

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., JANUARY 2, 1902.

FORTY-SECOND YEAR
No. 1.

MR. W. P. TURNER AND APIARY, OF PEORIA CO., ILL.—(See page 2.)

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITORIAL STAFF.

GEORGE W. YORK, Editor-in-Chief.
DR. C. C. MILLER, } Department
E. E. HASTY, } Editors.
PROF. A. J. COOK, }

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

National Bee-Keepers' Association

OBJECTS:

To promote and protect the interests of its members.
To prevent the adulteration of honey.
To prosecute dishonest honey-dealers.

BOARD OF DIRECTORS.

E. WHITCOMB,	THOS. G. NEWMAN,
W. Z. HUTCHINSON,	G. M. DOOLITTLE,
A. I. ROOT,	W. F. MARKS,
E. T. ABBOTT,	J. M. HAMBROUGH,
P. H. ELWOOD,	C. P. DADANT,
E. R. ROOT,	DR. C. C. MILLER.

EXECUTIVE COMMITTEE.

ERNEST R. ROOT, President.
R. C. AIKIN, Vice-President.
DR. A. B. MASON, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

MR. FRIEDEMANN GREINER, of Ontario Co., N. Y., writing us Dec. 2, 1901, said:

"We are having a hard winter-time. Our bees went into the cellar just in time. Our outdoor-wintered colonies are seen to—so we feel easy."

THE APIARY OF MR. W. P. TURNER is shown on the first page this week. When sending the photograph, Mr. Turner wrote as follows:

I send a picture of my apiary located five miles northeast from the heart of a city, connected by electric street-car lines. The view is taken from the car-line looking northwest. The hives are fronting south, and are all paterus, but the frames are of the Langstroth type, and will fit in any of the hives.

Your humble servant stands in the foreground, is 57 years old, and has kept bees more or less the past 28 years in connection with farming. But in March, 1900, he abandoned the farm and came to this resort, and built the house on the extreme left, as partly shown in the picture. The good wife and oldest daughter are seen standing in front of the same. (Our other daughter happened to be away when the artist called to take the picture.) Our only son, Chas. L., and his family, are seen in the automobile coming down the street from the west. He and his cousin, F. I. Ellis, are the inventors and builders of said wagon. One or the other, or both of them, use it every day. They promised me an auto-delivery wagon at a future date. Their residences are shown at the extreme right—first is Charles' and next is Ellis'.

The carpenter shop and honey-house are south—just outside of the picture, by, or near, the solar wax-extractor shown; also about 15 more colonies of bees are located between my shop and the barn. The hives, 55 in all, stand 12 feet apart each way. I hope to have, by the end of another year, the little lot filled up, two in a place.

The past has not been a very good year for honey, although I am well pleased with the results. I can wholesale honey here at 15 cents for comb, in 24-pound cases, and extracted at 10 cents a pound, put up in 1½-pound Mason jars.

I used gloves the past season for the first time, and liked them well, as they keep the propolis off my hands, and save my awkward fingers a few stings.

I turned the nozzle of my Corneil smoker around, and think it perfect, as I can shoot the smoke right down on the frames, or in at the entrance, without any trouble. I have made, with a Barnes' combined machine, 80 hives and supers complete, except sections and pattern-slats; also 50 winter-cases that will insure bees against winter loss, since Jan. 1, 1901. I have used all the leading supers with varied success, and find I have to use separators on both sides of the sections, to insure nice, straight sections. My supers are made with followers and wedges at one end and side; when the wedges are removed the sections are easily taken out.

I am sorry I did not think to show my "hive-jack" and "uncapping-box" in the picture. The former is fine for holding hives, supers, and covers, for painting, and costs about 75 cents to make it. The latter is the best thing for uncapping I have seen, and costs about \$2.00.

The more I read the "old reliable" American Bee Journal the better I like it.

W. P. TURNER.

You might describe your hive-jack and uncapping-box for the benefit of the readers of the American Bee Journal.

(Exact size of the Pen.)

FREE as a... Premium

A Foster Stylographic PEN....

This pen consists of a **hard rubber** holder, tapering to a **round point**, and writes as smoothly as a lead-pencil. The **point** and **needle** of the pen are made of **platina**, alloyed with **iridium**—substances of great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and **do not leak or blot.**

As they make a line of **uniform width** at all times they are **unequaled for ruling purposes.**

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

BEST MANIFOLDING PEN ON THE MARKET.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

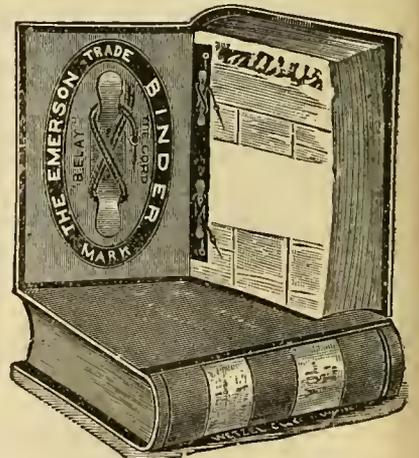

How to Get a "Foster" FREE.

Send **TWO NEW SUBSCRIBERS** to the American Bee Journal for one year, with \$2.00; or send \$1.90 for the Pen and your own subscription to the American Bee Journal for one year; or, for \$1.00 we will mail the pen alone. Address,

GEORGE W. YORK & CO.
144 & 146 Erie St., Chicago, Ill.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee

Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., JANUARY 2, 1902.

No. 1.

* Editorial. *

The Forty-Second Volume of the American Bee Journal is begun with this issue. Getting old, isn't it? But some things "improve with age," it is said. We trust it may be so in this case. We can not make any great promises as to the future, but we expect not only to do all in our power to maintain the pace already attained, but hope to make even a better record during 1902. With the hearty support of so many sympathetic readers, and with a determination to keep the American Bee Journal in the front rank, we look forward with high hopes to the New Year, and trust that it may bring richest blessings to all, whether readers of these pages or not.

Expressions of Appreciation of the American Bee Journal have been so abundant and hearty during the past few weeks, that we may be pardoned for taking a little space to thank most sincerely those who—whether renewing their subscriptions or requesting a discontinuance—have written us so kindly and so graciously.

Many people think that the world at large is often cold and unfeeling, but we are glad to know that "the world of bee-people" is seldom other than appreciative of honest effort and devoted toil. And to receive so many tokens of such enthusiastic esteem for the American Bee Journal is a source of great encouragement to those who plan and work to make its weekly visits a help and a blessing to all who read it.

So we desire to take this opportunity to thank most cordially all who have helped, in whatever way, to bring joy and gladness to this office, and to assure them that the expressions of appreciation, as well as the more substantial things that more often accompanied them, are greatly prized, and will aid in lightening the labors, as well as the hearts, of all whose united effort creates weekly the old American Bee Journal.

Selection of Drones.—In Le Rucher Belge are given some words of counsel as to rearing queens. From the noted French queen-rearer, M. Girard-Pabou. If the same pains had been taken to breed only from colonies giving best results that have been taken to breed for looks, there can be little doubt as to the progress that would have been made. Some pay little attention to the production of drones, which, for best results, should be

tolerated only in two or three choice colonies. C. P. Dadant says the influence of the male is greater than that of the female. Destroy carefully before their birth all drones in colonies other than the choice ones, and from 10 to 3 o'clock close with excluder-zinc the entrances of all colonies from which we do not want drones to fly to meet the young queens.

Honey Tooth-Wash to remove tartar from the teeth: According to Le Miroir, dentists use the following: Muratic acid, 1 part; water, 1 part; honey, 2 parts.

Cure of Bee-Dysentery.—It is well known that a good flight is a cure for dysentery in bees, but generally little is done to oblige bees to fly except to wait till the weather is warm enough. Loyalstone (in the Australian Bee-Keepers' Review) goes at the matter somewhat heroically, as follows:

On a warm day remove all bees from the hive, except the frame the queen is on, to a distance of 50 yards from the hive—then shake the bees off the frames, allowing them to fly back to their hive. Two such treatments, with about one hour's interval between them, will generally cure this disease.

Wasps and Bees Compared.—Mr. H. W. Brice has been investigating, and gives some notes in the British Bee Journal. Like the queen-bee, the queen-wasp is impregnated once for life. Unlike the queen-bee, the queens of the wasp (*Vespa vulgaris*) can be, and are, fertilized in confinement. In a state of nature they are fecundated within or in close proximity to the nest. The male wasp can live to fertilize several queens. At the mating season there are more queens than male wasps. While the larva of the bee takes in its food by absorption, the larva of the wasp is fed by the mouth, perhaps through the entire period, certainly after the first three days.

Changing Brood from one colony to another is practiced by many, but not always in the same way. Some think it advisable early in the season to take brood from strong colonies and give to the weak. Others think it advisable to take from the weak and give to the strong. Justification for these two practices so diametrically opposed to each other may be found in the different conditions. In a region where the honey season is long, or where a heavy honey-flow comes late in the season, taking away brood from a strong colony will result in a smaller return from that colony, but that loss will be more than made up by the gain from a weaker colony, which, without such help, would have given little or no return. For it must be re-

membered that a strong colony does not merely yield in direct proportion to its strength, as compared with a weaker colony. That is, a colony of 50,000 bees will store more than twice as much as a colony of 25,000 bees.

On the other hand, in a region where there is a single flow that comes early and does not last long, remembering that it is the strong colonies that are profitable, the bee-keeper takes from the weak and gives to the strong, so as to have as many strong colonies as possible.

In either case it should be borne in mind that brood should never be taken from a strong colony till it is very strong; for up to a certain point the stronger the colony the more rapid the building up; and the mistake of many is to take brood from a strong colony until it is so weakened that it can not continue to build up rapidly. Taking brood from a weak colony to give to a strong is another matter; in that case it is understood that the building up of the weak will be much retarded; but the weak would give no returns anyway, and the returns of the strong will be increased.

Feeding Robber-Bees.—S. E. Miller relates in the Progressive Bee-Keeper that the robbers got the start of him one day, when, for a time, he left the tent in which he had been extracting, and when he returned he found the tent roaring with bees. He filled the tent so full of smoke that they were glad to get out. He continues:

Still, I knew that after the bees had discovered the inside of my castle they would make extracting more than interesting, unless I could interest them elsewhere. I therefore carried some bodies, containing combs from which I had extracted the honey, outside, took a sprinkler and sprinkled water over the combs in order to keep the bees from becoming crazy, as they would have done had I allowed them to work on the undiluted honey. This worked very well, and I finished up the extracting with very little further bother from the bees. I carried out the empty combs as fast as extracted, and each hive-body full was given a good sprinkling with water.

For Ants About Hives, place a vessel (an old oyster can will do) containing a solution of sugar poisoned with arsenic or Paris green, covered with wire-cloth so that no bees can enter. The Schweizerische Bienenzeitung says this will not only kill the ants, but their brood as well.

The Size of a Queen-Cell, in Australia, according to an article in the Australian Bee-Keepers' Review, is that of an acorn, and of the same shape. Queen-cells must be larger in Australia than here, or acorns smaller.

Contributed Articles.

Honey Exchange in California—Other Subjects.

BY PROF. A. J. COOK.

IT is a safe proposition to make that anything that tends to improve the condition of the laboring classes, especially the farming part of a community, greatly benefits the whole country. It is equally patent that the farming population stand in need of nothing so much as of some system of general co-operation. Co-operation is in the atmosphere of our day. The farmer alone lags behind and is left out in the cold. All other kinds of business people, even the newsboys of the streets, have their combines. What would our railroads do except that they pool their occupations and all pull together?

I remember one day I was in San Diego, a little after noon-day. I must make El Cajon that afternoon, and get back in time for the morning train home. The El Cajon train had left; the distance and roads forbade a wheel, and I must, perforce, depend upon the liveries. I asked the price, and thought the terms exorbitantly high. The man at the stable stated that it was a long drive, and that I was to make it in quick time. The roads were heavy, and two horses would be required. Said he, "It is not too much."

I still had my opinion, and asked if there were other stables in the city. "Yes," he replied, "there is one just across the street, and several others near by. But," said he, "you will get no better terms. All the stables of the city have combined on prices." I thought, "Good," and secretly wished that all the farmers had combined.

The Citrus Fruit Exchange of Southern California has now been in operation for over seven years, and has been an eminent success. These are the things which it has done: Greatly lessened the expenses in preparing to ship; secured a more perfect grading of the fruit; employed salaried agents of their own in all the leading cities; developed new markets in the East; with surprising success distributed the fruits in the East with such skill as to prevent overcrowding or ruinous competition, and at the same time keeping all the markets supplied; doing all their business at an expense of less than three percent, and though the goods marketed bring in millions of dollars each year, they have met with almost no loss at all—less than one-eightieth of one percent during all their years of business. The receipts of their business the past year have been over eight millions of dollars, and yet there has been no loss at all. This is only one of several years with a similar record.

The wonderful success of this organization has proved, first, that co-operation among farming classes is possible; secondly, that here, as elsewhere, it means a tremendous increase in the profits of business. It works prodigious benefits in two ways—lessens the expense, and greatly advances the market price of the goods to be sold. This organization did one most important thing, if success is to crown the efforts of any such undertaking. They secured a very bright, able man to serve them as their manager—a man who could run a railroad or successfully manage any great corporation. Of course, this requires a large salary. They have paid it, and so far as I know have never grumbled at so doing. Here, too, they have followed the railroads, insurance companies and other such institutions.

I doubt if any farming enterprise throughout the country has met with greater success than has that of the Citrus Orchardists of Southern California. This, too, in the face of the fact that they have to ship their goods often for four thousand miles at exorbitant traffic-rates. Except for this Exchange, I believe the business could not have been maintained. Many of our best orchardists believed that the Citrus Fruit Exchange saved the citrus industry from ruin.

Last week the honey-producers of this section of the State met at the Chamber of Commerce in Los Angeles, and after due deliberation decided to organize after the fashion of the Citrus Fruit Exchange. I think they have modeled their association entirely after the pattern of the other organization. If they are as wise in their selection of their manager then they can hardly fail of success. Indeed, they have more to hope for than did the other organization at the time of its inauguration. The Citrus Exchange feels a deep interest in all kindred co-operative movements, and have liberally offered to give them the advantage of the services of their agents in the

Eastern cities. As these agents have been selected with great care, and are men of rare business energy, tact and acumen, they cannot help but be of signal service to this new enterprise. Similar organizations have been effected by the deciduous fruit-men, the walnut men, and the celery growers, and in every case these later organizations have greatly profited by just this courtesy—service of the salaried agents in the East. So far as I know, nearly all of the members of these several organizations are greatly pleased with their success, and believe heartily that they have substantially bettered their condition by this form of co-operative effort. I sincerely hope that other people throughout the land engaged in agricultural pursuits will also copy this exchange system of Southern California, that these evident benefits may be widely extended throughout our country.

I am all the more hopeful that the bee-men will make their new effort successful, as I hope it will be leaven that shall tell in its influence the country over. Apiarists are usually bright, intelligent, enthusiastic, and given to reading and studying. This will make it easy for other sections to copy any successful method that may bring conspicuous success. I believe the honey-producers of central California and of Arizona have already taken action. If they have not followed the plan which has been so markedly successful with our citrus orchardists, it behooves them to study into this system at once, and if it seems wise, incorporate its cardinal features in their own methods of work.

DISINFECTING FOUL-BROODY HIVES.

I was greatly interested in reading the discussion on disinfecting hives which occurred at the Buffalo meeting. It seems to me that the experience of Mr. McEvoy makes it certain that this expense is unnecessary. I am not surprised that this is so. We are told by experts that the spum of consumptives if exposed to the sunshine a few minutes loses its power of contagion. It will be remembered that Prof. Waite has shown that the microbes of pear-blight soon die and lose their power for harm if permitted to dry. They must be incorporated in the unctuous environment of pollen-grain or stigma secretion to be potent for harm. It is probable that the resin of buds serves them in like manner. We can easily believe, then, that honey must be the medium of transportation in order that the bacilli of foul brood may maintain their virulence. I think bacteriologists have claimed that these foul-brood microbes exist in the blood of the mature bees, including the queen, yet we have every reason to believe that the malady is spread only through the medium of honey. The suggestion given above also explains this peculiarity.

HONEY PROSPECTS FOR 1902.

The past week has been one of great encouragement to Southern California. Prosperity in every line here hangs upon the rainfall. We sincerely hope, and expectantly trust, that a generous season's rainfall was ushered in on last Tuesday, by a fall of a one-half inch of rain in a half hour. The ground was so thirsty that even the most of this was drunk up so that very little ran off. On Friday another very general downpouring commenced, which, up to Sunday morning, had aggregated two and one-third inches. It has rained some since, and the weather is yet threatening.

I believe California is hardly second to any other country in the production of honey, even though it has many barren years. When we have a year of bounteous rainfall, we then prove a record-maker. Only to imagine an apiary of 200 to 600 colonies all in one locality, and each colony producing upwards of 200 pounds in a single season! An apiarist with such a record can afford occasional years with no product at all. This is the more true from the fact that we have no winter problem in California. Bees fly and gather honey every month in the year. If we except the matter of starvation and foul brood, there are no evils that confront the apiarist except this one of drought and no harvest. Of course, no good apiarist will permit his bees to starve.

We have an excellent foul-brood law, by aid of which each county can secure a competent inspector whose duty it becomes to stamp out this disease wherever it has gained a foothold. Nearly all the counties where bee-keeping is at all important are proceeding under the law.

Droughts are not sufficiently common to become an offset against the enormous production of favorable years.

THE LONG-TONGUED DISCUSSION.

It is an encouraging sign that the bee-keepers have become so generally interested in the matter of the tongues of their bees. It is not alone in connection with the red clover that this matter assumes importance. There are other flowers than the red clover with long nectar-tubes. While it is true

that Italian bees are more persistent workers than are Germans, yet I feel confident that the greater production of honey which comes through this race is not a little due to the fact that they can reach the nectar of many flowers where it is entirely inaccessible to the common black bee.

Mr. Hawley, of San Diego county, said to me a few days since that certain queens which he obtained from an Eastern queen-breeder had greatly surpassed all others in his apiary. I believe that much of this is due to this matter of longer tongues. Some years ago I measured a large suite of tongues from different races. They were all treated in exactly the same way, and I have no doubt that the results were reliable. The record was decidedly in favor of the yellow races.

I am also firmly convinced that the careful bee-keeper can do very much to breed bees that shall have these longer sucking-tubes. It will be remembered that the glossometer which I invented some years since, and which secured a medal at the Paris (France) Exposition, makes it easy for us to determine what bees possess the longest tongues. In this instrument a square of glass is stretched diagonally from the edge of a similar-sized fine wire gauze to within one-half of an inch of the opposite end. The two triangular edges of this enclosed space consisted of wood. The fourth half-inch space was also closed with a wooden door. By smearing the glass with nectar and placing the instrument in the hive, it was easy to see which bees possessed the longer tongues. If desired, the glass can be ruled, and the distance of each line from the gauze marked. I have no doubt that with this glossometer, coupled with care in breeding, any apiarist might soon secure bees with much longer tongues than he would otherwise have in his apiary. All are free to make and use this glossometer.

Los Angeles Co., Calif., Oct. 28.

James La Barre—Originator of V-Shaped Top-Bar.

BY JOHN R. SCHMIDT.

MR. JAMES LA BARRE, a bee-keeper from the wilds of Kentucky, is not only an accomplished bee-master but also a master of long-distance walking, he having walked from Covington, Ky., to Washington, D. C., a distance of over 600 miles in 23 days.

This was not done for the mere satisfaction of a foolish notion, or accomplishing a senseless bet, but for the purpose of obtaining justice; and, secondly, the means of livelihood justly due him for his services to his country during those long, bitter days of the Civil War.

Through hatred and jealousy, an officer of the company in which he served, caused a serious charge to be placed against him, for which he was promptly court-martialed without even a chance to defend himself. Years after the close of the War, La Barre applied for a pension, and was immediately confronted with the court-martial, and his application was "turned down." His untiring endeavor to clear his name of the so-called injustice done him, led to his going to Washington on foot, to plead his cause before Congress. The case was unheard, owing to the short session of that body last fall, but undismayed by this failure, and with the able assistance of Hon. Shattuc, he will endeavor to be more successful this fall, and vows he will not give up until the unjust charge is removed, and, if necessary, expected to start from his home in Kentucky, again on foot late in October, in order to be present when the body met.

Mr. La Barre is a bee-keeper of extremely keen observation, and one of many practical ideas; his extensive knowledge of the bees having been gleaned through this method, as he reads little from choice.

It is not generally known that it was he who first conceived the idea of a V-shaped top-bar as a comb-guide. Early in the 60's he accidentally noticed that the bees in a box-hive, in building their first comb, extended it along a strip of wood

which had been nailed on the inside of the box to cover a crack. Quick to see the point, he applied V-shaped strips where he wanted the combs built, and the bees, true to their nature, used these as starting points.

In 1877, while visiting the late Chas. F. Muth, he mentioned the matter, and asked him to apply the V-shaped bar to the frames in the Langstroth hives manufactured under his supervision. It was done, and afterward the V top-bar became a fixed feature of the Langstroth portico hive. Several have claimed this invention, but Mr. La Barre being indifferent as to who reaps the benefit of his bee-knowledge, remained quiet and let them fight it out among themselves.

From boyhood Mr. La Barre has kept bees in Old Kentucky. The many years of association with these loved ones is turning his hair a silvery gray, and bending his once sturdy form. Nevertheless, he loves them still, and the increasing silvery condition of his fast-fading hair only tends to personify a mind that is as clear as a bell. Hamilton Co., Ohio.

Odds and Ends of the Season Cleaned Up.

BY G. M. DOOLITTLE.

BEING mainly through with the hurry of the season of 1901, I have had a little time to look over more carefully the different bee-papers coming to my address than I could do in my hurry during the busy season when they arrived. And in this looking over I came across some items which I will say a few words about.

"SPHYNX-LIKE"—GOLDEN BEES.

The first of these items is found on page 601 (Sept. 19), where Mr. Hasty seems to think that I should do some "shouting" for the "Golden Bees," if they are desirable. And, "on the other hand, if they are undesirable bees, sphynx-like silence while selling them by the hundreds, looks too much like the spider-and-fly sort of ethics." So it would look as if I was compelled to say something in this matter (even though it may look like a little free advertising), or allow the thought to go out that I was willing to play the "spider-and-fly" act.

The real truth is, Mr. Hasty, that I have never "pushed" either the golden or the leather-colored bees, but simply advertised *Italian* bees and queens, making no claims other than the following, which appears in my circular:

After having thoroughly tested all other races of bees, I have discarded all but the Italians, as none proved so good with me, all things considered. I have taken great pains to breed my bees up to the highest standard of perfection as *honey-gatherers*. I do not claim all that purity of stock that some do, nor lay so much stress on golden bands, but I do claim that for *honey-producing* my bees are second to none."

That is all there is of it, Mr. Hasty; and I will leave it to your own good judgment whether there is any "spider-and-fly sort of ethics" there or not. As nine out of ten order the *goldens*, I send them what they order, just the same as I do the other tenth who order the leather-colored stock. Perhaps I can make the matter a little plainer to you.

Mr. Hasty has two daughters. Both are excellent, good girls, and as to excellence of character, winning ways, and working qualities, there is really no choice, which Mr. Hasty knows by years of association. But one has blue eyes and auburn locks, while the other has raven hair and jet black eyes. Mr. Hasty loves both of these girls alike, and sees the goodness of both, regardless of the color of their eyes or hair. In the course of time two young gentlemen come along, and one is infatuated with the golden-haired daughter, while the other sees nothing but perfection in the dark hair and eyes of the other. The first thinks it very strange that the father can not see that the daughter with the auburn hair and blue eyes is superior in every way to the other, and wonders that he is not continually praising her; while the second is considerably "riled" because "Old Man Hasty" is not loud in proclaiming that the one with raven hair and black eyes is the *ne plus ultra* of the whole family. But Mr. Hasty keeps on in the even tenor of his way, saying, "Both are good girls."

I was never guilty of pushing color or extreme purity, for, like "Pa" Hasty, I have never been able to see that there was anything but minor differences between the two grades of Italians, namely, the dark-colored or golden. And so I have done, as undoubtedly Mr. Hasty would do under like circumstances, allowed the lover of each to make his own selection. But as I was accused of "pushing" the goldens, I simply denied the truth of such a statement, without stopping to qualify the matter as I have taken pains to do here, through Mr. Hasty's having compelled me to do it, that I might not stand as a "fraud" before the public.

JAMES LA BARRE.

"A BACK NUMBER."

And "John Rambler" (page 745 of Gleanings), thought that Doolittle was doing all the "whacking at long tongues," because he was becoming "a back number." Bless your heart, old friend, Martin. I care not whether I am a back number, a middle number, or wheresoever I am, if I can only aid some brother or sister bee-keeper, by making the road a little easier for them. The motto "on the wall" when I am writing for publication has always been, "Help a little." You know the "good Book" says, "Bear ye one another's burdens," and, also, "Inasmuch as ye did it to one of the least of these, ye did it unto me." And the man who is working for the uplifting of humanity, by the way of adding his mite to the sum total of knowledge, cares not where he stands in the ranks, and does no "whacking back" because some one remarks on his "losing prestige."

I said what I did on the long-tongue matter because I believed that the pushing of a premature, if not a fallacious, matter, would work injury to the greater number of the bee-keeping world; and results have proven that I had cause so to do. And I pushed with the "vigor" accorded me, that all would know that it was not a "milk and water" halt I was calling. I see that it was necessary under the "stampede" then on, to "swing the red lantern" with all my might, no matter how badly I was "pommelled" for so doing. And I did it, and got the pommelling, too. But I freely forgive all, and especially Mr. W. T. Stephenson, (page 598—Sept. 19,) as he did it with the best of motives. Neither can I "place a higher value on long tongues," as Editor York thinks I may (page 627—Oct. 3,) after my experience of the past summer, for the results prove, by a careful measuring of tongues by Prof. Gillette, that those Italians having the shorter give by far the larger yields of red-clover honey. And this also proves that the long-tongue fad was not only premature, but a mistake as well. It is also well to proceed slowly when stepping upon an untried "structure."

LARGE YIELDS—A CORRECTION.

On page 637 (Oct. 3), there is recorded a yield of 340 pounds of section honey, all nicely capped and marketable, together with 10 pounds of honey in sections partly filled, making 350 as a total of section-honey from one colony. And the producer, Mr. John Lenney, wishes to know if "this is not the best record that you have ever heard from one colony;" to which the editor replies in a foot-note: "Yours is certainly a good yield of honey, but we believe Mr. Doolittle once secured 566 pounds of comb honey from one colony in one season." The correction I wish to make is that the 566 pounds which my colony gave was *extracted* honey. (Correction accepted.—Ed.)

My highest yield of comb honey from a single colony in one season was 309 pounds, hence Mr. Lenney's colony went ahead of mine 31 pounds of marketable honey (as my 309 pounds was all nicely finished), or 41 pounds in all. And unless I have failed to note or remember, Mr. Lenney's 340 pounds of marketable section honey from one colony in one season is the largest yield ever reported, and he should have the credit of it, and of standing "at the head," until some one can rightfully claim that place with a larger yield.

HONEY PRICES—BEING MISUNDERSTOOD.

It seems at times, that, try as hard as I may to make a thing plain, some will misunderstand what I write, and I "fell to wondering" whether the trouble was on my part, or on the part of the reader. Very likely on the part of both, for such is generally the case. My mind was called afresh to this matter in reading page 749, (Nov. 21). There I am credited with advising, in Gleanings, that the producer *retail* his honey at 12 cents a pound where the market quotations will lead us to expect that some commission merchant in a distant city would sell the same at 13 to 15 cents; and nearly a column of space was taken to prove that such advice was wrong.

Well, had I ever given such advice it *would* have been wrong, and surely Editor Root would not have endorsed such a *wrong* thing by putting at the head of that article, or "conversation," the words "orthodox advice," as he did, this showing that E. R. Root understood the matter in the light of selling at *wholesale* (not at retail), as I intended to advise. I have always considered it worth 2½ cents a pound to retail honey by the section, where the same was peddled from house to house, as we would infer that Mr. J. L. Hyde proposes to do with the 700 pounds he will sell out of his 1000, "by a little push of it to families in my vicinity." Pushing it around to families cannot very well mean aught but a retail trade, and hence, in this case I would advise a price of 14½ cents with a prospect of honey selling at 13 to 15 cents abroad.

In the conversation alluded to in Gleanings (pages 781-2—Aug. 15), the reader will note that the honey was all graded and *cased*, which meant the selling by the case at least, and selling by the case is generally considered as a wholesale affair, even though but a single case is taken.

Then I spoke of prices at our nearest *railroad station*, which, it seems to me, could not possibly be construed into a retail affair. And again, I spoke of selling *outright*, which means the disposing of the *whole* crop in a lump; yet notwithstanding, Mr. Hyde interprets all of this as meaning "the market price at 12 cents retail."

Then, having misunderstood, he goes on to argue how such advice as I gave would bring the price of comb honey down to 8 cents a pound as "the established price." And "Mr. Hustler" readily sees "why men should not jump at everything that is printed in the bee-papers." When a man starts into a line of reasoning based on false premises, it is quite easy to see something which is not a reality, and a something which would never have "seen the light" had said man made sure he was *right* in his premise at the start.

No, no; Doolittle would never advise doing anything to lower the price of honey, so long as the honey-producer stands to a disadvantage when compared with most of the products of others; nor would he advise ever selling at wholesale where the producer can retail his product at a price enough higher to compensate amply for the labor of retailing.

HONEY ON COMMISSION—A MISTAKE.

Then I think Mr. Hyde makes a mistake where he concludes 300 pounds of honey "is not enough to sell on commission," by which I take it he means that 300 pounds would be too small an amount to ship to a commission merchant in some distant city. Some of the very best sales commission merchants have ever made for me—sales from one to three cents above market quotations—have been where I have shipped them only from 100 to 200 pounds. In fact, the records of these transactions for the past 23 years show that in no case where I have shipped commission merchants 1000 pounds or more of honey has he sold the same at as good an average price as has the same man or firm where I have shipped only from 100 to 200 pounds at a shipment. And the freight is no more per hundred pounds in a single hundred pound shipment, than it is where ten or twenty-five hundred is shipped, as it is always reckoned at so much a hundred pounds, as far as I have had freight-rates quoted to me; with no restrictions as to the number of hundred pounds that must be sent at one shipment.

My idea as to why a small shipment sells for a better price than a large one is, that many of the small grocery men can dispose of the whole of a small lot of honey, where they could not do so with a larger lot; and as the commission merchant is better pleased at not breaking up a shipment, the smaller lots go first, while the prices are generally at their height, or their best; and the larger shipments are only broken up later on, or sold as a whole, and so sell at the reduced price that generally obtains after the holidays are over.

Then, again, the smaller lot is more in the line of a retail trade with the commission merchant, and as the smaller grocer can get just what he wants in the small lot, he purchases the same, even though he pays a little more for it. So don't think that where a bee-keeper has from 100 to 500 pounds more than his home market calls for, that it will not pay to ship the same on commission, for it will pay in two ways: First, it will bring as much, or more, than a large lot in market; and, second, the sending of it away often saves the breaking down of the home market, through the lowering of prices.

Onondago Co., N. Y.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention

The Buffalo Convention.

Report of the Proceedings of the Thirty-Second Annual Convention of the National Bee-Keepers' Association, held at Buffalo, New York, Sept. 10, 11 and 12, 1901.

(Continued from page 822.)

Prof. M. B. Waite, of the Department of Agriculture, Washington, D. C., also delivered an address on "The Relation of Bees to the Orchard," but a copy of it has not been secured for publication.

Pres. Watrous then called upon Prof. S. A. Beach, of the New York Agricultural Experiment Station at Geneva, who read the following paper, on

Spraying in Bloom.

Spraying commercial orchards to prevent attacks of injurious insects and diseases is a practice of comparatively recent origin. According to Lodeman (Lodeman, "The Spraying of Plants," 63, 65), the first published record of successful treatment for the codling moth by spraying with Paris green, is in the Report of the Western New York Horticultural Society for 1879, and the first publication of a regular experiment station to give the results of using Paris green against this insect, is the Annual Report of the New York State Station at Geneva for 1885.

In the period from 1887 to 1894, through the efforts of the United States Department of Agriculture and various agricultural experiment stations, it was demonstrated that by the use of certain fungicides, notably the Bordeaux mixture, some of the most serious orchard diseases, such as apple scab, pear scab, quince leaf and fruit spot, and plum leaf spot, might be kept under control. During the latter part of this period some fruit-growers commenced the practice of spraying orchards systematically to prevent certain diseases. In the treatment of apple, pear, and quince orchards Paris green, or an equivalent arsenical poison, came to be usually combined with the Bordeaux mixture so as to apply both an insecticide and a fungicide in one treatment.

As early as 1889, Cook, then entomologist for the Michigan Agricultural College, stated that bees might be poisoned with Paris green sprayed upon fruit-trees when in bloom. He urged that spraying should not be practiced during the blooming season, and that, if necessary, such a requirement should be made by law. (A. J. Cook, Bul. 53, Mich. Ex. Sta.: 4, 5.)

After that, whenever experiment-station writers published directions upon this point, they uniformly advised against spraying in bloom. In 1896, Webster published the results of experiments conducted at the Ohio Experiment Station in 1892 and 1894, by which it was proved that bees are liable to be poisoned by working on blossoms

sprayed with Paris green or with Bordeaux mixture and Paris green. He reports that shortly after some trees were sprayed, one of the colonies of bees located near by became extinct. Arsenic was not only found in the abdomens of the bees, but it was also found in the dead brood in the hive. (F. M. Webster, Bul. 68, Ohio Ex. Sta.: 52.)

We have already noticed that even prior to 1895 some fruit-growers had adopted the practice of spraying their orchards for the prevention of fungus diseases, and of combining with such treatment the application of arsenical poisons to kill the insect enemies. Such was their success that their example was soon followed by many others, and within the next three or four years spraying came to be generally regarded as a necessary operation in successful orchard management. But some of the fruit-growers experienced more or less difficulty in trying to follow the instructions of the experiment stations as to when the spraying should be done, especially in treating large apple orchards. In this eastern section of the country, the apple orchard, as a rule, constitutes but a portion of the farm, the remaining portion being devoted to other crops. At the time when spraying should be done, other important farm work also demands attention. This is especially felt when the season has been unfavorable for field-work. Under such circumstances, when the fruit-grower was crowded with work, the practice of spraying apple-trees in bloom has had its origin. It was tried at first from considerations of necessity or convenience rather than from any idea of the superiority of this plan of treatment over that recommended by the experiment stations. Orchardists who had not completed the spraying of their trees before the blossoming season began, continued to spray in some instances after the blossoms opened. They chose to take the risk of injuring the crop by spraying in bloom rather than risk injury from diseases and insects. Later, the idea that the best time of all for spraying is when the trees are in full bloom gained considerable headway.

As soon as they found that fruit-growers were beginning to spray orchards when in bloom, the bee-keepers at once became much concerned over the effect of such a practice on their business. The publications of experiment stations and of the United States Department of Agriculture assured them the bees were liable to be poisoned by working on blossoms which had been sprayed with insecticides. In New York State the bee-keepers set to work vigorously, and by 1898 secured

the enactment of a law which still stands on the statute books, making it a misdemeanor to apply any poisonous substance in any way to fruit-trees in bloom. (Chap. 325, Laws of 1898.) Some of the fruit-growers had by this time become so thoroughly convinced that better results could be obtained by spraying apple orchards in bloom than by spraying at any other time, that they strongly opposed the passage of the law and afterwards tried to get it repealed. Unsuccessful in this, but still confident that their views were correct, they kept at work until an amendment to the law was finally secured, whereby the experiment stations at Cornell University and at Geneva were permitted to spray plants in bloom for the purpose of testing such treatment in comparison with the treatment commonly advised. Accordingly, in 1900, work on certain phases of this subject was undertaken by both of the stations named above. The results, so far as published, are given in Bulletin 196 of the Geneva station, to which publication those who are especially interested are referred.

One of the questions bearing upon the subject of spraying in bloom which is sometimes asked is, whether treating the open blossoms with the spray mixtures does not directly help to set the fruit. An understanding of the way fruit sets will conduce to a clearer idea of what influence the spray mixtures may reasonably be expected to have in this direction. An apple-blossom cut through the middle shows different parts as here illustrated: (The following 6 illustrations are from Bulletin 196 of the New York State Agricultural Experiment Station, Geneva, N. Y.)

The outer green portion which covers the bud is called the calyx. When the blossom opens, the calyx turns backward. It persists on the fruit where it may be seen by examining the blossom end of the apple. Next, within the calyx are the showy flower-leaves. Neither these nor the calyx are essential to the setting of fruit. Up to the time the blossom opens, they give protection to the very delicate central organs, but they may then be cut away without interfering with the setting of the fruit. The essential organs are the stamen and pistil. The pistil occupies the very center of the flower. It divides above into five green threads which at the proper time exude from their tips a sticky fluid. Below it contains the little egg-cells which, when fertilized, develop into seeds. The stamens are thread-like and tipped with yellow sacks of powder called pollen. They surround the pistil. When the pollen alights upon the sticky tip of the pistil—i. e., upon the stigmatic surface, if conditions are favorable—it sends out a sprout in a way somewhat analogous to the sprouting of grain in warm, moist soil. This pollen-tube grows downward through the soft tissues till it reaches the egg-cell, which is then fecundated and thus stimulated to continue growing into seed.

This, in brief, is the way fertilization of the apple takes place. If fertilization does not take place, there is no further development and the entire flower withers and falls away. Since the essential organs are composed of very tender tissues, it is not surprising that injury may follow when they are hit by the spray mixtures. Neither is

it strange that Bordeaux mixture should prevent the germination of the pollen. The Bordeaux mixture holds its position as a leading fungicide, because it prevents the growth of fungous spores. The germination of pollen is more nearly analogous to the germination of fungous spores than to the germination of grain cited above. Since the Bordeaux mixture is deadly to one, it may be expected to have a similar effect upon the other. That it does have such an effect is proved by laboratory experiments which formed a part of the investigations previously mentioned. The ordinary combination of Bordeaux mixture with an arsenical poison prevented the growth of pollen in laboratory cultures, as also did even lime alone, while in corresponding cultures, in which these substances were not present, the pollen germinated and pollen-tubes grew. Bordeaux mixture alone—1 to 11 formula—was added to cultures in varying proportions, and the effect was remarkable. With 200 parts of it in 10,000 parts of the culture media, the growth of pollen was practically prohibited, for the pollen did not grow except in rare instances; 100 parts in 10,000 in some cultures, but not in all, wholly prevented the germination of the pollen; sometimes 50 parts in 10,000 gave a similar result, and even the very slight proportion of 2 parts in 10,000 in some cases showed an unmistakably adverse influence on pollen-germination. Since pollen must alight upon the stigmatic surface, and there germinate before fertilization can take place, these results are highly significant to the fruit-grower.

From the facts which have been presented it is clear that applying the spray mixtures on the open blossoms, instead of assisting directly to set the fruit, may wholly prevent it.

But some fruit-growers feel sure that spraying in bloom has caused a positive improvement in their apple crop. How can such results be accounted for? One of the worst diseases in New York apple orchards is the scab. Does spraying in bloom give some degree of protection against this disease? It is well known that the amount of damage from this disease varies greatly in different seasons. In 1896, for example, the apple crop was remarkably free from injury from the scab, even on trees which had never been sprayed. In 1898, on the contrary, in Western New York, the scab became virulent so early in the season that in many cases it killed a considerable portion of the blossoms, and later continued the destruction on the immature fruit.

The apple-blossoms grow in clusters having perhaps from 5 to 7 in the cluster, although the number may vary considerably. They do not all open at the same time. The one in the center opens first and is normally the strongest and forms the largest fruit. Those immediately around the central one open next in order, and lastly the outside blossoms of the cluster open. The whole process generally takes from a week to 10 days in this part of the country. It varies with weather conditions. When the last ones are opening, the central blossom has usually passed out of bloom. Not only is there this difference in the time when the different flowers in a cluster open, but also in the same way tree-clusters which are less exposed to the heat of the sun

are correspondingly retarded in blooming. Consequently, all of the clusters on a tree do not begin blooming at the same time. It appears, therefore, that there is no one time when all the apple-blossoms on a tree are open. Of those which are open, some are sure to escape being hit in the center when the spraying is done in an ordinary way.

When there is an abundance of bloom, and when the apple-scab becomes destructive as early in the season as the time when the blossoms are opening—as was the case in 1898—spraying once in bloom might not destroy enough of the blossoms to reduce the crop of fruit seriously and yet give a degree of protection against the scab which would result in improvement in the amount and character of the crop; but it has not yet been demonstrated by rigid experiments that even in such a season spraying in bloom gives superior results to those which may be obtained by spraying just before and just after the blooming season. In order to get conclusive evidence on this point, it will be necessary to continue the experiments till a season arrives when the conditions are somewhat similar to those which obtained in Western New York in 1898.

Does spraying in bloom ever bring about an improvement in the crop by thinning the fruit?

In the experiments reported in the bulletin already cited, it was found that apple-blossoms which were treated with the spray—the ordinary combination of Bordeaux mixture and an arsenical poison—in the early part of the blooming season, generally failed to set fruit. Blossoms which had been open several days before they were hit by the spray seemed to have reached a stage where such treatment did not interfere with the setting of the fruit. Some results which are apparently conflicting, may be reconciled by a clear understanding of this point. It appears that there is a difference between the older blossoms and the newer ones as to their susceptibility to injury from spray mixtures.

Experiments were also made in which portions of trees were sprayed repeatedly during the blooming season, thus hitting the new blossoms as they open from day to day. As a consequence, scarcely any blossoms set fruit, nearly all being destroyed by the treatment.

One spraying, if well done, may be expected to destroy a large portion of the freshly-opened blossoms, and thus thin the fruit. Such a result was in fact obtained in some of the experiments with apples in 1900, and with pears in 1901. In case there is a light bloom, it seems that spraying at a time when most of the blossoms are freshly opened, may cause the loss of a considerable portion of the crop. Some fruit-growers who have tried it have become convinced that spraying under such conditions has caused them very serious loss.

In the experiments in which spraying in bloom has thinned the fruit, the amount of marketable fruit has not always decreased. Such results are similar to those obtained where the fruit has been thinned by hand. This suggests the practical question, whether the process of spraying plants in bloom may be used as an economical method of thinning the fruit. Our experiments on this point have not been

carried far enough to give conclusive results.

