonies of bees, and have always had the same return of wax in ratio to the amount of honey produced. You will notice that it takes (according to my estimation) about 5 1-20 pounds of honey to produce one pound of wax. Only one kind of hive in my opinion is suitable for wax-production, and that is the "Long Ideal," of 25 frames—20 would do but 25 frames are better. I use the ordinary Root-Hoffman standard frame. The "long ideal" gives the space required for clustering room, a thing absolutely necessary for wax-production. The clustering-room is too cramped in 8 or 10 frame hives. I have all frames with a small stick across center, in place of wire. At extracting time I take out all frames containing honey, extract the honey, then cut out all comb save about one inch attached to top-bar for starter. To describe it better, I will take a case of one hive, "long ideal," 20 frames.

I have to fit a queen-excluder to this hive, which I use the first time I open the hive to extract. I find all the brood-comb, place it together at the front of the hive and place a queen-excluder behind them to prevent the queen from getting to the back. Should there be more than 8 frames of brood in the hive, I place the oldest of them behind the excluder. I keep the hive this way till the approach of winter, when I withdraw the excluder till next season. Occasionally I remove two frames from the brood-chamber, replacing with empty ones from the back.

At first extracting I take, say 10 frames, and cut out all combs, leaving a starter on each and replacing frames in the hive. On the top of this hive I have a kind of super 3 inches deep with canvas cloth on the bottom. After replacing frames I place this super on top and pour into it two-thirds of the honey extracted from the frames, place the lid on top and the bees are forced to consume the honey as it comes through the cloth, and commence comb-building.

At the end of 4 days I open up the hive again and find combs built again, with a fair amount of fresh honey in them; I go through the same process, extracting the honey, cutting out the comb, and returning to the hive, this time returning all honey extracted, together with the one-third left from last extracting, to be sucked through the canvas at the bottom of the super.

After the second process, I generally wait from 5 to 7 days, according to the weather, and again proceed as before, giving back all honey extracted each time to the end of the season. You will notice I always leave two frames at the back. This is to keep the bees in a contented frame of mind. It seems to upset them a lot if the whole of the frames are cleared from the back each time.

After extracting the honey I run it into a watering-can with the nose off, and after replacing frames I place super on, pour the honey in and replace close-fitting cover.

I have tried this experiment with 10-frame two-story hives, queen-excluder between, but with little success, as I could not feed sufficient honey through the super. The extra weight of honey forced it through the canvas too quickly, and the bees could not get sufficient clustering-room without over-crowding one another; in fact, any other hives but the "long ideal" proved failures for wax-production. As I said before, I have experimented on this plan on various colonies of bees, and find the return of wax is 1 pound for every 5 1-20 pounds of honey returned to the hive.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Likely Robber-Bees.

I would like to know the meaning of these actions of a colony of bees: The bees come from the hive with their feet locked, and struggle to get apart, and when they finally get separated one goes into the hive and the other flies away. The bees seem to be working all right.

MASSACHUSETTS.

ANSWER.—A foreign bee has probably made an entrance into the hive to steal some honey and has been nabbed by one of the sentinels. Struggling to get loose, the robber works toward the outside, and quickly flies away as soon as loose.

Some Swarming Difficulties.

On page 488, I read with much interest the swarming difficulties of "Illinois," which he says would knock into a cocked hat all theories he could find in two bee-books. But I think I have just had an experience with one of my colonies which will "go him one better."

On July 22, the first or prime swarm issued, and was duly hived, but after being hived about an hour came out again and left. The next swarm issued on July 27, but it returned to the parent colony after a short time, and before properly settling (2 days later, July 29) another, the third, swarm issued, but the queen had been caught in an Alley queen-trap, and queen and bees were properly hived and went to work all right. The next day (July 30) the fourth swarm issued, but we again caught the queen and destroyed her, the bees returning to the hive. The next, and fifth swarm came forth August 1, and again the queen was trapped, and bees returned to hive as before. I thought this was quite enough swarming for one colony, but while I was standing in front of the same colony this morning (August 3), and thinking of the trouble they had caused us, another swarm, the sixth one, came forth. I put the queen-trap in front of the hive just in time to catch this queen also, and killed her, thinking the bees would soon return, but as they did not seem inclined, I cut them down from the tree in which they had settled, and mixed them with the swarm hived on July 29. Everything seems all right now, and I hope they will not swarm any more. This one colony swarmed 6 times in 13 days, and 4 queens were caught in the trap and killed. The question I would like to have answered is this:

Did I do the proper thing in this difficulty? and what may be the cause of so much swarming? I may add that the weather has been warm and clear during this time.

MISSOURI.

ANSWER.—July 27 a swarm issued and returned, leaving the colony as strong as before, and when the bees returned July 30 and August 1 it was practically the same as if no swarm had issued, reducing the number of after-swarms to two, not by any means a large number. Put a queen-excluder under a hive before the colony swarms, and the bees may swarm out a dozen times, first a number of times with the old queen in the hive, then more times after a young queen has emerged. If you had left the bees entirely alone, there would hardly have been so many attempts at swarming; or if you had hived them each time there would not have been so many issues. If you had returned the swarms without killing the queens you might have done better, for the colony was left un-reduced in strength, and so long as two queen-cells were left in the hive the bees would continue to swarm. Instead of returning the swarm to the mother colony, if you had added the swarm July 30 to

the one hived July 29, it is likely there would have been no further swarming. Better still, if you had put the swarm on the old stand July 29, putting the old hive on a new stand, that would likely have prevented further swarming.

Rearing Long-Lived Queens.

1. Are queens reared in full colonies over an excluder, from larva not over 3 days old, reared either by the Doolittle cell-cup plan or by the Alley plan—are queens reared thus inferior to queens reared under the natural impulse of the bees, as by swarming or supersedure?

2. If so, are they inferior only as to longevity, or does it also make them inferior in prolificness?

I have read with considerable interest the articles from Dr. Gallup, as appearing in the Bee Journal, and, although I would rather that the Doctor had been seriously mistaken in his observations, than if he were not, yet the important part of the thing is to know whether we are really rearing queens by the aforesaid plans that will not give us the amount of long-lived workers as will those naturally reared by the bees.

ILLINOIS.

ANSWERS.—1. They may be just as good. They may also be inferior. To be just as good, conditions as to strength of colony, yield of honey, and other things should be all right.

2. When they are inferior they are likely to be inferior in both respects.

If Dr. Gallup is right in saying that queens reared by the Doolittle plan or by any other plan than by swarming or superseding are necessarily inferior, then Mr. Doolittle is either ignorant or dishonest. It is easier for me to believe that Dr. Gallup is utterly wrong than to believe that Mr. Doolittle is either a fool or a fraud. Neither does Mr. Doolittle stand alone, for a large number of others that I believe are intelligent and honest stand with him.

Bees Getting Black and Cross.

What is the cause of our bees getting black and cross. When I first got them, and for 3 years, I did not see any black bees, and now more than $\frac{1}{4}$ of them are blacks, when they were all golden Italian, and all the bees here came from the bees I brought. There were no bees in the woods here.

MINNESOTA.

ANSWER.—It must be the working in of black blood. Your young queens might meet drones from colonies a long way off, and it would be difficult for you to be certain there were no other bees within a radius of five miles.

As to the cross bees, it is quite likely that if you observe carefully you will find that all your colonies are far from being alike. It may be that a single colony furnishes most of the culprits. If so, kill the queen of that colony and give them a queen of better stock.

Diseased Brood—Feeding and Moving Bees.

1. I have another nut for you to crack, and it is a serious one this time, I think. I have 7 colonies in box-hives about 16 miles from here. Last April, the men that kept them hived a fine swarm in a 10-frame hive, on 1-inch starters. They filled the hive full of comb, and have a lot of honey. They had a good-looking queen, a few old bees, a little brood sealed, and a little not sealed; a few eggs in worker and drone cells. The most or all that was sealed, and part of the unsealed, was dead. The dead ones are a little dark, and very tough, but not ropy; they smell a little sour, but not much odor at all. The other two frame-hives are all right, and the box-hive seems to be, too. They are in the hot sun; it has been from 100 to 108 degrees in the shade for the past 6 weeks. Do you think it is either foul or black brood? No such disease has ever been here.

2. If it is either foul or black brood they must have caught it by using comb foundation. What do you think about it?

3. If not black or foul brood, what do you think it is?

4. If I send a sample to Dr. Howard, how large a piece, and how should I send it?

5. Would it be safe to ship a few colonies about 500 or 600 miles?

6. If so, would early frost be the best time to do so?

7. I expect, on account of very dry, hot weather, to have to feed some. Will it be best to feed before or after I move them.

8. Would it do to put one hive on top of the other in the car? If so, ought I to nail strips to hold them together?

ANSWERS.—1. I doubt it being either.

2. It is pretty generally agreed in this country that foundation will not carry the disease, and there are other ways by which it may be carried.

3. I don't know.

4. Send a piece two inches square in a tin or wooden box. Of course, the shape and size is not very important.

5. They have been shipped farther than that.

6. Then or a little later would be a good time.

7. The combs will be lighter and less likely to break down if you do not feed till after moving. But if you move before feeding you must move early enough so that it will not be too cold to feed afterward.

8. It will be all right to put one on top of another providing you manage to give air enough. They should be fastened firmly in some way so they cannot move about. Strips would be all right.

Robber-Bees—Uniting Bees—Kingbirds.

I have just purchased 3 colonies of bees in box-hives, which I will number 4, 5, 6, respectively, according to their size. I also have two colonies in a weak condition. Nos. 2 and 3. After getting the box-hives home I placed box 4 on top of a 10-frame empty hive; box 5, which is quite strong, on a stand a few feet to one side; and box 6, a rather small colony, I attempted to transfer by the Heddon short method, but in spite of all the pounding with a hammer and smoking I could do, the bees refused to leave the box. Finally I ripped open the box, and the bees went in the air. Finding mostly empty combs, and brood in the combs with the box, I went to hive No. 3 to get a frame of honey, and on my return the bees from the transferred box were going into box 4, making a great swarm. I immediately looked for the queen of box 6, and after searching half an hour found her on a post near hive 3, having been carried there on my person when I got the frame of honey. I placed the queen on the brood in the new hive, but there were scarcely a hundred bees within.

To-day the big colony 4, busied itself by robbing hives 2, 3 and 6; these colonies were so weak in numbers, and the robbers were so plentiful, that there was no fighting. The robbers also hung in the entrance and unburdened each home-coming bee of her load of honey and pollen. On opening the hives I found what looked like a good-sized colony, so I closed the entrances of hives 2, 3 and 6, carrying them into the middle of a potato-field, where I left them to hum until you can tell me what to do with them.