In our investigations we have tried to find out what effect the application of the ordinary spray mixtures to open blossoms has upon the blossoms and upon the crop of fruit. There is another phase of the subject which interests the fruit-grower, and that is the extent to which bees and other insects are needed for cross-pollination in order to secure a good setting of fruit. It has been proven that with some varieties cross-pollination must occur before any fruit can be formed. Others are fully capable of setting fruit without cross-pollination. Between these two extremes are found many imperfectly self-sterile varieties, among which are all gradations between self-sterility and self-fertility, with corresponding independence of or dependence upon cross-pollination for the setting of fruit. Even some varieties which are classed as self-fertile, may produce better fruit when cross-pollinated than when self-pollinated.

Pollen is naturally distributed from one blossom to another by the agency of either winds or insects. Some kinds of pollen are easily distributed by winds; others are not adapted to wind-distribution, but are easily carried by insects. Apple-pollen belongs to this latter class. Whether or not the fruit-grower may secure better crops when insects aid in distributing the pollen, must be determined by learning the needs in this direction for each particular variety of fruit which he grows. In case he is growing self-sterile or imperfectly self-fertile varieties having pollen not readily distributed by winds, the poisoning of bees and other insects which visit the blossoms would work him injury. He then would have a common interest with the bee-keeper in preserving the lives of the insect visitors of the flowers.

A considerable amount of work has been done for the purpose of determining which ones among our cultivated varieties are self-fertile, and which are imperfectly self-fertile or self-sterile. At some experiment stations further investigations on this subject are in progress. Much yet remains to be done, however, in order that full and satisfactory information on this important point may be available to the fruit-grower.

Another question which is worthy of attention in relation to the subject of spraying in bloom is the effect of fungicides upon bees. We have seen that if spraying in bloom results in an improvement of the crop of apples, such improvement may come in part from protection against the attacks of the scab fungus, and in part from thinning the fruit. Neither Paris green nor any other recognized insect poison is needed to secure these results. They may be obtained by using Bordeaux mixture alone. It is desirable, therefore, to know whether there is any danger of poisoning bees by spraying blossoms with fungicides alone. It is worthy of remark in this connection, that in all of the extensive use of Bordeaux mixture it has not yet been known to poison insects. Finally, from what has been said, it appears that the desirability of spraying in bloom is a subject concerning which more information is needed in order to reach a decision which may be accepted by all

as being correct. Among the questions which should be investigated further are these:

1. May bees be poisoned by spraying open blossoms with Bordeaux mixture or other fungicides not combined with any recognized insect poison?

2. Does spraying just before and just after blooming give as good protection against injurious insects and diseases as a corresponding number of treatments, one of which is made during the blooming season?

3. At what stage of blooming has the process of fertilization progressed so far as to escape danger from the application of spray mixtures?

4. What cultivated varieties may be expected to show improvement in fruit-production as a result of cross-pollination secured through the agency of insect visitors?

The following conclusions must be accepted as now well established:

1. Bees may be poisoned by applications of arsenical poisons to open blossoms. The brood in the hive may likewise be poisoned.

3. The application of ordinary spray mixtures to open blossoms may stop the further development of the blossom, either through the corrosive action of the spray upon the pistil, or by pre-

venting the germination of pollen on the stigmatic surface.

3. With apple and pear trees, having an abundance of blossoms, spraying once in the blooming season has thinned the fruit; spraying repeatedly, so as to hit the blossoms as they opened from day to day, has practically destroyed the crop of fruit.

4. The productiveness of many of the varieties of fruit which are more or less self-sterile, is increased by cross-pollination secured through the visits of insects to the blossoms.

S. A. BEACH.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

ANTS AND BEES.

Yes, Mr. Working, it's possible that ants may rob a queen-cell—may do worse, may grapple and destroy a queen. The number of species of ants are immense, and no two species alike; so it won't do to judge of the whole by the species we may happen to have known. Perchance the ants we have known never meddle with grain: but there are ants that will carry it off by the bushel. The ants most of us have known are comparatively harmless to bees: but there are ants so ferocious that bees, unless effectively protected, can not survive near them at all. Bees show anger when multitudes of little ants, too small to grapple with, get scattered among them in opening an ant-infested hive. And if ants abound, don't rub a bee-hive with anything that ants like, preparatory to hiving a swarm in it. Myriads of the little nuisance will go right in; and the bees, if I mistake not, will go out. I may be wrong, but my impression is that ants, bulk for bulk, are much stronger than bees, so that when big enough to be grappled with they are always too strong to be handled. Also, they are very hard and smooth, and afford no flat surfaces, so that getting a sting into one of them is a practical impossibility, likely. Page 680.

THE UNIVERSAL NEED OF AN EDUCATION.

Both parents and children the country over are still somewhat infected with the pestilent idea that there is no use of very much education unless one is going to be a teacher or something in the professional line. Thanks to Prof. Cook for his attack on that idea, page 682. *Specially* need a rich education in order to be comfortable while digging a ditch or breaking stone. I would also put in strongly: Education prolongs life. Multitudes of people, scarcely old yet, die of a mild, chronic wretchedness. Time and age have rendered the former routine of their lives impossible, and they have nothing to be interested in. Digestion cannot go on properly—we might almost say no other bodily function can go on properly—while the mind is in a state of wretchedness. The net result is that the body deteriorates and ages more in one year than it would need to do in two years; and soon something trifling carries you to the grave.

FEEDING BEES "GARDEN SASS."

And so Louisiana wants to set his bees to eating vegetables. As the extreme South has no wintering trouble except starvation, teaching the bees to eat "garden sass" would be in the nature of a panacea. He finds they eat somewhat at baked sweet potatoes. Let him feed 'em a big lot more—and then tell us instead of expecting us to tell him. Possibly the Californians can go him one better by feeding cooked sugar-beets. The Italians are already in the van by raising watermelon patches and feeding melons sliced on the ground. And Dr. Peiro—but then he's no "garden sass." Page 712.

TWO KINDS OF DRONES FROM ONE QUEEN.

Two kinds of drones from the same mother is not exactly evidence in favor of absolute purity, we grant. I think it is very common, however—so common that such a queen is not called impure. We say instead that the Italian (not far back) is a mixed race, anyhow. Page 716.

"ROAD-TRAP" FOR RABBITS.

Iowa comes to the front with bad roads that serve the useful purpose of rabbit-trap. Bunnies think they can get across to the other side and get awfully taken in. But—look out there! You'll get trapped, too, if you don't exercise care in getting the game from the trap. About the first report we've had in favor of a clay road at its prettiest. Page 717.

VETCH NOT A GOOD HONEY-PLANT.

Glad to hear from the man who raised vetches by the acre for years—I. Hiller, Washington State. It seems that (like cowpeas) bees work on the stems, not on the flowers—but no surplus from that, not even results enough to stimulate brood-rearing. The consensus of a number of reports seems to be that it is rare to see a bee on the flower of the vetch. Page 717.

CALIFORNIA VS. AUSTRALIA.

I am surprised at the Australian Bee-Bulletin for inquiring why California beats Australia in honey. Next they'll be asking why British Colonial government isn't so good as American State government. Page 718.

THOSE STONE SHADE-BOARDS.

Stone shade-boards! And they're pretty, and well liked, and only cost a few cents each. If Mr. A. E. Willcutt will cut us all a supply and arrange to send them by mail, we'll propose him three cheers. Pages 722 and 727.

SOME "LONG SMELLERS" IN OHIO.

Why, Mr. York, you ought to be willing to credit the bees with longer "smellers" than we've had. When Wood County oil and gas was in its prime we often smelled it unmistakably plain and strong 30 miles away. We are due north, so only an occasional turn of the soft south wind would bring it. On one or more occasions I waked up in the night and smelled it without going out-of-doors. As a matter of an opinion I am well persuaded that, on just such a moist and gentle south wind, and at morn, before the currents of the day have got started up, bees could smell a forest of basswood in bloom much more than 30 miles—many times over as far as they could afford to go to it. Page 724.

A MINIMUM OF UNFINISHED SECTIONS.

On page 727, Mr. Doolittle writes well on the minimum of unfinished sections. For years I have had very little trouble from that source. Wonder if it's locality, or strain, or kind of super. It is certainly not any fussing on my part to prevent it—and I *think* that locality plays on the wrong side. Strain and style remain; and I guess it's both combined. Good hybrids of long standing, and the (now unusual) two-story wide-frame. Four bait-sections all in one frame—two above and two below—and that frame put to the warm side of the middle. Always 40 or 48 sections put on at once. Notice: Let no beginner copy at wholesale till he asks his bees whether they like that sort of thing. Mine do. In a poor, lean field, which, nevertheless, has possibilities all the season long, it's just the lazy man's hallelujah arrangement—put it on in June and take it off in November.

BREEDING FROM THE BEST.

Dr. Miller's answer to South Carolina on page 729 is right. (Breed from both.) But still, if you have excellent bees, and are trying to make them better, the longer line of unbroken excellence you can get the more hopeful the last queen ought to be as a breeder. This on general principles—not drawn from any particular set of cases.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Clarifying Beeswax.

Some foundation I bought two years ago I have melted and sold as wax, not having need for more foundation; but this does not have the golden yellow appearance as wax which it had as foundation, and which the purchaser of the wax insists it must have, or cut the price heavily. It was strained through muslin when melted; it is not dirty, but has a very cloudy appearance. I have seen reference to the use of sulphuric acid for producing the golden yellow color, but I tried it and it made the color worse than before, and the wax was inclined to be mealy and crumble easily.

IOWA.

ANSWER.—Try cooling it slowly. If you have not had much experience with beeswax it is possible that when you have it melted you allow it to cool very rapidly. The result is that the particles of impurity have not time to settle, and are frozen in wherever they happen to be, giving a more or less dirty and cloudy appearance. While the wax is very hot, there will be more or less movement among the particles, somewhat after the nature of boiling, and there will be no settling of impurities so long as it is in this condition. After it becomes cool enough so there is no movement akin to boiling among the particles, try to keep it in this liquid condition a long time, and by the time it begins to assume the solid condition the particles of impurity will have had time to settle.

A small quantity is harder to manage than a larger quantity. If the quantity is small, you can help matters by having water in the vessel with the wax, for a gallon of water with a gallon of wax will stay hot longer than the gallon of wax alone. Let the wax stand on the stove and let the fire die out in the evening, and in the morning you may find it clarified. Keeping the wax covered will keep it hot longer. If the quantity is small enough, a good place to put it is in the oven of a cook-stove just before the fire dies out in the evening. Put the stove-handle in the oven and shut the oven door. Hunting the stove-handle in the morning will help to keep you from forgetting to take out the wax.

Long-Tongued Bees—Mating in Confinement—Black or German Bees vs. Other Races.

1. Have the expectations of those who purchased queens of the "long-tongued" variety been fulfilled?
2. Has there been any advancement made "along the line" of having queens mated in confinement the past season? Hasn't some one been experimenting with the tent method?
3. Are not the black or German bees the hardest we have? If not, why are they likely to supersede the other races?

MASSACHUSETTS.

ANSWERS.—1. I don't know. Very likely some are disappointed, and some well pleased. Some may have expected a great deal too much. Length of tongue alone will hardly warrant a perfect bee, although some good authorities seem to think that bees with tongues of unusual length are more likely to have unusual industry. Without knowing anything positively about it, I should suppose that a bee with a very long tongue *might* be lazier in some cases than its fellows with shorter tongues. Other things being equal, Mr. F. B. Simpson says he would prefer long tongues, and so should I. But we can hardly settle that long tongues are of great value just from a single case or two. Neither are we warranted in entering a general condemnation from a single case, as Mr. Doolittle seems to have done on page 775 (1901).

2. I do not know that there has been anything later than the tent method, so fully published some time ago.

3. I don't know. It is possible that blacks may be harder, but that fact, if a fact, is not proven by the fact that Ital-

ians become mixed with black blood. That may come from the mere fact of numbers. I think it is not so hard to keep out black blood as it was some years ago, and it would probably be an exceedingly difficult thing for most bee-keepers nowadays to keep blacks pure.

Rearing Italian Drones and Queens Early.

I have two colonies with Italian queens from which I want to rear queens and drones in the spring. How early should I begin stimulating in order to rear them before the black bees of the neighborhood start breeding.

CALIFORNIA.

ANSWER.—It is not considered advisable to practice stimulative feeding before blacks start breeding at all. For bees wintering outdoors, whether black or yellow, begin breeding before the weather is warm enough for bees to fly, and it is not advisable to stimulate bees by feeding when they cannot fly out about every day. But as soon as weather comes so that bees take daily flights, then you may begin operations. If there are flowers from which they can gather freely, stimulative feeding will make little difference. But if there come days when the weather is good but pasturage lacking, then a little feeding will keep up brood-rearing.

See that the colony from which you wish to rear drones has abundance of stores, and make every effort to have it strong. Add frames of sealed brood from other colonies (brood from black colonies will be all right), so that the colony will be very strong, and put frames containing more or less drone-comb in the middle of the brood-nest, and you will have done about the right thing to have drones earlier than the average.

Killing Bees in Box-Hives and Extracting the Honey.

I have bought bees in 20 box-hives that I wish to kill and extract the honey from the combs. As I cannot use an extractor to get the honey, please tell me how to get it from the combs. Also, the best way to kill the bees.

INDIAN TERRITORY.

ANSWER.—Kill the bees either with sulphur or bisulphide of carbon. Without an extractor I know of no way to get the honey out of the combs without injury to the combs. If you do not care to preserve the combs, melt them (honey and all), allow the mass to cool, then remove the wax from the top. The probability is that the honey will not be of the best quality, for it does not take much heating to spoil it. Set the vessel containing the honey in another vessel containing water, and let the heat be so mild that it will be a long time melting, and the honey will be better than if rapidly melted with great heat.

Unusual Amount of Dead Bees.

I have 24 colonies outdoors, well packed, but there is an unusual amount of dead bees in front of the hives at this early date (Dec. 4.) What is the cause? and what may I expect as a result in the spring?

ILLINOIS.

ANSWER.—I don't know. It's an exceedingly hard thing to pass judgment at long range without particulars. It may be there is nothing wrong. Sometimes an unusual number of old bees, or a number of bees of unusual age, may make a larger showing of dead bees, in which case you may expect weaker colonies in the spring. The kind of weather may have something to do with it. If bees are confined to the hive a considerable time by very severe weather the appearance in front of the hive will be different from what it will be if the weather is warm enough to allow the dead bees to be partly cleaned out but not carried away. In any case, all you can do is to see that the bees are as well protected as possible, and hope for a favorable spring.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

The Family Friend

An old and true friend that will help you in times of distress. When racked with pain you would give anything for relief. In the hour when the little child, too young to make its wants known, lies suffering, its little face drawn with agony; in the hour when the good wife, worn and tired, needs an arm to lean on; at all such times, when the calling of a doctor means a dangerous delay, besides great suffering and a heavy bill, there is nothing else so good as a bottle of

WATKINS' Vegetable Anodyne Liniment.

We receive numberless letters like these:

SAVED THE CHILDREN.

CLARA CITY, Minn., June 14, 1901.
We had five children sick with diphtheria last winter and carried them all through in one week without any doctor. Watkins' Vegetable Anodyne Liniment should be used at once as soon as any symptoms appear. We mixed two teaspoonfuls of Watkins' Liniment with two of vinegar and one of salt. Have some of the mixture once an hour, also rubbed the Liniment on outside of neck.

OTTO PETER.

HORSES WOULD HAVE DIED.

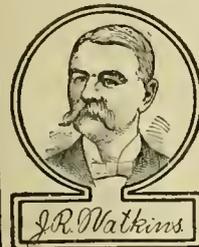

SHUSSEWANA, Ind., June 18, 1901.
I have used Watkins' Vegetable Anodyne Liniment for nine years and find it the best remedy for colic in horses I ever knew. I saved two horses with it that would have died. Cannot speak highly enough of it.

HENRY CATTON.

The best thing made for Cholera Morbus, diarrhea, flux, rheumatism, cuts, cramps, strains, burns, colic, mumps, sore throat, diphtheria, frosted limbs, etc. For horses and colic it cures sprains, cuts, scratches, bruises, sweeny, colic, etc. Of course when you read this advertisement you may not feel the need, but the need of it may arise at any moment of the day or night, and then its worth can not be counted in dollars and cents. Order it the next time our agent calls, or if we have no agent in your county, send us your name and address at once, and we will see that you are supplied.

FREE! FREE! FREE!

We send out a beautiful 100 page illustrated Home Doctor and Cook Book absolutely free, and want to place your name on our mailing list. It is the cleverest and most complete thing of its kind ever issued. Write for one to-day.

Wanted a Man. We want one good, open-eyed young man in each neighborhood who has a little ambition, and an inclination to get on in the world, to write to us. We are in a position to start him in a good paying business of his own. We have lots of young fellows, "boys" you might call them, who are making a nice thing selling Watkins' Remedies.

The J. R. Watkins Medical Co.
10 Liberty Street,
Winona, Minnesota, U. S. A.

Sulphuric Acid to Cleanse Beeswax.

Asked as to the strength needed, Gleanings in Bee-Culture says:

Sometimes a 5-percent solution will do the work; then as strong as is required. That is to say, one part raw acid to 10 parts water; but if the wax is very dirty or black you may require to use as high as 25 percent. Use acid enough to get the yellow color. It is cheap; and when you have secured the proper color you can make your wax enough more valuable to more than pay the expense of the acid.

Increase of Honey-Yield.

Very often we see the question asked: "Is there any plant that will pay to grow for honey alone?" Whether such a plant exists I will not try to say, but I do wish to say that this question sounds a little foolish, for who would wish to cultivate a plant that furnished only nectar, while there are so many nectar-yielding ones, which furnish also excellent crops of fruit and grain? I am of the opinion that new plants for supplying nectar are not half so desirable as would be giving more attention to some of our present field-crops, and study to have them coming on at the proper time to fill up the vacancies between the main flows from the natural sources.

I also incline to the belief that longer-tongued bees are to be desired more than short-tubed clover, for the reason that though the short-tubed clover may be had, advantage over the one single plant is all we have; while by lengthening the bees' tongues till they can work on red clover, hundreds of plants equally as valuable as red clover would be brought within reach of the bees at a single step.—L. E. KERR, in the American Bee-Keeper.

Don't Be a Clam.

Don't be like a bee-keeper I once knew. He told me he had "invented" a new way of rendering combs; it was far ahead of any other way. I replied, "If it is any better than the solar wax-extractor then it is good." "Solar wax-extractor?" said he. "What is that?" I explained it to him. He appeared quite disgusted with himself. "Why," said he, "that is what I have, and I thought that no one else had ever seen such a wonderful thing, and I was going to take good care that he never did." He then took me to where his extractor was, and I tell you it was a crude affair. He did not subscribe to any bee-journal, and so was ignorant of the strides that were being made in apiculture; and when he found out a good thing he kept it to himself instead of telling it, and thus helping to brighten the lot of others.—Australian Bee-Keeper's Review.

The Bee in Law.

R. D. Fisher tells something about it in Gleanings in Bee-Culture. A decision of the New York Supreme Court is that—

"A man's finding bees in a tree standing upon another man's land gives him no right, either to the tree or bees; and a swarm of bees going from a hive, if they can be followed and known, are not lost to the owner, but may be reclaimed."

Mr. Fisher further says:

Where one discovers bees in a tree, obtains a license from the owner of the soil to take them, and thereupon marks the tree with his own initials, he gains no property till he takes possession; nor can he maintain tres-

To make cows pay, use Sharples Cream Separators. Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

OUR NEW CATALOG, describing and listing the **FINEST LINE OF BEE-KEEPERS' SUPPLIES IN THE WORLD**, will be ready about the first of the year. pass against a third person who cuts the tree and takes possession of them on a subsequent license from the owner of the soil. The two licensees stand on an equal footing; and he who first takes possession becomes the owner.—Ferguson vs. Miller, 1 Cow. (New York), 243.

This case has been commented on adversely, and critics say it is bad law. The better law on this point is promulgated by the Vermont Supreme Court in Adams vs. Burton, 43 Vermont, 36, where it is held that one who has obtained a tacit consent from the owner of the soil to cut down a bee-tree thereon, and get the honey, has, while in the act of cutting down the tree, a superior right over a third person to whom the owner has given subsequent consent, but without revoking the former's authority. The court said: "These parties stand, as between themselves and as respects the legal principles applicable to the case, in precisely the same position as though neither had any authority from the owner of the tree, and both were trespassers upon his rights, or as though there were no individual owner of the tree. How, then, would the case stand? No principle is better settled than that a person in possession of property can maintain trespass against any one who interferes with such possession who can not show a better right or title."

With regard to swarms not wild, but issuing from colonies in the possession of a bee-keeper, Mr. Fisher says:

If bees temporarily escape from the hive of the owner, who keeps them in sight, and marks the tree into which they enter, and is otherwise able to identify them, they belong to him, and not to the owner of the soil. In such a case the property draws after it possession sufficient to enable the owner of the bees to maintain trespass and recover damages against a third person who fells the tree, destroys the bees, and takes the honey, notwithstanding such owner himself is liable to trespass for entering on the land of another for a similar purpose without authority. The right of ownership continues; and, though he can not pursue and take them without being liable to trespass, still this difficulty does not operate as an abandonment of the bees to their liberty by nature. Hence, the dictum that "the owner of the soil is entitled to the tree and all within it" is true only so far as respects an unreclaimed swarm.

A Kink in Queen-Rearing.

A little kink I got this year for rearing queens early in the season and late in the fall, when bees will do really good work in any other way, was this: Remove the old queen, then close the hive and gently blow smoke in at the entrance, pounding slightly on the hive till the bees are alarmed so they will fill themselves with honey. Now open and shake half or more of the bees into the nucleus-box I have explained about before. This box is so arranged that the bees have access to what is known as "queen-candy," such as is used in sending out queens in the mails. The box of bees is carried to the honey-house and left till the next day, at which time the colony is given a prepared lot of queen-cups, and the bees put back. They will "go for" cell-building "to beat the band." Twenty-four to 36 hours later put in a frame of honey on either side of the frame of cells, and take all the combs having brood in them from the hive, shaking and brushing off all the bees. This adds a new impetus to the matter, and brings forth queens of the very highest type of perfection, especially if the colony is fed in addition, so that much heat is kept up all the while, till the queens are ready to emerge.—G. M. DOOLITTLE, in Progressive Bee-Keeper.

Five-Banders Not Uniform.

I never yet have seen all the bees of so-called five-banded queens show uniformly five yellow bands. The best average for one queen is, perhaps, 50 percent with five bands; 25 percent with four, and the rest with three. As a rule, we do well to get 25 percent five-banded workers, and the rest three and four

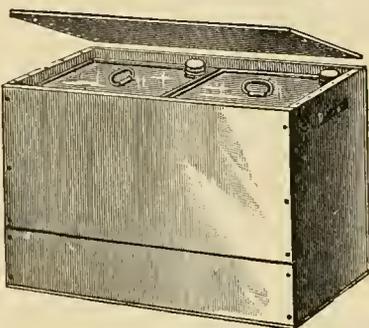

—BEST—

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two or more 60-pound cans of Alfalfa, 7½ cents per pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

banded, all from the same queen. I never yet have seen a uniform number of bands from any one queen of the extra-yellow stock. —Glennings in Bee-Culture.

GENERAL ITEMS

Good Year for Bees.

This has been a good year here for bees and honey. Most of the honey has been light, very little dark honey in my crop. My bees averaged over 100 pounds to the colony, and I have disposed of almost all of it at a good price in the home market. M. BEST.
Lucas Co., Ohio, Dec. 16.

A California Report.

My crop from 126 colonies (in fair condition) was 22,514 pounds of extracted honey, with an increase of 10 colonies. I now have 203 colonies. I make my increase in the valley out of a low grade of honey. I keep down increase in the mountains by giving room and ventilation. My crop sold in the retail way at 5 to 7 cents a pound.

S. Q. CONKLE.
Orange Co., Calif., Dec. 3.

Report for 1901.

My bees did well the past season, yielding an average of about 70 pounds of comb honey per colony. H. G. WYKOFF.
Warren Co., Iowa, Dec. 12.

Results of the Past Season.

Last spring I had 30 colonies of bees, and I secured 1100 pounds of comb honey and 1200 pounds of extracted, besides increasing to 49 colonies. JOHN EENIENBURG.
Cook Co., Ill., Dec. 15.

Not a Good Season for Bees.

I met with a bad accident a little over a year ago. My horse ran away and I broke my hip at the joint. I can not walk a step without crutches. The surgeon tells me that I can walk pretty well in another year, but I am afraid he is mistaken, as it has been over a year since it was broken, and I can not step on it yet. I have to hire a man to take care of my bees. I put 50 colonies, apparently in good order, into the cellar Dec. 4.

The past was not a very good season for honey here, being too dry. I had about 1300 pounds of nice honey, which sold at 12 cents per pound.

I like the American Bee Journal very much, and don't want to do without it as long as I keep bees. W. L. MITCHELL.
Whiteside Co., Ill., Dec. 14.

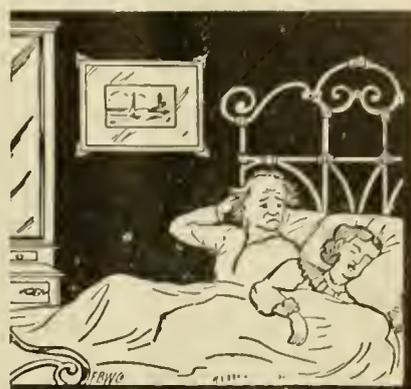

Bees Did Well.

My bees did well this year for this part of the country. I have about 110 colonies, and had a little over three tons of honey in one-pound sections. Two colonies produced a little over 200 pounds each. WM. M. DICK.
Ford Co., Ill., Dec. 14.

First Summer With Bees.

This is my first summer with bees; I got plenty of stings, but no honey. I also had some experience with transferring and robbing.

I have three colonies of bees, the third being very late, and reared a good deal of brood in September and October. I thought they must be fed, so I made sugar syrup and fed it in a Boardman feeder, placing the feeder in the center of the entrance. This left space on both sides of the feeder, and it wasn't very long before the other two colonies were robbing the feeder, and the hive, too. Although

Snoring Stopped Instantly,

prevented and cause permanently removed by a neat and simple device which affords no inconvenience to user. Failure is Impossible. The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the knife.

The Novelty Knife is a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

I contracted the hive-entrance so that only one bee could enter at a time, there was no fighting, and the hive was soon empty.

I fed again, and the robbery was repeated, so I piled hay in front of the hive and fed under this; but the bees crawled right into the hay. I then poured several pails of water over the hay, and the trouble ceased.

After this I fed \$2.00 worth of sugar. The two colonies had their combs full. The third colony got rather slow about carrying it in, so I think they have enough for winter. I fed this sugar in the open.

I have received the Emerson binder, and must say that it is the best way to get the full worth of the Journal; easy to refer back and find articles which you need just now and don't quite remember. I have a full sheet of lined paper in the back of my binder, in which I keep a memorandum of articles that I will need later on. THEODORE FLUEGGE.

Dupage Co., Ill., Dec. 16.

Honey-Locust.

I enclose some leaves and a blossom for naming. The bark is very smooth, and the tree has a fine foliage.

Frogs and toads can be found in creeks, springs, old wells, and in crab-holes near marshes. They sometimes freeze, which makes them blind, or partly so. A fish may be frozen as hard as a stick, but will swim after being in water awhile, but the eyes are damaged.

I am much pleased with the American Bee Journal. F. DURANT.

Winnebago Co., Wis., Dec. 12.

[The specimen sent for identification is the honey-locust—Gleditsia triacanthos—and belongs to the Leguminosae family. Prof. Cook, in the Bee-Keepers' Guide, page 363, calls attention to the honey-locust as an excellent nectar-producing plant, along with others of the same family. These plants blossom early in the year, in May and June, and the bees produce a fair quality of honey from them.—C. L. WALTON.]

Bees Flying—No Snow.

The ground is bare and no frost in it. The last few days the temperature has stood at 55 and 60 degrees, and my bees are flying. We have not had snow enough yet to track a cat. To be sure, all through November it was very cold. For the last two years we have not had snow enough to go sleighing.

HENRY M. BARTLETT.

Plymouth Co., Mass., Dec. 14.

Enjoys Her Bees.

I enjoy the pictures of the apiaries, and will try to send one of my apiary. My bees are in good order, and well packed for winter. I have them on the summer stands with blankets over the brood-combs instead of the gum-cloth, and bags of open canvas filled with dry leaves on the blankets. I have never lost a colony from cold. My bees are a great pleasure to me. MRS. E. G. BRADFORD.

Newcastle Co., Dela., Dec. 10.

Early Winter is Warm.

The weather is quite warm to-day, and bees are flying. If the winter continues this way there will be no loss of bees from freezing, that's positive, but when we have a warm, open winter we also have a poor season for honey the following summer. W. W. MCNEAL.

Scioto Co., Ohio, Dec. 13.

Did Well With Bees.

I have done remarkably well with my bees this year, and am satisfied with the results of the season, 40 pounds to the colony being my average. I have sold all I had to spare right here in my home market for 15 cents per section. I do not produce any other kind of honey. When my customers buy the sections

A New Game.—A new guessing game is to show some illustration, or give a name either of them made familiar through advertising, and guess who uses the illustration, or what line of goods is handled by the advertiser named. If one were to mention the name Shumway, almost every one would say at once, "Seeds," so thoroughly have the two been advertised for more than 30 years. Mr. Shumway's announcement appears elsewhere in this issue, and is headed, "Good Seeds Cheap." It contains a special offer, and mentions his new catalog. Write for it to-day. Address, R. H. Shumway, Rockford, Ill., and please mention this paper.

ELECTRIC Handy Farm Wagons

make the work easier for both the man and team. The tires being wide they do not cut into the ground; the labor of loading is reduced many times because of the short lift. They are equipped with our famous Electric Steel Wheels, either straight or stagger spokes. Wheels any height from 24 to 60 inches. White hickory axles, steel hounds. Guaranteed to carry 4000 lbs. Why not get started right by putting in one of these wagons. We make our steel wheels to fit any wagon. Write for the catalog. It is free.

ELECTRIC WHEEL CO., BOX 16, QUINCY, ILL.

direct from the hives, they know they are getting pure honey, and no mistake.

I would not be without the American Bee Journal for three times its cost. I always hail with delight its weekly visits, and generally read it through from beginning to end before I stop, and then re-read it in a day or two.

R. P. DAVIS.

Lamar Co., Tex., Dec. 9.

Not a Glowing Report.

My report is not very glowing this season. From 32 colonies I got 750 pounds of section honey and 45 swarms, which makes 77 colonies to put into the bee-cellar. I am hoping for a better season next year. There was a great amount of bloom but no honey in it.

FRANK E. KNAPP.

Wadena Co., Minn., Nov. 31.

A California Interview.

I saw a keeper of bees from the hills the other day who was much discouraged at the low price of honey. He can't afford to keep posted by taking a bee-paper. Don't be discouraged yet, fellow bee-keeper; wait for the New York bee-disease. "Why, what, what is that?" Black brood, of course. "Never heard of it." Why, it spreads faster than foul brood. Foul-brood germs are mostly carried in honey, wax, hive-parts, etc., while black-brood germs are supposed to go miles in the very nectar-yielding flowers.

"Holy smoke; if it ever gets out here in California it will ruin us. Raise the price of sage honey, sure pop."

E. ARCHIBALD.

Los Angeles Co., Calif., Dec. 9.

WHAT OUR PATRONS SAY
 Get 50 chicks from 50 eggs often.
HATCH EVERY GOOD EGG EVERY TIME.
 Never gets out of order. Needs no attention at night. Regulates perfectly. Best on earth.

—THE—
The Bee-Keeper's Guide;
 Or, Manual of the Apiary,
 —BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

CONVENTION NOTICES.

Minnesota. The Southern Minnesota Bee-Keepers' Association will hold its next annual convention in the County Commissioners' room at the Court House in Winona, Jan. 21 and 22. A good program has been arranged, and a large attendance is expected. All are invited.

E. B. HUFFMAN.

Wisconsin. The Wisconsin State Bee-Keepers' Association will hold its annual convention in the State Capitol, at Madison, Feb. 5 and 6, 1902. This promises to be a large convention. All are invited to attend. There will be excursion rates of 1 1/2 fare for the round-trip, good for all of the first week in February.

N. E. FRANCE, Pres. ADA L. PICKARD, Sec.

California. The California State Bee-Keepers' Association will hold its annual convention in the Chamber of Commerce, Los Angeles, Jan. 15 and 16, 1902. We will try to have a good program. Come and exchange your bright ideas with your neighbors, and get some of the moss rubbed off your back.

J. F. MCINTYRE, Sec. G. S. STUBBLEFIELD, Pres.

"Snor-o-dont" is a new device to prevent people (not poultry) from sleeping with open mouths. Sleeping with open mouth is the first cause of a large percentage of all nose, throat and lung troubles. It can be prevented only by some mechanical agency. Snor-o-dont does it completely, and stops all snoring instantly. Read the advertisement.

HONEY AND BEESWAX
 MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The honey market is of a slow nature with little change in price of any of the grades. Choice grades of white comb honey, 14 1/2 @ 15c; good to No. 1, 13 1/2 @ 14c; light ambers, 12 1/2 @ 13c; dark grades, including buckwheat, 10 @ 12c. Extracted, white, 5 1/2 @ 7c; amber, 5 1/4 @ 5 1/2 c; dark, 5 @ 5 1/4 c; the scale of prices varying according to flavor, body and package. Beeswax steady at 29c. R. A. BURNETT & Co.

NEW YORK, Dec. 19.—Comb honey continues to be in good demand, and while the market is not overstocked, arrivals of white honey are sufficiently large to meet the demand, while buckwheat is rather scarce. We quote: Fancy white, 15c; No. 1, 14c; No. 2, 12 @ 13c; and buckwheat, from 10 @ 12c. Extracted remains dull and inactive with plenty of supply of all kinds. In order to move round lots, it is even necessary to shade the quotations, which are: White, 6 @ 6 1/2 c; amber, 5 1/2 @ 6c; dark, 5 @ 5 1/2 c; Southern, 55 @ 60c gallon, according to quality. Beeswax firm at 28c. HILDRETH & SEGELKEN.

CINCINNATI, Dec. 20.—The honey market is rather dull on account of the warm weather. Extracted sells only to manufacturers from 5 @ 6c; better grades alfalfa water-white from 6 @ 7c; white clover from 8 @ 9c. Fancy white comb honey sells from 13 1/2 @ 15 1/2 c.

C. H. W. WEBER.

ALBANY, N. Y., Dec. 20.—Honey in good demand now, as this is the most satisfactory time to sell. Grocersmen are stocking up and will buy lines, when late they only buy enough to piece out. Fancy white comb, 15 @ 16c; mixed, 14 @ 15c; buckwheat, 12 @ 13c. Extracted, white, 6 1/2 @ 7 1/2 c; mixed, 6 @ 6 1/2 c. H. R. WRIGHT.

OMAHA, Dec. 20.—New comb honey is arriving by express in small quantities from Iowa and Colorado, and selling at \$3.50 per case in a retail way. California extracted honey is being offered carlots at 4 1/2 @ 4 3/4 c per pound, f.o.b. California shipping-points, but we have not heard of any sales having been made thus far. The production of extracted honey seems to be quite large this year in Colorado, Utah and California. PEYCKE BROS.

BOSTON, Dec. 20.—The demand for honey is easing up, somewhat due in part to the holiday season at which time it is much neglected.

Our market at the present time runs 16c for strictly fancy in cartons; No. 1, 14 @ 15c; No. 2, 12 1/2 @ 13c. Extracted, light amber, 7 1/2 @ 8 1/2 c; amber, 7c. BLAKE, SCOTT & LEE.

DES MOINES, Dec. 20.—There is very little doing here in new crop of honey. Some small lots of near-by produced comb honey are on the market and selling in a retail way at \$3.50 to \$3.75 per case. We do not look for much trade in this line before Sept. 1. Our market does not consume a great deal of extracted honey. PEYCKE BROS. & CHANEY.

DETROIT, Dec. 20.—Fancy white comb honey, 14 @ 15c; No. 1, 13 @ 14c; no dark to quote. Extracted, white, 6 @ 7c. Beeswax, 25 @ 26c. M. H. HUNT & SON.

SAN FRANCISCO, Dec. 18.—White comb, 11 @ 12 1/2 cents; amber, 8 @ 10c; dark, 6 @ 7 cents. Extracted, white, 5 1/2 @ 6c; light amber, 4 1/2 @ 5c; amber, 4 @ —.

The steamer American, sailing from this port on the 14th inst., for New York, carries as part cargo 726 cases honey, including 200 cases taken on at Seattle. Spot stocks are not heavy. Values are steady. The extreme southern part of the State has long been noted for its fine honey, but there is some extracted now on market from Monterey county which will compare favorably with the choicest honey ever produced in this or any other portion of the globe.

KANSAS CITY, Dec. 20.—Up to the present time only small lots of new comb honey have been on the market, and these met with ready sale on the basis of 15 @ 16c per pound for fancy white. For next week heavier receipts are expected and quotations are issued at \$3.10 @ \$3.25 per case for large lots, which would be equal to about 14 @ 14 1/2 c; the demand being quite brisk, a firm market is anticipated. Inquiries for extracted are a little more numerous, but large buyers still seem to have their ideas too low. In a small way 5 1/2 @ 6c is quotable. PEYCKE BROS.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

MR. WM. RUSSELL, writing us Dec. 30, said:

"Perhaps the most important event of the late convention of the Minnesota Bee-Keepers' Association was the raising of the dues to one dollar per year, and thus being able to join the National Bee-Keepers' Association in a body. If a few more of the States could see their way to take the same step, the 1000 membership mark would soon be passed."

A RUSSIAN APIARY will be found illustrated on page 26. When sending the photograph, Mr. Alexander Fourier had this to say:

"We have read the American Bee Journal four years, and we are very glad to send you the picture of one of our apiaries, which are situated in the Ural Mountains, near the town of Oufa. During the winter of 1899-00 we lost 500 colonies on account of bad honey-dew. In the spring of 1900 we bought 160 colonies of bees in Caucasus, in native basket hives, and moved them 2800 miles.

The photograph shows our home apiary, taken after transferring the Caucasus bees into movable-frame Dadant-Quinby hives.

We have all the best Russian bee-books, latest edition of "A B C of Bee-Culture;" "The Honey-Bee," by Benton; Dandant's "Langstroth on the Honey-Bee;" Cook's "Bee-Keepers' Guide;" Doolittle's "Scientific Queen-Rearing;" and, besides, all the Russian bee-papers. We also have a comb foundation mill, a 6-frame Cowan improved honey-extractor, etc.

Yours truly,

ALEXANDER FOURIER.

MR. R. C. AIKIN seems to have furnished an interesting acrobatic feat (or two feats) for the enjoyment of the late convention of bee-keepers at Denver. The Bee-Keepers' Review describes it as follows:

"The president was tilting backward and forward in his tilting arm-chair, when he put a little too much enthusiasm into his backward tilt. A horrified look on his face, and frantic efforts to recover his equilibrium were of no avail—over he went, with arms and legs sticking in the air. He rose to his feet laughing, and the audience laughed with him, and all passed off as smoothly as though arranged according to program."

MR. A. E. RITSCHER, of Morgan Co., Ill., whose roof-apiary is represented in the picture on the first page, wrote us as follows when sending the photograph:

In March, 1898, I purchased two colonies of bees at \$5.00 per colony. I thought the price high, but I received such strong colonies that they gave two swarms and over 100 pounds of surplus honey the first year, proving much cheaper than common bees at \$1.00 per colony.

I placed the bees on the roof of my store-building, on the corner of Main street and the Public Square, causing some comment, but my bees attend strictly to business, flying out over the tree-tops, and are seldom seen on the street.

The first swarm caused much merriment. When the alarm was given, business was suspended for a time, the street filled up with people, the barber shop brought out their mirrors, and bells, pans, water and sand were used, until the poor bees, nearly scared to death, settled on a low branch of a large tree, right in front of one of our leading dry goods stores. Advice and suggestions were now freely given, fun and jokes were the order, and laughter ruled the street.

A hive, was soon brought and put on a

sheet near the tree, and the twig cut off and placed in front of the hive. The crowd—which now was as large as at a village fire—formed a circle, and watched the bees crawl into the hive. When I returned to town (being absent at the time) the swarm was put on the roof by "the boys."

I use the 10-frame hives, with Danzenbaker supers for comb honey, ventilated covers or hoods covered with grey Niagara water-proof paper, painted with Alden Spear's Asbestine Cold-Water Paint.

I winter the bees on the summer stands, and they have done well at 23 degrees below zero (Feb. 9, 1899), and 112 degrees in the shade last summer.

I have bee-books, and get much information from the American Bee Journal, but I still have much to learn.

A. E. RITSCHER.

Mr. Ritscher also wrote that the picture was taken by "the devil" in a printing-office which is located on the floor just below the bees. So there is one "devil" that can find "a hot place" any time he wants to get up on the roof above him, and "stir up the bees."

W. L. CHAMBERS, of Arizona, is called the youngest big bee-keeper in the world, by Editor Root. Frail of physique, and poor in health, he had to be taken out of school early, and not being able to do the ordinary hard work on his father's fruit-ranch, he took to bees. At the age of 15 he started with 7 colonies, which he bought and paid for out of his own savings in chicken money. Foul brood came nearly cleaning out his apiary the first season, but he weathered it through, increased only so fast as the profits from the bees would provide the means for further enlargement, and now, at the age of 20, he is the possessor of 500 colonies.

The Bee-Keeper's Guide;

Or, Manual of the Apiary,

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
 144 & 146 Erie Street CHICAGO, ILL.

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., JANUARY 9, 1902.

No. 2.

* Editorial. *

Foul Brood Laws in Every State should be demanded by bee-keepers. It is not necessary to wait until the disease has a strong foothold. It is much better to keep the disease out than to try to eradicate it after it has begun its work. Most commendable work has been done by the inspectors of foul brood in Canada and some of the States where foul brood had taken up a residence. Does any one doubt that it would have been economy to have been at the same expense and labor *before* rather than after the establishment of the disease?

Improvement of Stock.—In a careful consideration of this subject in *Revue Internationale*, it is said that when we have found a queen of exceptional qualities, every care must be taken to give the queen and her progeny the best chance possible for health and vigor, the chief care being to see that there is never any scarcity of food in the shape of honey of good quality. In the opinion of the French writer sugar syrup can not replace honey, and if sugar syrup alone be consumed the eggs will be of inferior quality, and a mediocre generation of workers will result. So it is unwise economy to take away from a colony too much of its honey.

No Set Program at bee-conventions seems to be getting to be the rule rather than the exception. Good thing. A written paper, no matter how good, may be spoiled in the reading, and in general will be enjoyed just as well when read at home in a bee-paper. But the bright thoughts that are brought out in a live discussion are the things that make it worth while to go to a bee-convention. If, however, the time is to be taken up entirely with no set program, depending upon the question-box for subjects, it is of prime importance that there be a wide-awake presiding officer, or the discussions will sometimes run away with him, taking up much time with matters of little importance.

Inspector Rankin's Report.—This report, as published on page 823 (1901), shows not only that much work has been done by Mr. Rankin in Michigan, but that still more work is needed. It is a somewhat alarming statement that more than half the apiaries visited by the inspector were invaded by foul brood. The case does not look so

bad when it is remembered that he would be likely to visit only those apiaries that were suspected. Still, the fact remains that he found 119 infected apiaries in the State, and out of 3286 colonies inspected, he found the number of diseased colonies to be about one in eight. How many infected colonies in the State were not found at all by Mr. Rankin can be only a matter of surmise, but it is not hard to believe that the number may be considerable after reading the inspector's statement that many bee-keepers whose apiaries are troubled by the disease seemed to have no idea that they had any serious trouble on their hands; and it is quite possible that in many cases the owners of diseased colonies do not suspect the presence of the scourge.

Bees Supporting a Hired Hand.

As showing what a colony of bees may do in exceptional cases, the following from G. M. Doolittle, in *Gleanings in Bee-Culture*, is interesting:

I wish to tell you about something which pleased me during 1872. I bought an extractor, and, being determined to give the bees the care they needed, and knowing that the time the bees needed the most attention came in hay-time, I hired a man to take my place in the hay-field. It so happened that he commenced work on the day bass-wood commenced to bloom. Previously I had hived a prime swarm, and concluded to devote them to extracted honey. The man worked 16 days at \$1.75 a day, and I extracted honey enough from that colony during those 16 days to pay the man for his work. I tell you this to show that, when properly managed, in a fairly good season, one swarm is equivalent to a man at work in the hay-field, and so it will not pay to neglect a whole apiary to go into the field to work, as many would-be bee-keepers so generally do, and afterward growl about the bees not paying them.

Selling by Case or by Weight.

The Rocky-Mountain Bee Journal thinks injustice was done Colorado bee-keepers in a late number of this journal by the Editor and R. A. Burnett & Co., in the strictures that were made against selling honey by the case. There is certainly no desire to do any injustice to the good bee-keepers of Colorado, whom this journal holds in high esteem. So far as they are concerned, the matter is put in a very different light by a full understanding of the case, and in order to that end it is a pleasure to give here in full the following from the Rocky Mountain Bee Journal:

The Colorado State Bee-Keepers' Association has adopted the following standard of weights per case in the grading and classification of comb honey:

"No. 1.—Cases of separated honey to average 21 pounds net per case of 24 sections, with a minimum weight of not less than 20 pounds for any single case; cases of half-

separated honey to average not less than 21½ pounds net per case of 24 sections, with a minimum weight of 20½ pounds for any single case; cases of unseparated honey to average not less than 22½ pounds net per case of 24 sections, with a minimum weight of 21½ pounds for any single case."

"No. 2.—Cases of separated honey to average not less than 18 pounds net per case of 24 sections; cases of half-separated honey to average not less than 19 pounds net per case of 24 sections; cases of unseparated honey to average not less than 20 pounds per case of 24 sections."

Thus it will be seen that the objections of the Burnett Co., as to short weight, fall flat. The lightest weight of sections admissible in the No. 1 grade is 14 ounces, so we fail to see where the 9 and 12 ounce sections can get in. Under our rules light-weights are sold as culls, and every bee-keeper is anxious to avoid producing them.

The common practice all over the country in retailing comb honey is to sell by the section, and not by weight. The retailer likes to buy by the pound, but invariably sells by the section, and is thus enabled to make more than a legitimate profit, and it comes out of the producer. We fail to see the injustice of compelling the retailer to purchase by the piece, so long as he sells by the piece, especially when the weights are guaranteed, as in the case of buying of members of the Colorado Association.

As the language stands, the remarks of the American Bee Journal plainly infer the charge that the object in selling by the case is a dishonest one, but we are charitable enough to believe that such a meaning was not intended. There are dishonest people in every calling in life, and those among bee-keepers who desire to be dishonest will find ways to accomplish their trickery whether they sell by the case or weight.

Selling by the case is growing in favor, and where all parties are disposed to be fair and honest there has been no trouble nor cause of complaint. It is a matter that rests largely upon individual honor and self-respect, and the same is true throughout all the business world.

Under the Colorado rules we grade by color, finish and weight, and when a case of No. 1 or No. 2 is offered, we know, if it is graded correctly, how it looks and the least it can weigh. We base prices upon the minimum weight only. The advantage, if any, accrues to the buyer, and the slight loss to the producer, if any, is much less than the cost of weighing.

The Burnett Co. is one of the few thoroughly honest and reliable commission-houses in the great inland metropolis, and their opinions are entitled to serious consideration, but the system of selling comb honey by the case is too well grounded in Colorado to be discarded at their simple behest.

The American Bee Journal hereby apologizes to the Colorado bee-keepers for even the *seeming* of injustice, at the same time disclaiming any unkind intent. Like many another case, the misunderstanding comes from a difference in the use of terms, or perhaps to be more exact in this case, because the same term may be used to mean two different things. What does selling "by the case,"

"by the piece," mean? There was a little quiet amusement in the late Chicago convention when, after Mr. R. A. Burnett had said he never sold honey "by the case," a member "called him down" by saying Mr. Burnett had sold thousands of cases of honey "by the case." It was true that all the honey was weighed, and so it was sold by weight, but in a certain sense it was also sold "by the case," for it was not sold "by the section," nor "by the car-load," but "by the case."

When the grocer retails section honey, he either sells it "by weight" or "by the piece." When retailed "by weight," it is universally understood that each section is weighed; and as universally it is understood that when sold "by the piece" there is no weighing, and the weight is not considered. As "by the piece" has meant without regard to weight, so "by the case" has had the same meaning. But Colorado bee-keepers now have a new meaning for "by the case," a meaning which they have a right to use, only it needs to be explained to the uninitiated, for, according to their rules, weight is distinctly considered, and they are practically *selling by weight*. If any one will turn to page 759 (1901), he will see that what is said there had no reference to selling by Colorado rules, which distinctly have reference to weight, for the thing specially mentioned on page 759 is, "so much per case of 24 sections, without reference to the actual weight of honey contained in the case." Selling by the case, with a certainty of 21 pounds for every case, is a very different thing.

If it is true that by the Colorado system there may be a gain to the buyer, with no real loss to the seller, it is hard to find fault with it.

But why not buy and sell by actual weight? There should be a uniform method, and "by the case" can hardly become the general method.

Cold-Water Paint for Hives.—L. T. Chambers writes in the Australian Bee-Bulletin:

For years I have been trying and looking for experiments in the way of discovering a paint which will be inexpensive and yet durable, and I am happy to say that at last I have found what is needed. Cold-water paint needs simply mixing with water in place of oil, saving the cost of the oil. The powder of which it is composed is no dearer than white-lead, but will spread much further, and will adhere to any surface with more tenacity than oil paint, being unaffected by weather, and at the same time it is water-proof as well as fire-proof.

Nothing is said as to the composition of this powder, and it remains to be seen what others may think of its value.

Does a Queen Carry Foul Brood?—Le Rucher Belge quotes a writer in the American Bee Journal, who says it is the workers and never the queen which carry foul brood from an infected to a healthy colony. Editor Wathelot insists that a queen may carry the spores to a healthy colony, and warns against putting into such colony a queen from one that is diseased.

A Knotty Problem is what the American Bee-Keeper calls the problem of nominating and electing officers of the National Association. About right.

The Buffalo Convention.

Report of the Proceedings of the Thirty-Second Annual Convention of the National Bee-Keepers' Association, held at Buffalo, New York, Sept. 10, 11 and 12, 1901.

(Continued from page 9.)

Pres. Watrous then called upon Prof. H. W. Collingwood, editor of the Rural New-Yorker, who delivered an address on,

The Pomologist and the Fruit-Grower.

I am not a bee-keeper, although I help keep my neighbors' bees. I don't pretend to be a pomologist. I'm a plain fruit-grower, far enough along to realize that, with all his proud dominion over the lower forces of nature, man cannot produce the finest and most perfect fruits without the help of his friend, the bee. That, I believe, will be the conclusion of every fruit-grower who will really study the question.

The relation between the fruit-grower and the bee itself are physical, mental and moral. Interfere with a bee's notion of duty and right, and she at once administers a stinging rebuke to those faint-hearted humans who permit others to interfere with their homes and privileges. Perhaps some of you have heard of the young man who said he called his sweetheart "honey," and in 24 hours she broke out in an attack of the hives.

The mental relations appear when a thoughtful man studies the wonderful life and habits of the bee, and the social order that prevails inside the hive. That man must admit that even the civilization that has been inspired by human wisdom falls short of this in some essentials of justice and equity. The moral aspect appears when, in the latter part of summer, the bees swarm to your fruits, and you try to follow out the principle of the Golden Rule in your relations with the bee-keeper. You learn then how much easier it is to be a bear than it is to forbear. One must learn to use the memory of services rendered as oil for the rusty machinery of patience.

There are two worthy citizens who upset the theories of the scientific men—Jack Frost and Mr. Honey-Bee. Ice and honey are two crops which remove no fertility from the soil. A man might cut ice on his neighbor's pond for years, and make a fortune by doing so, yet all his work would "cut no ice" in the great American game of robbing the soil. The pond will not be injured in the least. In like manner my neighbors' bees may take a ton of honey from my fruit-trees, and it may sell at a good price, yet my farm has not lost five cents' worth of plant food, nor would I have been a cent better off if the bees had not taken an ounce of the nectar, but had simply acted as dry-nurses to my baby fruits without pay

or reward. Both frost and bee bring unnumbered blessings to man, yet most of us will spend more time growling at some little injury which they do as they pass on, than we will in praise and thankfulness for all the benefits they heap upon us. I have known fruit-growers and pomologists who, when they found the bee sucking some cracked and worthless old fruit, forgot that the bee did more than they in the making of these fruits. If they were in the bee's place they would probably demand 75 percent of the finest fruit in the orchard as payment for their labor. Such folks make me think of the housekeeper who found fault with the minister. The good man came into the house of sickness with a message of divine hope and love and faith. He cheered the hearts of all; and yet when he went away the housekeeper found fault with him because he forgot to wipe his feet on the door mat, and tracked some mud on her kitchen floor. What a world this would be if we could learn to judge others, not by their little weaknesses, but by their great acts of loving service!

If one would look for the ideal relations between the fruit-grower and the bee-keeper he would find them inside the modern cucumber-house. The cucumber is "cool" way down to the courtship of its flowers. Matrimonial agents are required, and formerly these were men who went about with long brushes dusting the pollen upon these bashful flowers. It has been found that bees will do this better than the men, and most cucumber-houses now have their colonies of bees. Inside the glass house the grower has no desire to throw stones at the bee-keeper, because they both wear the same clothes; and the man who can not get on harmoniously with himself has no business out of jail. I say that, well knowing that some of the darkest life tragedies in the world's history have been caused by the evil side of a man's nature obtaining mastery for the moment over the good. In the orchard or fruit-farm the conditions are very different. Here a man may feed the bees which belong to somebody else, and he does not, like the cucumber-grower, see that the bees actually save him the wages of a workman, which would be nearly as necessary without the bees. Most men do not, I think, fully understand who the bee is and what he really does. Let us state his case fairly. I understand, of course, that common facts about the bee must be an old story to those who are here. The greatest value of such a meeting is the fact that one may talk over your heads or through you to the thousands who may never join either society, and yet who will profit by your work.

THE BEE AS A CITIZEN.

Man has never tamed the bee as he has the horse or dog or ox. These animals have surrendered their freedom, and tamely submit to man's dictation, changing even their shape and vital functions at his will. Turn them loose, and after a few hours of clumsy freedom they will come back and beg to be taken under shelter into slavery. Even man himself loses the savage independence and love of liberty he knew when free as the hills, and at the behest of civilization puts his neck under the heel of those who are morally his inferior. Not so the bee. He has never surrendered the freedom that goes with wild things and wild life. Man coaxes and partly directs him, but he is still untamed, and still retains the courage and fearlessness which civilization takes from the heart of most animals, including man. Left to itself, the swarm of bees will not come begging shelter from man, but gladly and fearlessly fly off into the wilderness, to live as it ancestors lived.

The bee starts with the scope and purpose of its life-work clear. It does not need to go to school. From the first gleam of consciousness the bee knows that it is born to toil, without reward, without hope of posterity. Instinct, heredity, spirit, call it what you will, drives the bee on to labor without ceasing, without holidays or hours of lazy ease, and for what? Simply for the future—that dim, mysterious time for which he is ever prompted to provide. I said that the mental side of this question will present itself to any thoughtful man. Truly, the lesson of the hive goes deep into the human heart and soul.

THE BEE AS A WORKER.

As a boy I was brought up on the "busy bee" theory. The old man who considered himself responsible for my industrial training gave me to understand that the bee is a tireless worker who toils for the love of it and never quits. He wasn't trying to get me interested in the study of natural history—he was trying to get me to realize that some one loved to work, and he knew that he didn't. I am sorry to break down this ideal of childhood, for I have searched hard to find something that has no blood of the shirk in its veins. I can't tell my children the old story, for they will soon know that most bees in New Jersey appear to start work at 7:30 to 8 a.m., and knock off at 4 p.m. On wet days they usually quit entirely. This is much like the average hired man, who will take advantage of a light sprinkle to come in and sweep up the barn floor. The bee works on Sunday, while the hired man rides his bicycle. When the bee does start he keeps at his work, while the hired man stops to look at the clock.

When you tear down the childish ideal of the busy bee, and find that it has some of the bad habits of mortals, you do not destroy the whole picture. That would be true with some men; but with the bee it only brings to view a higher ideal than ever. The bee does a fair day's work, and then goes home and puts in a part of the night. A man, after doing his work in the field, will hardly help his wife wash the dishes after supper, but the bee works like a slave through the darkness at

the wonderful task of manufacturing honey. The short day of hard and consistent work furnishes enough for the hive-workers. If all men worked as the bee does, with as fair and just a division of labor, what a world we should have. The short, hopeful day's work would be sufficient if the idle and the rich would cease to live on the earnings of the overworked poor. The society in the hive permits but few drones, and kills them off as the winter comes on, while human society increases the number. Thus, as we grow older, we find that the bee is not the poor, aimless drudge we thought him, but rather one who lets his wits save his wings.

THE BEE'S GOOD WORK.

We can easily forgive the bee his short working days when we consider the good he does. There is no question about the debt fruit-growers owe him. People talk about the wind and other insects in fertilizing our flowers; but I am confident that any man who will really take the time and pains to investigate for himself will see that the bee is nearly the whole story. I have seen the certain results of his good work in a neighbor's orchard. Those bees "broke the trees" down just as truly as though they had climbed on the trees by the million and pulled at them. The appearance of those trees after a few years of bee-keeping would have convinced any fair-minded man that our little buzzing friends are true partners of the fruit-grower.

It has been said that the bee does not do this work because he wants to. He is pictured as a greedy, selfish fellow, born into the world with a single idea, who dusts his jacket with pollen, and does his work as dry-nurse simply as an incident. Nature puts the brushes on his legs and stomach, and he cannot help using them. Here, again, he is not unlike men. Most of us fight and slave and toil for our own selfish ends. We try to shake the good intentions out of our jacket, and a large proportion of the good we do in this world is done as a side incident, as we press on to accomplish something for ourselves. To my mind this is only another illustration of the wise and beautiful provision of Nature to lead the bee on from flower to flower with some motive of personal gain, and in this way compel him to do his work for pomology. I would that humans who toil, even past the allotted years of man's life, after wealth and power, might as surely leave behind them perfect fruits for the toil of others. The stout legs of the bee, as he crawls from flower to flower, kick life into the baby fruits. Surely, with this in mind, the pomologist can have nothing to "kick" about.

But ambition and the gratification of personal desires, lead both bees and men to scatter evil as well as good. All wings, except those of angels, attract, and will carry the germs of evil if they rub against it. It is quite likely that the bees will carry the germs of pear-blight from one tree to another—perhaps in quantities sufficient to spread the disease. Let us admit that; and yet no pear-grower who knows his business would have the bees stay entirely away from his trees. The bee also injures fruit to a certain extent. There may be times when he actually

leads in this bad work. When he does, he is starved to it. If he were fed at home, as every other farm animal would be at such a time, he would seldom do the mischief. In ordinary seasons I find little fault with the bee for sucking this cracked and broken fruit. We really ought to thank him this year for delivering us from the temptation to pack these worthless culls in the middle of the barrel. Our bee-keeping friends tell us that there is always some rascal that goes ahead with a punch, and breaks the skin before the bee will suck the juice. The yellow-jacket is said to be the culprit, and he is a safe one, for no one cares to argue the point with him. I don't like this hiding behind a yellow jacket. It is too much like the way some of these Christian nations have acted in China. Li Hung Chang and other yellow jackets before him have robbed the Chinese people for centuries, but that is no excuse for the looting and stealing on the part of the white men. Should not the bee-keeper feed his bees when their natural food is scarce and they really injure fruit? When I forget to feed my dog at home, and he runs to the neighbor's back yard for food which might feed the pig, have I a right to complain if the neighbor lives up to his legal privilege? My neighbor ought to remember that it was my dog's bark that tanned the hide of the tramp who frightened his children; but some neighbors are not built that way. They are like some pomologists who object when the bee tries to take pay for his services in a few rotten fruit. There are human beings who will run out of the best of homes. In fact, the more you feed them the more they run. Bees are much like humans in many respects. It is quite likely that a systematic method of feeding during honey-dearths in summer would eventually pay the bee keeper, just as many diary-men have become convinced against their wills that it pays to feed grain to cows at good pasture.

THE BEE AS A LAWYER.

Before the law the bee appears to have clearer rights than any other domestic animal. Recent legal decisions have made the bee's position very clear. In one noted case the bees flew into the orchard and unquestionably worked upon or damaged broken fruit. The jury finally decided, and I think justly, that the bees committed no real damage; yet had a cow or a hog broken into that orchard and eaten that same fruit, the owners would certainly have been liable for damages.

After reading the literature on the subject with great care, I think I am justified in saying that the bee has fuller and more complete legal protection than any other domestic animal. Why should not this be so, since, even in its wild state, untrained or directed by men, the bee is led by its very instinct to labor for the benefit of humanity? Certainly, no wild animal works for men as the bee does, and no domestic animal accomplished so much without direct harness or guidance.

Invoking the law against bees is running up against a hard proposition. Laws have been passed against spraying fruit-trees while in bloom. They are intended to give the bee legal protection. These laws have actually led some tough old fellows to spray at just

that time, so as to kill the bees. Some men are so perverted that they see a wrong and coddle it as a "personal right." These laws have helped the fruit-grower more than the bee-keeper, because they have led the scientific men to investigate and tell us *why* it is a mistake to spray too early.

It appears to have been settled that, before the law, bees are to be considered domestic animals—not naturally inclined to be offensive. A fair synopsis of the bee's legal status is about as follows:

1. Bees kept by a regular bee-keeper have become absolute property as domestic animals, and therefore enjoy legal rights.

2. The bee is not naturally savage. It is no more likely to commit serious damage and mischief than dogs, cats, cows or horses.

3. The law looks with most favor upon the animals which are most useful to man. No animal is of more actual service to man in proportion to his size and the mischief it commits than the bee.

4. After bees have been kept in a certain situation for a reasonable time without serious injury, it can not be said that it is dangerous to keep them there.

5. The bee-keeper becomes liable for injuries done by bees, only on the ground of actual or presumed negligence.

This seems to give the bee a clear field to go ahead about his business in his own way. It must be said that this strong legal position of the bee is largely due to the fact that bee-keepers have picked up some of the strong traits of the bees. When one of their number is attacked, they do not sew up their pockets and run off with their share of the honey, and as much more as they can get. They fly at once to the defense of their comrade, and make, not an individual, but a society matter of it.

The fruit-grower will obtain little satisfaction in a lawsuit against the bee or the bee-keeper. The bee is too good a friend of the judge. The relations between these two classes should be settled, not by the scales but by the Golden Rule. Every man who receives a benefit should remember where the benefit comes from. The bee-keeper might say with truth: "It is true that my bees feed upon my neighbor's trees; but they have not injured his farm, because they took no fertility away! He has no reason to kick, because they kick life into his fruit-buds."

This is all true enough, but it is only one side. The fruit-grower may say:

"These bees have increased my crop of fruit, but have they not been well paid for their work? I fed them, and the money in their owner's pocket comes from my farm!"

Two classes of men with interests which lap and nick in this way should never fight; for when one of them hits the other in the nose he is sure to blacken his own eye. They should recognize their mutual dependence, and treat each other fairly. The bee-keeper may say that the law gives him a right to put his hives close to another's dwelling. Still, if that location is offensive to his neighbor, the law which is higher than the decision of any human judge should lead him to put them elsewhere. I have heard of

an old farmer who insisted on keeping an old, brindled calf tied on his lawn. The calf was in every way offensive to his neighbors, and he had ample space for it behind his barn; but he thrust that calf under the very noses of his neighbors, because the law said he had a right to do as he pleased with his own. That man, like many others, figures that such magnifying of his legal rights gave increased dignity to his personal rights; and what a foolish mistake he made! The man who will use his legal privileges as an offensive weapon against others, when it should be drawn only in defense of true principles, is not a true pomologist or bee-keeper.

I regard the raising of fine fruits, and the training and rearing of bees, as the highest types of soil culture, and hence of human industry. He who can direct and watch the slow development of the perfect fruit, and lovingly guard it from plant disease and injurious insects through the long road to perfect maturity; and he who can patiently and skillfully guide and train the honey-bee through its long summer's work—such men ennoble and dignify labor.

Their work may be hard and constant. Their hands may be hard and rough; but the callous on the palm is not a badge of servitude, but an honorable scar from labor's battlefield. Such men are not mere drudges, with body and spirit broken on the hard wheel of labor; but, dealing with the fine and most delicate problems of Nature, they keep step with the Creator; they are in direct partnership with God himself; and, as such partners, they, of all men, should be guided by the wisdom and justice of the Golden Rule.

H. W. COLLINGWOOD.

R. M. Kellogg, of Michigan—I am not unmindful that it is now 11 o'clock. I was intensely interested in the last address, not so much at what has been revealed to us, as to the work that is going on. We do not know so much about pollination of fruit as we should, but we are learning fast. It is not so many years ago, if we were to go to a well-informed farmer and tell him that the plants that he cultivated were male and female, he would open his eyes and say, "Is that so?" He knew nothing about the organism of plants; but I might say that within the last four years that subject has made more rapid strides than in the previous many years. I have never owned a bee, but, fortunately, my neighbors have. Now, I have never seen an insect so well fitted for the work of helping the pomologist as that little, busy bee. Why did God create the bee and arm it with that little fuzzi all over its body and its eyebrows? Why was this done? And why did he put the nectar down in the bottom among the pistils, where the bees must dig to get it? Why was all this done, if it were not that there must be some agency to carry the pollen from one flower to another? I know of no other agency. They tell us that the wind does that. Will you tell us, then, how this pollen can be supplied in sufficient abundance, unless there is a magnet to draw it to that particular flower? God made the bee for that particular purpose. Now I suspect that we don't know as much about pollen as we should. I notice

that lately a large number of postal cards were sent to different fruit-growers inquiring about self-fertilizing ability of the Kieffer pear, and the answer came back that this pear is self-fertilizing in some instances, and not in others. I apprehend that this is a mere physical condition of the trees, and in the meantime we must have something to carry the pollen. The bee always carries its pollen-brush. It will throw its arm over and brush it all off and put it on its thigh, and as it digs down it gets it all over its eyebrows. Now, on my farm, I had within three miles of me, colonies of bees. I never had any fruit injured by the bees. I have stood there and seen them at work, and the whole trees perfectly roaring with the bees at work all through the spring, but where I now live, I am sorry to say, I do not know of a colony of bees within miles. I had never seen, until the other day, a honey-bee on the farm, and I know that our fruits are not perfectly pollinated as they would be if bees were there. I am going to secure the presence of bees. I know that they cut a figure. I want to tell you one thing about spraying plants in bloom. I never spray my trees in bloom, but I did have a little misfortune. You have all learned that it is absolutely necessary to tell a hired man at least six times what you want done, and then go and see that he does it. Now, I have a patch of strawberries which I take great pains to make perfect, and every spring we spray our strawberries. I have a cart fixed up that sprays three rows at a time, and it sprays them very thoroughly. I set the hired man to spraying, and he also sprayed my specimen patch, and of all the knotty, deformed fruit that you ever saw, I got them off that patch. The spraying had killed the pollen. I think there is no question but that the bees are killed by spraying.

Dr. Miller—I think, Mr. President, that, considering the charges made against the bees, we are ready to rest the case.

Pres. Watrous—I will say for the benefit of some who have thought the bee-keepers hadn't had a fair show, it was my understanding that the program was arranged through a friendly consultation of the officers of the two societies, and that everything has been just as fair as possible. I want to say that I believe the results have been very good. I hope so.

Dr. Mason—I think the bee-keepers feel that we have made no mistake in, selecting these gentlemen who talked to you to-night, to present our case.

Pres. Watrous—I think not.

Adjournment of the joint session.

After the adjournment Pres. Root called for a meeting of the National Bee-Keepers' Association present to finish up the business of the convention.

Fifth Annual Report of General Manager of the National Bee-Keepers' Association.

THE UTTER VS. UTTER CASE.

In my last annual report I stated that the celebrated case of Utter vs. Utter, in Orange County, New York, had been appealed to the County Court. It will be recalled by most of the mem-

bers, that in the trial before a Justice of the Peace, wherein it was charged that the bees had injured a peach-grower's fruit, the Justice had decided against the bee-keeper, and assessed the damages at \$25 and costs. This case came on before the County Court on appeal, and occupied several days. A number of witnesses were introduced by the fruit-men, attempting to prove that bees *could* and *did* injure sound peaches. On the other hand, the association put such experts on the witness stand as Frank Benton, W. F. Marks, A. I. and E. R. Root, and O. L. Hershier, who were able to convince the Court and Jury that the bees were innocent.

After summing up the case by our able and learned legal counsel, the Court instructed the Jury as to the law, and they were not slow to overrule the judgment of the lower court, and acquit our friend, the innocent bee-keeper.

This ended one of the most widely advertised and hotly contested bee lawsuits which has come to my attention. There is no doubt of the influence which this verdict will have on future troubles of this kind. The case ought to be briefed for future use, and would have been if I could have carried out my own plans.

THE CITY OF ROCHESTER VS. TAUNTON.

Another case almost as notorious as the one just mentioned came to an issue in Rochester, N. Y. In Dec., 1900, an attempt was made to pass an ordinance prohibiting the keeping of bees within the City limits. This movement appeared to be directed against one particular bee-keeper, and was probably a case of jealousy or spite. Having been appealed to by the bee-keeper, a member of our Association, such advice and printed matter was sent him as the General Manager was capable of supplying, and it was thought for a time that the persecution was at an end; but, in April, 1901, an ordinance was again presented and *passed*, declaring it unlawful to keep bees within the City limits except with the consent of all lot owners within 100 feet of the place where it was purposed to keep bees. Our member was notified by the City authorities to remove the bees. W. F. Marks, one of our directors, was requested to visit Rochester and investigate. He did so, and reported that Mr. Taunton was keeping his bees in a proper manner. He was advised not to remove them. He was arrested and tried before a police Judge. I employed the best legal talent to be found in the City and defended the bee-keeper. After a hard legal battle the ordinance was declared unconstitutional, and another victory scored for the Association. All the daily papers of Rochester reported the case, and, in all, columns were published about the ordinance and its miscarriage. There has probably been more newspaper notoriety concerning these two New York cases than all others which had previously gotten into the courts.

KEEPING BEES IN A PROPER MANNER.

Another case was reported from a small town in Michigan, where a bee-keeper was ordered to remove his bees from the town limits. Mr. Hutchinson was requested to investigate and report, which he did, advising the mem-

ber to remove his bees, which Mr. Hutchinson thought had not been handled in a manner to make good neighbors, or a good case to fight.

This is to show that we do not advise resistance in every instance. Bees may be so manipulated as to become a nuisance to near-by neighbors, and it is not the purpose of the present management to encourage such careless methods. It should be the aim of all bee-keepers to convince the uneducated public that bee-keeping is not only a legitimate industry, worthy of encouragement on economic grounds, but they should endeavor to prevent annoyance to neighbors by intelligent methods. For example: If I had a near neighbor, I would never take my bees out of the cellar on wash-day. If I lived in town, I would try to avoid the unpleasant experience of chasing swarms into my neighbors' yard, by clipping my queens or by pursuing a system of management which would discourage swarming. I would try to handle my bees at all times in such a manner as to prevent robbing, and the consequent consternation and irritability sure to follow. If all these things were looked after by bee-keepers, there would be less opposition to our pursuit.

SETTLEMENTS WITH COMMISSION MEN.

During the past year the General Manager has been appealed to in several instances to assist in getting settlements with commission-men who had neglected to remit, and he has been able to render assistance that was heartily commended.

BEES AND PEAR-BLIGHT.

A great commotion was started in California last spring on the charge that bees carried pear-blight, and in one county the Board of Supervisors was petitioned to remove all bees at least *two miles* from the pear-orchards. In the subsequent discussion on this subject certain orchardists and bacteriologists have made grave, but reckless, charges against the bees, as though bee-keepers had no rights which fruit-growers ought to respect. It seems to be forgotten that bee-keepers were in California long before pear-growers, and, according to the reasonable law of priority, were entitled to the field.

I know nothing about the conditions in California, but in my own locality bees were kept many years before twig-blight appeared. How did it get here? Did bees bring it? No one believes they did.

If bees are so guilty how does it happen that trees blight which never had a bloom on them? Why do they blight mostly long after the blossoming period?—(which is the case here.) Why do they blight badly one year and not the next? And if bees are guilty as charged, what good would it do to banish the domestic bees when the legions of wild ones would be left to carry on their work of destruction?

I am satisfied that, when the whole truth is known, this unjust persecution will cease, and that every thoroughly scientific observer will take his hat off in the presence of God's busy hand-maiden, the wonderful, the useful, the necessary bee.

FINANCIAL STATEMENT OF THE TREASURER, DECEMBER 29, 1901.

RECEIPTS.

Balance on hand from last report.....	\$ 521.15
Received during year, dues, including \$27.34 received through Sec. Mason.....	673.91

Expenditures for 1901.....	476.39
Balance on hand.....	\$ 718.67

NOTE—The amount received does not represent membership, as many State and local societies join in a body at 50 cents per member.

IN CONCLUSION.

For five years I have rendered this Association such services as my limited abilities fitted me to perform. Other and more congenial work has been neglected that I might discharge the duties of General Manager in a manner to satisfy my own conscience. While some of the work has been hard, I have found many sympathizing friends and kind treatment generally. To all who so generously contributed to make this the largest and strongest bee-keeper's society in America, I tender my most grateful thanks; but I must beg to be relieved from the cares of this responsible office. I wish to turn over the insignia of office and all its emoluments to my successor—a stronger, wiser, less busy, more useful man. Fraternal yours.

EUGENE SECOR.

General Manager.

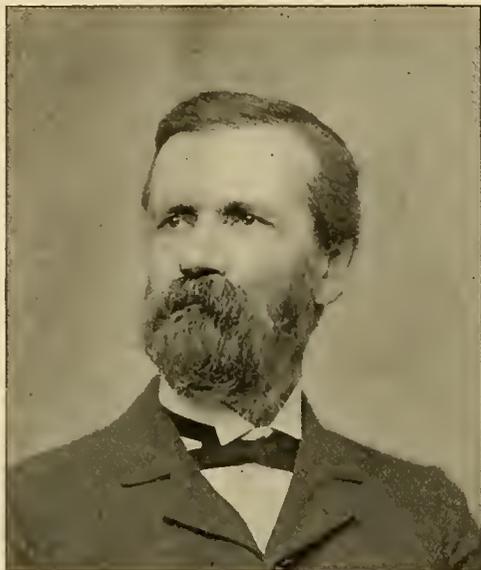

Forest City, Iowa, Dec. 26, 1901.

Langstroth on the Honey-Bee.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

EUGENE SECOR,
General Manager National Bee-Keepers' Association.

Contributed Articles.

Selling Comb Honey By Weight vs. Case.

BY R. A. BURNETT & CO.

WE have read the article by D. W. Working, secretary of the Colorado Bee-Keepers' Association, on page 822 (1901), also the editorial on the same, which, in our judgment, is all that is necessary to say on the article referred to.

Our purpose has never been to enter into a controversy on the matter in question, but to set before those interested, our opinions. We think this has been accomplished; now we will let the matter percolate through the many minds that have been giving it consideration from the different standpoints, and we are quite agreed in thinking that some ignorance will be dispelled by what has been written and said.

Since the time this matter was before the Colorado Association, we have been privileged to meet the earnest, active, and well-meaning manager of said Association, in the person of Mr. Frank Rauchfuss, and we are now more convinced than ever before, that limited experience is liable to give erroneous impressions. While his experience with bee-keepers in Colorado, and that of selling their honey as an Association, seems to work reasonably well so far as their necessities were concerned, also the methods pursued to get the producer to grade their honey seemed to us without objection, yet when it came to settling with the producer for the amount of honey tendered the Association, and the selling of it to the wholesale dealers, Mr. Rauchfuss himself explained, "It was not quite equitable." As, for instance, a producer who furnished honey properly filled and capped that averaged 21 pounds, and no more, and got just as much for the number of sections he had as the producer whose honey averaged 23 pounds or more to the case of 24 sections.

As to the question of light-weight sections, the honey being equally desirable in appearance, should sell for just as much as that weighing the maximum, but should be kept by itself, so that the light and the heavy sections would not be put in the same case, for, while there may not be any higher price obtained for the light weight than the heavy, there are some retailers who prefer one and some the other, and the wholesale dealer wants to be able to furnish what the retailer desires. In case there should be a greater demand for the light-weight sections than the heavy, they would be sold more readily, but not often at any higher price.

Mr. Rauchfuss meeting with the different dealers in honey will no doubt be greatly to the advantage of the Association, and it will give the buyers confidence that they are in safe hands, even if they do at times have to pay the money before they get the goods.

Cook Co., Ill.

Honey-Vinegar—Directions for Making.

BY C. P. DADANT.

MR. DADANT:—Would you please tell me the best and quickest way of making honey-vinegar, and how long it takes to make it? It will be better to tell you I want to make it in large quantities for market. Do you know of any way in which the process could be materially hastened by means of a little machinery? I mean, for instance, by the means used in ordinary vinegar-making. I do not know of any one more willing to give me information, or more able. Will you please help me out? You probably know better what I need than I am able to ask.

ONTARIO.

From time to time, the question of honey-vinegar comes up as a new thing, and yet has been debated and discussed many times over in the bee-papers. Upon receipt of this enquiry, I concluded to refer our friend to some previous article of mine in the American Bee Journal, but I soon found that it was quite a task to hunt it up in back numbers, and after considering that very few, probably, keep their bee-papers on file, I concluded it was best to give the matter a special article.

There are evidently many bee-keepers, even among the most practical, who do not consider the honey-vinegar question as of any importance, if I judge by the number of persons who send us their beeswax still soaked with honey. Yet, to a large apiarist, there is quite a loss in throwing away the water in which the cappings have been melted. I see that Prof. Cook quotes Bingham as saying that the cappings of 1,000 pounds of honey will give honey enough for 45 gallons of vinegar. I should hesitate to set a figure as representing

the exact amount, because the amount of honey in cappings depends upon the manner in which the extracting and uncapping were done, upon the temperature, and also upon the length of time during which these cappings have been allowed to drain in a properly-made capping-can. But there is no doubt that, to the apiarist who extracts thousands of pounds, the amount of honey left in the cappings, even after the most thorough draining, represents a value which he cannot afford to lose. Whenever the apiarist ships his beeswax, dripping with honey, as I have so often seen it, he certainly does not appreciate the amount that he could save with little exertion.

When we extract honey, we allow the cappings to drain for a long time. When the time comes to render the wax, we first wash the entire mass in hot water. Any kettle or boiler that is used to render beeswax will do for this purpose. An amount of water sufficient to soak the cappings is first put in. The cappings are then carefully broken up into fragments so that the water may thoroughly soak through, and the mass is heated until it is about as hot as your finger can stand. We then remove the fire, and, with a large skimmer, made of a wire frame, with a wire-cloth sieve, we lift out the cappings. Usually the thickest portion of them is taken out by hand, and the sieve used only for skimming off the floating remnants. In order to get the very smallest particles of beeswax, the

C. P. DADANT.

liquid may then be passed through a flour-sack. The cappings thus washed are put into a coarse sack and pressed in any sort of small press. We use a diminutive cider-press screw with a small, flat, wooden platform. A very light pressure on these cappings will drain all the sweetened water out of them and leave them about dry. They can be melted afterward by the usual process, this operation being intended only to remove all the honey for mead or vinegar purposes.

The liquid thus obtained will not appear very clean, but our apiarist will have to bear in mind that it is "clean dirt." Of this he will have no doubt if the extracting has been properly and neatly done. All the contents of the capping-can come from the surface of combs which the daintiest persons would readily have eaten; and when the liquid has undergone fermentation, the dregs will settle to the bottom, and all the froth and foam, and all the cloudiness, will disappear.

Now as to the strength of the liquid: The reader understands that it is impossible to judge of this by the cappings. The honey-water, after it is made, must be tested. Those who have saccharometers would not be at a loss, but not one in five hundred of our apiarists, except in California, where wine is largely made, would have such an instrument. Here is a simple method:

Put a gallon or so of the mixture in a pan, enough of it to float an egg. If the egg goes to the bottom and lies on its side, the mixture is too weak, and it must be evaporated down

or more honey must be added. If the egg floats about in the liquid, or, when dropped in, turns its big end up quickly and remains in that position, there is enough honey to make a good, ordinary grade of vinegar. If the egg just stops at the top, it will make a very strong grade. If it shows more than a spot the size of a dime, the liquid is too heavy, and more water must be added, at least till the egg almost sinks.

It must be borne in mind that the stronger the wine or vinegar that is sought to be made, the longer it will take to make it. Too great a quantity of saccharine matter will fail to go through the alcoholic and acetic fermentation, and will always retain a strong percentage of sweetness. From a pound and a quarter to a pound and a half of honey per gallon will make a very good grade of vinegar, fully as strong as the ordinary cider-vinegar, and of a better flavor. A greater quantity will make proportionately stronger vinegar, but will require much more time. Some advise the use of only a pound of honey to a gallon of water. This, in my estimation, is too small a quantity, but the fermentation in such a proportion will take place very rapidly.

Now as to the making of this vinegar: It must be borne in mind that there are two very distinct processes which must follow each other in the making of vinegar. The first is the alcoholic fermentation, by which the saccharine matter—whether honey, grape-juice or apple-juice—changes into alcohol. The second is the acetic fermentation, by which this alcohol changes to vinegar, so that without alcoholic fermentation no acetic fermentation is possible. It sometimes happens that both fermentations go through together and continuously, but they are much less thorough, and occupy more time.

Although honey, like grapes and apples, contains most of the elements that go towards fermentation, these elements cannot develop fully unless the circumstances are favorable. Too high a temperature, say above 170 degrees, Fahr., will destroy the germs of fermentation. Too low a temperature, say below 60 degrees, will arrest or retard their development, though it will not be destructive to them. A temperature of 75 degrees to 90 degrees is the most favorable. If at this degree the liquid does not promptly begin to show signs of disturbance by the production of gas bubbles and a slight noise with a vinous smell, the fermentation must be hastened by furnishing to the liquid the missing germs. This is done by mixing into the liquid, fresh grape-juice, apple-juice, or yeast of some kind. It does not take a great deal of ferment to start a fermentation, because those germs are self-reproducing in any sweet liquid at the proper temperatures. This is the most important point. As a matter of course, the contact of the air is needed, but this is sure to be provided for, as the vehemence of the fermentation, when once begun, will increase the bulk of the liquid, producing carbonic-acid gas which must escape or burst the vessel. For this reason the fermentation must always be in open vessels.

When the vinous fermentation is well under way, the contact of the air will at once induce the secondary or acetic fermentation, which, although less tumultuous, still gives rise to the production of gases.

If things are favorable—the temperature right—at the end of one or two weeks the vinous fermentation will be over, and the acetic work will begin. At this time the contact of the air is most needed for every part of the liquid. To secure this, the makers of vinegar allow the liquid to drip slowly over a wide surface. Some use a barrel filled with coarse shavings and soaked with vinegar already made. The barrel is open at the head and set on end with a faucet at the bottom to allow the liquid to pass down into another barrel. I am told that some manufacturers of vinegar, here, use corn-cobs instead of shavings, and this is perhaps even better. A barrel full of the already fermented liquid is allowed to leak slowly out, passing through the soaked cobs and steadily changing by the contact of the air and of the already acid vinegar which soaks the cobs. If the temperature is right, I am told that in this manner the most acetic fermentation will take place within a few hours. I say, "I am told," because we have never taken the trouble to do it in this way. After the vinous fermentation has taken place we have always kept our vinegar in barrels in a warm cellar, relying on the slow action of the atmosphere to make our vinegar.

There was a time when we thought it would pay to make vinegar for sale on a large scale. We have given this up. Too much cheap vinegar is sold at less than it would cost to make good honey-vinegar. It is true that a limited quantity can be sold to judicious persons who prefer paying a trifle more—say a couple dollars more per year—for their supply of vinegar rather than endanger the life of the family by taking the risks of the vile compounds that are sometimes retailed at 10 to 12 cents or less per gallon. But in the apple-growing district

like the locality that we inhabit, cider is too plentiful, and the making of cider-vinegar too common to leave much room for a large sale of honey-vinegar. Yet, we always have on hand a barrel or so of vinegar, made from honey and wine mixed, to supply a limited number of customers who have learned to appreciate it.
Hancock Co., Ill.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

A Question on Breeding.

I got a queen last summer and her bees were all fine looking ones, and I reared several queens from her. One of my neighbors reared several from her, and I do not know whether he got a queen that seemed purely mated or not, but I got only one, and he said that all of his that he had looked at were just as I said mine was. Some of my bees had not a band on them, and some were nice bees, from the same queen. Only one seemed purely mated; her bees were all dandies, and she was the only yellow queen that hatched from the queen I got. Is there such a thing as a bee cropping out of an old cross of 20 years back? I did not rear any other queens last summer that were impurely mated.