Hives 2 and 3 have each an old queen, while number 6 has a nice, young queen.

1. So far there has been no fighting. Do you think the robbers, that are inclosed in these hives, will harm the queen?

2. Will they unite with the other bees after being shut up with them?

3. How long can I safely keep them locked up?

4. If I feed sugar-water with a Boardman entrance-feeder at night, will that help to make them stay?

5. Would you advise me to unite the 3 colonies now, leaving them the young queen? or let them drag until fall, when I can secure bees from box-hives that the farmers are going to kill for the honey in them?

6. If I unite the 3 colonies, will that be a good time to introduce an Italian queen? or would it be better to wait until fall, when I add the bees from the farmers' box-hives?

7. There are a happy pair of kingbirds in our orchard that eat a good many of my bees; they are building a nest of grass and cobwebs. Do you think they could materially reduce the number of workers in a medium-sized colony of

bees? Birds are my friends and I would not harm them willingly. My text-book says but little of them.

ILLINOIS.

ANSWERS.—1. They may and they may not. If they do not molest her at first, they will not do so after being shut in for a time.

2. Yes.

3. That depends. If there is no danger of smothering or starvation they might be shut in for two or three weeks, but not without loss.

4. Hardly.

5. Hard to tell; perhaps it would be as safe to unite them now; but if you can keep them from being robbed out, they might be left separate, providing each has a queen.

7. Some think kingbirds do little or no harm, while others think they weaken a colony rapidly. Perhaps both are right, for they may not be the same at all times and in all places. By watching closely you can give a pretty good guess whether they are doing serious harm.

It looks probable that you operated at a time when little or no honey was coming in, and possibly were a little careless as to starting robbing. Look out for that in the future.

Swarming Questions—Scraping Sections.

1. I find a colony of black bees preparing to swarm. I cage the queen, and cut out all the queen-cells at two different times, the last cutting being about 10 days after caging the queen. The queen is then released. A month or so later, upon opening the hive, I find one large queen-cell from which a queen has emerged (being open at the end, with flap still attached), also eggs all through the hive, and a number of swarming-cells with eggs laid in them. Now if the old queen is good enough to swarm with, why did they rear a young one?

2. Upon examining a colony of bees and finding, we will say, 3 or 4 queen-cells in process of construction, how am I to tell whether it is a case of swarming, or supersedure?

3. I have had a swarm this year from a colony in which the queen was reared this season. Upon examination I find a number of colonies with this year's queens reared in hives now occupied preparing to swarm. Isn't it an unusual occurrence? I believe in one of your answers you stated that such *did not* happen.

4. What is the easiest and best way to clean or scrape sections after being taken from the bees, so as to prepare them for market.
NEW YORK.

ANSWERS.—1. I don't know. The case is a very exceptional one. Years ago I treated a great many swarms in the way you mention (cutting out cells twice and releasing the queen after 10 days caging), only I caged the queen *after* the colony had swarmed, and never did a colony swarm the same season after such treatment. I felt greatly indebted to G. M. Doolittle for the plan. You are not likely to have a repetition of your experience in the next forty years.

2. You can't tell at all by the looks of a cell whether it is meant for swarming or supersedure. But you can sometimes make a pretty good guess by noting conditions. A small number of cells is likely to mean superseding rather than swarming. If cells are present in a weak colony, or if the colony has not a large amount of brood, you may guess supersedure. But often conditions are such that it's an even thing which way you'd better guess.

3. It may happen if the queen was reared very early in the season. Such a queen is much the same as a last year's queen. I wish you would tell us if you have had any queen swarm that was reared in her own hive this season as late as June.

4. Quite a number of machines were talked about not so very long ago, and it looked hopeful that we would have a machine that would greatly shorten the work, but nothing has been said about them of late, and I know of nothing better than a sharp case-knife, and a lap-board, having on it a block about an inch thick and four inches square.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special prices on 50 or 100. Free Circular. Address all orders to

GENERAL ITEMS

Bees a Pleasure.

My apiary is always a great pleasure to me, and this season the honey crop has been unusually good. The white clover bloomed in abundance, and my bees gathered much fine honey from it. All of my colonies are in good condition, and I have some nuclei which are very interesting.

I have always read the American Bee Journal with much interest and profit.

MRS. E. G. BRADFORD.

Newcastle Co., Dela., July 31.

A Wet Season.

So much rain fell during basswood bloom that the bees worked lots of days in the rain; when it got too heavy for them they had to quit business, but part of the time they worked rain or shine. I had some idea why they did it, so I looked, and they did not have anything to live on, and that was why they had to push out in the rain. But at this date they are gathering some nectar. White clover is in second bloom, or took a second growth; for a while it looked as if it would not amount to much, but now it is looking

very well. I am inclined to think the amount of nectar is small; some colonies will store enough to live on, some will store a small surplus, and some will hustle to live through without feeding.

It is warm to-day, as warm as it has been this summer; bees are lying out more now than ever. They seemed strong last spring, but it was too wet in June for them. CHAS. ELLIS.
Newton Co., Ind., July 27.

A Long Honey-Flow.

Our honey-flow comes all through May, June, July and part of August, from maple, willow, white clover, red clover, alsike clover and fireweed and some other weeds. The white clover furnishes honey all the season, as there are no hot days to kill it, and it does not slobber horses here like it does in the East. F. M. McPHERSON.

Whatcom Co., Wash., Aug. 2.

Tough Season in Western Iowa.

This has been a tough season with us in western Iowa, not a pound of surplus taken off yet; last year at this time we had taken off 1,000 pounds, with 1/2 less colonies. Too much rain and cold wind when white clover bloomed; what little they got from basswood was needed and taken to keep house on. Rains came through the early part of sweet clover bloom, and now it is about done blooming, and very little surplus in sight. Heart-ease and Spanish-needle may spring up on stubble-fields so we will get winter stores, but we will not glut the market with section honey.

I guess if we get to Denver we will have to go on foot, and that is hard on a cavalryman. C. E. MORRIS.

Carroll Co., Iowa, July 30.

"Prime Swarm" and "First Swarm"

On page 501, Mr. G. M. Doolittle says a prime swarm is often erroneously called a first swarm. Please tell us what is the difference between a prime swarm and a first swarm. INQUIRER.

[We respectfully refer the above to Mr. Doolittle himself for answer. Perhaps his "locality" makes the difference.—EDITOR].

Too Dry in Georgia.

Many of the readers of the Bee Journal up North, are having discouraging times on account of the wet weather, but down in Georgia we are having too little rain, and are getting very little honey; but we keep right on getting the experience.

Mr. Dobson and I have 12 colonies in the rear of our shop. They were largely black bees, but we have been introducing Italian queens since they were transferred from the box-hives. When we received 4 queens we took one colony and divided it and removed the queen, and at the proper time we liberated the queens, but they balled them and we caged them again two days longer. Then we looked for queen-cells and in one we found 18 cells which were destroyed. The next time we opened the hive there were 8 more, and the third time several more. Then we

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal

put the bees in one hive on new foundation, and the brood and comb in the other. This arrangement succeeded and all are doing well now.

We are feeding all these young colonies in order that they may fill the brood-combs and be ready to fill the supers when the fall honey-flow comes on. Is not this a good arrangement?

We have two colonies that are nearly all Italians, and can discover more difference in them than among the blacks.

F. S. DUNKLEE.

Haralson Co., Ga., Aug. 5.

Cooler Season on Record.

The season here was a great disappointment to most of the honey-producers. The most of those who were extracting got a short crop, while the comb-honey man got little or no honey.

With the exception of a few warm days this has been the coolest season and summer on record.

L. L. ANDREWS.

Riverside Co., Calif., Aug. 4.

Did Well on Clover.

Bees are busy working on basswood; they did well on clover and raspberry. We have a little over 100 pounds per colony now, and basswood is not over yet.

E. E. COVEY.

Emmet Co., Mich., July 29.

Reading the Bee Journal Pays.

I am satisfied the American Bee Journal has paid me many dollars in the production of honey this year. I have 18 colonies of bees and the most of them have produced 100 pounds of comb honey to the colony, this season, while my neighbors' bees have made a bare living. I attribute this wholly to the management, as I have learned many valuable lessons from the American Bee Journal that would have taken years of experiment.

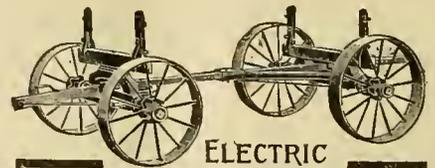

W. P. BROWNING.

Barry Co., Mo., Aug. 5.

Worker Foundation in Sections.

I notice on page 491 something on comb honey and excluders. I have never been troubled much with the queen going up in supers. I use no honey-board of any kind. Although I have a lot of zinc ones I cannot call to mind that I ever had any drone-cells in sections filled with brood. In taking honey a short time ago I noticed one super that the bees had not gone out of, (I use escape-boards); it was full of bees, and they were cross. I smoked them and opened the super, and as I took out section by section I found drone-comb, and instead of capped honey a drone in every cell, just ready to come out. Dr. Miller, in replying to above, says, "I use top and bottom starters of worker foundation, filling the section entirely full." He says "worker foundation." Is this not the same that all bee-keepers use for their sections?

Now suppose the Doctor does fill his sections full of worker foundation, would that prevent drone-comb? I seem to get that idea from the last lines of his remarks. He says, "Or unless the sections were so filled with worker-foundation that there was no chance for drone-comb above the su-

per." Now, I don't put any foundation on the bottom of my sections, but put in 3 inches; that leaves a space below, and the bees fill the comb down to the bottom of the section.

If the Doctor has a worker foundation different from others will he please tell us about it?

J. W. C. GRAY.

Pratt Co., Ill., Aug. 2.

Hard Season on Bees.

I have 20 colonies of bees. This season has been a hard one on them. I had to feed some in June to keep them alive. They are doing better now, storing in the supers some.

FRED LOCKWOOD.

Greene Co., Wis., Aug. 6.

Expects to Go to Denver.

I expect to attend the Denver convention, and want to be one of the boys when I get there.

The honey season has been all I could ask for, up to Aug. 1, but since that time the bees have been almost idle.

I hope to see you and many of the boys at Denver.

E. DAVISON.

Finney Co., Kans., Aug. 4.

Not Much Honey.