IOWA.

ANSWER.—Atavism, or breeding-back, is well known to exist in the human race and other animals, and I know of no reason why it might not exist among bees. But going back 20 years would be going back anywhere from seven to twenty or more generations, and that would be going back pretty far. Neither is there anything, I think, in the case you mention that cannot be accounted for without any atavism.

Sowing Sweet Clover for Cattle, Bees and Seed.

1. I am thinking of seeding 40 acres to oats and sweet clover in the spring. I will keep the field pastured down until the first of August, by cattle, then let it get a good fall growth; only perhaps feed it down some in September and October. Could I reasonably expect to secure a good stand?

2. The following spring I will run cattle on the field until June first so as to keep it fairly eaten down, so that it will not grow so rank, but thicker; let the bees work it until ripe, then cut for seed, binding with a common grain harvester. Can you suggest any better plan to pursue?

3. How many bushels per acre of seed can I count on?

4. Would not the tramping of the cattle insure a stand? The oats would make feed for the stock before the sweet clover is big enough.

5. Could I count on any surplus honey from these 40 acres of sweet clover with 100 colonies of bees to work it?

Sweet clover grows very vigorously along roadsides here, wherever it gets a start, and in places its seed blows over fences and comes up in pastures, but cattle never let it even get into bloom. Cattle are very fond of it when they once get a start on it.

IOWA FRANK.

ANSWERS.—From what I know of you I should feel more like asking than giving advice about sweet clover. Still I don't object to telling you some of the things I don't know about it. There are really a few subjects that come in the scope of bee-keeping upon which I have studied and experimented so much and yet know so little for certain. Especially as to making a success of getting a stand. One year I had a piece of ground put in as fine condition as I knew how, sowed it with oats and sweet clover, had a fine stand of clover, although it did not grow very strong; but the following spring not a plant was left alive; all heaved with the frost. I think the mistake was in having the ground too mellow, although if it makes strong enough growth for the roots to grow deep enough it may be all right. Still, I should prefer to have the ground very hard, for I never saw a roadside that seemed too hard to grow sweet clover.

Another year I sowed sweet clover with oats, cutting it with the oats, and it didn't wait for winter, but died right off. The fatal mistake was probably in cutting it too low, especially

AN APIARY OF ALEXANDER FOURIER, OF RUSSIA.—
(See page 18.)

as the cutting was followed by dry weather. Last season I sowed several acres, and I failed still earlier, for not ten seeds to a square rod ever came up. I don't know, but I think it might have come up better if the ground had been harder or the weather not so dry. But where there has been any kind of a stand that has been left from season to season, it seems to do fairly well. Now, if you haven't lost all faith in my knowledge of sweet clover, I'll make a guess at the answers to your questions.

1. If I understand you, you will turn cattle on the field after a fair growth has started, taking them off about August 1, and return them in September. My guess would be that it will be a dead failure. And yet it is possible that it may be an entire success. Something depends on the cattle. If they have been trained to eat sweet clover they will likely eat it down so close as to kill it. If they don't care for it, their tramping it down may be its salvation. It is possible that it might be a good thing to turn the cattle in when the seed is first sown, so as to have it thoroughly tramped in.

2. If there is a stand the following spring, I should rather keep the cattle off till it has a pretty fair start, and be on the lookout not to let them eat it down too close at any time. And yet I have seen it on the roadside where it *seemed* to have been eaten down close all summer, and it grew but little higher than white clover, but even at that height it kept persistently coming up and blooming all summer and fall, making really a pretty carpet on the side of the road. Your idea to keep it down till June 1, or till it is ready to bud for blossom, is all right.

3. I don't know. I think I've seen a statement as to the crop somewhere, but don't know where to turn to it now. Perhaps some one may help us out.

4. As I have already shown, I have great faith in the tramping of the cattle, but there is the danger that they may undo all the good of the tramping by too close eating.

5. I don't know. It's too dangerous a question to guess on, but if I were obliged to guess I would guess yes, for in all probability there are other plants from which the bees would at least get something, and at any rate I should count on considerable value from that 40 acres. Indeed, if you force me down to confession, I must confess that I'm not sure but 100 colonies might store surplus from 40 acres of sweet clover without any other help.

Now a word before we part. You'll sow that field, and if it isn't a success you'll keep as still as a mouse about it. Please don't do that way. Tell us all about your success, and your failure, and tell us as nearly as you can how to make the same success and to avoid the same failure. If you succeed in having 40 acres of it to come up good and strong the second spring, you can crow over me like everything, and I'll stand it like a major.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

OPTIMISM OR PESSIMISM—WHICH?

I say optimism, every time. Some say pessimism. Paul said, "Faith, hope, charity, these three, and the greatest of these is charity." Wasn't it a good trio? I feel like blessing Paul every day for that chapter—13th of 1st Corinthians—which, next to Matthew 5th and John 14th and 15th, seems to me the most inspiring of all literature. How much poorer I would be—how much poorer the world would be—had Paul failed to pen that wondrous essay on Love.

I said yesterday, to my large, splendid bible class, that the three greatest personages that had blessed this world with their glorious—none too strong a word—presence, were Christ—no one would say nay to that; Paul—if any one would to that, let him read Corinthians, 13th chapter; and Moses. These three words—faith, hope, charity—aren't they matchless? Take away faith, which means trust, confidence, and the world would go to pieces instanter. I think Paul would have said that a man without faith in God and his fellows lacks the very foundation of all worth and usefulness. I know he said "Faith is an anchor to the soul, sure and steadfast." How fortunate are we parents who can feel assured that our children rejoice in this faith.

Years ago I committed to memory, that I might always have with me at command, that beautifully suggestive verse—or was it a loving command?—also from Paul: "Add to your faith virtue, to virtue knowledge, to knowledge temperance, to temperance patience, to patience godliness, to godliness brotherly kindness, and to brotherly kindness charity." We see, as in the grand trio, faith here is the foundation of the stepping-stones, the grand start-off. So it is in any life.

Yesterday I was asked in bible class, why some excellent people had unworthy children. I have thought of that much. I believe the first and chief reason is, that they are so busy that they neglect the most precious belongings of any man or woman—the blessed children—and so lose their trust, their confidence. A bad environment is very hard on virtue, very menacing to a true, right life; but if a girl is absolutely confidential with mother, and a boy with both father and mother, they will be safe in a pretty bad environment. We parents must keep the faith of our children. When that goes, then God help, or the child goes to the bad.

But Paul was giving a grand climax—faith, hope, charity—a climax evidently, for he says "the greatest of these is charity." Then hope comes in even after faith. Thank God, the great Paul was an optimist. He had faith in God, and in his fellows, and so was full of hope. The world has many "side-shows" full of horrible sights. The group of boys hidden behind wall or fence, with their cigarettes, their profane utterances, and foul, dirty speech; the horrid saloon, which we must all aid to our utmost to bring to naught; worst of all, the brothel, fed by the lecherous speech of the boys lurking in the shadow of the wall. Sometimes the main tent shows only filth and blackness. God be praised that such places are becoming more and more rare.

Despite this ugly show of evil, the world was never so good as to-day. Faith, hope and charity occupy more seats than ever before. There is more of Christ, and less of anti-Christ, abroad upon the earth this morning than ever before since the morning stars first sang together in that erst-day of creation.

We see the boy profane, disrespectful, and with the cigarette, and we sometimes sigh for the old days when there was more reverence in the world. We have only to open our histories, or think of our own early experience, if it was at all wide extended, and reaches back a score or two of years, to find of a truth that Reverence takes a higher seat now, this very morning, than she ever occupied before in all the Earth's history. Yes, we may be filled with hope. We have a right to be optimists. God is still in the world, he is ever at work. As the grand result of that work, faith is to-day more rich and full in the human heart, hope is more inspiring, and love is more perfect and con-

trolling than ever before. Knowing and feeling this, we may all be optimists, and urged on by the hope that gives us more abundant faith, and helps on to a more perfect love, we may be God's own agents in gilding the world with still greater brightness. And it will be our greatest glory that we help to build on to the faith, hope and love which shall still more abide.

Pessimism cheers no heart, brightens no path, and is an offense against the very God that gives us all the delights of home, all the glory of living.

Optimism keeps our own hearts warm and true, floods with sunshine myriad other hearts, and is our best praise-service to the All-Father.

THE DOG.

I fear I may have wounded some heart in my show-up of the dog. I fear I was wrong. My father had a dislike for dogs. May be I inherited a similar dislike. Perhaps my father's oft-expressed aversion, and that when I was first reaching out for ideas and sentiments, at that early, susceptible time, when feeling so easily and quickly takes root, gave me a prejudice which has never let go. My father was severely utilitarian. He saw in the dog only a meat-eater and a bill of expense. He would often call my attention to a shiftless, no-account man, with his two or three worthless curs.

An excellent neighbor near by has a dog that often makes the night wretched by hours of howling and barking. Surely, such a dog has no rights that any man is bound to respect. Yet I know that the best uses of pets is not the mice caught, not the cash which they hand over to the family exchequer. The dog that gives comfort to parents and children, that quickens sympathy, that builds up in the heart affection, that calls out love and the spirit of sympathy, is all right. My nearest neighbor has a dog named "Sam." Sam is a most proper dog. He never barks at night, though, like California roosters, he has frequent reminders that it is possible to make night hideous; he never barks at passing team, and, indeed, he is a "gentleman" dog. I see he brings real comfort to the home, so I am glad that Sam is one of our respectable "citizens," and would have him banished on no account.

My nearest neighbor on the other side is like the other, one of the very best neighbors that ever blessed a community. He has a dog "Jocko." Jocko is old, and ought to know better than ever to bark at the hours sacred to rest and quiet. Once in a great while Jocko speaks out. I think it is at displeasure of another dog, that thinks his bark an adornment of any time or hour of night. When Jocko barks his master goes at once and administers a smart reproof, that I think smarts. At least it quiets Jocko, and usually is sufficient for days. I am glad Jocko is one of our number. He disturbs very little, and is a pleasure to several good people.

The other dog is a consummate nuisance, as is any dog, boy, or man, that disturbs the quiet and peace of the night. More than this, he dashes out at passing team or vehicle in a way that few horses can stand, and thus is ever a menace to life and limb.

THE HORNED TOAD.

He is a pretty fellow, neat, clean, agile, friendly. He is as much a feature of the California roadside scenery as is the real toad or frog of the East. His coat is of sober gray, though prettily striped. Its color hides its owner, as against the gray of earth; his toadship, when quiet, is as if not. And why the many sharp horns all over his body? They, too, give friendly protection. Mr. Gopher-Snake finds him hard to swallow. He is too thorny a morsel. Really, he is no toad at all, but a lizard. His shape is like the toads, except he has a short tail, and so his common name, which should be horned lizard. He is not as quick as the other lizards, or swift, which are more snakelike in form, and are possessed of a longer tail. They, too, are very common here. Both have a dangerous country to live in, as there are so few toads and frogs that owl and snake are often forced to go to bed hungry. So they are quick-eyed, day and night, for any morsel to break their fast.

The common lizard is swift to take flight, and usually hies away from danger. The horned lizard is too spinous; neither owl nor snake like the many horns. Our little friend feeds mainly on ants, which he picks up with a dexterity that is amazing. A queer thing about our little pet, is the habit of throwing blood from its eyes when vexed or annoyed. I have known it to throw several small drops,

GENERAL ITEMS

Bees Did Fairly Well.

My bees did fairly well last summer. I got 80 pounds of honey to the colony. I have 12 colonies wintering on the summer stands, packed with leaves. FRED ROBY.

Hall Co., Nebr., Dec. 21.

Too Wet for Bees the Past Season.

Bees are in winter quarters once more. We have to make ours as comfortable as at small an expense as possible, for while we take pleasure in the pursuit in a small way, we have to use economy if we want to be ahead at the end of the season with anything but experience. Now, experience is a very good thing, but experience blended with a few shekels derived from the same pursuit makes a better combination, so long as honesty predominates.

Our 13 colonies went into winter quarters well fortified with bees and honey. It was too wet the past season for bees in this locality. Our bees worked on the red clover when the weather was so they could work.

M. P. Lowry.

Armstrong Co., Pa., Dec. 18.

Anti-Adulteration—The Past Season

EDITOR YORK:—You did a good thing for the "fraternity" by writing and publishing the letter on page 771 (1901). But strange the Chicago Tribune is so loth to do the bee-keepers and their customers justice. Nothing less than printing your letter in full in that paper should have been done. I know all bee-keepers will thank you most heartily for the letter.

The past season in this vicinity has again been a little discouraging, though very much more encouraging than the two seasons before the last, which were total failures.

Bees generally wintered well last winter, coming through in good shape, but the cold, wet spring retarded brood-rearing, except where extra pains were taken with colonies by feeding, etc.

Apple-bloom was very scarce—a source from which we usually expect much nectar. Most of us were very much surprised to get any clover or basswood honey, but we got it, and of good quality—about half an average crop.

Buckwheat bloom and fall blossoms were sure, we thought, to yield us a good crop, because bees were in extra-fine condition, but alas, not nearly half a crop was harvested, owing to the drouth, perhaps.

Bees went into winter quarters strong in numbers, with plenty of honey, but have not had a flight for six weeks.

White comb honey is bringing as high as 17 cents a pound, wholesale; fall honey about 14 cents on the average; extracted, white, is 12 cents retail; no call for it at the stores to retail.

GEORGE SPITLER.

Crawford Co., Pa., Dec. 12.

Meltose, Again.

We had a fine flow of honey the last two weeks of June; then the drouth came and cut everything off—pastures, meadows, and all crops, about one-half.

I got just about an even 25 pounds of very fine comb honey to the colony, spring count, and 10 swarms. Only one of the latter stored any surplus.

I doubled up and killed off, so that I now have the same number in the cellar that I had last winter—26 colonies.

I received a letter not long since from the Sanitas Food Co., some one having sent in my address. They say this in regard to Meltose or "Malt Honey."

"It is the latest triumph in the art of preparing cereal foods by natural processes. . . . It should be substituted for cane-sugar, syrup, honey, and all artificially prepared sweets."

The Italics are mine. Also, any "inquiries would receive prompt attention," etc.

I asked them to explain how they could truthfully claim meltose to be a natural product, while they classed honey with artificially prepared sweets?" I also volunteered the information that bees do not gather and store honey with their "cunning little feet." And, too, I ordered a sample of meltose. Five days after my letter was mailed a reply came back—pretty quick time.

I want them to have the benefit of a correction in regard to the "cunning little feet" of the honey-bee which, they say, was a stenographer's error, and should have been, "that cunning little thief, the honey-bee."

The sample of meltose has not arrived yet, as I hoped it would before sending this letter. Those who have tasted it call it a very palatable sweet, but I have no fears that it will interfere with the honey-trade.

By the way, they apparently forgot (?) to answer the question I asked, for nothing was said in their letter in regard to it.

A. F. FOOTE.

Mitchell Co., Iowa, Dec. 19.

[This meltose product was pretty well aired in these columns several months ago. We have a sample of it, and prefer the poorest grade of extracted honey to meltose. Of course, tastes differ, but bee-keepers need not fear its becoming a competitor of honey.—EDITOR.]

Poor Season in Oklahoma.

Our season has been very poor. No one except myself and one other bee-keeper got any surplus. Those who are keeping bees on the old style will lose most of them this winter.

I find I can't keep up with the times without taking bee-papers.

F. W. VAN DE MARK.

Oklahoma Co., O. T., Nov. 18.

Our Editor's Den—Other Matters.

Are we an up-to-date people? Recently I visited the "Old Reliable," and will tell of a few things I saw, and leave it to you. We readers know nothing about what energy is required to get out the Journal; if we did we would have a fit.

There are no type-setting machines, all the forms being hand-set. Everybody is as busy as bees in a good flow of nectar.

"George" is doing the two-man act; attends to all correspondence, is errand boy, editor, and, in fact, does everything possible to save cost, and anything that will add to the improvement of the Journal—he is right after it.

While I was there I saw several double armfuls of letters ready for mailing, these all going to delinquent subscribers. "George" told me it cost some \$80 or more to send out all these statements—\$80 of wasted energy—but it must be done. This waste, if it were added to improving the Journal, would be a good thing.

He also said if the books were balanced we could have a much better Journal; he could put in a type-setting machine that one operator could do the work of four or five type-setters; the saving would go to the readers in the way of improvement in the Journal.

Mailing day! Well, if all the readers could see it. Why, it gave me a shamed face to think we were so small as to demand a premium queen when sending in a new name, just because "George" said he would give it. It appeared to me as if some of us wanted the earth, and fenced in. As to mailing day, well, they were busy with wrappers and paste, all hands and the cook—"George's" cook, if you please—Mrs. York was there, not as a spectator, but was at the mailing table, and was as busy as any one of the other three girls.

The office boasts of a "devil," but we thought him to be a rather old one. He, too, was busy. The supply department looked as if it needed a boy or so; they were busy with the honey-trade.

Go there as I did for five days at the den, and see if you can come away without feeling

OUR NEW CATALOG, describing and listing the **FINEST LINE OF BEE-KEEPERS' SUPPLIES IN THE WORLD**, will be ready about the first of the year. If you have not been receiving a copy annually, send us your name and address and one will be mailed you free. Prices will be same as last season with the exception of the narrow, plain sections with no bee ways, which will be 25 cents per thousand less.

as if we crazy people were hard task-makers. To please us, he gives all his time—can't even get a single day to go fishing. You may ask, Why? Simply because we expect so much for a little money. And so many appear to think that editing a bee-paper is fun, and can be done just because they read the paper but forget to send in their dollars.

"What is the 'Old Reliable'?" you will ask. It is the best bee-paper in the world, I think, if you will only take pains to see the other ones. These bee-papers are like Pat's whiskey—none bad, but some better than others.

That Chicago bee-keepers' convention was worth going to see. You beginners will do well by attending some of them. I knew several of the bee-keepers from their pictures in the Bee Journal. They were a fine lot of people.

Dr. Miller must have had a cold, as he did considerable sneezing while seated at the piano. He is just as nice and clever out-of-doors as he is in the "Question and Answer Department."

Some things I learned last season. They were talking about bottom starters for sections. I tried them, but cut them too tall, so they lopped, and the bees fastened the comb to the separators. Hereafter, if I use them, I will cut them very low, say from a quarter to half an inch tall. It was said that 40 colonies of bees would carry off from five to ten gallons of water daily, when the heated spell was on; that our black bees outstripped the long-tongues.

Now, readers, what are we to do about that type-setting machine? It is up to all of us. Let's have it. **J. P. BLUNK.**

Webster Co., Iowa, Dec. 20.

[We hardly knew whether to let the above go in or not; but, after thinking it over, we decided that we'd have to let that Blunky Iowa man have his own way, or he'd Blunk at us later with some more of his Blukety-Blunk stories.—EDITOR.]

Helpful Hints for Beginners.

On the night of Dec. 12 the mercury ran down below zero in just a few hours, with a cold northwest wind blowing a gale, accompanied with a light fall of snow. The succeeding night was also a zero night, the first zero weather that this locality has experienced this winter.

My experience in wintering bees out-of-doors in this locality is that they must be protected on the north and west by a high board fence, or with timber, or evergreens, or a hill. Such protection should be provided even if they are in chaff hives. I am confident that the north wind and snow and sleet driven against the hives does more damage than steady freezing weather, if the bees are not confined to the hives too long.

Apiculture is made up of many little details, and there is no other business known to the writer that will suffer as much from the neglect of little matters. What little attention bees do need must be given at the right time to be of any use to them. Though the work done by the bee-keeper may seem a very small matter, it amounts to a great deal to the bees.

You might as well try to run a locomotive without steam as to try to run an apiary without a bee-smoker. At times only a little smoke is needed. When handling bees most persons think that a bee-smoker can be dispensed with, and often go to the hive and open it up or pull off the cover. The consequences are, they have a mad lot of bees to contend with, stinging everything within their reach, when, if a little smoke had been used, all would have been well. I never go to a hive to open it without first lighting the smoker, although quite often it is not needed.

Every person owning two colonies of bees should subscribe for a good, live bee-paper (if he has not already done so), and also get a good text-book, and then study them thoroughly. The bees will increase as fast as your knowledge, and faster, in two good seasons.

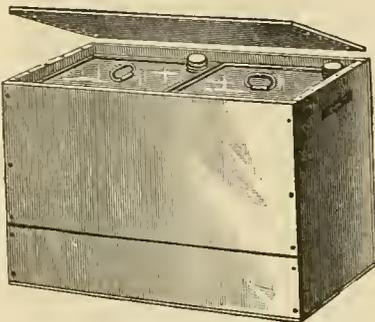

All hives should rest near the ground, with a half brick under each corner of the hive. Then heavily-laden bees can reach the en-

—BEST—
Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two or more 60-pound cans of Alfalfa, 7½ cents per pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

trance without rising the second time. Many bees miss the alighting-board and have to rest before they are able to take wing the second time. This matter of having hives near the ground is a very important one, from the fact that many queens, in coming out with the new swarms, fall to the ground, disabled in some way, so they are unable to rise with the swarm with which they must get back into the hive again. Hence, a hive near the ground has a big advantage in this matter alone.

It is almost useless to inform a beginner in bee-keeping that it is quite an important matter to have his hives, section-boxes, frames and honey-supers all in readiness for the bees long before they are needed, at least before the bees get to swarming or the honey harvest comes on. From many years' experience in this line of work I find that the winter season is the proper time, and the most convenient, to do this work. If you haven't a good, warm place to work, and the proper tools to work with, you can not be a successful bee-keeper.

If you have new hives to make they should all be made, painted, and stacked away in some dry place. Or if you have a lot of old ones, fit them up and make all one size, and repaint them. I would not try new hives if I had a lot of old ones on hand to be fixed up. Supers should be made and filled with sections, but don't forget to put in separators if you want nice, straight comb honey; they are always needed.

Cass Co., Nebr., Dec. 14.

J. M. Young.

Facilities for Moving Bees.

Referring to the remarks of Afterthinker Hasty, on page 745, in which he comments on Mr. Atchley's plan of moving bees, the Southland Queen says:

We do not think that Mr. Hasty fairly understood the matter he had under consideration when he wrote the above. In the first place, the shipping or moving cases are not so frail as he imagines, for the same have been used several years to transport colonies of bees a distance of about 500 miles; cases being sent up by express, and bees coming back by express also, and those cases are good for several years yet. We make these cases light, weighing but little over five pounds each, yet strong and well ventilated, and bees

MARILLA.

suffer but little even during our hottest weather. We have wagons made especially for hauling bees, and no danger of horses getting stung. In fact, we have hauled several large colonies turned loose together in the "bee-wagon," engaging queens before putting them in, and again dividing the bees at the point of destination. We can move about 100 large colonies to each wagon-load, and with two wagons an apiary of 200 colonies can be moved at one draught.

Feeder for Outdoor Feeding.

We make a trough or tank about 10 feet long and 18 inches wide of heavy zinc, and have a wooden box for it to sit in for protection. We make a float to fit inside the zinc trough by using strips of wood edgewise encased in a frame, the strips being 1/4 of an inch apart. The feed is poured in through a funnel, and the float rises up and sinks down as food is taken. The bees can not fall into it. You will think at first that the feed-trough is not half large enough, but when the bees are down to work right, some coming, some going, and some loading, they do not seem to be in each other's way at all. The funnel is made fast, and under it is encased with wire-cloth, that the feed can be put in without the bees getting into it. From 1000 to 1500 pounds of feed can be given to 100 colonies in a single day, when bees are well started.—Southland Queen.

Ill-Advised Advice.

The Rocky Mountain Bee Journal refers to the remark of R. C. Aikin in the American Bee Journal, that "there is an epidemic of bee-fever in Colorado" as a true remark, and says:

The extraordinary demand for bees thus created has sent prices skyward, but this rather stimulates than deters investment in that kind of property. "What does six or seven dollars per colony amount to for an institution that will return 100 percent on the investment in a single season?"—they reason to themselves. We are informed that one party, entirely inexperienced, has bought 200 colonies, paying \$7.00 per colony, and will undertake to run them alone next season. His nerve is certainly to be admired, but—it's too bad that he did not consult some bee-keeper friend, whose kindly advice would have saved him the vexation and loss that lies in the near-by future.

Recently some of the Denver dailies undertook to boom the bee-business by grossly exaggerating the profits to be derived from it, and advising all their country readers to engage in it as a swift and easy way to get rich. Very foolish advice, indeed, yes, even criminal, because if followed in the promiscuous manner in which it was given, great disappointment and loss would be the general result. To advice of this character (and volumes of it have been given) may be credited the "epidemic of bee-fever" that is sweeping over Colorado.

A Good Convention.

The Chicago convention, Dec. 5, 1901, was a great success, both as to interest and numbers in attendance. C. P. Dadant, W. L. Coggs, and others brought it up nearly, if not quite, on a level with the old Northwestern conventions which were so popular. No reason why there should not be a Northwestern at Chicago every fall. Editor York is a capital presiding officer.—Stray Straw in Gleanings of Bee-Culture.

Size of Honey-House.

I presume you would want me to tell how much room I would want for a 200-colony apiary. Well, a 12x14 foot workroom, an 8x12 foot extracting-room or section-cleaning room, and a 12x30 foot storage-room.—Mr. LYTLE, in the Rocky Mountain Bee Journal.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The honey market is of a slow nature with little change in price of any of the grades. Choice grades of white comb honey, 14 1/2 @ 15c; good to No. 1, 13 1/2 @ 14c; light ambers, 12 1/2 @ 13c; dark grades, including buckwheat, 10 @ 12c. Extracted, white, 5 1/2 @ 7c; amber, 5 1/4 @ 5 1/2 c; dark, 5 @ 5 1/2 c; the scale of prices varying according to flavor, body and package. Beeswax steady at 28c. R. A. BURNETT & Co.

NEW YORK, Dec. 19.—Comb honey continues to be in good demand, and while the market is not overstocked, arrivals of white honey are sufficiently large to meet the demand, while buckwheat is rather scarce. We quote: Fancy white, 15c; No. 1, 14c; No. 2, 12 @ 13c; and buckwheat, from 10 @ 12c. Extracted remains dull and inactive with plenty of supply of all kinds. In order to move round lots, it is even necessary to shade the quotations, which are: White, 6 @ 6 1/2 c; amber, 5 1/4 @ 6c; dark, 5 @ 5 1/2 c; Southern, 55 @ 60c gallon, according to quality. Beeswax firm at 28c. HILDRETH & SEOKLEN.

BOSTON, Dec. 20.—The demand for honey is easing up, somewhat due in part to the holiday season at which time it is much neglected.

Our market at the present time runs 10c for strictly fancy in cartons; No. 1, 14 @ 15c; No. 2, 12 1/2 @ 13c. Extracted, light amber, 7 1/2 @ 8 1/2 c; amber, 7c. BLAKE, SCOTT & LEE.

DETROIT, Dec. 20.—Fancy white comb honey, 14 @ 15c; No. 1, 13 @ 14c; no dark to quote. Extracted, white, 6 @ 7c. Beeswax, 25 @ 26c. M. H. HUNT & SON.

SAN FRANCISCO, Dec. 24.—White comb, 11 @ 12 1/2 cents; amber, 8 @ 10c; dark, 6 @ 7 cents. Extracted, white, 5 1/2 @ 6c; light amber, 4 1/2 @ 5c; amber, 4 @ —.

Market for best qualities of both comb and extracted is moderately firm at current rates, with no heavy stocks in this center of any description. The lower grades are not eagerly sought after, however, and offerings of this sort draw forth hardly any competitive bidding worth noting from either large or small buyers.

CONVENTION NOTICES.

Minnesota.—The Southern Minnesota Bee-Keepers' Association will hold its next annual convention in the County Commissioners' room at the Court House in Winona, Jan. 21 and 22. A good program has been arranged, and a large attendance is expected. All are invited. E. B. HUFFMAN.

Wisconsin.—The Wisconsin State Bee-Keepers' Association will hold its annual convention in the State Capitol, at Madison, Feb. 5 and 6, 1902. This promises to be a large convention. All are invited to attend. There will be excursion rates of 1 1/2 fare for the round-trip, good for all of the first week in February. N. E. FRANCE, Pres. ADA L. PICKARD, Sec.

California.—The California State Bee-Keepers' Association will hold its annual convention in the Chamber of Commerce, Los Angeles, Jan. 15 and 16, 1902. We will try to have a good program. Come and exchange your bright ideas with your neighbors, and get some of the mss rubbed off your back. J. F. MCINTYRE, Sec. G. S. STUBBLEFIELD, Pres.

New York.—The annual meeting of the New York State Association of Bee-Keepers' Societies will be held in the parlors of the Kirkwood Hotel, Geneva, N.Y., Wednesday, Feb. 5, 1902, commencing at 10 a.m. All interested in bee-culture are cordially invited to be present. Subjects of importance are to be brought before this meeting, and it is desired to have a large representation of bee-keepers in attendance. C. B. HOWARD, Sec., Romulus, N. Y. W. F. MARKS, Pres.

A Really Successful Incubator.—No incubators are better known, or are more widely popular than the SUCCESSFUL INCUBATORS, made by the Des Moines Incubator Company, of Des Moines, Iowa. The factory of this company is believed to be at least as large as that of any similar institution in the world.

A few years ago no incubator company would have dared to guarantee satisfaction on its products, but such an incubator as the Successful is no longer an experiment. The largest and most successful poultry farms hatch chickens by artificial incubation. Poultrymen find incubators necessary to the economical production of chicks on a large scale. Many of the best known breeders of poultry use the Successful Incubators and Brooders exclusively.

So large has the volume of business done by this Company in the East become, that a branch office and warehouse have been opened at Buffalo, from which the Successful Incubators and Brooders are shipped to customers in the Eastern States at a great saving of time and expense to the purchaser. Large quantities of these machines are also shipped to foreign countries.

Five different catalogs in five different languages are published by the Des Moines Incubator Company. They are all free except the catalog in English, for which a charge of four cents is made to cover postage. No more instructive book on poultry culture can be secured anywhere than one of these attractive catalogs.

The Successful Incubators and the Successful Brooders have well earned their title: "Life Producers and Life Preservers." The company requests that all correspondence be addressed to the office nearest the writer.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two or more 60-pound cans of Alfalfa, 7½ cents per pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO. Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER
IN AMERICA

42d YEAR.

CHICAGO, ILL., JANUARY 16, 1902.

No. 3.

* Editorial. *

The Lies About Honey are re-appearing in various forms in both newspapers and farm journals. Mr. Newton Bawn sends the following, which appeared lately in a department conducted by J. S. Trigg, of Rockford, Iowa, who is an agricultural writer of considerable prominence, and should know better than to "get off" such stuff:

"A cute machine manufactures the artificial comb and a swindler takes it and fills it with glucose honey, scattering here and there a dead bee on the comb, and the deluded purchaser eats it, associating it with apple-bloom, the fragrance of white clover and summer flowers, while the stuff is made of paraffine instead of beeswax for the comb, and glucose for the nilling."

If Mr. Trigg doesn't correct that paragraph *at once*, a good many thousand people will now know where he belongs. It is exceedingly unfortunate that any one should be willing to write a thing like that, and thus put himself down as—as—well there isn't a word of truth in the whole paragraph.

We have written Mr. Trigg, requesting him to publish "The Truth About Honey," in his paper. He should be only too anxious to get a statement like that, which appears over the names of responsible men.

Carbolineum.—A warning is sounded against the use of this material in hives, as it may affect the flavor of honey. It ought to be a fine preservative for bottom-boards, where it would perhaps not affect the honey.

Sweet Clover as Forage.—A short time ago Gleanings in Bee-Culture asked for reports as to whether stock would readily eat sweet clover. From Michigan, Ohio and Indiana come responses that say neither horses nor cows will eat it unless starved to it. From New Mexico comes the report that horses and cows will eat it down as clean as if a mower had gone over it. M. S. Gosney reports as follows from Kentucky:

Last fall I sowed some five acres in timothy. The winter was hard, and, supposing I would have a light catch in February, I sowed sweet clover, got a fair stand, and more than half a stand of timothy. When the timothy seed was ripe and had begun to fall, the sweet clover was from 18 inches to 2 feet high. I turned in three horses which had never learned to eat sweet clover. After a few days I noticed they were eating the clover and leaving the other grasses, of which there was an abundance—not only timothy, but blue-grass and Bermuda grass; but they ate nothing but the clover until they got the last

bit of it, and, owing to the extreme drouth, I fear the sweet clover will all be killed. My buggy-horse ate sweet-clover hay greedily the first time he ever saw any.

These reports are about as contradictory as usual. Sometimes two men in the same locality give opposite reports. The probable fact is that some stock have learned to eat it and some have not. One man writing to Gleanings seems to think there must be some sinister motive in the mind of any one who advocates that stock should be taught to eat sweet clover, saying:

"You certainly have had enough evidence, such as Mr. Zurburg's, to convince a jury or an honest man. Why should we wish our stock to learn to eat it?"

The testimony of a thousand men might be given that stock would not touch sweet clover, but if a single reliable man should testify that he had seen horses and cows eat it greedily, no honest jury would decide that sweet clover was worthless as forage. The time was when hard coal was considered worthless as fuel, because no one knew how to burn it; but when one man actually succeeded in burning it, his testimony that it was good for fuel outweighed all the negative testimony that could be piled up against it.

There are a good many people who know from personal observation that sweet clover has a value as a fodder-plant, and their number is constantly increasing.

The Sting of the Queen-Bee is thought by some to be of use in the act of egg-laying. B. Hamlin-Harris says in the British Bee Journal:

I have myself repeatedly seen the queen-bee, while actually laying eggs, work her sting up and down, as if by such an act the process were made easier. I think it is simply common-sense to suppose that such would be the case. But must we not seek an answer to our question from a different and more fundamental source?

The question is, What relationship exists between the sting and the egg-laying organs? Surely, they both belong to the same system, and bespeak the feminine sex. The sting is essentially a part of the female, and not the male. Would it be surprising, then, if one organ assisted the other, though, perhaps, in a very small degree?

Bees in Hot Countries are sometimes said to be lazy about storing after having learned in a tropical climate that they may depend upon the flowers for a continuous supply. In the British Bee Journal, A. C. Sewell writes from South Africa:

One has only to watch the hives to dispose of any charge of want of energy. I have seen them returning with pollen in the early dawn before sunrise, and in the evening, when it was so dark that I had to put up my

hand before the entrance to feel them going in, and a colony will build up with great rapidity.

The constant breeding that goes on must also require a large quantity of honey that would otherwise go into the supers. There is no long period of rest in winter, but one finds up country, where the climate is colder, that the harvest is better, and it seems to me that in order to get good honey in quantity a winter sufficiently cold to dry up vegetation and produce a dormant condition is necessary.

Basswood Not a Success in Colorado seems to be the verdict, according to reports in the Rocky Mountain Bee Journal. The trees die down to the ground each season, and make no substantial growth.

Do Bees Get Honey from Corn?—A discussion with regard to this is on in Australia. Hessel Hall, who says he secured, during the past season, between three and four tons of corn honey, is quoted in the Australian Bee-Bulletin as saying:

When the maize-fields are in bloom, if no other honey-flow is on, the whole apiary makes for the corn-tassels. At such times the bees roar and show signs of excitement over their work, such as they never show except when they are bringing in honey.

During the period of maize-bloom the bees working on maize bring in large quantities of dull, greenish-colored honey, mild and pleasant in flavor, candying speedily into soft, white crystals, rather brittle in the grain. This honey is not so glutinous as most honey, cuts differently in uncapping, and, when new, carries with it the odor of the maize-blooms.

"The Truth About Honey" is something that few people aside from actual bee-keepers know much about. It is unfortunate, too, both for the general public and the producers of honey.

Recently, the old lie about the manufacture of comb honey was revived, and it is again going the rounds of the press, greatly to the detriment of honey sales in certain localities. One of the greatest offenders lately was the Chicago Daily Tribune. And the worst of it was, that when this influential newspaper was requested to publish a refutation of its slander against honey, it gave only a few lines of truth, when it had used considerable space in which to tell what was not true.

In view of the many misrepresentations that are current, the Chicago Bee-keepers' Association appointed a committee at its meeting in December, for the purpose of preparing a statement for the general newspaper press, that should aid in setting the reading public right on the honey question. Their report has been given out for publication to all the Chicago daily newspapers, and now it only remains to be seen whether they will

publish it, and thus desire to correct the errors which they have helped to circulate.

Wishing our readers to see the report of the committee referred to, we give herewith a copy of it, and would suggest that all endeavor to have it reprinted in their local newspapers. If any paper will publish this report, and desires to have the pictures also, we will, upon request from the publishers of any such paper, mail electrotypes of the engravings free, and also a printed proof or copy of the report. We offer this so that no bee-keeper need part with his own copy of the American Bee Journal.

Here follows the committee's report:

The Truth About Honey.

A Committee of the Chicago Bee-Keepers' Association Corrects Some Popular Errors.

Some statements with regard to honey, which are very far from the truth, having been published, the Chicago Bee-Keepers' Association appointed the undersigned a committee to give to the public a statement of the exact truth with regard to the purity or impurity of honey as found upon the market.

Honey is not only an appetizer, it is an article of food of the highest value. Unlike sugar (which makes such a strong demand upon the digestive organs that it is a prime factor in the establishing of that terrible scourge, Bright's disease, and other diseases), honey lays no heavy burden upon any vital organ, and its use as a daily article of diet tends toward health and long life. Such being the case, it is of the first importance that the pure article should be obtained.

Honey is found upon the market in two forms: liquid, and in the comb. The liquid is obtained by throwing it out of the comb by means of centrifugal force, in a machine called a honey-extractor, in which the comb of honey is revolved so rapidly that the honey flies out of the comb somewhat as the mud flies from a wagon-wheel when the wheel revolves rapidly. When thus obtained it is called extracted honey, and may be found put up in tin or glass packages. It varies in color from water-white to almost black, the color depending upon the flowers from which the honey was obtained. Nearly all honey granulates upon the approach of cold weather, having somewhat the appearance of lard, and in this form it is preferred by some. It can be restored to the liquid form by heating it slowly, as too much heat spoils its delicate flavor.

It is not a hard matter to mix glucose with extracted honey, the mixture varying in character according to the quality of glucose used, the ordinary glucose of commerce containing matters unfit to enter any human stomach. Thanks to the efforts of the National Bee-Keepers' Association and the valuable aid of the Illinois Pure Food Commission, the operators in this vile work of adulteration have found Chicago no longer a safe field in which to operate, and it is now not a difficult thing to find pure extracted honey just as stored by the bees. Respectable grocers have no difficulty in offering you an article that they may warrant as pure, having on the label the name of some reliable producer or dealer.

Comb honey is that stored in waxen cells, the marvelous workmanship of the honey-bee. The statement that no pure comb honey can be found upon the market in Chicago, but that it is all "manufactured stuff made up of glucose and paraffine," could not possibly be farther from the truth. The sim-

ple truth is that *not a pound of comb honey that was not made by the bees is to be found in all Chicago.* There is not a pound of it in all the world, and never was. The Department of Agriculture at Washington, D.C., has also issued a statement that there is no such thing as manufactured comb honey.

The following offer, made by a man of undoubted financial responsibility (and the undersigned are willing to add their own financial responsibility to his), bears upon the case:

"I will pay \$1000 in cash to any person who will tell me where comb honey is manufactured (*i. e.*, filled and capped over) by machinery; or I will pay the sum to any one who will find machine-manufactured comb honey on the markets for sale."

That offer, made in all good faith, has been standing for years, but no one has claimed the \$1000. The offer still stands, and if the mass of comb honey is manufactured it ought not to be a difficult matter to find a pound—just one little pound—of such manufactured honey through which to obtain that \$1000.

The truth is, that when you find honey in the comb you may be absolutely certain that the bees, not man, put it there. It may vary in color, it may vary in quality; all flowers do not yield the same honey; but it was all stored by the bees.

It ought not to be a difficult matter for any one with the exercise of a little common sense to convince himself that there is no such thing as manufactured comb honey. Take any two samples and compare them. While they may look in general alike, it will be easy to see that there is so much difference in them (variations in the irregularities upon the surface and on the edges) as to show that they could not possibly have been made in the same mould. No two samples of comb honey exactly alike can be found in all Chicago. So they could not have been made by any machinery except that of the bee.

The statement, "Genuine honey has brown coloring around the cells; glucose honey is perfectly white," could only be made by one densely ignorant of honey. The truth is, that all honey-comb, when first made by the bees, is white as the whitest found on the market. If it is left in the care of the bees it becomes dark, and if left with them for several years it will become almost black. All of it would obtain the "brown coloring" simply by being left long enough on the hive. The white is more beautiful to the eye (no better to the taste), so it is taken from the hive generally before the bees have had time to darken it.

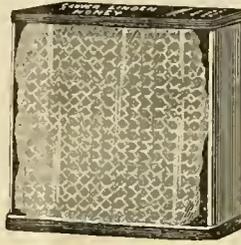

This is the truth about honey.

GEORGE W. YORK,
President Chicago Bee-Keepers' Association.
C. C. MILLER, M. D.
C. P. DADANT.

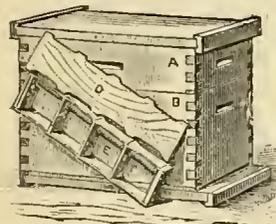

LATER.—A day or two after delivering a copy of the committee's report or statement to the Chicago Tribune, it was returned to us with the following note:

"The Editor of the Tribune regrets that he can not make use of the manuscript, which is respectfully returned herewith. This does not mean necessarily that the article is not meritorious, as on account of the large number of manuscripts received it is not possible to print all."

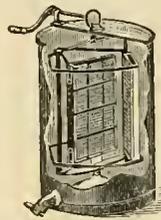

But little comment on this is necessary. The Tribune thus admits that it had room to publish lies about honey, but it has not the space to allow the truth to appear about it!

COMB HONEY.

BEE-HIVE.

HONEY-EXTRACTOR

We hope those of our readers who are so unfortunate as to read The Tribune, will let its editor know what they think of its way of doing things. It has plenty of space for liquor dealers' advertisements, sporting stuff, etc., but declines to correct its own misstatements that are of untold damage to an honest industry.