We began the season with 6 colonies. The weather was not favorable in fruit-bloom; it rained the most of the time, and continued until basswood bloom, when the bees worked some in the supers. White clover is blossoming fairly well, where it had not been killed during the dry spell last year.

Our bees nearly all swarmed in one day, and all nice, prime swarms, and a few after-swarms.

Last year we had a fair crop by this time, but this year we have not much to show, unless we get a good honey-flow in the fall.

We have 14 colonies now. I like the American Bee Journal very much.

NICHOLAS KLEIN.

Blackhawk Co., Iowa, Aug. 4.

Not a Great Honey-Flow.

The honey-flow is nothing great here. It was too cold and wet in the spring, and now it is cold at night, so the flow is very meager. The basswood yielded only 3 or 4 days. There is lots of bloom but the flow is light.

I have 100 colonies now, but will not get a very large lot of honey.

F. E. KNAPP.

Wadena Co., Minn., Aug. 8.

Not An Encouraging Report.

The spring was so wet that our bees did nothing, hardly making a living, and they got the swarming-fever the worst I ever saw. They would come out and cluster for a few minutes, then go back to the parent colony, and lots of them would leave the new hive directly after being hived and go back to the parent colony.

I don't believe, out of 16 colonies, I will get enough honey for my own use. Up to the present time I have not received a pound of honey. Between my practice and the bees I have been jumping this summer.

There are quite a few here, who, like

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.

myself, keep bees in a small way, but none of them report any honey, so far. White clover is nearly gone. There may be some fall flow here, but we get the most of our honey from white clover. Every one here works for comb honey.
DR. W. H. ELLIS.
Calhoun Co., Iowa, July 31.

Best Season for White Honey.

This has been the best season for white honey in this part of Wisconsin that we have had for a good many years. I have taken from one to three supers from all of my colonies that got down to business, and I think I took the fourth super from one or two.

There has been a perfect sea of bloom from white and alsike clover, and it yielded nectar well. Basswood also was rich with honey this season, though we haven't a great amount of that.

I have increased from 90 to 117 colonies, and for about two weeks had from a few up to 19 swarms daily; the 19 came out on Sunday, of course.

B. T. DAVENPORT.
Green Lake Co., Wis., Aug. 4.

Poor Season for Honey.

This has been a very poor season for honey in this section of the country. I had 18 colonies, spring count, and have only about 100 pounds of comb honey, up to this time. There has been plenty of white clover bloom all summer, and there is plenty of bloom at this date, but there is no nectar in it—the bees do not notice it. Alsike clover failed to furnish any honey this season. I have sowed 3 bushels of buckwheat; it is in full bloom, and the bees are just having a real nice time from day-break until noon; the balance of the day they do not seem to work much. I expect some honey from buckwheat.

There are a few bees kept in box-hives in this neighborhood by farmers on the old plan—do nothing and get nothing. They grumble and say there is nothing in keeping bees. They will not take the American Bee Journal to learn anything about caring for and handling their bees, so there is no improvement or gain in their lives as bee-keepers. What little I have learned about bees and their keeping has been from the American Bee Journal.

H. C. KUYKENDALL.
Clark Co., Ill., Aug. 5.

Honey-Plants of Australia.

No doubt you will be surprised to receive this letter from South Australia. Last September I subscribed for the American Bee Journal, as I had often heard of it, and I have received much valuable information from reading it.

I am a beginner in keeping bees, and have 60 colonies, which I think is a pretty good start.

Thinking it might interest some of your readers I send an account of the honey-plants in this part of the world. First of all, about August, the bees start to get pollen from wild flowers, and a little from almond and other early fruit-trees, which last until October, when the dandelion or cape-weed blooms very thickly on all farms. About two weeks later bees swarm, if the blue-gum follows; if it does not

they do not, as a rule, swarm that season.

Our main honey crop, which we get about every other year, first of all comes from blue-gum, then red-gum, which blooms from December until February and are the best honey-trees we have. About the first of April the peppermint or a sort of box-tree blooms, and lasts until June, and sets our bees right for winter; and if it does not rain too much we get between 3 and 4 60-pound cans per colony for the season.

I believe it would pay American and California bee-keepers to plant trees, as they stand forever. A. R. BELL.

South Australia, June 16.

Robber-Bees Stinging.

Having noticed, incidentally, that Mr. Hasty has been more than willing to dignify (?) my writings in his characteristic way, I here tender him congratulations, although I would not by any means have my friend get a "bloated" conception of my worth to the bee-keeping world.

That there were in the great army of honey-producers a man, a woman, or child, who would assert that the statement that robber-bees sting the defenders of the hive they are going to rob, was assumption, rank with the mildew of centuries past, I could not believe until I read it in his "comments" in a recent issue of the Bee Journal.

Now I wish to say to the readers of this paper, that if any statement of mine herein recorded will not stand the crucial test of modern practice I want the hammer of truth to fall squarely upon it. But to this practical apiarist and critic for the columns of the American Bee Journal, I would suggest the fairness there would be in first giving the matter an impartial test before "passing it up" as mere fiction. Let him effect a genuine case of robbing on the part of Italian bees, and then concentrate these forces suddenly on a strong colony of pure blacks, and record the results. If he doesn't find that the robbing bees sting with effect when they meet with determined opposition, I'll agree to "eat my old hat" for the edification of Mr. Hasty.

W. W. MCNEAL.

Cook Co., Ill., Aug. 1.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

DAIRYMEN ARE DELIGHTED to meet those who work for us. Cow keepers always have money. We start you in business. You make large profits. Easy work. We furnish capital. Send 10 cents for full line of samples and particulars. DRAPER PUBLISHING CO., Chicago, Ills.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Aug. 11.—Some comb honey produced in 1902 is now on sale. Fancy brings 15c; anything off in appearance or quality sells at 13@14; for white; amber grades, 2 and 3 cents per pound less. Extracted is selling at 6@7c for white; light amber, 5½@6c; dark, 5@5½c. There is a fair demand for all grades and kinds. Beeswax steady at 30c. R. A. BURNETT & CO.

KANSAS CITY, Aug. 2—Receipts of comb honey increasing; fairly good demand. New fancy white, 14@15c; No. 1, 13@14c; amber, 12@13c. Extracted, white, 6c; amber, 5@5½c. Beeswax, 22@25c. C. C. CLEMONS & Co.

CINCINNATI, July 26.—Considerable stock of 1901 crop fancy comb on the market and sells at 14@15c; there is a call for new comb honey, as yet none on the market; this market demands fancy comb; all other grades discourages trade. Extracted is in fair demand at 5½@6c for amber and 7@8c for clover. Beeswax, 25@30c. THE FRED W. MUTH CO.

ALBANY, N. Y., Aug. 1.—We are having some calls for new comb honey, but no receipts to speak of yet. No price established yet, but think can get 15@16c for good white comb. Extracted, demand light.

The crop of honey near here is light, owing to so many colonies of bees having been destroyed. H. R. WRIGHT.

NEW YORK, Aug. 11.—New crop comb honey from New York and Pennsylvania is beginning to arrive in limited quantities. There is a good demand for fancy white at 14c, and No. 1 at 13c, and exceptionally fine lots will possibly bring a little more. Lower grades quiet at from 10@12c. As to extracted honey, fancy grades are in good demand at from 6@6½c for white, and 5@5½c for light amber. Southern in barrels and half-barrels quiet at from 47½@50c per gallon, according to quality. Beeswax dull at from 27@28c. HILDRETH & SROELKEN.

CINCINNATI, Aug. 2.—Some small lots of new comb honey have been coming in, but as the weather is so warm there is very little demand. That sold to stores brought 15c for fancy.

The market for extracted was more lively, brings as follows: Amber, 5@5½c; alfalfa water white, 6@6½c; and white clover, 7@7½c. Beeswax, 30c cash. C. H. W. WEBER.

SAN FRANCISCO, July 23.—White comb, 10@12½ cents; amber, 7@10c; dark, 6@7 cents. Extracted, white, 5@—; light amber, 4½@—; amber, 4@— . Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There are moderate quantities arriving, with asking figures in the main above the views of wholesale operators. Business doing at present in this center is principally of a small jobbing or retail character, and in this way transfers are being made at an advance on any figures which would be warranted as quotations based on values for round lots.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

* Editorial Comments. *

Change in Going to Denver.—We find that the Chicago & Northwestern train on Tuesday, Sept. 2, at 10 a.m., which we reported that Dr. Miller and others of us would take from Chicago, does not make very good connections, so we have decided to leave on the 6:30 p.m. train out of Chicago, on Monday, Sept. 1. This is a fine train, and arrives in Denver at 7:50 p.m. the next day—only about 25 hours.

We trust there may be others who will join our party on the way.

The Government Chemist on Glucose.—Prof. Wiley was quoted as saying :

“A mixture of glucose with food products, I maintain, is not injurious to health, neither is it a fraud.”

The editor of the *Modern Farmer and Busy Bee* wrote him and received the following reply :

DEAR MR. ABBOTT:—You are right in supposing that I am incorrectly quoted in regard to a mixture of glucose. My argument before the committee was all to the effect that glucose when sold under any other name is a fraudulent article, but that I had no objection to glucose being sold under its own name. I illustrated particularly the matter of honey, where glucose was added without informing the customer, I considered to be an unmitigated fraud.

I will send you copies of the testimony both before the Senate and House Committees, as soon as I can get hold of them. The Senate report has been already published, but I have been able to get but two copies so far. The House report is still in the hands of the printer.

There is greater opportunity now than ever before to secure legislation, and a little influence brought to bear upon the Speaker and your Senators and members of Congress would prove of wonderful effect.

With sincerest regards, I am, faithfully,
H. W. WILEY, *Chief.*

Bee-Keeping as a Department of Study.—This country rather prides itself in its advanced educational methods, but so far as the matter of education in bee-keeping is concerned, other nations can be found much in advance. There are among other nations schools for special instruction in the science and art of bee keeping, the government providing free tuition under experienced instructors, and in some of the common schools elementary instruction in bee-keeping is given. At Vienna a building has been erected solely as a place of instruction in bee-keeping, equipped with all necessary conveniences for such a school.

Michigan took the lead in putting bee-keeping in the curriculum of study in Michigan Agricultural College, but not more than 3 or 4 other States have followed her example, among which is Texas. Why should not the young man or woman who goes to an agricultural college have an opportunity for instruction in bee-keeping as well as in other departments usually taught? Is there any reason

other than the very unsatisfactory one that such a thing has not been done in the past? It might be an interesting thing to have a symposium giving the reasons of the presidents of the different agricultural colleges for leaving bee-keeping out of their courses of study. The columns of this journal are open for any of them, or indeed, for any one else, to give some good reason or reasons why it is not the proper thing to instruct the students of agricultural colleges how to care for bees as well as other farm stock.