Washington as a Bee-Country.—A writer in Gleanings in Bee-Culture, who has kept bees in that State for six years, gives a charming picture of Washington west of the Cascade Mountains, where pretty much everything combines to make life worth the living—no hot weather, the average in summer being 70 degrees, seldom below 40 degrees in winter, no mosquitoes, flies or gnats, no snakes except garter-snakes, no wind-storms, no thunder nor lightning, etc.—and then comes this wet blanket:

"But he won't find this a very good bee-country, for the simple reason that the summers are entirely too cool."

Weekly Budget.

MR. FRED H. HUNT'S APIARY appears on the front page this week. He calls it "Wheatridge Apiary," and it contains 90 colonies. Mr. Hunt reports the last season as being not a very favorable one in his locality, the average surplus honey per colony being much below the normal.

MR. A. E. WILLCUTT, of Hampshire Co., Mass., writes as follows, in reference to "stone shade-boards":

MR. EDITOR:—Please send word hastily, to our "hasty" friend "Hasty," to clear his throat for giving the three cheers mentioned on page 9. I will gladly send him a "sample dozen" of the "stone shade-boards" "by mail," if he will send the required postage. They will all be sent in the "flat," and each piece under separate cover; he can "mail them up" at his leisure. A. E. WILLCUTT.

MR. F. W. L. SLADEN, a prominent apian writer in Egglund, writing us Dec. 20, 1901, said, among other things:

MR. GEORGE W. YORK.—
Dear Sir:—I have only just got back to England from a three-months' trip amongst some of the prominent bee-keepers in the Eastern States and Canada. I very much regret I did not get as far as Chicago.....

I was very sorry I was not able to get over early enough to attend the National convention at Buffalo. However, all the American bee-keepers I called upon treated me splendidly, and I had a very good time indeed with them. Amongst those I called on were, Ernest R. Root, Frank Benton, Capt. Hetherington, G. M. Doolittle, W. F. Marks, and C. W. Post and Dr. Fletcher of Canada. I was also very glad to make the acquaintance of Mr. Ashmead, of the National Museum, Washington, D. C., who is deservedly held in very high esteem by the hymenopterists of this country.

Yours very truly,
F. W. L. SLADEN.

It was indeed unfortunate that Mr. Sladen could not be at the Buffalo convention; that he would have met many others that would have been pleased to meet him. He must come again, and remain longer.

Contributed Articles.

Wintering Bees—Indoor and Chaff Hives.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes me from the State of Illinois, saying: "I have kept bees for a number of years, but have lost from one-half to two-thirds each year in wintering. I have always wintered them outside. If I cannot devise a safe method of wintering I shall be compelled to go out of business. I desire to construct a special repository to hold about 100 colonies. Please give me some idea how to proceed—size, etc. Also kindly describe your method of indoor wintering, answering through the columns of the American Bee Journal."

I wish our correspondent had told us whether he used chaff hives, or those having only single walls, for, should it be that he has used only single-walled hives, then the best advice to give would be for him to try chaff-packed hives, for, in many localities in his State, chaff hives succeed fully as well as cellar-wintering, even in the extreme North, and it would seem that, even did he use chaff hives, there must be some

G. M. DOOLITTLE.

fault outside of the hives, which would cause a loss of from one-half to two-thirds of his colonies each winter.

An undue consumption of honey during the period of confinement, brought on by cold weather, seems to be the main cause of winter losses. When bees remain in that quiescent condition, which is required for safe wintering, a pound of honey a month suffices the whole colony, and in such a condition a colony could pass six months of confinement with ease. But if the same colony becomes uneasy from their confinement, these same bees will eat from five to seven pounds a month, and soil their hives and themselves so as to cause their loss in from six weeks to two months from the time they commence to eat so voraciously.

The chaff hive tends to keep the bees in the required quiescent condition, as thereby the bees are surrounded by porous walls, which carry off the moisture passing from the bees' bodies, also retaining the warmth generated by themselves, thus keeping the interior of the hive at a more uniform temperature than is possible without the chaff packing, this lessening the consumption of honey, and enabling them the better to throw off the larger part of the moisture contained in their food so that their bodies can contain the rest till the weather shall become sufficiently warm for them to fly.

In all locations where a chance to fly is likely to occur as often as once in from three to five weeks, I doubt about there being any better mode of wintering than by using chaff-packed hives. But where winter holds sway for from three to five months, with seldom, if ever, a day occurring that is warm

enough for the bees to get out on the wing to relieve themselves from the accumulation necessary, through a constant taking in of honey (as fuel) to maintain the warmth necessary even in chaff hives, then it is best to provide them with a better protection than these chaff hives can afford. And, so far as is now known, cellar (or indoor) wintering, gives the best protection for the bees that there is under such circumstances.

To be sure, the chaff hives have a seeming advantage over cellar wintering, in that the bees are allowed to fly if an opportunity permits during winter, but this is offset by a more uniform temperature, and a consequent decrease in the consumption of stores in the cellar, where the bees need but little food to keep up the necessary warmth they require during the period of partial inactivity which winter compels them to pass through.

From all of my experiences in the past, I would not advise wintering in any special repository constructed above ground, as these are dependent upon the warmth created by the bees for their value, and experience has proven that a number of colonies do not seem to be able to keep up the uniform temperature required in any building above ground, as well as each would do singly in chaff hives. Hence, nearly all now agree, that, where it is advisable to use a special repository at all, said repository should be in the shape of a cellar partially or wholly underground, the latter being always preferable, from the fact that the temperature of the earth, at a depth of five or six feet, is very near the one being right for the safe wintering of bees where they must be confined for four or five months.

A good cellar under a dwelling usually answers the purpose required, and where it is large enough so that a part of the same can be partitioned off for the bees, making the partition, and the floor above, double-walled, the space between the walls being packed with corkdust, chaff or sawdust, (the former excelling anything else where it can be procured), there is little need of looking further for a good place to winter bees. If we do not have such a cellar under our dwelling, and our winters are too severe for bees in chaff-packed hives standing out, then it would be well to build a cellar entirely underground, if possible. And with a rise of ground near the apiary, or having a small hill or mountain near at hand, the possibility is right at hand, as the cellar can soon be "hewn out of the mountain" with a shovel and pickaxe. And the further back in the ground you go the more even temperature can be secured, and the more even the temperature, the better the bees will winter, provided that temperature is somewhere between 42 and 50 degrees above zero.

The entrance to this cellar should be protected by three or four doors, so that the dead-air space between the doors will serve to keep the cold from the outside from passing in too rapidly.

And the above, or last described, is just such a place as I have used for wintering bees during the past 25 years. As to size, allow 10 cubic feet to the hive, the cellar being 6½ feet deep. As to how the inside should be fixed, when to put the bees in, and when to take them out, etc., almost any of the bee-books will tell, to which all interested are referred.

Onondaga Co., N. Y.

Triangular Wooden Comb-Guide—The Original Inventor.

BY M. M. BALDRIDGE.

On page 5 I find the following statement: James La Barre, of Kentucky, "a bee-keeper of extremely keen observation, and one of many practical ideas," but, "he reads little from choice." "It is not generally known that it was he who first conceived the idea of a V-shaped top-bar as a comb-guide. Early in the '60's he accidentally noticed that the bees in a box-hive in building their first comb extended it along a strip of wood which had been nailed on the inside of the box to cover a crack. Quick to see the point, he applied V-shaped strips where he wanted the comb built, and the bees, true to their nature, used these as starting-points."

"In 1877, while visiting the late Chas. F. Muth, he mentioned the matter and asked him to apply the V-shaped bar to the Langstroth hives manufactured under his supervision. It was done, and afterward the V top-bar became a fixed feature of the Langstroth hive. Several have claimed this invention, but Mr. La Barre, being indifferent as to who reaps the benefit of his bee-knowledge, remained quiet, and let them fight it out among themselves."

The foregoing must be a surprise to many pioneers who used the Langstroth hives prior to the year 1860. The writer became acquainted with this hive in the year 1857, and began using it quite extensively in western New York in the spring of 1858, and he does not now remember the time when the V-shaped wooden guide was not used therein. As Mr. La Barre "reads little from choice," this may explain why he now claims to be the original inventor or discoverer of the triangular or V-shaped wooden guide. If he had been a reader of "The Hive and Honey-Bee," by Father Langstroth, prior to

1860, he would have found therein several references and illustrations in the 2d edition, published in 1857, of the triangular or V-shaped wooden guide he now claims as his invention in 1860 or thereafter.

As before stated, the writer first met the Langstroth hive in 1857, and this was at the apiary of the late Moses Quinby. Mr. Quinby had about 90 of these hives in use in his apiary at that time. He took pains to show and explain this hive in detail to me. I don't now distinctly recollect about seeing the triangular guide in the hive at the time, but I believe it was in use that year in all his hives. Later on, and during that year, I found the Langstroth hives on exhibition in Buffalo, and at the New York State Fair. The man who was exhibiting this was R. C. Otis, whose home was then near Kenosha, Wis. Mr. Otis had a colony of bees in the Langstroth hives and was handling and exhibiting the same to the visitors at the fair. He had also empty Langstroth hives on exhibition there, and my recollection is that they were all supplied with the V-shaped top-bars.

The following spring Mr. Otis made my father and me a visit at our apiary in Niagara Co., N. Y., five miles north of Middleport. My father bought the county right to manufacture and sell the Langstroth hive in Niagara county in the spring of 1858, and he had 200 new hives made that year in Lockport for our own use, and to sell to others, and I know that all the hives made that year were supplied with the V guide in the top part of the brood-frames.

So much for history.

Kane Co., Ill.

[Almost the next mail after getting the foregoing from Mr. Baldrige, we received the following from Mr. C. P. Dadant on the same subject:—EDITOR.]

ORIGINATOR OF THE V TOP-BAR.

Permit me to rise for a correction to an article published on page 5, by John R. Schmidt, as to the originator of the V top-bar. This gentleman says that Mr. James La Barre was the first man to conceive the idea of a V top-bar as comb-guide, and states that this discovery was made in the '60's. It is a matter of small consequence, practically, as to the first originator of the idea, but historically I believe we should know the truth of any claim. I believe the idea may have been original with the gentleman named at the date stated, but he was not the originator of the first V top-bar, for this was used by L. L. Langstroth in the '50's, and not only is this mentioned in his book, edition of 1857, but a picture of the frames with triangular bars at the sides as well as at the top is included among the plates, and a special description is made of the triangular piece.

On page 196 of the same work are found the following words:

"The great point to be gained is to secure a single comb on each frame. This I have effected after many experiments, and the device may be applied to any hive so that expense of a few cents will always secure straight combs."

This invention of the triangular bar seems to have been one of the points or features of the Langstroth patent, which cost its owner so much trouble and brought him so little reward, though the invention was revolutionizing the culture of bees.

Not only was the triangular top-bar a feature of the Langstroth hive 20 years before the time, when, as reported by Mr. Schmidt, this idea is said to have been suggested to Chas. F. Muth by Mr. La Barre, but at that same date—i.e., in the edition of 1857—a description is given and a cut, Plate III, Fig. 10, of a gauge for cutting these triangular top-bars on a power circular saw-table. So, granting that Mr. LaBarre may have suggested the idea to Mr. Muth, who suggested it in turn to Mr. Langstroth, (which is much to be doubted), there is an error of more than 20 years in the dates. I trace this to 1857, but if I had the first edition of the book in my hands, I firmly believe I could trace it at least five years further back.

The triangular top-bar is not an absolutely safe guide, but it answers in most cases. A very important point is to have the frames at proper distances from center to center. Although the bees themselves make slight variations, their combs are never closer together than $1\frac{3}{8}$ inches. If the frames are placed too close to each other the bees may build the first comb right, but the next will be thrown out of the center of the bar, and, the regularity being broken, they may jump from one frame to another and curve their combs into all sorts of shapes, after they have once departed from the straight course.

Brood-combs are built with great regularity, as a certain space is needed in which to hatch the brood—a greater distance than that absolutely indispensable being apt to make their

combs too difficult to keep warm. On the honey-combs, however, they show much less regard for correct measurements, and, especially at the end of a season, they will readily lengthen out the cells of the outside combs to a very disproportionate size.

Thus, if we use only the triangular comb-guide to secure straight combs in the frames, we must be very careful to keep proper distances. We have always been inclined to give the bees ample room, and, for this reason, we follow Quinby in his method of putting the frames $1\frac{1}{2}$ inches apart from center to center.

While ransacking our bee-books for information on the subject, I see that Bevan, in his book on the honey-bee, dated 1838, recommended putting the "bars" closer together in the center of the hive than at the outside. He had evidently noticed what I mention here, that the brood-combs needed to be closer together than the honey-combs, and for that reason found it advisable to place the latter at a greater distance from each other. He made his bars $1\frac{3}{8}$ inches in width, and placed the center ones seven-sixteenths of an inch apart, while the outside ones were placed nine-sixteenths from each other. This made the distance one and nine-sixteenths from center to center on the brood-combs, and one and eleven-sixteenths on the storing-combs. This distance seems too great, and it is doubtful that there could be much regularity in combs built on those bars; but, at that time, the movable idea had not yet taken hold of the bee-keeping world, and the men of that day had not the remotest idea of the great steps that would be made in the next 60 years.

Debeauvoys, who had evidently foreseen the results that might be achieved with a hive that could be taken to pieces without injuring the combs, had made a failure of his discovery because he had left out the anti-propolizing idea—the prize feature of the Langstroth invention.

Before the invention of the wax sheet stamped with the imprint of the cells, which later gave rise to the modern comb foundation, Mebring had devised a stamp to be used on the underside of a flat top-bar which made an impression of the outline of the comb. This impression, afterwards filled with beeswax, was said to succeed well, but was soon superseded by what was known as a *comb-guide*, made of a thin strip of melted beeswax on the underside of the frame. The latest method is a narrow strip of foundation wedged into a groove on the under side of the top-bar. This is the surest of all guides, barring a full sheet of comb or of foundation. But the triangular top-bar, which makes the subject of this article, is still used in many hives, and will probably be used as long as apiarists want a cheap comb-guide.

Hancock Co., Ill.

C. P. DADANT.

A Case of Bee-Fever—He "Had It Bad."

I have been a subscriber to the American Bee Journal for the past two years, and very little could I do without it. I find it a great help to me at every turn. I commenced to keep bees about five years ago, and have had all kinds of luck since then with them—good, bad, and indifferent. They were at all times a source of amusement to me, if not one of profit, having honey to sell but once in all that time (1901). But a sweet time it has been at the table all that time. Honey, honey, honey, three times a day, and sometimes oftener. Oh, no, not from surplus, dead colonies being the most frequent source of supply, until the last season.

My first start was made by trading poor debts for poor bees. In this way I got three colonies, which were neither a pleasure to the sight nor a profit to me, but they nevertheless gave me a "swell" time, while they lived, and a sweet one after they died. No Irishman ever had a longer or finer wake. We feasted them, at their expense, all winter and well into the spring.

The next year I had better luck, trading bad debts for better bees, getting three colonies this time, which built up strong for winter, but no surplus yet. One of these died during the winter, leaving a hive full of honey. I also captured an Italian swarm, in the timber, late in July, which, although a poor year, filled a ten-frame hive—for themselves—before frost. This strain of bees I still have, and they have never failed to yield me excess honey, except the first year.

Up to this time I had only a mild case of "bee-fever," but the next spring, with the return of warm days, the symptoms became more pronounced, and I developed the itch (to be a shining light in beedom, by some discovery or invention—a dangerous symptom, financially), which, I understand, is very apt to develop early in the disease. I had already subscribed for the "Old Reliable," and got "ABC of Bee-Culture." That was

my undoing, and, incidentally, rather hard on the bees. The fever raged higher and higher; I became delirious; visions of golden queens floated before my eyes. I began to believe the advertisements of the queen-rearers, even so far as to send my good money to them. I divided and subdivided, Italianized and Carniolanized, formed nuclei and reared queens. Bee-ideas chased bee-ideas, up one side of my brain and down the other, most of them too large to get out the natural openings for ideas, except so misshapen as to be unrecognizable. Smoking became a fixed habit with me; I would not introduce my friends without first smoking them, for fear they would quarrel; nor open a conversation without it, dreading being stung (by a sharp tongue). In fact, I had smoker with me constantly—if not a bee smoker, a pipe, cigar, or cigarette.

I was also afflicted with hives, as the season advanced. The Dadant, the Danzenbaker, the Heddon, the Langstroth, the chaff and the Simplicity, and others that were not so simple—the six, eight and ten or more frame, deep and shallow, box, barn and palace, swarming and non-swarming hives, in endless procession, until I developed repeated attacks of arthritis. Things went on in this way, getting worse and worse. Ideas of single, double, quadruple, sextuple, etc., had their turn, until I must have a bee-house large enough to hold all my colonies. Having a small building not in use, I finally finished, after much study and expending some money, a model bee-house with accommodations for 14 colonies. I moved my bees in, not without some objections from the bees, however, which did not seem to appreciate the efforts I was making to convert them from their primitive ways of secreting themselves in any old place, to the more enlightened ways of domesticity, and with the same degree of bigotry, shown by some heathen tribes, to civilization, fought to (with) the bitter end.

I moved 12 colonies to their new home, and at first everything went along swimmingly, but winter came, and it got too cold to swim, or something else happened; at any rate, they began to die a slow and lingering death. First one colony died; we used what honey they had left. Then another would, by that time, become sufficiently ripened by death to be fit for table use. Death, the grim destroyer, continued to wreak vengeance until the gentle zephyrs of spring came, when, on examination, I found I had but one colony to occupy my fourteen-room bee-house, and they were showing signs of lonesomeness.

Strange to say, with the death of the bees, the fever began to abate, until it was almost gone, and I am convinced that if the last colony had died the disease would have been cured. But, with the return of spring, the symptoms began to get worse, and I passed through all the stages again, with but little better results than before, from a honey standpoint. I increased to twelve colonies again by fall, four of which I managed to pull through in spite of the bee-house. About this time, I might say that a house fell on me, and I took a tumble, that, perhaps, the bees did not want to be domesticated to the extent of living in an improved flat. So, early in the spring, I moved them back into hives (the four which were left), and they showed their appreciation by producing 380 pounds of comb honey, and increasing to twelve colonies once more.

The disease has subsided into a chronic condition, which I have been told is incurable, and is subject to relapses each spring, until death relieves, not only the sufferer, but also those afflicted with the sufferer.

The history of this disease dates back into the earliest times of which we have any writings, and, as far as I can find out, it has never received sufficient recognition to have a scientific name given to it. A careful study of the disease will show that all symptoms lead to irritation of the bees, and, as irritation, unless relieved, always leads to inflammation, I would suggest a combination of the two words *apis* (bee) and *itis* (inflammation), which would make the word *ap-is-i-tis* to be the scientific name of "bee-fever." This may not be scientifically correct but it would elicit sympathy for a sufferer of the disease where it now provokes mirth.

Thanking you for your kind indulgence, in listening to the plaintive lamentations of an apisletic,

I am, yours, etc.,

C. M. B.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Convention Proceedings.

Report of the Ontario Bee-Keepers' Convention, Held at Woodstock, Dec. 3, 4 and 5, 1901.

REPORTED BY R. F. HOLTERMANN.

The annual meeting of the above association began Dec. 3, at 2:30 p.m. Members of the association had been gathering during the early part of the day and spending their time in discussing subjects of interest to themselves. Pres. Newton opened the meeting by calling upon Mr. Craig to lead in prayer. The minutes were read by Secretary Couse, and at the close a committee was formed to investigate an omission of names of the officers of the Ontario Bee-Keepers' Association during the joint meeting of the International and Ontario, in Toronto, at which time R. McKnight was president.

President Newton's Address.

Ladies and Gentlemen:—It is with pleasure that we meet again in convention. Another year has passed, and we are here to talk over the past and make plans for the future. The first of the new century has been very profitable to most bee-keepers, not only by the good flow of honey but by the good prices which have been obtained for our product. In fact, I may well say that we have to-day as good prices as we had ten or twelve years ago. Surely, this is encouraging. The quality, as far as I have been able to judge, has been extraordinary.

Now as to our expectations for next year's crop: Bees in most parts have gone into winter quarters with good, ripened stores, which means much towards good wintering; and the roadsides are massed with white clover, and judging from this we may well look for a big crop in 1902. I doubt not, the most, if not all of you, have come here with the hope and expectation that this would be one of the most enjoyable and profitable meetings ever held by our Association. To make this a veritable reality can best be accomplished by each one taking part in the discussion, and so contributing his or her portion of information for the general good.

It was with deep regret that we learned the news of the sudden death of our ex-president, Dr. Thom, who held the position of president in the year 1884, and was much esteemed by all members of the Association. But these calls are but warnings to each of us that some day we, too, shall be called hence to our reward.

It will be remembered that at our last annual meeting a motion was passed to the effect that the Association deem it advisable to make an exhibit at the Pan-American. The matter was brought before the Ontario Government, and they decided to help us. At our executive meeting in May it was my pleasure to be appointed to go to Buffalo to install the exhibit. We made a generous call to bee-keepers of the Association to help us. We succeeded in getting a good supply of extracted honey, but not a great deal of comb. However, the extracted and comb were of a very fine quality. Our display was not large, but was greatly admired by all visitors. I may note a few remarks gathered by passers-by and entered in my register book:

"Canadian honey—what part? Ontario. Ontario is all right." "Magnificent exhibit." "Very artistic exhibit, and very clear honey." "Grand honey and beautiful exhibit; I'm glad I came upstairs to see it." "O, look at the purified honey! Isn't it fine? It's a very pretty show-up, ain't it?" "O isn't it fine? The Canadians may be slow, but they know how to put up a honey exhibit." There were only 21 exhibitors in all for the judging of awards. We were awarded the Gold Medal for the collective exhibit of honey, and 33 diplomas of honorable mention for our exhibit. I have to thank the members who so willingly aided us in making Canadian honey famous at the Buffalo Pan-American.

While at Buffalo I had the pleasure of attending two sessions of the National Bee-Keepers' Association, which so kindly extended an invitation to our society. I was pleased to see so many Canadian bee-keepers present, and enjoying the meeting. Every one reported a profitable convention.

During this year, also, Canadian honey has been represented at Glasgow, Scotland, being taken from the exhibit which was at Paris, in 1901; but I have been unable to find out what awards were given.

One of the questions at our last meeting was. Would it pay us to exhibit at Buffalo, knowing we had a duty of one and two-third cents per pound to pay to gain a market in the United States? I feel safe in answering it now, that I believe it has paid our Association. First, by showing the world that we can produce a very fine quality of honey in Canada—in fact, second to none; and that we as Canadian bee-keepers take a pride in our pursuit to put our honey tastefully on the market. I believe if we push for a market in the United States, even by paying the duty, we shall gain it, because American people seem to realize that Canadian laws are far more strict than their own. Our pure-honey bill is all right: let each member of our society try to enforce it, and by doing so we shall make a market for our product.

It will be laid before you for your consideration, the advisability of making stronger the bill which we now have in regard to spraying of fruit-trees while in bloom. We all know it is a serious question in some parts of the country to bee-keepers; let us all put our shoulders to the wheel and try what can be done.

The inspector of apiaries, so far as I have been able to learn, has been attending to the duties of his department in a manner which I trust will be satisfactory to all. His report will, however, be submitted for your consideration. My attendance at the exhibit at Buffalo, and meeting with the many bee-keepers of Ontario who do not belong to any bee-keepers' association at all, has brought me to think that they do not realize the advantages given to the members of the Ontario Bee-keepers' Association. I would strongly advise that a small pamphlet be published setting forth the workings of our society and its advantage to bee-keepers, and have a copy placed in the hands of every bee-keeper in this land.

The matter of forming a guild, or exchange, will be brought to your notice by Mr. Andrew Patullo, M. P. for North Oxford, who has so kindly consented to take that subject for the basis of a few remarks to us.

In conclusion, I thank you for the confidence reposed in me a year ago in placing me in the position I now occupy. I trust you will all assist in making these meetings pleasant and profitable to each one of us, for in union alone there is strength.

JOHN NEWTON.

J. D. Evans, in reply to the President's Address, said he was at a disadvantage, not knowing what was about to be said. He wanted to praise Mr. Newton for the excellent and responsible work he had done this year, as president, especially in connection with the Pan-American Exhibition; he had managed to do the thing economically. He thought it would be an advantage to make the law in connection with spraying more stringent. In his own district he had no trouble—the people were anxious to have bees about them. They found it an advantage in fruit setting; even this year they had apples when others had none. More educating should be done, and plenty of it. Doctor Fletcher's address in connection with the value of bees to the fruit-grower had been circulated, and more work in such directions was desirable.

Rev. W. F. Clarke congratulated the president upon his good work; he was pleased to hear of the success of the exhibit at the Pan-American. If Canadians would do justice to themselves they would hold their own with any country.

A resolution of congratulation and thanks was passed to Mr. Newton.

Mr. Newton said he forgot in his address to mention that the thanks of the association were due to Mr. Miller for supplying glass packages to help make the Pan-American exhibit attractive. A vote of thanks was then tendered Mr. Miller.

FOUL BROOD.

Prof. F. C. Harrison, bacteriologist, who has recently returned from a year or more of study at the leading bacteriological institute in Europe, gave the result of his work during the past season with foul brood. He stated that the work undertaken with foul brood at the Ontario Agricultural College during the past year has been rather limited. The only thing attempted this year was some means of destroying germs of foul brood in combs. One remedy had met with good success; that was, disinfecting combs and hives with the vapor of formalin. Pieces of comb had been taken containing wax and comb several years old, dead brood, capped brood, and cells of honey into which had been put foul-brood germs. These were placed in a box the size of the ordinary hive, the lower entrance in the box having been plugged, leaving only sufficient room for the entrance of a rubber hose coming from the disinfecting apparatus, similar to that for disinfecting plants, etc. The formalin gas apparatus was as follows:

An alcohol lamp, and upon it a reservoir with a 40-degree

solution of formalin. When the alcohol lamp was lighted the gas was soon generated. At the top of the box a one-half inch opening had been left; out of this the atmosphere passed as the box filled with formalin gas. When the box was full the gas would pass out of the upper orifice, detected by the odor. The apparatus was then withdrawn, both openings plugged, and the comb left under the influence of the gas for one hour, after which exposure no growth was obtained, four tests in all having been made. The honey-cells known to be affected gave no growth. The pressure obtained in generating the gas might in a measure account for the results. This cure would be practical in a large apiary. Other appliances used in disinfecting would answer.

Prof. Harrison also mentioned that some years ago he had taken a lot of cells or spores and placed them on glass in semi-darkness. He had tested them about every six months and had made a test very recently. Although where the cells had been placed nearly four years ago and exposed as per above, the last test showed they were still alive, showing that the spores were extremely resistant. In conclusion, Prof. Harrison said he hoped that the method of disinfecting he had given would be tested during the coming season.

Mr. Evans—I believe that this is one of the most important statements yet made in connection with foul brood.

Mr. Hall—Are the capped cells you mentioned, capped larvae, or capped honey?

Prof. Harrison—Capped larvae.

F. A. Gemmill—I think that the method given should be tested, and, if found better than the present, adopted.

Mr. Hall—We often have doubts about the surplus combs on infected hives, and other combs; these could be disinfected in the method given. I am very glad to hear the report.

J. K. Darling—How about bees and brood?

Prof. Harrison—Any in the box would, of course, suffer the same fate as the germs.

Mr. Evans—Would it not be well to shake the bees off the combs, then treat the combs and return the bees? An experiment in this direction might be tried.

R. H. Smith—Does the treatment make the combs objectionable to the bees?

Prof. Harrison—It does not injure the most delicate fabric.

Mr. Smith—Will the bees, if there are any dry scales, remove them from the base of the cells?

Mr. Gemmill—Do you think, if the scales were dry, they would be disinfected in the scales?

Prof. Harrison—Those I tested were moist, and it would doubtless be better to moisten them.

A. Laing—Why not turn the bees back to the combs, and after ten days repeat the operation? The bees would then be practically clear?

Prof. Harrison—As long as I fed carbolic acid, although growing millions of spores, no foul brood could be produced; but as soon as I left off feeding, foul brood developed.

Mr. Holtermann—It would not do to return the bees to the combs, and after ten days repeat the operation, because the bees, when disturbed, take up perhaps infected honey and return this to the comb, and there is no guarantee that they may not repeat this operation the second time.

A Member—What about McEvoy's method?

Mr. Holtermann—The combs are taken away, and the bees cannot store the infected honey in cells. I am afraid that bee-keepers, in their attitude, are rather inclined to despise scientific help and investigation—not in words, perhaps, as much as in attitude. Remedies and results are given such as this, and yet bee-keepers go on just as before.

W. F. Clarke—No wonder bee-keepers despise science when the inspector has drilled into them to despise science, and they are taught to hold to the theory of spontaneous generation, which no scientist to day holds.

Mr. Clarke read the Cheshire remedy, and wanted to know why this remedy had been ignored on this side of the Atlantic. Was it national jealousy, personal feeling, or what?

Prof. Harrison said if we will read Bulletin No. 12, issued by the Ontario Agricultural College, we will find considerable work has been done in this investigation. Carbolic acid will not destroy the germ; 2 percent solution will not destroy the germ in six days; 1 in 500 will prevent the germination of spores. The carbolic acid, in the strength mentioned by Mr. Cheshire, will not kill the spores, but may prevent their growth. Formic acid has a much greater value in disinfecting. Some honeys have more formic acid than others; buckwheat has almost twice that of clover honey. Bee-keepers had even noticed the sting more severe when the bees worked on buckwheat honey. He (Mr. Harrison) had spent several weeks with Mr. Bertrand, in Switzerland; he had also studied the disease in Austria. In those countries they had a race of bees which had a natural immunity from foul brood; for this

reason, he believed, the bees here, not being immune, the remedies which were a success in Europe were not such in this country—the bees were not immune to the same extent.

Mr. Clarke—Is phenol and carbolic acid the same thing?

Prof. Harrison—Yes.

Mr. Clark—Was 1 to 500 not a success?

Prof. Harrison—Only as an antiseptic; not to destroy the germs.

Mr. Holtermann—I would like to ask another question: Under what conditions does the germ grow again, which has been treated with carbolic acid 1 to 500?

Mr. Harrison—When you cease feeding. As long as you feed it is all right. The bees object to carbolic acid; formic acid is Nature's remedy. I may say we are always pleased to conduct at the College investigations along this and other lines. With the strength of staff we have we cannot conduct experiments for individuals, but where for public good, we will be pleased to carry on investigations. You help us by sending material, and we will help you with our appliances, and perhaps increase knowledge.

J. E. Frith—Have you been working on foul-brood experiments just for one year?

Prof. Harrison—No, for four years.

PICKLED BROOD—OTHER MATTERS.

The question of pickled brood was brought up, and it was thought well that the disease in New York State be investigated.

It was decided that samples be sent to Prof. Harrison, Ontario Agricultural College, Guelph, Ont., Canada, who promised to investigate them.

Wm. McEvoy, inspector of apiaries, suggested that bees be sent to Mr. Harrison to measure the length of their tongues.

J. B. Hall welcomed the Ontario Bee-Keepers' Association on behalf of the Oxford Association; he spoke of the incorporation of the Ontario Bee-Keepers' Association, the Colonial and Indian Exhibition, the Foul Brood Law, and eulogized Mr. McEvoy and the work he had done. Another important work was the Spraying Act passed through the instrumentality of the Association; then the Pure Honey Bill. The Chicago Exhibit, and that at the Pan-American, were also a success, and had done much to educate the local public and other nations as to Ontario honey.

The president called on Mr. Evans to reply, who responded thus:

"I am very glad to come to Woodstock; I knew the Ontario could teach the Oxford Association nothing, but we expect to learn a great deal from the Oxford [laughter]. We are quite ready to accept all the good things Mr. Hall has said of the Ontario Association. I think much has been done, but the end is not yet."

(Continued next week.)

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Dividing, or Artificial Increase.

What is your plan for artificial increase? I don't want any natural swarms—I can't manage them—and my family are too afraid of them to give me much help. EAST.

ANSWERS.—If you had asked for a plan I might have answered you readily, but when you ask for *my* plan you make the question more difficult. I have no plans of my own, and do not always follow the same plan, taking just what seems to be the most convenient at the time. Probably the nucleus plan is followed more than any other. A nucleus is formed and a ripe queen-cell given to it, and then when the queen gets to laying, it is strengthened by means of a frame of sealed brood. If the nucleus be started sufficiently early, no aid will be needed to have it built up sufficiently strong for winter.

If you will take the trouble to send the question on a postal towards the last of May, I shall be glad to go more into detail, and advise you just what to do to start your cells and form your nuclei.

Transferring—Paper Trimmings for Packing.

1. In the Heddon short method of transferring, what would you do about the queen that will be reared in the old hive while waiting 21 days for all the brood to hatch? According to my count, a new queen will be hatched, and have quite a little brood, before the 21 days expire.

2. How will paper trimmings from a book-binding do for packing bees for winter? ILLINOIS.

ANSWERS.—1. The bees will take care of that matter to suit themselves. If the old queen is yet in full vigor, the young queen will likely be destroyed, otherwise she may be superseded by the young queen when the two parts are united. If you wish to save both queens, of course you can interfere.

2. I can only guess. I should think there would be danger of their being packed a little too solid; but if sufficient pains were taken to loosen them up they might be all right.

Feeding a Mixture of Sugar and Honey.

I have a colony of bees in a box-hive, given to me by a neighbor, and it is short of stores. There is no way to get to them from the top of the hive, and I have been wondering if I could not carry them into the house-cellar, where the thermometer registers about 40 degrees, turn the hive bottom-side up, and lay upon the lower end of the combs a roll of sugar and extracted honey (mixed), leaving the hives in this position until spring. NEW YORK.

ANSWER.—Your scheme ought to work all right, only it would likely be better if the cellar were nearer 45 degrees. There is some danger that you will use too much honey and too little sugar—in other words, your candy will be too thin. If you find it so thin that it will not stay up in place (and very likely you will find it becoming thinner after it is given to the bees), take the candy away and work some more sugar into it so as to make it thicker and dryer.

Hive for Producing Extracted Honey.

I desire to run my bees for extracted honey and would like to know if you consider it any advantage to have a hive wider than the 10-frame. Can swarming be kept down better with a wider hive? NORTH CAROLINA.

ANSWER.—I don't know for certain, but I think there might be less swarming with a hive larger than 10-frames. It would, of course, be more unwieldy, but you might not care much for that. It would be a good plan for you to try the larger hives on a small scale, carefully comparing them with the 10-frame hives, and then you would be able to tell better which would be best for you.

Early Stimulative Feeding.

I have four good, strong colonies of bees with "red clover" queens, and want to divide as far as practicable and have the colonies so formed *all* in readiness for the honey-flow the last of June. I expect to feed liberally of both sugar and meal.

1. How early in the winter is it advisable to begin stimulative feeding?

2. Are granulated sugar syrup and say, rye meal, all the food necessary? What do you recommend?

3. How far do you consider it safe to carry the dividing, and at how early a date?

It appears to me that the further (and the earlier) they are divided, the more good, strong, young queens we will have laying.

But where is the principal danger?

ANSWER.—1. Don't try stimulative feeding in the winter on any account. Wait until the bees are flying daily.

2. Some think sugar syrup as good as honey for breeding purposes, while others think it very inferior, and only to be used when honey cannot be had. Probably no one thinks rye meal or any other substitute so good as natural pollen. If possible to have good honey and pollen, I should prefer it to anything else.

3. If it appears to you that the earlier you begin and the more you divide, the more good, strong, young queens you will have laying, I'm afraid it appears wrong to you. You can begin so early that your queens will be of little value, and if you divide too early or too much you will be the loser. As far

north as you are (41 degrees), if you get young queens to laying before June they are not likely to be of the best.

If you begin stimulative feeding in the winter, or too early in the spring, you may have fewer bees than to let them entirely alone. Indeed, it is possible to ruin a colony entirely by injudicious early interference in the way of feeding. If your object is to get as much honey as possible from the white honey harvest beginning in June, it will probably be best for you to do no dividing before the time of the harvest. Something, however, depends on the strength of the colonies in the spring, and upon the weather at that time. The thing I'm afraid of is that somehow you've got it into your head that by beginning very early to feed, and using feed enough, you can increase largely your number of colonies, and at the same time your harvest of honey. Please set that down as a serious error. Stimulative feeding is a two-edged sword that is not very safe in the hands of a beginner, unless he be of a very cautious turn. Your safe plan is to let it alone, if not entirely, at least till weather is warm enough for the bees to fly daily, and it will be a safer plan to do no dividing till about the time of natural swarming.

Was It Foul Brood?

I now have 23 colonies from 10 that I bought last spring. I had one colony very weak when bought in April: it didn't do well all summer; it was in a box-bive. In August I transferred it to a Langstroth hive, and noticed nothing wrong in the appearance of the bees or brood. Sept. 28, after I had all fixed for winter, this colony swarmed out. I didn't know it for a week, and I then discovered it was gone, and the other bees robbing the honey. I shut it up at once and afterwards examined the hive and brood. The brood was all capped, filled regularly, no vacant cells, but looked entirely natural; but on opening the cells there was a rotten mass, attended with some odor quite offensive. I burned the frames, combs, brood, honey and all, in my house furnace.

1. Was that foul brood?
 2. If so, can I hope that the bees that robbed part of that honey will have it consumed by winter use before brood-rearing in the spring, and consequently escape inoculating their brood and hive with the disease?
 3. If not foul brood, what, probably, was it?
 4. In view of all the facts, what should I do, and when do it?
- My other colonies are strong, and have lots of honey, and are well-packed in winter-cases, filled with planer-shavings, and a super full of shavings on top of the frames. OHIO.

ANSWERS.—1. Possibly, and possibly not.

2. If it was a case of foul brood you may pretty safely expect the disease to be carried to the robbing colonies.

3. I don't know. It is just possible there was no disease at all.

4. Let the bees alone till warm weather. In the meantime study up the subject carefully in your books and back numbers of bee-papers, and thus you will become so well informed that when warm weather comes you will be well armed to meet the foe, if foe it proves. Don't omit Dr. Howard's pamphlet on foul brood.

Can Bees Hear?

Do you think bees can hear?

SUBSCRIBER.

ANSWER.—Opinions are divided. Some authorities whose opinions are deserving of consideration insist that there is no evidence that bees can hear. As proof that they do not hear, instances are cited in which whistling and loud noises close to the bees have failed to make the bees show in the slightest degree that anything had been heard, while a slight touch upon the entrance-board would bring from the bees an immediate response. Such proofs, however, are only negative. If twenty men should testify that they had not seen Smith kill Jones, their testimony would be outweighed by the testimony of one man who had actually seen the murder. That a bee shows no sign of having heard a sound can not be considered proof positive that it has not heard the sound. Sounds may be produced in which bees have no interest, and no heed paid to them, while sounds to which we might pay little heed might produce a lively impression on them. If you were taken by a band of brigands, and they should state in the most positive terms, but in language unknown to you, that you are to be killed forthwith, you might pay little heed to it, and the brigands might say you were deaf; but if you were to hear the

APIARY OF A. KUBIN, ST. CLAIR CO., ALA.

same thing spoken in your own tongue, the brigands would be likely to say that your hearing was acute.

If you put your ear to a hive on a still summer evening, the great variety of sounds heard will awaken the inquiry, "Why do bees make all these noises if they cannot be heard?" But that is no positive proof that they do hear. Some years ago when one of my colonies swarmed with a clipped queen, I moved the old hive to a new place; but the bees of the returning swarm found it and began to enter, making as usual a loud call. I moved the hive to a new place, and the bees soon found it. Then I put it on a wheelbarrow and started to travel with it; but whenever I stopped the bees seemed to hear the call and began to cluster about the entrance. That was kept up for some time, and I can hardly understand how the bees found that hive unless they heard the call. It will not do to say they recognized the hive by sight, for if the same hive were moved, at a time when no call was made, only to the distance of six feet, but beyond another hive, the bees would never find it. Yes, I think bees can hear, but I don't know.

Have They Enough Winter Stores?

I have seven colonies of bees this fall. Two of them are from the woods; one of these is in the chunk yet, the other I put on dry combs and the brood. Then I fed them 11 quarts of half water and half sugar, well stirred. Will they have enough till warm weather? WISCONSIN.

ANSWER.—If I understand you correctly, you gave them 5½ pounds of sugar. That would be equivalent to about 7¾ pounds of honey, and it is considered wise to have about 30 pounds of honey for out-door wintering, and 25 for the cellar.

Method to Keep Down Increase.

I do not wish any increase. My queens are all clipped. I work for comb honey, and want to re-queen all my colonies. How would it work to have a supply of virgin queens on hand at swarming-time, and when a swarm issues destroy the old queen, clean off all the queen-cells in the hive, and when the swarm returns drop a virgin queen among them? Do you think that would put an end to swarming? MICHIGAN.

ANSWER.—Very likely it might prove successful in most cases. A virgin queen would be kindly accepted if very young without any difficulty, but there might be trouble if she were several days old. At a guess, I should say that in some cases the bees would start cells again. Please report after you have experimented.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

REVERSIBLE WALL MAP

—OF THE—

UNITED STATES AND WORLD,

WITH SPECIAL INSET MAPS OF

China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,

Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. **Very useful in every Home and Office.**

66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued.

No Home or Business House should be without it.

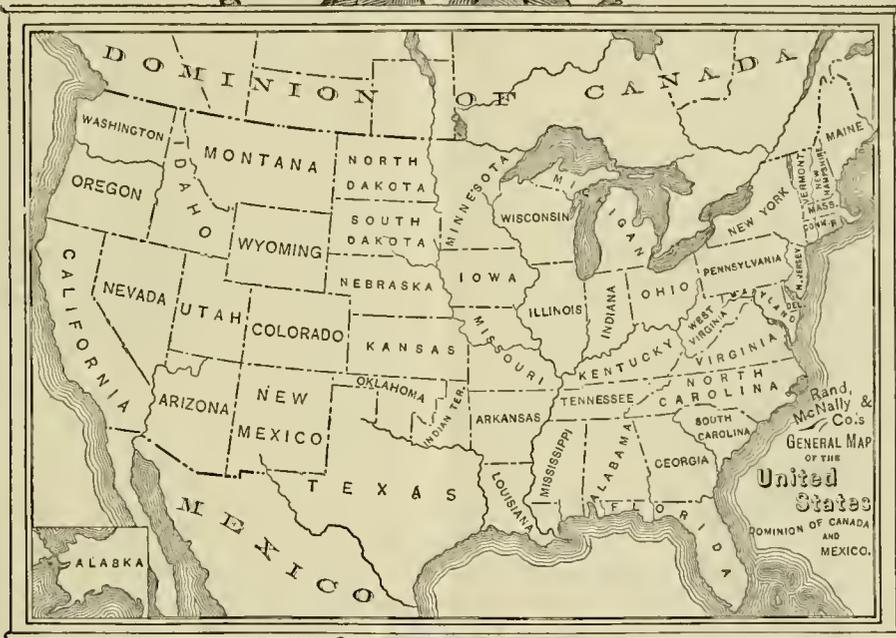

The xx Plates

are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance

a salient feature of this map not approached by any similar publication.

A xxx Marginal Index

is one of the invaluable features.

It gives an alphabetical list of countries, their location on map, style of government, population, area, products, minerals, imports, exports, etc.

It has been pronounced a **xxx Photograph of the World**

The 1900 Census xxx of the largest American Cities is given.

One side shows a grand map of our great country, with **counties**, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, capitals, rivers, mountains, products, business, etc., a veritable photograph of the UNITED STATES AND WORLD.

The map is printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

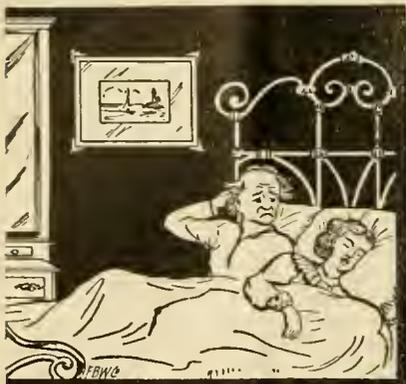

1901 EDITION.—Every reader should consult it every day. The plates show all the new railroad lines and extensions, county changes, etc. Especial attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahama Islands.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. **The Inset Maps** are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps on one sheet, all for only \$1.50, sent by mail or prepaid express; or we will forward it free as a premium for sending us **Three New Subscribers** at \$1.00 each; or for \$2.00 we will send the Map and the American Bee Journal for one year. Address,

GENERAL ITEMS

Bees Seem All Right.

My bees are in the cellar, and seem to be all right. The temperature is from 45 to 48 degrees.

—GEO. A. OHMERT.

Dubuque Co., Iowa, Jan. 6.

Bottom Frame-Spacers, Etc.

I have been a subscriber to the American Bee Journal for nearly two years, and I am much interested in all it contains; but I do not remember to have seen anything written about two things, of which I claim to be the originator. First, it is a piece of tin so notched out as to allow the brood-frames to fit to the notches, which piece is nailed to the bottom-board about half way of its length. This arrangement holds the frame steady, and they can't by any means get irregular, and is a very valuable convenience.

The next is this: Instead of using a honey-board on top of the supers, I have adopted a piece of crocus or gunny-sack cut in shape to fit over the super, and to hang down an inch or so on all sides on the outside. Of course, the bees will stick it to the top of the sections or super-frames—so they will a honey-board; but with my arrangement you can easily pull it up when necessary, and look in, and replace it. With the honey-board you have to pry, and pry, and split, and worry considerable before you can get it up, and very often split it before it will come up. It has another advantage: It can be managed to act as a ventilator in the hot summer, by placing an inch strip of wood over the top, and let the top of the hive rest on the strip. This gives a gentle draft of air from above, and not too strong to interfere with comb-building. Has any one tried these two arrangements?

—JOHN KENNEDY.

Adams Co., Miss., Dec. 12.

[Notched arrangements of wood, wire, and perhaps tin, for holding bottom-bars in place, were in use perhaps 40 years ago. Covers or gunny-sack or other cloth were also used to some extent some years ago.—EDITOR.]

A Woman's Report for 1901.

It was a poor year for bees; late spring, then a drouth, then too much rain, and then no fall flow of honey. Some colonies did well for me, but I did not average a dollar to the hive. I sold all the honey I had at 15 and 20 cents a pound, and could have sold more to my customers if I had had it.

All the bees have plenty of stores for winter, unless it is one colony that I was moving to another part of the yard, and noticed it felt rather light. I will make candy and keep it under the Hill's device, and under the cushion, so that, if they should be short, they can get it. One of the grocerymen last fall gave me a lot of candy that had become unsalable. I was afraid of the coloring, so I kept it until spring and used it as I have spoken of before. When I took out the cushions they had it all used up, and such a mess of bees as I had; they made a lot of comb in the sections in the fall, but could not get honey to fill them, so I will have nearly a hundred to commence with in the spring, the most of them full of comb.

I have not seen any one hive bees as I do, and as I get so many helps in the American Bee Journal, I feel that it is my duty to give others the benefit of my experience. So before swarming-time next season I will give my way of living them.

I get the sections cleaned, and those that have not much honey in them I take a super and put in four section-holders and put it in a hive which I think has a little comb, and uncap where the honey is, and put them in on the section-holders, and cover it up; the

bees of that hive will clean them out nicely, and not tear the comb any. When cleaned out I take out and put in more, until all are done, and there is no danger of robbing; the other bees do not know anything about it. I kept two sections on the porch to try that way, but they tore the comb considerably; but on the top of the hive they did their work nicely. I put some on two hives, but one can put them on as many hives as may be desired.

I could not get along without the American Bee Journal. There have been two or three articles that have been worth the price of a year's subscription. I look for it every Friday, and have to look at all the headings, however busy I am. I credit whatever success I have to the Bee Journal. One of my neighbors has four colonies, and she did not have a bit of honey; she feels she can not afford to take the Bee Journal because her bees have not been profitable to her. She will face the hives to the south, and some of the combs melted down. She did not have any shade. I shaded mine on top, and on the sides where I did not have other shade; then I have tall evergreen trees on the north side and partly on the west, to keep the cold winds off in the winter.

Mr. Andrew M. Thompson, of Allegheny Co., N. Y., wants to know whether any one can show a better record of wintering bees than he can. I am not a gentleman bee-keeper, but an old lady, 73 years old Dec. 16, and as I had not kept a record of my bees I can speak only for the past two years. I keep them on the summer stands, and have not lost any the past two winters, and I do not think I lost any the winter before. I put on top the brood-frames a Hill's device, a piece of sacking over that, then a good cushion, most of them filled with cork-trimmings, the rest with maple leaves. I leave the entrance the same as for summer, the length of the front. To keep out mice, I put a strip of wire two inches wide in the front, which allows the bees to go in and out at will.

I have always had my hives face east, and leave the same in the winter. I set a board slanting in front, and when it snows I go to them all and draw the board out at the top, and brush the snow away and lean it back against the hive at the top. On some I have boxes, or frames, I should say, with no top or bottom, large enough to set over the hive, so I can pack leaves or dry grass between the hive and box, then a cover of boards with tar paper. Some I have fodder standing around three sides, and a little around the front corners and the tops over the hives. I have most of them in pairs, with fodder around them, and dry grass or leaves between.

I have 16 colonies, and all nicely packed for winter. I finished the last outside on Thanksgiving Day. I have tried the tar paper as I read of in the Bee Journal, letting it come to the ground, then packed grass and sod all around on top of that a little ways, so the cold wind can not go under the hive. They are set on frames 6 or 8 inches from the ground. I pack the hives, as I said, with the tar paper around before I set up the fodder to keep the cold from going under. The box-frames are banked up the same (not at the entrance, of course), so they are better cared for this winter.

I buy dry-goods boxes to use for my bee-business, and knock them to pieces, as they are cheaper than lumber. My means are limited, and I am alone, and have to do everything myself. If I live till spring I may report what success I have this winter.

If the foregoing finds a place in the "Old Reliable," Andrew Thompson can judge for himself whether or not this is what he asked for.

SARAH J. GRIFFITH.
Cumberland Co., N. J., Dec. 2.

An Old-Timer's Methods.

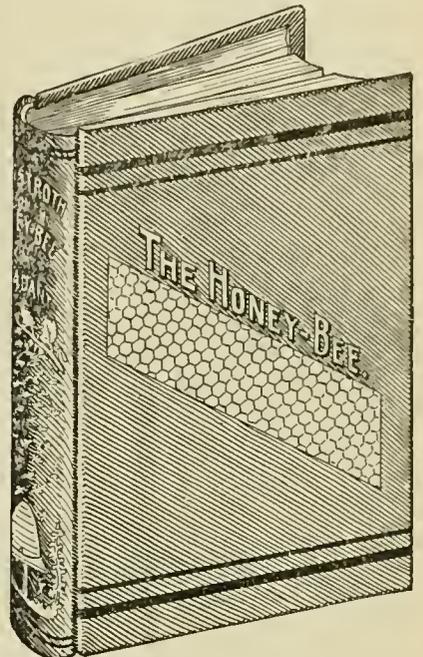

A grape-vine is a nuisance in the bee-yard. I now have a fine cherry orchard trimmed high enough for one to walk under, and it gives good ventilation between the branches and the bee-hives, with shade all the hot part of the day. My hives are 8 to 10 inches from the ground, all in good, well-painted hives—no rags stuffed in cracks, and the alighting-boards are as wide as the bottom of the hives.

I once bought burlap by the acre, and cut

The Honey-Bee**

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly ex-

plained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

and sowed sacks for chaff cushions till the wee hours of the night, then hauled oats chaff to the barn to use for filling, and in spite of all I would lose some bees. There was too much work in this, so I adopted this plan, which has been a success so far for some years:

First, I see that every colony has plenty of stores; then I take supers (without section-holders), cut a thin board just to fit in the rabbet at the top of the super. Then scrape clean the top-bars of all burr-comb, if any, then set the super on the hive. The bees have room to pass over all the brood-frames as they may have occasion. I put nothing whatever in the supers. I have a lot of boards cut and ready to drop in the supers, and in a few hours one man can put on a great many supers. This plan has been a success with me for some years. I once bought a lot of the Hill's device, which are now as worthless as a last year's bird's-nest.

In my judgment, there are too many new-fangled things gotten up for the benefit of the inventor and the man who manufactures them, and great effort made to make the new bee-man think that without these he is not up-to-date in bee-keeping. In fact, I do not think the bees themselves like so much red-tape.

I do not tinker much with my bees. When they swarm I give them a good house to commence in, and then let them alone. I get lots of honey almost every year. Owing to the severe frost and freeze of Sept. 18 and 19, 1901, the honey-flow was cut square off, which left me with more unfinished sections than I have ever had at one time in my 30 years of bee-keeping. J. W. C. GRAY.

Platt Co., Ill., Nov. 26.

Candied Honey — "Educating" the Public.

In a letter recently received from Mr. R. C. Aiku, of Colorado, he writes that he put up over 20,000 pounds of honey in lard-pails, let it candy, and that now there is less than a fourth of it left, or a total of 16,000 pounds of candied honey sold in three months. He is now buying more extracted, and proposes to put it in paper bags, just "to save money and to head off the tin trust," as he says.

This goes to show what can be accomplished in one's own locality by educating the consumers. In the East they have been taught to call for extracted, not candied. It may be well, in view of the large amount of the glucose product on the market in jelly-tumblers, with a little piece of dry comb in it, to educate our customers to the use of candied honey. Just imagine, if you please, the glucose people trying to make their product candy solid. If the consumers of the whole United States were "educated" or made to understand that our product in the granulated form of a certain amount of consistency was absolutely pure, they would buy honey in that shape and give the glucosed jelly-tumbler the go-by.

There, now, I do not mean to advocate that we of the East should put out candied honey exclusively. Oh, no! but I only desired to show that where a locality is "educated" to the use of honey in this form, it would buy quantities and quantities of it, as well as clear extracted, because it would know it was getting pure honey.—Gleanings in Bee-Culture.

A Long-Tongued Canard.

A wild statement is going the rounds of the European bee-journals, the last one I've seen it in being Le Rucher Belge, a really excellent journal. In that it is said in all seriousness that Mr. Root, the well-known American bee-keeper, has succeeded in obtaining long-tongued bees of such excellence that, notwithstanding the high price at which Mr. Root sells them, \$200 apiece, he has not been

OUR NEW CATALOG, describing and listing the **FINEST LINE OF BEE-KEEPERS' SUPPLIES IN THE WORLD,** will be ready about the first of the year. If you have not been receiving a copy annually, send us your name and address and one will be mailed you free. able to supply the demand, and has been obliged to start an additional queen-rearing establishment in Texas to help out!

Now, I wonder how many of our foreign friends will make the proper correction by saying that the A. I. Root Co. merely valued *one* queen (that was never offered for sale) at \$200, and never sold a queen for more than \$10.—[It is evident that some of our friends across the water see through a glass darkly. That is to say, they have acquired only a smattering of English, and a very poor smattering at that, with the result that they do not read aright. Whew! if we could sell queens for \$200 apiece, and not supply the demand, we would go out of the supply business instant.—EDITOR.]—Stray Straw in Gleanings in Bee-Culture.

Long-Tongue Bees.

At last, thanks to Editor York (American Bee Journal, page 691), my error has been specifically pointed out, and I am glad to correct it, for I did not say what I meant. I said, "I believe that long tongues are of no value only so far as they represent an increase of vigor;" I meant to say, "I believe that long tongues are of no value except in those cases in which they represent an increase of vigor." Mr. Doolittle's measurements tend to confirm this position.—F. B. SIMPSON, in the Bee-Keepers' Review.

The Future of Alfalfa.

A correspondent in this issue refers to the fact that the growers of alfalfa hay are beginning to cut earlier than usual; that instead of two cuttings in a season they now get three. The result is that the mower now begins its work just about as soon as the plant begins to bloom. If it should be found more profitable, in point of hay, to cut early and often, and before full bloom, the ranchmen will, of course, look to their own interests, and not to those of the bee-keepers. There is a bare possibility that the time will come when bee-keeping in the alfalfa regions, where hay is the sole object, will not be as profitable as now. Those who think of going into these new localities would do well to take this into consideration.—Gleanings in Bee-Culture.

Bees and Grapes.

This season being extremely dry, the bees did no good at all around here, many starving, so that there are only just a few bees in our town. Having a demand for them, we sold most of ours, so when the grape season was in, the bees did not bother the grapes at all so far as we know, but a man in town told us that the birds were destroying his grapes, as he saw them doing it, but did not see a bee around.

We noticed here last season (1901) some grapes (we believe they were Concord), were left on the vines until they were over-ripe, so that one could smell them for 30 feet away, and we never saw a bee on them at all.—J. W. ROUSE, in Progressive Bee-Keeper.

Time Required to Improve Bees.

In Gleanings in Bee-Culture S. E. Miller took the ground that if we should now begin the work of securing long tongues in bees, our grandchildren might be needed to bring the work to an issue. Referring to this, a Stray Straw in last Gleanings says:

Rather discouraging is the outlook for improvement according to what is said on page 974. It is true that some improvements have required generations, as mentioned. But there's another side. Some of the improvements have been compassed in a year. Within 12 miles of here lives a man who lately gave \$1750 for a single carnation plant. It is hardly likely that a lifetime was spent on that plant. Agrippina is a rose of low growth. One day Rev. James Sprunt found a branch of an agrippina shooting away above the rest. That's about all the time it took him to produce a new climbing rose—the

James Sprunt. One day a white rose was found growing on a branch of the pink rose Catharine Mermel, and from this sport, as it is called, was at once established the beautiful white rose, the Bride. Many other new varieties have come from sports.—[You are right. The case of an insect and that of an animal, so far as the element of time is concerned, is not alike. Of queen-bees we may be able to get several generations in a season; of cattle, for example, not more than one in a year. Then it is true that a "sport" will sometimes reach away in beyond the characteristics of the parent stock.—EDITOR.]

CONVENTION NOTICES.

Minnesota.—The Southern Minnesota Bee-Keepers' Association will hold its next annual convention in the County Commissioners' room at the Court House in Winona, Jan. 21 and 22. A good program has been arranged, and a large attendance is expected. All are invited.
E. B. HUFFMAN.

Wisconsin.—The Wisconsin State Bee-Keepers' Association will hold its annual convention in the State Capitol, at Madison, Feb. 5 and 6, 1902. This promises to be a large convention. All are invited to attend. There will be excursion rates of 1 1/2 fare for the round-trip, good for all of the first week in February.
N. E. FRANCE, Pres. ADA L. PICKARD, Sec.

New York.—The annual meeting of the New York State Association of Bee-Keepers' Societies will be held in the parlors of the Kirkwood Hotel, Geneva, N. Y., Wednesday, Feb. 5, 1902, commencing at 10 a.m. All interested in bee-culture are cordially invited to be present. Subjects of importance are to be brought before this meeting, and it is desired to have a large representation of bee-keepers in attendance.

Wanted Comb and Ex-tracted Honey!

State price, kind and quantity.
R. A. BURNETT & CO., 199 S. Water St., CHICAGO 33Atf Please mention the Bee Journal.

For Sale Clover and sweet-clover Extracted Honey, at 7 cents, in kegs and cans.
DR. C. L. PARKER, 3Atf Station A—R. F. D., SYRACUSE, N. Y. Please mention Bee Journal when writing.

Wanted—Honey.

Car Lots or otherwise; will pay highest market price, spot cash. Address, stating quantity, quality, and price desired at your station. Will send man to receive when lot is large enough to justify.
THOS. C. STANLEY & SON, 31Atf FAIRFIELD, ILL. Please mention Bee Journal when writing.

15 Volumes of the AMERICAN BEE JOURNAL for sale. All complete except a single week's copy missing. Address,

Daniel Wyss, New Philadelphia, Ohio 2A4t Please mention the Bee Journal.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white)....	\$.75	\$1.20	\$2.50	\$4.50
Sweet Clover (yellow)....	.90	1.70	4.00	7.50
Alsike Clover.....	.90	1.70	4.00	7.75
White Clover.....	1.00	1.90	4.50	8.50
Alfalfa Clover.....	.80	1.40	3.25	6.00

Prices subject to market changes. Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack.

Add 25 cents to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

GEORGE W. YORK & CO. 144 & 146 Erie Street, CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The honey market is of a slow nature with little change in price of any of the grades. Choice grades of white comb honey, 14 1/2@15c; good to No. 1, 13 1/2@14c; light ambers, 12 1/2@13c; dark grades, including buckwheat, 10@12c. Extracted, white, 5 1/2@7c; amber, 5 1/4@5 1/2c; dark, 5@5 1/4c; the scale of prices varying according to flavor, body and package. Beeswax steady at 28c. R. A. BURNETT & CO.

NEW YORK, Jan. 9.—Comb honey continues in good demand with supplies pretty well exhausted, and we quote: Fancy white, 15c; No. 1, 14c; No. 2, white, 13c; amber, 12c; dark, 10@11c. Extracted dull with large supplies and quotations on large lots generally shaded in order to effect sales. We quote: White, 6 1/2@7c; amber, 5 1/2@6c; dark, 5@5 1/2c. Beeswax firm and rather scarce at 28@28 1/2c.

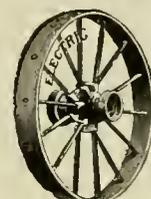

HILDRETH & SORLEEN.

BOSTON, Jan. 4.—Comb honey is in good supply and not working off as well as we would like to see at this time of the year. Prices are ranging as follows: Strictly No. 1, 15@15 1/2c; No. 2, 14c. Extracted, white, 7@7 1/2c; light amber, 6 1/2c.
BLAKE, SCOTT & LEB.

DETROIT, Dec. 20.—Fancy white comb honey, 14@15c; No. 1, 13@14c; no dark to quote. Extracted, white, 6@7c. Beeswax, 25@26c.
M. H. HUNT & SON.

SAN FRANCISCO, Dec. 31.—White comb, 11@12 1/2 cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5 1/2@6c; light amber, 4 1/2@5c; amber, 4@—, Beeswax, good to choice, light, 20@28c; dark, 24@25c.

Business doing is not brisk, but is at generally unchanged values, the market being moderately firm at current rates, particularly for choice to select. Stocks in this center are of quite moderate proportions, and it is the exception where special selling pressure is exerted, or less than full current figures prove acceptable to holders.

In Olden Days

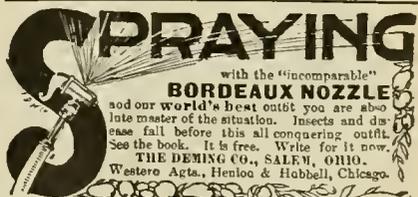

men were broken on the wheel, now they buy **Electric Steel Wheels**, and save money. They fit any wagon. Made with either staggered or straight spokes. Let us tell you how to make a low down wagon with any size wheel, any width tire. Catalog tells. It's free. Electric Wheel Co., Box 16, Quincy, Ill.

Please mention Bee Journal when writing.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers **one ounce** of the seed for sending us **ONE NEW** subscriber to the American Bee Journal for a year with \$1.00; or will mail to any one an ounce of the seed and the American Bee Journal one year—both for \$1.30; or will mail an ounce of the seed alone for 35 cents.

A Novel Incubator House.—The accompanying illustration shows the incubator house made and used by Mrs. Ruth Morris, on her farm in Norton Co., Kan. The house is what is known in that part of the country as a "sod house." Large blocks of mud are dried in the sun, and then placed on top of each other with a soft mixture between, very much after the manner of erecting an ordinary brick building. Across the top, timbers are placed which are covered with sod, then a layer of mud, upon which is placed another covering of sod. After the building is erected it is washed off with water to close all cracks and crevices; then grass and flower seeds are scattered all over it, and in a short time the structure has a beautiful

covering of green and gray, here and there studded with beautiful blossoms. These houses are dry, clean and comfortable. Many farmers use them for dwellings, while the stables and barns are similarly constructed.

In the foreground is a Hen Brooder, and you will observe that the chicks are as lively as those cared for by the mother hen. Mrs. Morris is standing beside a 100-egg capacity Wooden Hen which she has refilled for the sixth time. Both were bought of Geo. H. Stahl, Quincy, Ill., to whom she writes:

"I have just finished my fifth hatch with the Wooden Hen purchased of you last February; averaged 90 percent of all fertile eggs. Hatched the first setting in a Kansas blizzard, and got 80 percent of all fertile eggs."

Mr. Stahl's catalog contains 16 colored views including a chart showing the "Development of the Chick." It may be had free, if you mention the American Bee Journal when asking for it.

BEE-SUPPLIES!

ROOT'S GOODS AT ROOT'S PRICES

Everything used by bee-keepers. POWDER'S HONEY-JARS. Prompt service. Low Freight Rates. NEW CATALOG FREE.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Alfalfa Honey--7 cents a pound in lots of 4 cans or more.

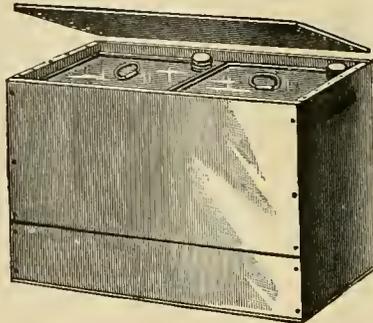

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

CHICAGO, ILL., JANUARY 23, 1902.

No. 4.

Editorial.

"The Truth About Honey."—The report of the committee appointed by the Chicago Bee-Keepers' Association, and published in these columns last week—was given a prominent position in the Chicago Daily News of Jan. 10. We took a copy of the report in person to Editor Smith, of the News, who had it appear under large head-lines reading as follows:

"Pure Honey in Plenty. Committee of the Chicago Bee-Keepers' Association Makes Statement. Is in Denial of Report. Says Adulterated Article Can Be Found Without Difficulty. No Artificial Comb-Honey."

When it is known that the Chicago Daily News has an evening circulation of about 300,000, it will be seen what a wide reading the report will have. Up to the time of this writing, no other daily paper in Chicago has published the report, though all the morning papers were furnished with a copy of it by us in person.

We hope that wherever it is possible to get that statement in the local newspaper it will be done. Bee-keepers everywhere can not do a better service for truth and justice than to ask the editors of their local papers to copy it, or to send to us for a proof or copy with electrotypes of the three pictures as we printed it last week, and then place it before their readers.

Don't Discourage the Farmer from keeping bees, says A. E. Willcutt in the American Bee-Keeper. Then he asks the following pertinent questions:

Did our large producers, specialists and noted queen-breeders, like "Jonah's gourd," spring up in a single night? or did they, like the rest of us, start with a few colonies, and work their way upward?

Did the reader ever see, or hear of, a horse that wasn't a colt before it was a horse? I never did.

Did not some of our most successful apiarists commence bee-keeping in some back farmyard, with only one or two colonies?

Mating Queens in Confinement.—Less has been said about the matter this year than last, but it seems all have not been idle. Mr. W. E. Flower reports that he made a fertilizing tent and succeeded in getting our queen fertilized. As this is much poorer success than had previously been attained, it might seem hardly worth while to pay any attention to Mr. Flower's efforts. But when it is considered that the previous matings had

been secured in a tent measuring 30 feet each way, and that Mr. Flower operated with a tent 12x10x6 feet—a thing within reach of almost any bee-keeper—we can all heartily wish him entire success in his future efforts, and watch him with interest, if indeed we do not follow his example.

Instead of putting his nucleus hives outside the tent, he put them inside; then if a queen flew when a hive was opened, she would be inside the tent. He first put into the nuclei drones from the other colonies; but they worried themselves to death trying to get through the excluder at the outside entrance. Then he put in the nuclei frames of sealed drone-brood, and the drones from these behaved differently and seemed to feel at home, flying freely in the cage, and returning to the hive at night.

Success to you in your further efforts, Mr. Flower. Or, may you and your scheme be a "blooming" success.

Starting Queen-Cells with Eggs.—A writer in the Australian Bee-Bulletin proposes to take away from a colony its queen and all its unsealed brood, leaving nothing but eggs in the hive, and says:

"Only eggs being present they cannot start too-old larvæ to make queens with.

A novice is very likely to entertain this view, and yet there can hardly be a surer way to get bees to start queen-cells with larvæ too old. For they are not satisfied with what queen-cells are first started, but will continue to start cells for several days, and by this time the larvæ will be too old. If all are allowed to remain, no harm will be done, for these later and poorer cells will be among those destroyed by the bees. The harm comes when the ignorant novice takes the cells one at a time and distributes them. The experienced bee-keeper will see that in the distribution of cells each nucleus shall have two or more cells, so as to give the bees a choice, and among those given there will be, in each case, one that shows by its appearance that it is not among those later started.

The Comb-Honey Slander.—It is encouraging to know that at least some of the papers that gave place to the misrepresentation of comb-honey have shown a willingness to do all in their power to right the wrong they have unwittingly done. Editor Root says:

Nov. 28 the Chicago Chronicle published one of the worst slanders on the honey-business I have ever seen. It was to the effect that bee-keepers themselves were implicated in this manufacturing business, and therefore did not like to have the matter exposed. I sat down and wrote as nice a reply to that paper

as I knew how, and a few days later I had the gratification of reading in their columns my letter in full.

There is also encouragement in the thought that the Department of Agriculture at Washington stands on the side of right. The Ottumwa (Iowa) Courier published the usual canard, to which Editor Root replied, and a half-column retraction followed:

"It seems," says Editor Root, "the editor of that paper, after receiving my letter, wrote to headquarters, the Department of Agriculture, Washington, asking if it were possible to manufacture comb honey, etc. The Department promptly replied in a long letter, over the signature of Prof. Frank Benton. In this letter the entomologist showed how impossible it was to manufacture the comb and fill it with glucose, and then stated that \$1,000 had been offered for a single sample of adulterated comb honey for a period of many years, without a taker."

This, coming as it does from the Government of the United States, bearing the Department seal, will have great weight, and I suggest that those who answer these canards about honey always incorporate in their replies the statement that the Department has denied *in toto* the foolish stuff that has been going the rounds of the papers."

Capping Queen-Cells Early.—In the Australian Bee-Bulletin, A. A. Roberts says when only eggs are allowed in a queenless colony, the bees may cap the queen-cells too early; and F. W. Penberthy says he has seen queen-cells sealed with very young larvæ in them, in one case an egg only!

Influence of Nurse-Bees on the Queen.—A few years ago the idea was advanced by writers in foreign papers that there was a marked influence upon a royal larva made by the nurse-bees, so that an egg reared by nurse-bees other than those of the same hive in which the eggs were laid might produce a queen very different from what she would have been if the feeding had been done by nurses that were progeny of the queen that laid the egg. F. B. Simpson seems inclined to this view in the last number of the Bee-Keepers' Review.

Undoubtedly, any growing animal may be affected to some extent by the quantity or quality of nourishment it receives, but no facts have ever been brought forward to show that it made any noticeable difference what nurse-bees fed a royal larva. If the nurse-bees have much influence on growing royalty as some have urged, it ought not to be difficult to prove it by a single exchange of eggs. Take a very cross and a very gentle colony, and let each rear a queen from an egg taken from the other colony, and when the resulting queens get to laying, the progeny of each should resemble largely the nurse-bees that

did the feeding. If there has been any case of this kind it has not been widely reported.

Again, if a colony of pure blacks should be compelled to rear a queen from an egg taken from pure Italian stock, the colony should remain, at least for some weeks, with no very great change. On the contrary, the change is sudden and entire, so far as can be seen, to just what it would have been if the young queen had been fed by Italian workers.

Bleaching Extracting-Combs.—In order to get the very whitest extracted honey, it is believed by many that the use of new combs, or combs that has never been used for brood-rearing, is desirable. In a communication from Robert J. Krause, he proposed to bleach the combs by having them immersed in a weak solution of bleaching powder or sulphuric acid, from one season to another. Two troughs are to be made holding, each 1,000 combs or more, with an arrangement to run the solution so slowly from one to another that the air would all escape from the cells, the solution being run by a somewhat ingenious arrangement, every few days, from one trough to another.

He desires an opinion as to the value of his scheme. It could hardly be used except in the South, for freezing would prevent the plan from working, besides doing some injury to the combs. The question arises, whether continuous soaking would not be sure to loosen the combs entirely from the frames. Would there be any object in bleaching any combs except those blackened by brood-rearing? And would it not be a cheaper plan to keep extracting-combs and brood-combs entirely separate? Our friends in the warmer portions of the country who extract on a large scale will probably be able to give a reliable opinion as to the value of the scheme.

Weekly Budget.

MR. ANDREW CARLSON, of Chisago Co., Minn., called to see us recently when on his way home, having been visiting in Indiana. He reports a good honey crop the past year, mainly from basswood. He keeps from 75 to 100 colonies of bees.

MR. S. Q. CONKLE, of Orange Co., Calif., is one of the car-load honey-producers of that State. A view of his beautiful apiary in the mountains appears on the first page of this number. When sending the photograph he wrote thus:

"I send you by this mail a photograph of my Mountain Apiary. I commenced the season last March with 126 colonies, built over 700 combs, and took out 25,514 pounds of extracted honey. The season closed in July, and owing to a severe attack of lagrippe I missed getting my bees in condition for the main honey-flow by about ten days. The increase was 10 swarms. I give room and use the extractor to keep down increase. I make my increase in the valley after the honey season is over in the hills, using the fall flow of low-grade honey.

I have now 203 colonies, and the crop sold at $4\frac{1}{2}$ to 8 cents a pound, depending upon the amount the purchaser took and the quality. I sold the beeswax at 24 cents a pound.

To show how honey crops turn out in California, most of the bee-men in March and April said we would get about a fourth of a crop. We had late rains, and that makes honey. The crop was light amber, very little being water-white.

I have had something to do with bees for 20 years. I must speak of four honey-days we had last May. The weather was muggy, and the ground and hives were covered with loaded bees—couldn't put a foot down without crushing bees. The hum of a lot of bees in a good honey-flow beats any other music.

The country is very dry here at the present time (Dec. 21). S. Q. CONKLE.

A PARDONABLE ERROR, it seems, was made by us on page 18, in referring to an acrobatic feat proformed by the president of the Colorado Bee-Keepers' Association at its last convention. We have received a letter from Mrs.

are using all kinds of hives from the box-hive to the improved dovetailed hive.

I had the pleasure of meeting W. S. Forney, whose apiary is located in a small town at the foot of Bald Eagle Mountain. He is employed by the Pennsylvania Railroad Company, and has an apiary of 25 or 30 colonies, which he runs as a side-issue at the rear of his home. It will be noticed that he has a few chaff hives, and some of his own make. Mr. Forney is seen raising the cover from one of the chaff-hives, and his four boys are his helpers. I am glad to say that the young bee-keepers are taking a great interest in bee-culture. Mr. Forney told me that when he is away at work, these boys give the swarms and can find the queen as readily as he can. They are not afraid of bees; in the apiary they can be seen without veil, gloves or hat.

Mr. Forney runs his apiary mostly for comb honey, being in a good basswood location, and finds a ready sale at home for all he produces, and at a good price. As a bee-hunter

APIARY OF W. S. FORNEY, OF LYCOMING CO., PA.

Aikin, protesting against the statement that it was her husband whose chair (not Mr. Aikin himself) became so tipsy as to cause its occupant to take a backward somersault. It appears that it was the new president of the Association, Mr. J. U. Harris, who caused the fun by the unusual performance, that, while not exactly on the program, was an enjoyable feature of the session.

Our error is easily explained. It is the usual thing for the new president to preside at the next meeting, and not at the one where he is elected. So we supposed, of course, it was Mr. Aikin, who had been president up to that time, who somersaulted in his chair.

We certainly would not willingly deprive Mr. Harris of any credit in the matter; nor would we desire to give Mr. Aikin more credit than is due him. So we most humbly beg the pardon of both good men, and hope it will not occur again—the acrobatic performance, we mean.

THE APIARY OF W. S. FORNEY is shown on this page. Mr. W. H. Heim, of the same county (Lycoming Co., Pa.) wrote as follows concerning it and the bee-keepers of his locality:

As I had the pleasure of visiting some of the bee-keepers in Central Pennsylvania, I thought it might be of some interest to tell what I have seen among them. I find they

Mr. Forney can not be excelled, for he has captured quite a number of runaway swarms, and transferred them into hives. He showed me some very nice Italian bees that he found in trees on the mountain. W. H. HEIM.

THE WISCONSIN STATE convention will be held in the State Capitol, at Madison, Feb. 5 and 6, 1902. The following is the program:

President's Address—Pres. N. E. France.
Moving Bees—Gustave Gross.
Description of My Cellar—C. A. Pierce.
Production and Care of Extracted Honey—Elias Fox.
How I Produce Comb Honey—Mrs. Evans.
Address—George W. York.
Co-operation of State and National Associations—Pres. N. E. France.
Value of Good Queens and Methods of Introduction—Secretary Ada L. Pickard.
Beeswax Production—C. A. Hatch.
Benefits Derived from Attending Conventions—Jacob Hoffman.

The secretary's notice also contains this paragraph:

The above program will be interspersed with music. A general discussion will follow each topic and a free use of the question-box will be a prominent and valuable feature. Excursion rates have been secured, one and one-third fare, good for the entire week. These conventions are interesting and profitable and every bee-keeper in the State should attend. Come and enjoy the good things with us.

We trust it may be a largely attended meeting. Wisconsin always has good conventions because some of the biggest and best bee-keepers are in that State.

Convention Proceedings.

Report of the Ontario Bee-Keepers' Convention, Held at Woodstock, Dec. 3, 4 and 5, 1901.

REPORTED BY R. F. HOLTSMANN.

(Continued from page 41.)

Mr. H. Sibbald gave the following paper:

Out-Apiaries and the Prevention of Swarming.

Your committee could not have struck a subject more difficult to write upon, and yet of such live interest to the progressive bee-keeper of the new century. Mr. Hutchinson calls it the most hopeful field to which bee-keepers can turn their attention, and says "Keep more bees," which means "out-Apiaries."

There was a time when extracted honey brought from 15 to 20 cents per pound and comb honey was proportionately high; when the forests were plentiful and filled with basswood—that grand honey-tree, now almost extinct. The forests in addition contained, and retained, moisture; drouths were less frequent in consequence, and these forests also sheltered and protected our most valuable honey-plant, the clover.

Now new and undesirable conditions prevail; prices of honey have declined, the forests have been cleared away, drouths are all too common, and our production of honey is a more uncertain and less desirable occupation. Honey-crop failures occur with uncertain but too frequent regularity until the apiarist with 80 to 100 colonies, depending on them alone for a living, finds himself poor indeed, and must of necessity turn his hand to something else that will combine with bee-keeping and aid him in making a fortune, or at least in keeping the wolf from the door. Farming, fruit-growing, poultry and other things have been tried with varied success, but almost invariably to the detriment of the honey-bee, and the loss or sacrifice of the honey crop.

This seems to be an age of specialists, and our thought, time and attention must be concentrated upon one thing to make the greatest success of it. This can only be done, and the above noted changed conditions met, by increasing the number of colonies kept, so as to make provision in the fat years against possible lean ones.

But the difficult part is to tell you how to do it, and a saying I have heard comes to me, and seems quite appropriate. It is, "The more I know, I know I know the less," and so venture to give help on this new, hopeful field with fear and trembling.

To commence with, then, out-Apiaries ought to be so situated as to be within driving distance, and yet three or four miles apart. Any suitable yard with buildings adjoining, and cellar if possible, must be found; if with friends, who will take a kindly interest and prevent molestation, the better.

The uncertainty of the honey crops, and the difficulty of securing competent help at the right time, make it desirable that some system of management be adopted that will not require the constant attendance of any one in any particular apiary. So we must, therefore, clip all queens to prevent absconding swarms, while we bring all means in our knowledge and power to bear on the prevention of swarming, which is advantageous in any event, whether one yard or more are kept.

The first step toward this end might be to have young queens of a non-swarming strain (if such exists), or at least chosen for their virtue in that direction.

The second step might be to equalize all colonies in fruit-bloom, checking the strong and helping the weak, so as to have all as nearly as possible in the same condition, so that a yard can be manipulated together—all supered the same time, and extracted the same time.

The cause of swarming, as far as I understand, is the natural instinct of the bee when crowded and a honey-flow is on, so that it will be seen that the third step would be to anticipate their condition and wants, and provide room before they notice they are crowded. This necessitates having plenty of comb ready—two sets for each hive will be found convenient and almost necessary.

The first super might be put on at the close of fruit-

bloom, if colonies are reasonably strong; and the second one shortly after the clover-flow starts, and before the first is nearly full. All hives ought to be blocked up from the bottom-board to allow ventilation, using a wedge and blocks behind. Shade-trees will be found helpful; sun-caps, also, to keep the hive shaded. Then our real work commences and we must "get a move on" to keep pace with our industrious pets. First, we must study their conditions by a glance at the entrance and a peep in the supers. If they are working well at the entrance and storing honey rapidly all is well. More room may be provided, but if they are hanging out, sulking, acting queenless and not working, when other colonies in normal condition are doing well, examine the brood-chambers; this is necessary, and may reveal queen-cells started, no eggs, probably queenless, etc. It is useless to try to tell you here what to do in such cases; time will not permit, and, besides, these little details are known to all.

By visiting an out-Apiary once a week, and running over it in this way, you will catch nearly every swarm, and spend very little time on it.

Inexperienced help can be procured to aid in extracting, and a splendid crop can soon be harvested and secured by the bees.

All work must be quickly done, and any tinkering or slow method dropped. Wholesale manipulation must take their place.

H. SIBBALD.

R. H. Smith—As to out-Apiaries, I am only a beginner and have much to learn. I want to put on the first super during fruit-bloom. I require more than two supers, even four to each colony. If the queens are young I can work the colony to good advantage in an out-Apiary. During the height of the honey-flow they can be kept back, and if later they swarm no great harm is done. Honey should not be taken off early; it should be ripened well. Every preparation in the way of supplies—getting hives and supers ready—should be done before the season opens.

Mr. Miller—My system is to visit the out-Apiary once in four days. I use a divisible brood-chamber, and can see in an instant the condition of the brood-chamber and the age of the queen-cells, if any.

Mr. Chrysler—I keep only a few bees myself, but I am anxious to learn. For two or three years I have managed the Heddon hive without getting queen-cells started. I use two or three brood-chambers and then shut down the queen, and as the brood hatches the cells are filled with honey. I use starters in the new supers, and add supers as required.

Mr. Frith—Are those out-Apiaries a paying concern?

Mr. Hall—I would not do without out-Apiaries; in one locality you may have honey and in another none.

Mr. Byer—I believe in hiring some one to put in the out-Apiary during the honey-flow and swarming season.

ADDRESS BY MR. PATULLA.

Mr. Andrew Patulla, M. P., for Ontario, being present, was asked to give an address. Mr. Patulla said he was delighted to be present at such an influential meeting. He did not know why he was asked to give an address unless bee-keepers and journalists were students. He had heard Mr. Sibbald's paper and the discussion with pleasure; he noticed bee-keepers had their troubles, but journalists had neither basswood nor clover, and in politics they never make honey, but much too freely vitriol. He knew they represented a large and growing interest, and has felt this for some time. He was proud of their record at the Pan-American, and he felt that that work was of profit not only to bee-keepers but to the country and Nation at large. He remembered when cheese was first brought out. Mr. Ballantyne and others, had, in a quiet way, established a reputation for cheese, which had resulted in millions of dollars worth of business. In one year, the last, the export butter industry had doubled from three million to six million dollars. Almost every branch of agricultural industry had been developed from sources such as this. Poultry was going to do much in the British market. He dwelt on these because these were related to honey, and this development would result in greater consumption of honey at home and abroad. The United States has spent millions of dollars to induce Germany and other countries to use corn. With honey he felt sure much could be done.

In closing, Mr. Patulla stated that he had thought a good deal of bee-keeping, many in Oxford holding a prominent place among bee-keepers. If by their united action their honey could be classified, and unitedly handled, he believed much advantage would result to the members. There were government agencies which could be used; he would

throw out this suggestion in view of the splendid record just won at Buffalo.

Pres. Newton—Mr. Sladen, of England, was at Buffalo, and asked for some samples, and among others he had eulogized Canadian and basswood honey.

MARKETING HONEY—A BEE-KEEPERS' EXCHANGE.

Mr. Gemmill was pleased to see Mr. Patulla at the Oxford convention. It was decided at the last meeting of the Oxford Association to bring the suggestion of a Bee-Keepers' Exchange before the Ontario Association. He was grateful to Mr. Patulla for bringing this matter up.

Mr. Frith advocated an exchange.

Mr. Brown favored developing the home market first, then the foreign.

Mr. Couse—I somewhat agree with Mr. Brown. I believe Canadians are having greater faith in Canadian goods. The Government had taught them to do things well; they were honest in their dealings, and Canadians had greater confidence in Canadian honey than United States people had in United States honey. This year all the honey could have been sold locally. Bee-keepers were amalgamating more and consulting more in selling.

Mr. Craig—The low price has originated not with the expert but with the smaller bee-keepers—those outside of the Association. I would advise trying to interest outsiders more. More could be made of the home market. As to the foreign market, they had not the regular supply. In poor seasons they are "left."

Mr. Dickinson—This question is a broad one. We should have an outlet in the years of extra-production. We have had such years; one year I had 1,000 pounds I could not sell. There should be an outlet. When fruit is plentiful honey is not in so great demand.