Referring to the apiary at the Agricultural and Mechanical College of Texas, Mr. Louis H. Scholl has this to say :

“This is an apiary that not every State has, and we Texans are real proud of ours. I have had charge of it for some time, and we have fixed it up just like the good books say. Bee-keeping will now be taught the students who attend school here, and it is certain that some will go away with a good knowledge of apiculture, and will make successful bee-men when they launch out for themselves.”

“We have had a grand meeting, and some more good things to advance the interests of bee-keeping in this State.”

Amount of Brood in a Langstroth Frame.—Editor Root and Dr. Miller are having a set-to as to the amount of brood in a Langstroth frame, the former believing there is a border of honey at the upper part which bees are loth to cross to reach the sections in the super, the latter claiming that his bees have brood nearly to the top-bar, and he thinks Mr. Root is out of the way in estimating that a Langstroth frame will be filled only about two-thirds full of brood. Mr. Root referred the matter to their queen-breeder, Mr. Wardell, a bee-keeper for over 30 years. Mr. Wardell was asked, “How full are the average Langstroth frames filled with brood in our apiaries?” He replied :

“That depends on the time of year. Before the honey-flow, when the bees are breeding strongly, the brood will be much closer to the top-bar than during the honey-flow. During the swarming season there will be on an average about two inches or more of honey circling over the brood.”

A Comic Book on Bees is mentioned by Albert Gale, in the *Australasian Bee-Keeper*, and a number of extracts from the book are given that seem funny enough to one familiar with bees and their habits. Of the extracts a very few may be repeated here :

Speaking of drones : “One by one they sail off into space, irresistible, glorious, and tranquilly make for the nearest flowers, where they sleep till the afternoon freshens and awakens them.” That the drones must sail off into space to reach the nearest flowers is amusing ; that drones visit flowers at all is decidedly so ; that they fall asleep upon the flowers till the refreshing afternoon awakes them is irresistibly funny.

Of the queen : “During the slight spasm that visibly accompanies the emission of an egg, one of her daughters will often throw her arms around her and appear to be whispering to her.” “Is it not funny?” says Mr. Gale.

Of the nurses : “The nurse-bees feed nine or ten thousand eggs, the eighteen thousand larvæ, and the thirty-

six thousand nymphs." Mr. Gale finds nothing amusing in the feeding of eggs, but thinks it funny that the workers feed the nymphs after they are sealed up.

The strange thing about it is, that this book that Mr. Gale says is the only comic production on bee-life that was ever produced, is the same book that has been approved by some others as thoroughly reliable in its teachings, being nothing less than Maeterlinck's, "The Life of the Bee." The charming manner in which the book is written seems to have blinded the eyes of its reviewers to the many glaring absurdities that Mr. Gale finds for the seeking, and of which he gives nearly a score of samples.

* The Weekly Budget. *

IT'S DENVER NEXT WEEK.—Are you going?

IT'S THE NATIONAL CONVENTION Wednesday evening, and all day and evening Thursday and Friday.

MR. E. E. HASTY has been in rather feeble health, hence the omission of his department of "The Afterthought" for several weeks.

MR. CHAS. MONDENG, proprietor of the Minnesota Bee-Keepers' Supply Manufacturing Company, called at our office last week while in Chicago looking up machinery. He reports a good season's business, though the honey-crop is rather short in Minnesota.

OUR AFTERTHINKER, Mr. Hasty, has this said about him by "Stenog," in Gleanings in Bee-Culture:

E. E. Hasty's review of the apicultural world is always readable because interesting. As a critic he is "the good-natured man" of whom Goldsmith wrote. No stings about Hasty. Some funny literature consists of nothing else.

GEORGE F. ROBBINS, formerly of Illinois, but of late years manager of apiaries in Texas for E. T. Flanagan, died very suddenly on Aug. 3. It necessitated Mr. Flanagan's going at once to Texas to see to his property there. Mr. Robbins used to be a contributor of the columns of the American Bee Journal, and a good bee-keeper and writer.

A FULL REPORT OF THE PROCEEDINGS will be taken for the American Bee Journal. We have arranged with an expert shorthand reporter, and expect a fine report. If you have any bee-keeping friends that you would like to have subscribe for the American Bee Journal, you should be able to get them when you tell them of the Denver convention report. We are expecting the greatest bee-keepers' convention ever held on this continent, right in the midst of the greatest honey-producing region in the United States, and among the greatest lot of biggest and best bee-keepers on earth. Now, with such a combination something unusually good for bee-keepers should happen. We believe it will. Better go.

BEE KEEPERS' BADGES.—Referring to this subject, Mr. F. Greiner, of Ontario Co., N. Y., wrote as follows:

"Pres. Hutchinson is not in favor of a 3-cent badge to be worn by members of the National Bee-Keepers' Association at conventions or on other occasions. He wants something less conspicuous and of better quality. I fully agree with him. A button with a bee, he suggests, should show more artistic taste than the buttons I have seen so far. A very expensive insignia, I believe, is out of question, other-

wise a golden bee would be very becoming, and not conspicuous. To members who will pay their dues 5 years in advance, paying \$5.00, such a bee might be given as a premium. Otherwise every member would have to pay for the emblem. Are bee-keepers willing to do this? is a question."

We hope that a committee will be appointed at the Denver convention, with full power to act in this matter, so that a suitable badge of some kind may be secured for the members. Then, each new member should be presented with a badge when joining. If more are wanted afterward, let the members pay for them. They should sell for not more than 10 cents each, we think.

INTERNATIONAL BEE-EXPOSITION IN VIENNA, AUSTRIA.—A prospectus of this exposition has been received from the management, and preparations are already under way, although the date for the exposition is April 4-26, 1903. Fine quarters have been obtained, and during the course of the exposition three important excursions have been planned. A bee-keepers' convention will occur during the exposition, exact date not yet determined.

MR. WALTER C. LYMAN is one of the leading bee-keepers of Dupage Co., Ill. He has about 60 colonies some 20 miles southwest of Chicago. "Ye Editor" and wife spent part of a day with Mr. Lyman, his mother (80 years of age), and his sister. Mrs. Lyman is a dear old lady, but as young in mind and heart as ever. She is also just as much interested in current events as one 50 years her junior might be. The bee-business is not very rushing with Mr. Lyman this year. It has been too wet and cool.

MR. WM. H. HEIM'S HOME APIARY appears on page 557. When sending the picture he wrote as follows:

"Feb. 22, 1902 (Washington's birthday), was a day not soon to be forgotten in this city and nearby towns, as then a heavy snow-storm visited this part of the State, which was a curiosity, from the saying of old-timers, such as has not been seen for many years. The snow all came in one night, and was from 22 to 28 inches deep, delaying all trains and destroying telegraph and telephone wires.

"My home apiary (of which I send a photo, or a part of it) was, as you see in the picture, nearly covered with snow—a scene that put me in mind of Mr. A. E. Manum's apiary in winter, shown in the 'A B C of Bee-Culture.'

"Our snow did not last very long, as in a few days it began to rain and it was soon all gone."

"THE BEE-KEEPERS' GUIDE, or Manual of the Apiary," by Prof. A. J. Cook, the 17th edition of which we issued recently, is thus referred to by Editor Abbott, of the Modern Farmer:

This work has been thoroughly revised and brought down to date. Some 80 pages have been added and nearly 100 illustrations. In many respects this publication is the best of its kind in existence. It has the merit of being free from all personal advertising, and discusses matters in a way that makes them clearly understood by any one with a fair degree of intelligence. Prof. Cook is always an interesting writer, and, as he is a practical bee-keeper as well as a scientist, he has been able to state things so that they will be understood thoroughly by those who have but little knowledge of the industry. Every bee-keeper should have a copy of it in his library. Parents will find it an advantage if they will place a copy of this work in the hands of their children, even though they have never seen a colony of bees. It will give their minds a bent in the right direction, and furnish them information that will be of practical utility to them as long as they live.

The postpaid price of this book is \$1.20; or with the American Bee Journal one year—both for only \$1.75.

The Premiums offered this week are well worth working for. Look at them.

Convention Proceedings.

Report of the Texas State Convention, Held at College Station, July 16 and 17, 1902.

BY LOUIS SCHOLL, SEC.

The Convention was called to order at 3:30 p.m., on July 15, by Vice-Pres. H. H. Hyde, in the absence of Pres. Salyer.

The meeting was opened with prayer by F. L. Aten, after which came the reception of new members.

The election of officers for the ensuing year resulted as follows: President, Udo Toepperwein; Vice-President, W. O. Victor; Secretary-Treasurer, Louis H. Scholl, of Hunter.

The following committees were appointed: On resolutions, F. L. Aten, F. J. R. Davenport and H. H. Hyde. On program for next meeting: L. Stachelhausen.

Prof. F. W. Mally, State Entomologist at College Station, delivered an address on the apiary and bees located at the College, and how they were procured. He spoke as follows:

Prof. Mally's Address on the State Apiary.

MEMBERS OF THE ASSOCIATION:—It is no small pleasure to be able to report to you the establishment of an apiary at the Agricultural and Mechanical College since your last meeting. It is not often that our annual meeting can show progress and results in so short a time, as I am able to outline to you this afternoon. The apiary at the College is a direct result and monument to your first meeting and efforts as a State organization. If the value of organization needed any argument, kindly suggest a stronger one than this.

Many of you present today remember that I appeared before you to suggest how to proceed to secure proper funds from our State legislature for establishing an apiary at the College, in order that bee-keeping might be properly taught, and an important industry of our State receive due support in an educational way. I asked you to furnish statistics as to the value of your products, and the capital invested, and also requested that a legislative committee be appointed. This you did promptly, and during the session of the 27th legislature I left no stone unturned to prove to the finance committee of the House the importance of providing the funds asked for.

Mr. G. F. Davidson deserves special mention in this connection for having spent his own time and money to visit Austin and explain many of the practical details to the committee. Outside of the technical information required, or the support given the Bill by bee-keepers and others, the Hon. W. O. Murray, a leading member of the Finance Committee of the House, deserves unstinted praise.

He was the bee-keepers' friend from first to last, and but for his dogged determination to stick to his text, the bee-keepers could not to-day be invited to an inspection of the college apiary.