Mr. McEvoy endorsed all that Mr. Dickinson said.

Mr. Laing had been told of men who sold this year's honey very low. He advocated an organization such as the Colorado Honey-Producer's Association.

Mr. Brown spoke about getting at a way of finding out the amount of honey produced. There was more than five times the honey produced by men outside than in the Ontario Bee-Keepers' Association.

Mr. Pickett advocated local markets.

Mr. Roberts also advocated local markets; he could not get enough to supply the demand. As to England, they received there 8 cents per pound. If he had a ton he could have sold it as well as the few pounds he had.

Mr. Dickinson advocated the British market for the man with good honey and a considerable quantity.

Mr. Couse thought the best way was to buy out the small bee-keepers.

Mr. Sibbald—I have closely observed honey-markets and have had a good deal of honey to sell. Two years ago the honey crop was a partial failure; dealers got it early and made a good profit. This year they had secured it early, and this had helped them out. Fruit also helped them out. Bee-keepers should combine and get crop reports.

On motion of F. A. Gemmill, a committee was appointed to take in hand the matter of a Bee-Keepers' Exchange. Messrs. Hall, Frith and Laing were appointed such committee.

TUESDAY EVENING SESSION—DEC. 3.

R. H. Smith read a paper on

Exhibits of Honey.

Exhibits of honey at our local fairs and exhibitions have come to be recognized as much a part of agricultural displays as fruits or vegetables, and in any locality where bee-keepers have taken sufficient interest in agricultural societies, and attend their meetings, the directors have seen to it that the premiums were liberal and encouraging.

There is no better means of educating the general public in the nature and use of honey than a good display at fairs; I do not mean such as is usually called for in the many prize-lists, perhaps, "strained, five pounds" and "in comb, five pounds," which is often taken literally. The liquid is very much strained, but not all of the pollen is strained out of it, and, as I have seen large brood-combs shown for comb, all this is pretty good evidence that there was no up-to-date bee-keeper on the committee for revising the prize-list.

The secretary and directors of agricultural societies are generally progressive and intelligent men, who wish to have their exhibition outshine all the others, and to do this they must be well-informed, and I have always found them willing to do all possible in the way of allotting space and pre-

miums for displays of honey, especially after it has been shown what an attractive display may be made with honey, and other products of the apiary. Of course, I do not mean that display should be encouraged before quality—quality should count most, every time.

Some years ago, when living in the district of Muskoka, I exhibited honey at the Muskoka County Fair, showing the small quantities called for in the prize-list; it was classed with preserves, pickles and other home produce, and attracted no particular attention.

The next year I exhibited at the Industrial at Toronto, and, on my return to Bracebridge, applied for space at the county fair to put up a display of comb honey in sections, also extracted honey, both clover and buckwheat, some of it clear and some in the candied form, several hundred pounds altogether. Well, the result rather astonished me; I was overwhelmed with questions about honey. "How did it get into the little boxes?" "How was it some was so light and clear, and another kind so dark in color?" "What made it candy?"

People who had never seen or tasted honey before stopped to admire, and expressed a desire to purchase some; the result was, we sold all cull sections by cutting them into five-cent pieces, that were eaten on the spot, instead of candy; and many who had once tasted honey purchased some to take home with them. I had a crowd around the exhibit the whole time. The honey was all sold, and orders taken to be filled later.

This proved to be the best advertisement we ever had, and was the means of introducing honey into many homes where it was found to be so much more healthful and economical than many of the preserves in common use.

When on a visit to Muskoka, during the fall of 1900, I found the display of honey still kept up; the bee-keepers in that district, who are as progressive as any in the Province, evidently see that they are represented on the board of their flourishing county agricultural society.

A mistake is sometimes made, when attempting to make a display of honey, in not having a sufficient variety of packages. I have known an exhibit to be made of several tons of extracted honey, all put up in 60-pound cans in their cases. While such an exhibit may be impressive to the amateur who has a few colonies, to my mind it is not as attractive to the general public as a much smaller quantity would be if put up in a variety of packages of both glass and tin.

Another large exhibit I remember was all put up in one-pound glass jars. In both cases these were extremes, and were rather monotonous to the beholder. It must not be supposed that a good display of honey is made without some work. Honey of good quality is first required; the comb in sections, with its delicate, white cappings, must be freed from propolis and cased in new, clean, no-drip cases of various sizes, with glass on both sides to show the contents.

The extracted honey, if in the candied form, will be of the previous season's crop and put up in glass jars, or, if liquid, it is best to have a variety of packages of both glass and tin of a size and style that may be useful after the honey is used, with a sprinkling of fancy jars for display only.

I find it best to heat all honey, to be shown as liquid, to about 145 degrees to remove all signs of granulation; after it is cold it may be run into glass and pails of various sizes, that have been nicely labeled, care being taken not to use jars that have a green tinge, or it will give the honey an unnatural color.

The exhibitor is now ready to set up his display, and in doing this he has to be guided by the quantity to be set up, and the space at his disposal. A small exhibit artistically arranged is far more attractive than a large quantity massed together without design. And, last, but not least, if there are many entries, and he is trying to get ahead of his competitors, he must not forget that very likely the other fellow is doing the same.

R. H. SMITH.

Mr. Craig, in opening the discussion upon the subject, said that some thought this question did not receive the attention it merited. The producers at large centers come in contact with large buyers, and are also educating the public. Mr. Smith brought out desirable points—neatness and attractiveness are important. The Ontario Bee-Keepers' Association should take hold of this matter. At Toronto this year the exhibit was stuck in a tent. Exhibitors should get fair play. This exhibit was not local, but visitors from other countries saw the exhibit.

Mr. Evans corroborated what Mr. Craig said as to ac-

commodation. Suggestions had been asked from him and Mr. Hoshal as judge this year. One suggestion had been made to have the prize money for neat exhibit divided by the judges according to merit.

As soon as Mr. Pickett found clover was yielding well he asked for the same building, but could not get what was wanted. The grant should be conditional.

Mr. Holtermann said honey exhibits were important, in these days of keen pressure, and, what would be got, largely depended upon the pressure that could be brought to bear upon the committee. It was advisable to give the grant conditionally. A motion was carried to this effect.

(To be continued.)

No. 1.—Bee-Keeping for Women.

Some Practical Suggestions to Those Who Contemplate Going Into the Business.

BY EMMA WILSON.

Is bee-keeping a desirable occupation for women—that is, as a business? For some women, yes; for some women, decidedly no. It all depends upon the woman. There is no denying the fact that if you make a success of bee-keeping you will find hard work and plenty of it. You must be willing to work early and late during part of the year, and give up a great many pleasures that some other occupations would allow you to participate in, because bees must receive prompt attention, and certain things must be done at certain times even if there is a picnic or a tea-party you would like to attend; and sometimes it is hard to work when nearly all your friends are taking their vacations and are having such a good time, for their vacations are very apt to come during the bee-keeper's harvest.

If you are thinking of taking up bee-keeping as an occupation it is well to take these things into account, for you will have to face them, and some hot day, when the temperature stands at 90 degrees or 100 degrees in the shade, you will feel very much abused that you have to work while it is so hot, and others are playing. That is, you will be likely to feel that way unless you are intensely interested in bees, and to make a successful bee-keeper, be it man or woman, a person must be interested in bees—yes, bees must have a sort of fascination for one. If that is the case, you will be thinking a good deal more about what your bees are doing than about what your friends are doing, and you will be surprised when they pity you for having to work so hard, and sorry they have wasted so much sympathy on you. For if your bees are only bringing in lots of honey, what do you care if you do have to work hard and it is hot? That is just the condition of things you want. The harder the bees work the harder you are willing to work, for that means a good harvest for you.

Let me tell you, the hard part comes when the season is a failure, and you feel you are not getting any returns for your work; for even then the bees must be taken care of.

Can a woman successfully take care of bees? Yes, I think she can, if she is the right sort of a woman, with lots of energy and push, not easily discouraged, and possessed of lots of patience. Some of the work will be pretty heavy, and a sickly, delicate woman would be obliged to have help, but I really believe a healthy woman can successfully run an apiary entirely alone. I know of no healthier occupation. Of course, you must be willing to take the stings; that is part of the business. Fortunately, the human system becomes, in time, habituated to the stings to such an extent that you are, to a degree, immune to the poison.

I believe that women are, as a class, more patient and persevering than men, and are particularly adapted to bee-keeping. The great trouble is that they usually want to rush things too fast, and commence with a larger number of colonies than they are able to care for, when they really know nothing whatever of the business. It is best to go slow; very slow at first. It is well to learn by experience,

and sometimes the experience is quite expensive. I do not think I would try more than two or three colonies at first. If you are successful with these, gradually increase your number, always keeping in mind that it is much better to have one strong colony than two weak ones; for it is the strong colonies that give us the honey, and a lot of sickly, weak colonies are only an expense and not worth fussing with.

It will probably take you some time to learn this, but the lesson will have to be learned. Some way, a beginner is always so anxious to increase her number of colonies that it is hard to learn that it is not the number of hives with bees that counts, but the total number of bees. After you have become somewhat familiar with the business, through experience and the study of a good text-book on bees, you will not be so anxious to increase the number of your colonies at the expense of their strength.

About 18 years ago I was teaching, and my health began to fail, and my physician ordered a change of occupation and rest. I intended to rest one year and work with the bees in order to be outdoors as much as possible, and then go back to the schoolroom. I did not go back. In fact, I doubt very much if I would be living to-day if I had continued teaching. I have never been considered strong, and yet I have never missed a day's work throughout the entire honey season for 18 years, taking my share of the hard as well as the pleasant part of bee-keeping. For me it is very fascinating work, and I thoroughly enjoy it. It is remarkable the amount of hard work one can endure while working in the open air, when one's whole heart is in the work.

Perhaps the larger number of women who keep bees can spend only a part of their time and keep only a limited number of colonies, instead of spending their entire time at it as I have done. I feel sure there is much health connected with such work, if no great amount of wealth, and many a tired, nervous woman would be much benefited if she could spend a few hours each day in the open air working with bees, and, no doubt, add a considerable sum to her pin-money, besides.

McHenry Co., Ill.

In-breeding as Applied to Honey-Bees.

BY ADRIAN GETAZ.

This is perhaps the most important point to consider in our efforts to improve our races of bees. In-breeding means using male and female reproducers of close parentage, even brother and sister, or father and daughter. The more alike are the male and female parents, or the more closely related they are, the more surely will their characteristics and peculiarities be transmitted to their offspring. On the other hand, if the male and female parents are different in their peculiarities, color, qualities, size, etc., all sorts of variations may be expected in their descendants.

Now, suppose we have an extraordinarily good queen. If we can safely breed together her descendants, drones and queens, and keep up the process through the successive generations, the qualities of that queen will be transmitted to her descendants; not only transmitted, but also intensified and fixed. The word "fixed" means that the offspring will invariably possess the peculiarities of their parents.

If, on the other hand, in-breeding can not be practiced, we will have now and then to introduce some queens or drones of outside and comparatively inferior stock. Their offspring will necessarily be inferior and irregular compared to those of pure stock. In a word, every introduction of outside blood will be a step backward in our efforts to create a superior race of bees. Needless to say, that it would be a serious drawback.

NATURE'S WAY.

The chief argument against in-breeding is that "it is not Nature's way." In the state of Nature, mating between close parents is the exception, rather than the rule. In many plants, the female flowers are not on the same plant as the male. In others, the pollen is so situated that it can not fertilize the flower. Other pollen must be brought from some other plant by the wind or insects. The larger animals roam about, and find for mates all but their close relatives. Queen bees, ants and wasps mate away from home.

WHY IS IT SO?

Why is in-breeding injurious? or why is it avoided by the laws of Nature? I think I can give one reason, and I

will explain it by an illustration. To make it easier to understand, I'll take it in the human race.

Suppose we have, say, three families of people, and it is arranged that no one shall marry outside of his own family. Suppose, also, that one family has a tendency to weak lungs; the other to weak stomachs; and the third to weak eyes. What would the result be likely to be? Why, the probability is that the tendency to having weak lungs would increase in the first family, as the generations go by, until the last member would die of consumption. The last family mentioned would finally become blind; while the second would die out of liver or stomach troubles. Now, suppose that, instead of having them marry in their own families, we let them inter-marry and mix together. Then some of the children may inherit some of the defects of the father and some of the mother. Some, perhaps, the defects of both parents; and some none of the defects at all. Those that have inherited mostly the good qualities, will remain. *The fittest will survive.*

We do not know exactly how the present species of plants and animals have originated, but we know beyond a doubt that they have undergone many transformations, and that those best adapted to their environments have survived. The above illustration may give an idea why those propagated by mixing have survived, rather than those propagated by in-breeding.

THE BREEDER'S WAY.

Now, I am going to make a very bold proposition. While, in Nature, in-breeding would bring bad results, it does not necessarily follow that the same will occur in the hands of a skillful breeder.

In the above illustration, I took three families with defects; but the breeder of bees or other stock need not use defective stock or defective individuals. He can throw out all the subjects that are objectionable for some reason or other.

Suppose we were to take a colony of bees upon an isolated island. If we allow them to multiply just as they please, or if we rear queens indiscriminately, the defects that those bees may have will surely be perpetuated, as well as their excellencies. But, if we select only the drones and queens that possess the good qualities in the highest degree, and the defects in the least degree, we shall surely improve the good qualities, and eventually eliminate the defects altogether.

We have made one step. But the question may be asked: "Is that all that there is of it?" Granting that one of the evils, or, perhaps, the chief evil, of in-breeding is the transmission of defects; granting, also, that this can be avoided by a proper selection, is it not possible that in-breeding may yet be an evil in itself?

To this, all that can be answered is, "What do the actual facts show?" In breeding bees, we, as yet, have no facts to show, owing to our inability to control the mating of queens; but we have numerous instances in other kinds of stock.

Even a superficial knowledge of physiology will show, beyond any possible doubt, that the same general laws govern all the living creation—plants, insects, animals, and even the human race. Of course, there are differences, and they must be taken into consideration, but the underlying laws, the fundamental principles, are the same throughout; and if in-breeding can be practiced successfully with horses, cows, chickens, etc., we have all reasons to believe that it can also be practiced with bees; at any rate, until positive proof of the contrary is furnished.

ACTUAL FACTS.

In 1828, a French Merino sheep-breeder had in his flock a lamb with smooth, silky wool. He undertook to cross him with the ewes of his flock, but very few of the offspring showed the silky wool. However, when he was mated with those of his own daughters that also showed silky wool, all the lambs thus produced had also the same kind of wool. Thus was created the stock of silky wool Merino sheep. The whole race descended from that one lamb.

Concerning the Durham cattle, Chas. Colling had a bull which served the whole herd, including his mother, all of his daughters grand-daughters, etc., for six generations. This was the foundation of the present Durham race of cattle.

There is, at Lyons, in France, a large establishment which furnishes guaranteed reproducers of the different

breeds of stock. As the object is to have perfectly pure stock of the highest grade, the closest kind of in-breeding has been practiced. First, because an immense number of animals of each kind would have to be kept to avoid in-breeding; and, next, because the introduction of outside stock would have given irregular and often inferior animals.

On the Jersey stock the process has been followed seven years; and on the Friesian twelve years. All the animals are as perfect as they can be, and everyone raised is almost the perfect image of its ancestors.

The same can be said of the Merino sheep. Absolutely no tendency to run out or degenerate has been observed.

In the different races of pigs, the results are not so conclusive. The best races, that is, those that fatten the most and the quickest, cannot be submitted to close in-breeding without losing, to some extent, their reproductive powers. The mating becomes difficult, and the females have too little milk.

Concerning the Belgian hares and other breeds of rabbits, the results have been unexpected. All the breeds with brown or gray-brown hairs have maintained themselves throughout. Those having some white hairs, either in spots or mixed, have invariably drifted toward albinism; that is, toward a uniform white color accompanied with red eyes.

The celebrated stock of Toulouse geese has not changed a particle. The whole lot at the establishment is exactly like the original stock chosen eleven years ago.

Some of the chicken breeds have also denoted a tendency toward albinism. Those having white feathers finally became entirely white when closely in-bred. Needless to say, that the animals having any defect have been invariably set aside. This is absolutely necessary to successful in-breeding.

In regard to the in-breeding of swine, as noted above, the same peculiarities have sometimes been noted in the breeding of cattle. Bates, one of the founders of the Shorthorn race of cattle, practiced the closest kind of in-breeding during thirteen years; but the fecundity of his stock suffered, and he was compelled to introduce new blood three times, to maintain the fecundity. It is hardly to be supposed that the in-breeding in itself was the cause of the trouble. If so, it would have manifested itself in the Jerseys, Friesians and other milking breeds, as well as in the Shorthorns.

On the other hand, the same defect appearing also in the highest fattening breeds of swine, seems to show that the excessive tendency to take on fat is incompatible with a full development of the reproductive faculties. This could be expected, considering that an excessive disposition to fatten is something of a disease itself.

To obtain the best results in fattening, or creating a stock disposed to take on fat quickly and in abundance, it is necessary to keep the animals confined and very quiet, even in the dark, and fed with the richest food. Such treatment must be, in itself, almost enough to destroy the energy and the reproductive powers.

Concerning the tendency toward albinism in some of the Belgian hares, the manner in which they are kept may have something to do with it. If, instead of being shut up in more or less dark pens, they were in the open air and the sunlight, that tendency might not exist.

Considering that our best breeds of horses, cattle, sheep, swine and fowls have been obtained, I might say *created*, by choosing the best specimens, and then perpetuating them by the closest kind of in-breeding. I think we are perfectly safe in following a similar course in our efforts to create a superior race of bees.—Bee-Keepers' Review.

Knox Co., Tenn.

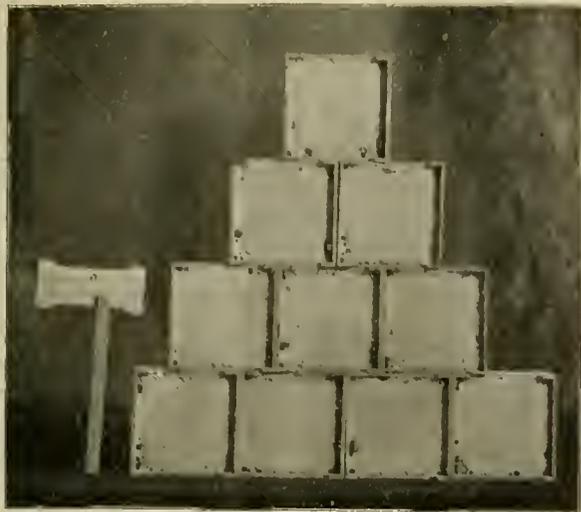

Some Results of the Season of 1901.

BY J. S. HARTZELL.

AS another season for the bee-keeper has ended, and with it the trials of implements and designs of various kinds, it is but fitting to express our convictions from experience.

Much has been written relative to various kinds of separators for supers, and, of the number, the so-called "fence" and plain sections have apparently been the favorites. I have been using for several years three kinds, viz.: Tin, veneer or solid wood, and the fence. My first experience was with tin separators, and after the lapse of 12 seasons I stand with Mr. Doolittle in believing tin the most economical, and that as fancy honey and as much per

HIVE-MARKER AND TEN SECTIONS OF HONEY.

colony can be produced with it as with any other separator made.

Veneer or solid wood separators are too frail. The fence has not only the same objectionable feature, but with it another fully as objectionable, viz., often ribby comb in sections. Not only this, but as the fence is made for use with plain sections only, I find it difficult in many instances to case plain sections when filled, without marring the cappings.

My favorite section is the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{7}{8}$, and so-termed two-way, and the use of tin separators; and my reason is, no danger of marring cappings when cleaning. The same can be said when casing.

In regard to hives, Golden's combination comb-honey hive has again proven best in the production of honey. And just here I would like to inquire why it was that *not one* of the gentlemen named in my article (published Nov. 22, 1900), accepted the proposition I made regarding their testing the Golden hive in 1901. But I am fearful—yes, confident—Prejudice is the enthroned power, and, if by trial forced in honor to acknowledge its supremacy, might injure our influence! If any of the gentlemen I named have anything to offer on the same terms to me, I am ready to accept, and will, to the best of my ability, give it a fair, impartial trial in 1902.

I have this to say regarding the Golden plan or system: I feel confident that if fairly tested there will be no cause of regret for having put it in practice, for had it proven an error on the part of Mr. Golden, long ere this I would have cast it to the four winds, and advised the fraternity of its failure.

LOSS OF QUEENS.

Yes, indeed, I lost 10 colonies out of a total of 93 the past fall. Queens were lost by being superseded, and young queens failing to return safely, after which robbing set in and the doubling-up with other colonies adopted.

Who of the vast number of bee-keepers can tell when a queen will be superseded, without examining the internal condition of the hive? If such there be, will he please inform the fraternity on the subject? However, it is well known that more queens are superseded in the late summer and fall than at any other time.

The remedy: Now I expect swords will be drawn, and objections filed. Kill all queens in the apiary at the close of the honey-flow, save those of that season's progeny, and see that all colonies are supplied with young queens. Thus the bee-keeper will be ever watchful until he knows all colonies are requeened. This was formerly, and hereafter will be, the plan adopted by me, and I am confident better results can be obtained from an apiary stocked with young queens than from old ones, or from young and old mixed.

HIVE-MARKERS.

Yes, I have used slates, etc. Last summer I ran short of slates, and an idea presented itself to me as follows: Take a piece of solid wood six inches long and half an inch

square; taper two sides so as to be three-eighths of an inch at one end; with hand-saw rip a kerf half the length of the piece. At the larger or square end drive in the center a two-inch nail, having first cut the head off, leaving five eighths of an inch exposed. The part of the nail exposed file tapering until sharp, then stick in the top of the hive. Take a piece of broken section, write on or letter, or use any motto you may have adopted, place it in the saw-kerf and a glance in passing through an apiary reveals in plain view the condition of the colony. Try it. To prevent washing off by rain, use indelible pencil, and an extra piece of section tacked flat-wise on the edge of the piece written on.

The last was an unfavorable season for the production of honey where my apiary is now located, being extremely wet. Rain, rain, rain, was almost of daily occurrence, and that, too, right at and through the basswood flow; not only then, but prior to and after. My honey crop was 3386 pounds—2993 pounds of merchantable sections, and the balance uncompleted sections, and of which I extracted those having the least honey, taking 180 pounds of extracted honey, keeping the remainder for my own use and for sale on the home market.

During the season I increased 10 colonies, but, as stated, I lost 10; thus, when returning homeward my apiary contained the same number at the close as at the opening of the season.

Fourteen colonies worked on the Golden plan yielded three supers each of completed honey, whilst only one colony on the general plan yielded the same amount.

Whether or not the bees were of the so-much-advertised long-tongue variety I do not know. I do know I have not made any purchases of that kind of stock, but if such there be, each and every apiary of 25 or more colonies has them. We know the human family has them, and great sensations and disturbances in neighborhoods are caused by them, oftentimes. Then, we have the long-fingered variety, too; both are very bad elements, requiring close and diligent watching.

Now, if the long-tongued bees can create as much of a sensation in the apiary as long-tongued people can in a neighborhood, I would then want them.

Who of the many breeders of long-tongued queens will guarantee their progeny to store more honey than bees from our ordinary queens? If such breeder is known, I would like to contract with him for queens for half the number of colonies in my apiary next season, on the following terms:

Tests to be made in 1903. Should the so-termed long-tongue variety store, on an average, five pounds more per colony than the others in the yard I will pay double the price regularly sold at; failing to do so, the breeder is to have no pay. I will, if desired, place an amount necessary to cover the cost of the queens in hands of the editor, on terms stated.

The above expresses indirectly my faith in the so-termed long-tongue variety.

Are all thoroughbred Jersey or Alderney cows good? Are all Norman and Clydesdale horses good? Do we find the greater number bringing fancy prices? Verily, no. It is only the few selected ones, and very often they prove no better than those considered inferior; and in breeding from the very select, the same results will evidently follow.

Finally, give me young queens; yes, queens of the past season's rearing for the season of 1902, and at the close of the harvest of 1902 see that all colonies are supplied with young queens for 1903, continuing the rearing or stocking each year with the close of the harvest. It will be the means of a live and healthy apiary. Young, vigorous queens means vigorous and healthy bees, able to withstand the storms of winter, and undoubtedly not so liable to disease. At stated intervals infuse some new blood, by requeening at least a few colonies by purchasing queens from some reliable breeder.

I herewith present a picture of 10 sections of a super of basswood honey produced by the use of the two-way sections and tin separators, on Golden's combination comb-honey hive. No selection was made to secure the best, my purpose being at first to have the entire super taken, but I found it would reduce the apparent size of sections too much.

The hive-marker spoken of appears at the left in the picture. Somerset Co., Pa.

The Premiums offered this week are well worth working for. Look at them.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

THE DR. MILLER NUMBER.

That was an excellent idea to have a Dr. Miller number. The pictures one at a time would not be so effective. Getting acquainted is a process not happily done by small dribbles—and, of course, all old readers enjoy anything approximating to getting acquainted with the senior member of the staff. I feel most interested in him at work at his desk. Desk as crowded as mine, but not so disreputably crowded. Face has a happy look, as if he enjoyed writing—and if he's like me he does.

By the way, our chief has been very shy about showing us his home, and family, and surroundings, and when-nobody's-looking style. Why not have a York number?—[We prefer to leave such things to the editors who enjoy showing themselves off in their own papers. Our family is only Mrs. York, and the "surroundings" are all rented.—EDITOR.]

CURIOUS WAYS OF CLIMATE.

How curious are the ways of climate. In the climate of Florida, it seems, wire-cloth lasts so poorly that burlap is recommended instead of it. Page 744.

DISCOLORATION OF HONEY BY THE COMB.

Dr. Mason is going it strong against discoloration of honey by the comb, if he is going to destroy all his extracting-combs and have new ones built. Page 742.

COLORS OF BEESWAX.

We expect the perfume of a flower to assert itself in some degree in the finished honey; but as to wax a different and very puzzling set of laws seems to come in. A diploma for the wise-head who can tell us fully about the how and the why of it. To a certain extent it seems as if the secretion of wax wipes out all original odors and colors and produces uniformity. And yet there are very great variations in wax, and lots of them. Once when in a supply store I found the place pervaded with an unusual perfume; and the lots of foundation piled up around was of a cherry-red instead of the usual color. Was told it was the usual color and odor of Jamaica wax. Page 751 gives us a number of these variations. One locality in Austria furnishes a wax with the odor of pitch, and too soft. A grayish-brown wax of almost no odor comes from India. Senegal wax is dark brown, and has an unpleasant smell; yet from Guinea comes a good wax. Guadalupe has a black wax. And the European bleachers say American wax is too hard to bleach. Manifestly it's not the latitude and longitude that does all this. What is it?

THE PICTURES OF APIARIES.

Did you mind (of course you didn't) that for a long time I commented on every apiary picture that appeared. After awhile the thing seemed to scrape and run hard—then I faced about and quit the pictures altogether. The beauty of the view on the outside of No. 48 almost tempts me back into the old rut again. Mr. Elliott ought to be a good man to be the Adam of such an Eden of rural simplicity.

HAND-PICKING DRONES.

And here is a subject that is fresh, and not yet shop-worn. How do you select in hand-picking drones? How discriminate between the desirable pater-familias of the "coming bee," and the low-lived proletarian that mates the other fellows' queens? Mr. Doolittle makes a promising start at an answer on page 764. Undersized and ill-shapen ones first killed off. "Nextly," he takes the hind ones, and spares those that rush around lively. Then all that vary much in markings from what seems to be the normal style of the colony have to go. Lastly, he ferrets out and kills all that show by their looks that they might have been born in some other colony. Not easy to give a better set of rules, I reckon. Yet at least two of them are open to some doubt as to whether the best ones are not the very ones that get killed. Never will be able (more's the

pity) to keep the approval of a drone in abeyance until you have examined a few of his "calves."

DOOLITTLE'S BEST SEASON—LONG TONGUES.

And so Doolittle secured his highest average last summer. Congratulations. For a season when so many did poorly it's nice. In the attempt to give the long-tongued bee a black eye (or nose), well, he must try again. Of course, any bees, if their snouts were as long as the elephant's, could fritter away their season with the aid of the swarm fever. And I fear that everything which conduces to prosperity increases a little the danger of that undesirable condition. Page 775.

SELLING HONEY.

Lots of people are troubled over the difficulty of selling their honey after they get it. They should read the Buffalo Convention, pages 772 and 773—read it twice over. Hard cases if they can do that without getting some valuable ideas.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

A COLD.

That's what I've got. And it does make one feel very miserable. We can but marvel at the cold. We are one day hearty and vigorous, and the world seems full of cheer and delight. The very next day we are in the dumps, and everything seems different. And all this because of a "cold" (as we usually call it) that has stolen in upon us.

I have no reason to complain; for it is three years since I have had a cold before, if I except a spell of lagrippe which came into every household of Claremont, a year or two ago, and treated all alike. Isn't that one of lagrippe's virtues? It never shows any partiality.

The cold is like the wind which, as we know, "bloweth where it listeth; we hear the sound thereof, but know not whence it cometh or whither it goeth."

My cold of three years ago I could explain. It came as the result of necessary exposure. This one is more baffling. We are told that the Esquimaux, in their home land, are never troubled with cold. I have heard this explained by the suggestion that colds always come from microbe attack, and the Artic cold is so severe that the microbes would freeze up, and so are not known in the polar regions. I wonder if we won't find, some day, that every cold is the result of an attack from these minute germs. I ween that that will prove true.

This year I have three very hard days each week when my work carries me almost to the limit of my strength. I have wondered if colds are not very much quicker to steal in upon me at times of great weariness; at such times the whole body is below par in vitality, and as the thief could easily enter the house of the sick person and rob him of his valuables, so, mayhaps, these thieving microbes steal in upon us at these times of weariness, and further sap the entire body of its strength and vigor. If this is the correct explanation, then these little, worthless intruders must have a special fondness for the mucous lining of nose and throat. By the feeling, I could easily be persuaded that they had entirely stripped mine from the subjacent tissue. They seem to grip these parts with their invisible teeth, and we are disturbed with the feverish congestion. And how the mucous glands act as if they would have every microbe carried away.

I suppose the moral of all this is always to guard against exposure, and double the caution in times of great weariness. I wonder if all our home circles know of the value of the warm water compress at such times. A napkin wet in warm water is placed about the neck and chest, and thickly covered with several layers of warm flannel. This will often bring great relief to the fevered throat and nose, and will often check the coughing spell at night almost instantly. We have found the same remedy one of the best specifics against croup in children. Possibly the perspiration induced scatters the venomous microbes.

Warm flannels in cold and changeable weather, good rubbers in time of damp and sleet, and the warm overcoat

to force off the chill of autumn or winter, are excellent protective measures, and by their use I believe we may baffle these insidious microbes. I have been planning all day that by the use of these and other kindred measures I may in the future force out these great disturbers of our peace and comfort.

ROADSIDE TREE-PLANTING.

The whole county of Los Angeles is thoroughly waked up on the subject of shade-trees along the roadside. Last week a convention was held in the city to arouse interest, direct attention, and give advice in the matter of shade-trees. Surely, no one thing improves a region more, or attracts settlers more surely, than beautiful avenues of uniform shade-trees.

Shade-trees are not a thing of a day, and so fullest time for consideration is not unwisely spent. Insect attacks, which are so common with some of our most beautiful trees, should be thoroughly studied. The maple in the East is a beautiful tree, and often a favorite for street planting, yet the borer, cottony scale, and the forest caterpillar like it as well as we.

The elm, too, is a favorite with the cankerworm, and the imported elm-leaf beetle. Might not these trees be wisely replaced with the equally handsome linden, and we at the same time add a valuable source of nectar, which will attract the bees and gladden the bee-keeper?

The beautiful pepper in California, which is rarely excelled in grace or elegance, unfortunately attracts the black scale and so is likely to be banished from Southern California roadsides.

Species of acacia and eucalyptus seem very free from insect attack, and may be very beautiful if wisely selected, and in resisting drouth probably have no equal. Surely, we can not afford bare roadsides, and long avenues of trees all of one kind are so incomparably attractive that all our home circles should consider this matter, and then may well follow the example of Los Angeles County, California, and

organize that no mistake may be made, and that every blow struck will tell for the most.

UNRECOGNIZED HEROISM.

I have been reading the past week some account of the life of the late Mr. Stevenson, the distinguished novelist, who, from his early life, had a grim fight with that terrible enemy—consumption. That he might better hold his own against it he pushed away off to the islands of the Pacific, where, far from home and friends, but not until he had made a most valiant fight, he was conquered. In all these years he was a tremendous worker. His forcible style and diction came not easily. Some of his works were written and re-written as many as ten times, and then cast aside as not worthy to be preserved. Is it any wonder that he reached the very top in his profession? To do this with disease and death ever close upon his track points him out as one of the world's great heroes.

It is also said that he was always sunny and cheerful. Friends and companions would never know that any grief or shadow ever entered his life. "To burn all one's own smoke," under such circumstances, is surely the supreme heroism. Those who knew him best also speak of Stevenson as winning almost beyond compare. Hero worship in this case was inevitable and Stevenson was the hero.

Few men can be thus winning, and preserve a really fine character. Stevenson did this. Perhaps the presence of death always staring him in the face gave to him his exceptional superiority. The following is one of Stevenson's beautiful prayers:

"The day returns and brings us the petty, irritating concerns and duties. Help us play the man. Help us to perform them with laughter and kind faces. Let cheerfulness abound with industry. Give us to go blithely on our business all this day. Bring us to our resting beds weary, and content, and undishonored; and grant us in the end the gift of sleep. Amen."

Report for Last Season.

Of the 52 colonies which I placed in the cellar in the fall of 1900, I found, when returning them to the summer stands April 4, 1901, that two had died and one had only a few bees, which I gave to another colony. The most of the colonies were strong, but I had to feed some.

The honey-flow was short, and rain came too late for fall honey, but nevertheless I have shipped 2222 at 13 cents and 63 pounds at 12 cents. I sold 97 pounds at home at 14 cents, also 400 pounds of extracted honey at 10 cents, and have about 300 pounds left. I lost about 300 pounds of comb honey which the bees ate. The reason of this was, we had a spell of very warm weather during which I could not take off honey, as I cannot stand a great deal of heat, and so I was late in taking it off.

I placed 52 colonies in winter quarters Nov. 22.

I commenced bee-keeping in 1890. July 9th (the same year) I had a third swarm, but had very little honey in the fall. I fed them all winter with thin sugar syrup, with good results. I will write about this at some later time.

A certain bee-keeper handed me a book in which I read that if bees swarm in very warm weather give them plenty of shade. This same man lost quite a number of swarms

Standard Belgian Hare Book!

BY M. D. CAPPS.

THIS book of 175 pages presents a clear and concise treatment of the Belgian Hare industry; its growth, origin and kinds; the sanitation and construction of the rabbitry; selection of breeding stock; care of the young, feeding, diseases and their cures, scoring, marketing, shipping, &c. First edition of 50,000 copies was sold in advance of publication.

Price, in handsome paper cover, 25 cents, post-paid; or with the American Bee Journal one year—both for only \$1.10.

Bee-Keeping in Oklahoma.

After marking down another failure in the bee-business in Oklahoma, I can say that though these be failures the American Bee Journal is not a failure. I shall not try to prolong the business any longer, but I am going where they can do something.

I have all the improved hives and appliances, but if there is no nectar one cannot have honey. I received a queen last summer and I introduced her just as nicely as could be. Three days after, she began to lay, and such a nice lot of eggs and bees no one ever saw; but just at that time the dry weather set in. What now? To-day I will have to feed them or they will starve. But I bought a swarm from a gentleman living two blocks from me, that came out the last of May, and, to my surprise, they have from five to seven frames filled from top to bottom, all sealed up. I sold this gentleman the comb foundation. I suppose they got in on the Texas horse-mint before dry weather set in.

I have a lot of nice combs that I have carried through the past summer. I stack the hives one on top of the other with bottoms off, and in the last one on top I set a tin cap or can, with two ounces of bisulphide of carbon, and close it up tight. It need not be bothered for a month. I do not think there is anything that will take its place.

G. W. MAUK.
Calahoma Co., O. T., Dec. 20.

Some Michigan Bees and Honey.

My bees are all "runaway stock," that is, all came from bee-trees that I found in the woods. They seem to do fairly well in gathering honey. My best colony that did not swarm last season produced 190 full sections and 12 pounds of extracted—202 pounds. The best that did swarm cast three swarms. From the old colony I took 56 filled sections and 12 pounds of extracted; from the first swarm, 90 full sections and 12 pounds of extracted; from the second swarm, 30 full sections and 12 pounds of extracted; from the third swarm 12 pounds of extracted and 20 partly filled sections, and they have more than they can consume this winter. Thus, 176 full sections and 48 pounds of extracted—224 pounds, which I think is very well for poor colony.

I noticed what you said on page 803 (1901) regarding the person that found some "real honey" in Michigan last summer. Did you not score them rather hard? Down here in this part of Michigan we are using sections without comb foundation, and any person not a bee-expert, after partaking of this honey, would naturally think, when trying to masticate honey on comb foundation, that honey was all artificial and bogus. This person was undoubtedly mistaken, yet all bee comb and honey readily brings 20 cents per pound, while with the

comb-foundation honey we can only get 15 cents. So let us have charity for the Michigan visitor while testing honey in the Chicago market.

Have you seen the new-style section? Bees will build the combs more true and perfect than with foundation furnished them, as there is no sagging, stretching, or warping of the combs.

D. H. METCALF.

Calhoun Co., Mich., Dec. 28.

Give Us Food and Air.

It is said that Indians don't like to live in houses because they cannot stand the enclosed air. Many a little bird will die when caged—not in want of food but in want of open air. Life is light. When the air is shut up it will cease to burn. Animal life needs, for the production of heat, one part of the atmosphere that is given free by plants, and the plants need that part which is given free by animals. Thus the atmosphere is always the same as long as the parts of it can be exchanged.

Animals or plants heavily fed need plenty of air, because the fresh air only helps to burn up the food, like it helps to burn up the oil in a lamp.

Now it is a fact that the physiological activity in plants, and the reproductive activity in animals, becomes dormant below 43 degrees, Fahrenheit. For this reason a colony of bees with about 50 degrees, Fahrenheit, will not require much food and not much fresh air; and for the same reason the supply of food and air must conform to the temperature.

As a rule the cluster of bees in winter has a temperature of about 70 degrees, F.; with this the respiration is decreased, but the bees cannot live entirely without fresh air. The supply admitted at the entrance is sufficient provided the bad air can pass off without any draft or condensation. The bees use up from the fresh air only one part, and give by breathing free another part that does not agree with their organism. Thus the air surrounding them becomes foul, if not renewed, and is converted into poison. The moisture it contains is condensed on the inside of the hive-cover, and the place of habitation becomes damp. The bees suffer badly, and if they are able to live until they have to go for pollen or water some day in April, they succumb under the influence of work and exposure. To remedy this the hives are ventilated; that is, in common practice the entrance is fully opened, or even the whole hive is raised on blocks at every corner. No doubt there is plenty of fresh, cold air to force out the foul air, and to dry up the moisture, but this rude attempt of ventilation is made at the expense of comfort. What would you think of a man who should attempt to ventilate his hen-house that way? No doubt there would be more fresh air in that house, or hive, than the inhabitants would like to have, and still they could have even more without a house or hive. Such rough treatment results in retarded activity when spring comes, if there is anything left of activity at all.

For ventilation in winter it is best to provide an air-space with absorbing material above the cluster which allows foul air and moisture to pass off. This

Controlling the Mating.

We propose to control mating of queens in the following way, but it will be carried on in a limited way only, for the present:

We are perfecting plans to carry on the mating of queens in North Dakota. We have a spot selected that has no trees or anything where bees could make their abode, except a house now and then. There are no bees here, far or near, and there can be no question about the mating when we select our stock in Illinois, and send nothing but the finest to this place that has no bees. And as it is quite windy here, the chances are that nothing but strong-winged bees will mate. We shall try hard for the very best results.

D. J. BLOCHER, Deinbeigh, N. Dak.

can be done by means of a cushion with chaff placed in the super. The only trouble is that the super does not shut up tight, and the cover cannot be sealed up tight. Then, too, if you want to look after a colony only once in the whole winter you have to take up the whole roof from that little house and let the warm air out and the cold air in. With that movable roof you can not put the hives so close together that they shelter themselves. No, every hive is put up separately, with five sides exposed to the change of temperature.

The supply of food and air is dictated by climatic conditions, and an even temperature secured in any way whatever is therefore just as important as this supply.

Cellar-wintering with its troubles and vexations, is advocated and practiced by many for the benefit of an even temperature, which could be secured out-doors just as well as indoors, if our hives had not so many loose parts and were not opened on top. This feature, however, is so predominant that one might ask, Why did Langstroth invent movable hive-parts or movable frames? There is more comfort in a solid house than in a booth, especially for winter. A good shelter is a saving in food, and if the question of air has no relation to the pocket-book, the question of food certainly has.

J. VOLKERT.

Chesterfield Co., Va., Dec. 17.

Must Have Fine Honey in Chicago.

I have been reading those articles in the American Bee Journal about adulterated and manufactured comb honey in Chicago, with a mixture of amusement, indignation, and pity for those poor, ignorant fellows who have been trying so hard and long to find a pure article of comb honey in your city! You must have an exceptionally fine lot of honey in Chicago if they cannot find any that looks dirty and crooked enough to insure purity. Oh, my, just send those fellows out here to Tioga Co., Pa., where we have not had a decent crop of honey in three years, nectar being so scarce in the fields that bees could not complete a box of any kind of honey, but would patch it up with from two to three or even four different shades, and as many flavors, and capped yellow, black and almost anything except white. It is enough to convince the most incredulous persons of its genuineness, allowing that they judge honey by that standpoint. And even if they had their doubts it would take them the remainder of their days to analyze it and find out what ingredients it was composed of.

I think you people have raised the standard of your bees too high in perfection of comb-honey building. Better leave it on the hive a while longer, and let the bees run over it with their dirty feet and smear a little bee-glue on it; and possibly it would be better to put it on the market with the boxes all smeared with propolis, then the earmarks of the bees would be more prominent!

I well remember, a few years ago, taking some nice white honey to the grocery, and a friend told me that after I went out a minister of the gospel came in and looked at the honey, and remarked that bees did not make that honey. It was too nice; it was man-

ufactured. I have had a great desire ever since to preach that minister a sermon on bees and honey, but never had a favorable opportunity; perhaps I may some time.

We have had a very severe winter so far. Bees have had only one partial flight since the last days of October.

I fear what few bees are left in this section will succumb before warm weather again makes its appearance.

I enjoy reading the American Bee Journal and hope it will continue to prosper, and gain in circulation as it deserves. I wish I could send a whole lot of new subscribers.

A. D. WATSON.

Tioga Co., Pa., Dec. 27.

Adding Supers Above.

I may say that this year all my supers of sections were added at first *above* the others, and rather in advance of the bees' requirements. Only when these last were taken to voluntarily by the bees were they removed below the partly-filled ones. It is more than a theory with me that this is a great aid to success, and I have generally practiced it in very hot seasons, as I find that it prevents loafing, acts as a cooler, assists ventilation, and thus acts as a preventive, or, at least, a deterrent of swarming.—D. M. M., in the British Bee Journal.

A Plan of Uniting Colonies.

About the middle of September I examine all hives and mark those which are not in a populous condition. These I strengthen by reducing the number by doubling up. All other things being equal, I select, for wintering, the colonies which have sent forth swarms, and consequently have young queens. I take two colonies, and if the colony to be united has a greater supply of good winter stores than the colony to which it is to be added, I exchange the combs one by one, and give the colony whose queen is to live the better

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

combs. I then kill the queen of the colony to be united with the one having the good queen, and after giving each hive a thorough smoking, place an empty super-body above the colony to be spared, and upon this place the queenless colony. The smoking seems to destroy the distinctive odor of each colony, and the bees from the upper hive readily unite with those having the queen, and all settle in the lower hive.

After two or three days I uncap the honey in the upper hive, and the bees of the united colonies carry all the honey into the lower hive. The bees live in perfect harmony, and with their increased numbers and greater store of honey, winter far better and gather more honey the next season than would the two colonies wintered separately. In this manner I have united more than 50 colonies, and in only one instance did I have disastrous results. These were caused by the fact that there were two queens in the upper hive, a condition of which I was not aware until about half the bees were killed. It sometimes happens that when the queen is old the bees will rear another, and allow both to remain in the hive until spring.—FRED HAXTON, in the Progressive Bee-Keeper.

Do Bees Hear?

A. H. Homersham (in the British Bee Journal), quotes Mr. Loveday and Mr. Sladen as saying that no evidence can be found that bees hear, and says:

My own experience goes to prove that bees cannot hear, or else they take no notice whatever of sounds. I have whistled and shouted and screamed as loud as I could within six inches of the flight-board, but all my efforts to attract attention were in vain. I made a special effort in shouting loudly one evening in midsummer, after all the bees had returned from the fields, but the peaceful hum of a full colony undisturbed went on. I then gently touched the alighting-board—an almost imperceptible touch—and instantly the humming stopped and a dozen or more bees were scouting about the entrances to find the cause of disturbance. Thus, while noise was unnoticed, the slightest jar was at once detected. I have watched several times to see the effect railway trains had on bees when shunting, or the whistling and rush of an express passing by, but all passed unheeded. I have also tried various experiments on bumble-bees, but without effect, so that I have quite convinced myself, and proved to my own satisfaction, that bees cannot hear.

Management with Two Stories.

wish you could tell us how the yield compares with that of the colonies that have the one story removed. I tried it pretty thoroughly, and was obliged to give up sorrowfully that I couldn't get as much surplus with two stories as when I took one story away. [If the two colonies are the same in strength, then the one that is contracted down to one story would, of course, have more honey. But if one colony is so strong, so boiling over in bees that it could not be squeezed down into the brood-nest of a single hive-body, then I should expect more honey from that colony than if we tried to squeeze it into one brood-nest and then made it get the loafing or swarming fever.—Ed.]—Stray Straw in Gleanings in Bee Culture.

Cyprian Bees in England.

In July last year I bought an imported Cyprian queen which turned out very prolific, and her progeny were very bright and pretty. The colony wintered well, and came out last spring overflowing with bees, and kept up the same condition all the summer. Indeed, it appeared stronger than any colony of bees in my apiary, and yet every one of my 160 colonies yielded me more surplus than the Cyprians. I really do not believe that I got ten pounds of honey from them; and only the other day I found the colony so nearly starving that I had to give the bees a large cake of candy to keep them going. On the other hand, they are good-tempered if handled properly. I do not prefer to use either smoke or carbolic acid when manipulating them. They are also first-class defenders of their own hives, but will find their way into other hives and stay there, but not a single black bee will be allowed in their hive. They are also the most inveterate "robbers" I have ever seen, and are always the first to find any "spoil," but I do not know where they put their ill-gotten gains, for, although I have tried several kinds of foreign bees before, none have been, with me, such poor honey-gatherers, and it is honey that we want and not bees.—JOHN BERRY, in the British Bee Journal.

Cyphers Incubator Catalog for 1902.—All who have seen a copy of the magnificent catalog issued a year ago by the Cyphers Incubator Company will be interested to learn that this company's catalog for 1902 is now ready for mailing, and is a distinct improvement over their great book of last year.

This new and complete catalog consists of 196 pages and cover, is 8x11 inches in size, and weighs over one pound. It contains a complete description of the Cyphers patent diaphragm, non-moisture, self-ventilating incubators, with fine color-plate reproductions of all sizes of the Cyphers incubators. It contains also an illustrated description of the Cyphers apartment brooders, and the full line of poultry appliances manufactured by this company. In it will be found beautiful half-tone pictures of over 200 of the largest and best known poultry plants of America, Canada and Europe, where the Cyphers incubators are in use.

The Cyphers Incubator Company is now completely installed in its great factory at Buffalo, N.Y. The company also has offices and sales-rooms in Chicago, Boston and New York City, and is in a position therefore to serve customers to advantage in all parts of the country at a saving of time and money in shipping by freight.

All who are interested in the latest developments in incubator and brooder manufacture should secure a copy of the Cyphers Incubator Company's complete catalog for 1902. See advertisement elsewhere in this paper. Kindly mention the American Bee Journal when writing.

CONVENTION NOTICES.

Wisconsin.—The Wisconsin State Bee-Keepers' Association will hold its annual convention in the State Capitol, at Madison, Feb. 5 and 6, 1902. This promises to be a large convention. All are invited to attend. There will be excursion rates of 1½ fare for the round-trip, good for all of the first week in February.
N. E. FRANCE, Pres. ADA L. PICKARD, Sec.

New York.—The annual meeting of the New York State Association of Bee-Keepers' Societies will be held in the parlors of the Kirkwood Hotel, Geneva, N.Y., Wednesday, Feb. 5, 1902, commencing at 10 a.m. All interested in bee-culture are cordially invited to be present. Subjects of importance are to be brought before this meeting, and it is desired to have a large representation of bee-keepers in attendance.
C. B. HOWARD, Sec., Romulus, N.Y.
W. F. MARKS, Pres.

Utah.—The Utah State Bee-Keepers' Association will hold its annual convention in the City and County Building, Salt Lake City, April 5, 1902, at 10 a.m. This promises to be an interesting convention. All are invited. It is desired to form an exchange for the protection and benefit of our bee-keepers. Come and aid a good cause. It is expected that every county will be represented.
E. S. LOVESY, Pres. J. B. FAGG, Sec.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The honey market is of a slow nature with little change in price of any of the grades. Choice grades of white comb honey, 14½@15c; good to No. 1, 13½@14c; light ambers, 12½@13c; dark grades, including buckwheat, 10@12c. Extracted, white, 5½@7c; amber, 5¼@5¾c; dark, 5@5¼c; the scale of prices varying according to flavor, body and package. Beeswax steady at 28c. R. A. BURNETT & Co.

NEW YORK, Jan. 9.—Comb honey continues in good demand with supplies pretty well exhausted, and we quote: Fancy white, 15c; No. 1, 14c; No. 2, white, 13c; amber, 12c; dark, 10@11c. Extracted dull with large supplies and quotations on large lots generally shaded in order to effect sales. We quote: White, 6½@7c; amber, 5¼@6c; dark, 5@5¼c. Beeswax firm and rather scarce at 28@28½c.

HILDRETH & SEOLKEN.

BOSTON, Jan. 4.—Comb honey is in good supply and not working off as well as we would like to see at this time of the year. Prices are ranging as follows: Strictly No. 1, 15@15½c; No. 2, 14c. Extracted, white, 7@7½c; light amber, 6½c. BLAKE, SCOTT & LEE.

DETROIT, Dec. 20.—Fancy white comb honey, 14@15c; No. 1, 13@14c; no dark to quote. Extracted, white, 6@7c. Beeswax, 25@26c.
M. H. HUNT & SON.

SAN FRANCISCO, Jan. 8.—White comb, 11@12½ cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5½@6c; light amber, 4¾@5c; amber, 4@— . Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Spot supplies are of very moderate volume, with demand for the time being not particularly active. Offerings are not being crowded upon the market, however, and prevailing values are being as a rule well sustained.

FARM RAISED POULTRY

A New Bee-Keeper's Song—

“Buckwheat Cakes and Honey”

Words by EUGENE SECOR.

Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

“THE HUM OF THE BEES in the APPLE-TREE BLOOM”

Written by

EUGENE SECOR and DR. C. C. MILLER.

PRICES—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for \$1.00 *strictly in advance* payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

“FACTS.”

Root's Catalog Now Ready

the names and addresses of 10 or more bee-keepers, we will send you in addition our 40-page semi-monthly journal, GLEANINGS IN BEE-CULTURE, for 3 months free.

Root's Extractors

It's a fact that Root's Cowan Honey-Extractors are acknowledged by far the best extractors on the market. You will make a mistake if you take one represented to be “just as good.” Our designs are the best, we use the best material, and our workmanship ship is unsurpassed. Insist on “Root's” Cowan.

Danz. Hive

It is a “Fact” that the DANZENBAKER HIVE for Comb Honey, is acknowledged by ALL who have given it a fair trial, the best hive for comb honey.

Gives Best Yields

It is a fact that bee-keepers using the Danz. hive get better yields from this hive than any other hives in their yards.

Higher Price for Honey

It is also a fact that the honey in Danz. Sections generally sells for a higher price, and always finds a ready market. We have yet to learn of a bee-keeper having comb honey in Danz. sections who had to hold his honey because of a dull market.

Agencies

It's a fact that Root's Goods are in demand everywhere. For this reason we have agencies all over the United States and upward of 25 foreign countries. A full list of agents sent on application.

Low Freight Quick Delivery

It is a fact that we are able by these agencies to furnish our goods quickly, and at low cost of transportation.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Alfalfa Honey--7 cents a pound in lots of 4 cans or more.

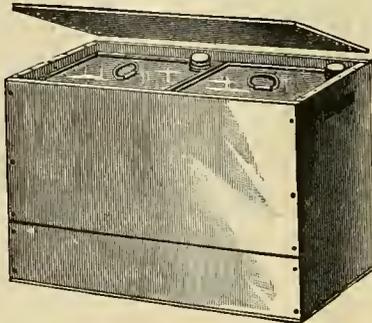

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

42d YEAR.

CHICAGO, ILL., JANUARY 30, 1902.

No. 5.

* Editorial. *

The California Convention was held in Los Angeles, Jan. 16 and 17. The following officers were re-elected:

President, G. S. Stubblefield; secretary-treasurer, J. F. McIntyre; vice-presidents, G. W. Brodbeck, H. E. Wilder, G. F. Merriam, M. H. Mendleson, and H. C. Williamson.

A Los Angeles newspaper report refers to the convention in part as follows:

It was decided to organize the business end of the Association on the plan of the Southern California Fruit Exchange, and to dispose of the honey crop through the latter's selling agencies, thus saving the association the extra expense of conducting independent agencies.

Each county will be organized into a separate exchange, each to elect one of its number to become a member of the Southern California Honey Exchange in this city, which plan centralizes the business here.

The following apiarists were appointed to organize their separate counties: Solas Wood, Santa Barbara; J. F. McIntyre, Ventura; R. B. Borden and R. G. Clark, San Diego county; E. A. Honey and Emerson Bros., Orange county; C. B. Schwaek, Riverside; D. A. Wheeler and H. C. Williamson, San Bernardino; Frank McNay, Los Angeles.

J. F. McIntyre, Maj. G. H. Marion and Prof. A. J. Cook, were elected as the Executive Committee. E. A. Honey, Frank McNay, T. F. Arundell and Allen Barrett were afterward added to the committee.

By organizing on the basis of the fruit exchanges, and disposing of their honey just as fruit is now marketed, the bee-keepers hope to work together in the upholding of the price of their product, and to help each other through the present dry and unprofitable season.

Read Up Back Numbers.—If you are like most bee-keepers, you are busier in summer than in winter. Often it happens that in summer the bee-keeper is so busy that when he receives a copy of this or any other bee-paper, his reading is more or less hurried, and sometimes the reading of some articles or parts of them are omitted altogether, because they do not seem at the time of immediate interest. When leisure comes for more reading in winter, it is well to go over back numbers, not only to read what may have been entirely omitted, but what may have been read in such haste as not to receive due consideration. Indeed, you will find many a time, that what you supposed was of no interest at first will be found later on to be of great practical interest. Then, too, the things that you read with care will generally bear reading again. An article that you read last June, may, because of something that you have since learned either in practice or from reading,

have such a different bearing that it will be practically new to you.

This advice will not be needed by those who are well to the front as bee-keepers, but to those who have not been in the habit of giving more than one reading to each number of the bee-paper they receive it may be well to suggest the advisability of trying the experiment of giving at least a second reading to them.

Wrong Spraying Advice.—Mr. John M. Sutton wrote us as follows, Jan. 18:

EDITOR AMERICAN BEE JOURNAL—
I have recently received from the Government, Farmer's Bulletin No. 38, or "Spraying for Fruit Diseases." This is a reprint originally published in 1896. On page 11, I find the following:

"Use bordeaux mixture, making the first application before the blossoms open. When the flowers are opening spray again, etc."

It seems to me this is in direct opposition to the present teachings, and should be corrected. I am sorry to see it in a Government publication.

JOHN M. SUTTON.

Certainly, all that is necessary is to call the attention of the Department of Agriculture's attention to its contradictory advice, when it will hasten to make proper correction. It is a good thing to report such matters when discovered, as even the Government sometimes makes mistakes.

Meltose Again.—Eugene Secor, the general manager of the National Bee-keepers' Association, wrote us as follows recently.

FOREST CITY, IOWA, JAN. 18, 1902.
EDITOR AMERICAN BEE JOURNAL—
Dear Sir:—Mr. F. L. Thompson, of Colorado, sent me, Dec. 14, 1901, a circular of a health food company doing business in that State, and called the attention to one paragraph which was objectionable to bee-keepers. I wrote the company and herewith submit the correspondence in full.

Respectfully yours,
EUGENE SECOR, *Gen. Man.*

Here follows Mr. Secor's letter to the health food company, dated Jan. 3:

GENTLEMEN:—I have your folder on health foods, and am glad to commend your general Pure Food Proposition. We have used a good deal of Battle Creek foods with satisfactory results.

But I notice under the paragraph describing "Meitose" these words:
"It should be substituted for *Cane-Sugar Honey* and all artificially prepared sweets."

I wish that this sentence might be altered slightly, as it conveys a wrong impression to would-be users of honey.

The fact is there is no such thing on the market as *cane-sugar honey*. It would not pay to adulterate with cane-sugar. The adulterations of honey are exclusively, I might say, of glucose, and in the extracted form.

Comb honey may be relied on as *pure*, or as natural product gathered by the bees.

Now can't you eliminate the word "honey,"

or add the word "adulterated" after the word "sugar," followed by a comma?

Make all the war you please on adulterated honey, but it is misleading to call it *cane-sugar honey*.

May I ask your reconsideration of this point?
Sincerely yours,

EUGENE SECOR, *Gen. Man.*

Whereupon the company written to responded as follows, under date of Jan. 6:

EUGENE SECOR, Forest City, Iowa.—
Dear Sir:—We have your letter of Jan. 3d, in regard to a misleading thought in our circular. Meltose is a pure product, and is designed to take the place of cane-sugar, and artificial sweets. Honey is a natural product, perfectly pure, and we do not class it among sweets that are harmful. On the contrary, we use it on our own tables very freely. The word *honey* should not have gotten into the circular, and was an oversight. We will see that the misleading thought is corrected.

Thanking you for calling attention to the matter, we are,
Yours very truly,

The above is just the kind of work the National Association should be doing constantly. It is educative. It is a benefit to the public to have such corrections made, and also a ways helps the cause of pure honey and its producers.

But why cannot bee-keepers themselves, from this time on, be on the lookout for misleading statements about honey, and write to the people who make or publish such errors regarding honey? A few of us can not do it alone, but all must help in the work of letting the public know more about pure honey.

Maeterlinck's "Life of the Bee," which at first was received almost as a work of perfection, is of late having its faults noticed. D. M. M., in the British Bee Journal, says, "I have only words of praise for Mr. Maeterlinck's book;" and then with what can hardly be entire consistency immediately adds:

"I would, however, much prefer if it had not contained a single word of the moralizings of his physiologist friend. This is an excess, pure and simple, which could well be lopped off."

Then he enters a somewhat emphatic caveat against the view of the author that the peasantry are filled with malevolence pure and simple.

Are Commission Merchants Dishonest as a class? In the Progressive Bee-keeper G. M. Doolittle answers this question in the negative. For 25 years he has shipped honey to commission merchants, shipping to as many as 25 different ones, and he thinks "commission men as a class compare favorably with any other class of men in the United States."

Weekly Budget.

JAS. A. STONE & SON make annual exhibits at the Illinois State Fair. On the first page and also on this page is shown the display they made at the last Fair. All the Lincoln Monument lacks is the statuary. It was made by the son, "Percy," and must have involved considerable work. Both the comb honey display and the monument received the 1st premium, or blue ribbons, as, apparently, they well deserved.

The Illinois State Fair has had fine displays in its apiary department for several years. While the number of exhibitors has not been large, the displays have been both large and good. In fact, this department is one of the most attractive of the whole Fair, and Jas. A. Stone & Son have contributed no little to this result.

MR. J. B. DODDS, the bee-inspector for Jefferson Co., Colo., has been in Chicago for about two weeks. He came with a car-load of No. 1 alfalfa comb honey, which he was holding at \$3.00 per case. A dealer here purchased 100 cases of it, and found that it weighed all the way from 17½ pounds to 24½ pounds, net, of honey per case. So the lightest cases cost about 17 cents per pound, while the honey in the heaviest cases cost about 12 cents. While it may have been all right to sell or buy the 100 cases, as a lot, by the case, any one may easily see the injustice it would be to the consumer were a case of the lightest sold to him at the same price as a case of the heaviest.

As the 100 cases averaged practically an even 20 pounds net per case, there was no injustice done the buyer or seller of this particular lot.

A GREAT MAP.—Calvin L. Walton, Ph. D., is a professor in the Lake View (Chicago) High School, and an instructor of marked ability. He has one of the maps that we are offering, and he expresses his opinion concerning its value in the following unsolicited manner:

DEAR EDITOR YORK:—For some time I have been waiting for a good opportunity to tell you how much we appreciate the Reversible Wall Map of the United States and the World, but find none better than the present. I say *we*, not in any editorial sense, but in a broad family way, meaning the entire household.

In the first place, the maps are very attractive in appearance. The bright colors will catch the eye and hold the attention of even the smaller children of the home, and they are studying geography before they know it.

In the second place, it is up-to-date and thoroughly reliable. The publishers have too good a reputation to maintain to allow any faulty or inaccurate map to go from their press, so whatever knowledge the boys and girls get from the study of these maps will not be gainsaid anywhere.

In the third place, there is a whole encyclopedia of geographic information on the two sides of the map. In country homes, where reference books are few, the marginal references will be found very ample and complete, so that when the map is thoroughly mastered one will have a very broad and comprehensive knowledge of geography and geographic history. The ocean currents, which have such an influence on the distribution of temperature, and which exercise such a general climatic control, are clearly defined and easily traced. Then the routes of the ocean vessels are

graphically shown, and one can see at a glance the growing need for a deep-water isthmian canal to connect our eastern and western coasts.

The most convenient place for hanging the map temporarily was the dining-room; and as we occupy but three sides of the table, the map was hung where all could see it, especially nine-year-old Arthur, who is studying geography in the public school. During meal-time the conversation generally gets around to some phase of geography or travel, owing to the presence of the map, and we find it infinitely better to talk about foreign places and people than about the block in which we live and the good (?) neighbors all around us.

I would most heartily recommend the map to every member of Prof. Cook's "Home Circle," (that includes every reader of this journal), feeling confident that the nominal price asked for it will indeed seem small when compared with its actual value and its educational influence in the home.

C. L. WALTON.

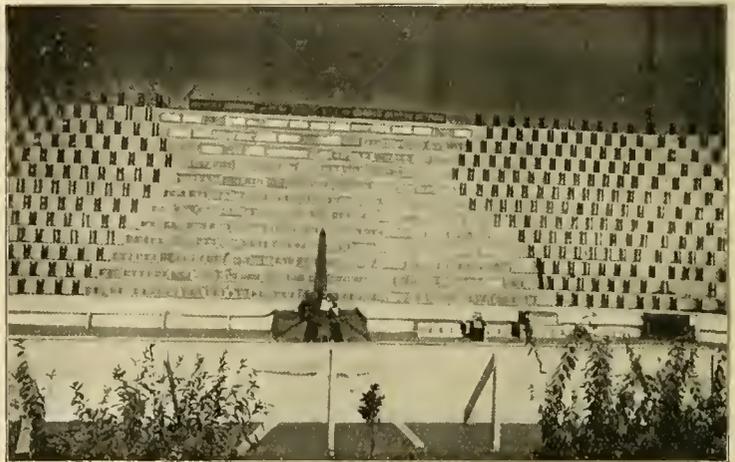

We believe Prof. Walton has not said a word too much in commendation of the map. It is indeed a fine one, and should adorn the

well. I think. I owe most of my success to the reading of bee-literature, especially the "Old Reliable" and other papers. Long may they live to proclaim the wonders of bee-dom, and speak for truth, temperance and righteousness.

R. RODENBERGER.

THE MEXICAN MUTUAL PLANTERS CO., writing us from Old Mexico, Jan. 8, reported that bees there were "doing well, queens laying, pollen coming in, and comb-building going on splendidly." Quite a difference between the condition of bees there and in Manitoba, Canada, on the same date.

MR. WM. W. CASE, of Hunterdon Co., N. J., is doing some good work in his locality to down the comb-honey lies that some people have been helping to circulate. In the Hunterdon County Democrat, under date of Dec. 31, 1901, Mr. Case has quite an article which includes the \$1,000 reward offered, and a

DISPLAY OF JAS. A. STONE & SON AT THE ILLINOIS STATE FAIR AT SPRINGFIELD, IN OCTOBER, 1901.

walls and instruct the people of every home. The price of the map alone is \$1.50 prepaid, or, if taken with a year's subscription to the American Bee Journal, both will be sent for only \$2.00. If we ever made a good offer to our readers it is this one. It shows *all the counties* of every State of the United States.

MR. R. RODENBERGER, when sending the picture of his apiary shown on page 78, wrote as follows:

In the spring of 1895 I caught the bee-fever; so I bought two colonies of bees in box-hives and transferred them into new ones which I had made the previous winter. I now have all hives and frames exactly alike, and all numbered as will be seen in the picture, which was taken two years ago. I now have 51 colonies.

Before I began with bees, I did not know the least thing about them, but got several text-books on bee-culture and have read everything I could get hold of ever since.

I sold my home last fall in Waukesha County, and bought a farm in Milwaukee County, where I am now located. I successfully moved my bees on one load, Nov. 15, a distance of 25 miles. I expect this to be a better location, as there is a great deal of sweet and white clover as well as basswood and golden-rod.

Considering all things, I have done fairly

statement of how the comb-honey lie was given to the public by Government Chemist H. W. Wiley, about 20 years ago.

It seems that Mr. J. S. Trigg, of Iowa, (see page 35), conducts a farm department in the paper Mr. Case wrote to, and the editor, in introducing Mr. Case's article, says Mr. Triggs signs his name and address, "and we have no doubt that he will either prove he is right or admit that he has been led into a misstatement by being misinformed."

We understand Mr. Triggs has since then done the handsome thing by admitting his error, and is doing all he can to counteract its mischievous effect. As soon as we see Mr. Triggs' correction we will place it before our readers.

But let all get "The Truth About Honey" published wherever they can.

II. W. CORNELISON reports that he started last spring with 93 colonies of bees and got 4,000 pounds of honey, for which he received \$475, and an increase of 25 colonies of bees, not counting the honey his family consumed. —Wasburn Co., (Wis.,) Register.

No. 5.—Apiculture as a Business.

Producing Not All; Marketing a Large Problem—Difference Between Selling at Home and the Foreign Trade—Effect of Competition.

BY R. C. AIKIN.

In No. 4 I called attention to some reasons why beekeepers fail in getting a crop and of making it pay, thus causing financial failure and bankruptcy, and the direct and indirect effect upon others. I now wish to show how, in large measure, to avoid these expensive failures.

First and foremost, remember that there are many people—bright and sharp people—who are giving time, money and energy to discover short cuts, cheaper methods of production, and in every way possible increase profits. When they succeed in very materially lowering the cost of production, whether it be by labor-saving devices, improved stock, methods that get 3 pounds of honey where but 2 used to be gotten, better marketing schemes, it matters not whether by all these combined, or how the product is cheapened, they can and will make it hard for the less experienced. If one proposes to go into any business, he should ask many questions, observe how others are accomplishing results, and whether the results are satisfactory. Try as hard as we may, and learn all we can from all sources, yet we will be behind—some other fellow outwits us.

Suppose some one wants to go into honey-production at this place. Suppose he finds out just what prices I get at the honey-house, and the wholesale prices at which I supply the stores. Knowing these things, is he ready yet to produce, expecting to sell his product upon this market? No; he has yet a large problem before him. He may be my equal as an apiarist, get as good crops, pack just as well, in every respect be my equal up to the point of having a nice product to sell; he then finds I have the trade, and if he gets it he has quite a job on hand. He must advertise, push and work up a trade.

So far I have been speaking of the local or home market. The facts are that I am now producing much more honey than our local market consumes, and in addition ship out large quantities. If any other apiarist opens a producing plant here he may in time divide my home trade with me, causing me to export more.

One fact must not be lost sight of in a producing field like this—the home consumption will not use the entire product, we *must* export the surplus. And, to increase the home consumption, we must lower prices if we are to sell the greatest *possible* amount at home. I do not mean that this is the only way to increase consumption, but that is one of the things that must be done to reach the highest possible home consumption, or outside, either. We may sell, say at 10 cents, and after having exhausted all other means a 2-cent drop will further increase the consumption. Putting the price on an equality with sweets of equal grade, or a little lower will bring the product into favor and displace more or less the other goods.

The real truth of the matter is, the marketing of a crop of honey is about as big a job as producing it. In producing, we have but the bees and ourselves to deal with, but in selling there is a multitude of people to please. One may be well fitted to produce, an expert with insects, yet a failure in dealing with his own kind. There is no use denying or ignoring the fact that to produce any kind of crop is but little better than half the battle. Every prospective apiarist must not only consider the matter of producing, but as well, how to market or get cash out of his product.

The home market is nearly always the best; it usually nets the most money; so much is sold that we do not have to supply a package for, nor are there any freights or middlemen's commissions to come out. At home we know better whom we are dealing with, less risks than when we ship, unless there is a firm sticking to the cash-with-order rule.

Successful home marketing is no easy matter; and away from home is harder still.

Some men can come into the field fully occupied, and, because of superior ability, or an advantage in facilities, or otherwise, drive out competitors. But only those without a proper moral conscience will do so; there should always be fairness in such things—in all things. There is, in this vicinity, some territory that would bear more stock, but the near-by and desirable places are already full. No one should think of coming into or very near to this town to engage in honey-production except by buying out some one already established; to do otherwise would be foolish, and an injustice to others now here. To put more stock into territory now well-stocked would reduce the yield per colony. It would mean that we must produce at a greater cost, and to make up for this we must sell greater quantities or at higher prices; but the rule is that it would be just the other way.

But let us see what else can be done: As I have said, there is country tributary to this that will produce more than is being taken from it—places that are not overstocked. But to occupy these one must go into undesirable places to live, or, living in the more desirable places, must have his stock far from home and transport long distances, going far to work, and having far to haul. Besides this, there are the outside or general markets to contend with, the product must be largely exported—shipped to large centers of distribution, as Chicago, Kansas City, etc.

Considering these outside markets, Kansas City is the nearest to this point of the United States. Denver is not a honey market in the sense that Chicago or Kansas City and other Eastern cities are. The immediate vicinity of Denver produces more than the city consumes, and so does the country over much of which Denver is a distributing center. Denver cannot be a distributing center for any great quantity of honey, although she does, and will, sell much by car-load sent to Eastern markets. This being true of Denver, the Colorado apiarist in any field that produces more than the *immediate* home consumption, must look to wholesale shipments by car-load to dispose of his surplus. These car-load shipments mean competition with the producers in the country to which we ship, or who are nearer to the consuming point; these near-by producers having the advantage by the amount of the difference in freight.

Of course, there will be many readers to whom all Colorado conditions do not apply, yet some of them will, and I am trying to cover the whole field and make this reach the greatest number of people.

I would say, then, do not fail to look carefully at all the various things that you must confront when you embark in the business. Let those who are in contemplation count well the cost, and as well let those now in the business see if they cannot find where they can improve. I write that, if possible, I may help those going into the business to go in right, for an intelligent and successful apiarist cannot begin to do the harm to *self and others* that is done by the careless and blundering.

I have already shown in previous articles that it takes a real, practical apiarist to succeed in getting the crops; and now in this article I am endeavoring to show that you need, and must have good marketing, or you fail. Consider *well* all these phases ere you jump. I will follow this with more of the minute details of management. Larimer Co., Colo.

Some Interesting Questions Answered.

BY G. M. DOOLITTLE.

A correspondent from Mohawk, N. Y., sends in the following questions, asking that I answer them in the American Bee Journal, and requests if any reader of this paper can throw any more light on the subject, that he will also answer them after they appear in print. Thus answering would be something after the old question or "query" department the American Bee Journal used to conduct, and I hope to hear from others who may have different opinions from mine.

GETTING HONEY FROM CAPPINGS.

1. "What is the best way to remove honey from cappings which will not run out?"

In my opinion the *best* way is to throw the cappings into the solar wax-extractor and allow "Old Sol" to look in on them for two or three hours. Then cover up, and the

next day lift the cake of wax off the honey, when you have both wax and honey in shape to use.

2. "Could these cappings be pressed in a cheese-press? If not, why not?"

I am not enough acquainted with a cheese-press to answer intelligently; but my judgment would be that the result would not be satisfactory; and that when the press was used for cheese again there would be some "tall talk" about that "nasty, sticky press." Rather than do that, I would rinse the cappings in water, and use the water for making vinegar.

UNCAPPING MACHINES.

3. "Do you know how Arthur C. Miller's uncapping machine is made?"

No, I do not know. If there is no secret about it, will Mr. Miller tell us about this matter through these columns?

PLACING COMBS IN THE EXTRACTOR.

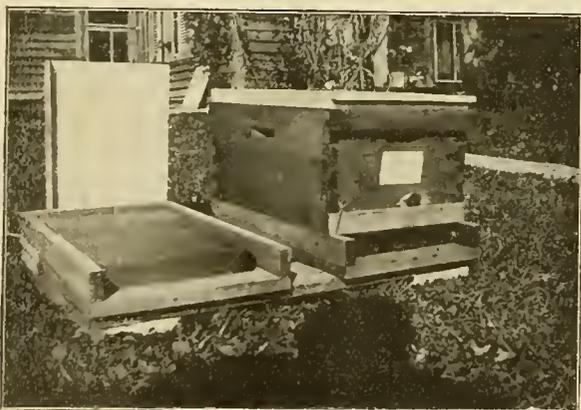

4. "Would a honey-extractor work if the combs were placed with the top-bar toward the center shaft and the bottom-bar out toward the side of the can? If not, why not?"

If I am correct, the honey-extractor works on the principle, that, when set in motion, the centrifugal force is greater than the atmospheric pressure on the honey in the cells, and this causes the honey to leave the cells, or fly from the cells, out and away, from the center, the same as water leaves a rapidly-turning grindstone and flies off and away from the stone. With the combs placed as our questioner suggests, the centrifugal force would cause the honey to press against the sides of the cells, rather than out at the open ends, and hence little or no headway could be made toward accomplishing the desired results. I should be pleased to hear from others in this matter. As the cells in honey-comb generally incline slightly upward, it would appear that better results could be secured, if any, by turning the top-bar toward the can and the bottom-bar toward the central shaft; but I do not think there is anything practical in the idea, anyway.

VENTILATING HIVES—CELLAR WINTERING.

5. "How should hives be ventilated while in the cellar? That is, at the top and entrance. Can they be stacked up as described in the Root catalog and not have the bees pile out all over the cellar and the one stacking them up?"

I use the Dr. Miller bottom-board and like it very much. This bottom-board has a bee-space on one side—the side

HIVE BOTTOM-BOARD USED BY DR. MILLER.

used during the working season—and a two-inch space on the other, which answers for a stand during the summer, and a place for the bees to cluster in during winter, when the board is "winter side" up; that is, where the cluster is large enough to hang below the combs, the cluster hangs down in this space. This space also allows all dead bees to fall below the combs, and gives all the ventilation necessary without further provision, during the time they are in the cellar. It also keeps the bees from falling off the combs, or setting out over yourself and the cellar-bottom, while putting in and taking out, as a small board closes the hive up tight while carrying in and out of the cellar. But, if the hives are reasonably handled, and the proper amount of care used, not to arouse the bees, as is best under

all circumstances, very few bees will leave the hive in putting in and piling up in the cellar.

While at the Auburn, N. Y., bee institute, a Mr. Mills gave us something new, which was that he made rims of $\frac{7}{8}$ -inch lumber of the size of the hive, and $1\frac{1}{2}$ inches deep, on one side of which he tacked the common wire-cloth, such as is used in caging and shipping queens and bees. On warm days, just before time to put the bees into the cellar, he tacked one of these rims at both top and bottom of each hive, the wire-cloth side being out from the hive, and a small entrance, being readily closable, provided in the bottom rim, for the use of the bees, should they have more days of flight before putting in. When putting in, this entrance was closed, and a piece of carpet was placed on top of the wire-cloth at the top, when the hives were piled up, rims all on, and no chance for a single bee to escape during all the winter, the same way Mr. Root pictures in his catalog.

Being told that this was contrary to all old practices, and asked if he had no trouble with the bees trying to get out, he said he was quite positive that he had less loss, and stronger colonies in the spring, in this way than in any other; while he avoided *all* loss of bees from flying out, and the disagreeableness of dead bees on the cellar-bottom. If my life is spared, I shall try this plan in a limited way next winter, as the dead bees on the cellar-bottom are always a nuisance.

PASSAGE-WAYS THROUGH COMBS.

6. "Which do you prefer, all things considered, holes through the combs, or a bee-space over the frames for wintering?"

I thoroughly tried the holes through the combs a score of years ago, and proved them of little if any advantage, while they were a very great nuisance to make, and after being made, were a still greater nuisance in having the bees fill them up the next year with cells of the drone size, so that each hive having such combs sent forth hundreds of drones above what I desired, so I gave the thing up as something not worthy of practice. My hives are so constructed that there is always a bee-space over the frames, and with the Mills plan, this space is one and one-half inches for the bees to pile up in, if they so desire.

CHOOSING A LOCATION FOR BEE-KEEPING.

7. "If you were single, at liberty to go where you wished, and intended to make bee-keeping your life work, what State would you choose, all things considered?"

According to the question, I would hunt out some good, unoccupied place in New York or Vermont, were *honey-production* to be my life work. Undoubtedly there are other States which would give a more agreeable climate, and *might* give a larger yield of honey, but the honey-resources of these States are immense, in favored localities, while their nearness to the great markets of Boston, Philadelphia and New York, which (with Chicago), govern the markets of the United States, makes a market facility unequaled by any other State giving an average good yield.

THE LONG-IDEAL HIVE FOR EXTRACTED HONEY.

8. "Is not the long-ideal hive the best hive for the production of extracted honey?"

It might be, were it best to extract every three or four days during the honey-flow, but as such a course is of questionable wisdom, the hive that allows of tiering-up while the honey is ripening, has the advantage, as I now see it. If there are others who think differently, I should be pleased to hear from them.

Onondaga Co., N. Y.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

PHOTOGRAPHING A BEE.

Honorary mention to Collins, of Denver, assisted by D. W. Working, for their photo of the bee, on the front of No. 50. We should have called it the photo of a live bee if they had not "given themselves away." Anyhow, the assistant knew enough of bees to put things in life position. What are those little spurs half way up the ligula? I think they are visible when we closely examine live bees, and they are very distinct in this picture; yet I don't remember to have ever seen a word about them in the scientific accounts. That the tip of the ligula has a semi-identity of its own, other than being a mere prolongation, is very natural—and praiseworthy.

Room for lots more of this magnified photo work before we reach Had-enough-town. Various parts of the bee (alive if possible) would be very welcome. Several years ago, if I remember aright, Ernest Root got a lucky snap-shot of a bee on the wing, which has done good service as a basis of pictures since.

A LONG-TONGUED NUMBER.

No. 50 seems to be a long-tongued number. All right, say we. No danger of getting too many facts on the subject. Say what you will about the uncertainties, we cannot afford to ignore any bright light which appears in front—only don't expect too much, or get too excited. When Mr. Rankin says that in five years' work for the Michigan Experiment Station he has found the best gatherers to be the long-tongued bees, as a rule—well, the testimony may not be final, but it is not to be pooh-poohed. If the tongue keeps on growing for some time after the bee starts out in life, that's an awkward fact which we must look a little out for, and be sure that we have mature bees.

"Nature has been breeding this tongue to a standard length for so long a time that it is not likely to vary rapidly under artificial selection."

If you're drunk on the new fad, drink a little of that and sober up. Thanks, Prof. Gillette. The professor is excusable for wondering how one or two hundredths of an inch can help very much on red clover. 'Sneets the *real distance that nectar can actually be taken out of a tube varies much more than that.* Interesting to see that the Cyprians lead. Just what might be expected, considering the vim of the race, and the severe conditions under which nature has bred them. It was not the lack of ability to get honey out of a posy that banished the Cyprians, but a job lot of unendurable qualities. But oh! for a honey-bee with a bumble-bee's snout on it! However, probably the shrinkage of the bumble-bee's dissected tongue is much less than in the case of the smaller species—to the extent that the honey-bee in actual work will compare better than do the figures on page 793.

HONEY FROM RED CLOVER.

Prof. Gillette wonders if those who have reported honey from red clover may not have been mistaken. By no means. Theoretically there are at least four different ways bees can gather it. When honey conditions are most favorable the whole inside of the tube, below the funny little knob which closes the top, appears to be moist with nectar (whether by secretion on the spot or by percolation from below does not matter;) and presumably all that's needed to get nectar is sufficient time and patience in licking at the damp surface. Furthermore, carpenter bees are quite plenty in some places, and they in gathering from red clover punch holes in from the outside. Presumably honey-bees could get quite a bit by following their path next day. Thirdly, we often see clover-tubes with a long section of the bottom filled with nectar. It is *supposed* that they sometimes fill up within reach of the honey-bee's ligula. Fourth, a fall drouth shortens the tubes of second crop clover materially; and they are supposed sometimes to be so short that the honey-bee can reach the bottom.

WATCH THE TONGUE-REACH.

I think brethren who feel at all *satisfied* with the dissection measurements would do well to spend a few hours closely watching bees at work on the stalks of sweet corn (as they do not infrequently), and see if their notions about the bee's ligula are not modified somewhat. In this work bees thrust the ligula between the sheath of the leaf and the stem—and it being a tight squeak they often fail to get under, and so by accident extend it along the outside in plain sight. My memory of this observation is that I was surprised at the length of their reach. Perhaps the professors will be.

Convention Proceedings.

Report of the Ontario Bee-Keepers' Convention, Held at Woodstock, Dec. 3, 4 and 5, 1901.

REPORTED BY R. F. HOLTERMANN.

(Continued from page 55.)

SIZE OF HIVES—CELLAR TEMPERATURE.

Ques. 1—Is a larger hive than an 8-frame desirable?

Mr. Hall said for extracted honey, the large one. He has one equal to an 11-frame Langstroth. For extracted, he wants the latter, for comb he does not care which.

Ques. 2—How close should an apiary be located to a dwelling so as to cause no annoyance?

Mr. Hall—I prefer them close, but you must manage rightly. The queens in cross colonies should be killed.

Mr. Sibbald—Much depends on how the bees are handled.

Pres. Newton related an instance where the bees were clearly made cross through bad handling.

Ques. 3—What temperature is nearest correct for proper cellar-wintering?

Mr. Hall—44 degrees, I like. I have wintered bees well at 52 degrees.

Mr. Pettit—Why then want 44 degrees? Do you not think there were conditions you did not consider?

Mr. Hall—No doubt.

Mr. Smith—44 to 50 degrees. I think it does them good to get a warming up occasionally.

Mr. Pettit—Seems much depends on the cellar. I believe and acute ear is the best guide.

BEES HANGING OUT—QUEENLESS COLONIES.

Ques. 4—If bees hang out of the hive, is it an indication of no honey-flow, or is something wrong with the bees?

If others are bringing in honey, and bees in certain hives are loafing, they are probably preparing to swarm. If a few bees are on the bottom-board, the colony is probably queenless.

Ques. 5—What is to be done with queenless colonies early in the spring?

If they have lots of honey, set them on top of another hive. It is not advisable to give them a queen.

RETAILING EXTRACTED HONEY—CARNIOLANS AND ITALIANS.

Ques. 6—What is the best way to put up extracted honey for retail trade?

One pound, 1½ and 3 pound jars, to dealers.

Mr. Evans—I want, for my customers, nothing less than 10 pounds.

Mr. Smith—It depends largely on the class of trade. We put it up in 10-cent tumblers to 5-pound pails.

Mr. Sibbald—In Toronto there are six half-pound jars sold to one one-pound jar.

Mr. Holtermann said it largely depended upon what the retailer educated the people to use.

Mr. Darling—It is not well to sell too large a package.

Mr. Craig—We must regulate ourselves by our local conditions.

Ques. 7—Does crossing Carniolans with Italians produce cross bees?

It does and it does not. Weed out the cross.

COMB FOUNDATION—BEST RACE OF BEES.

Ques. 8—Give us the most profitable method of getting foundation made into comb.

Give to the bees when gathering honey pretty fast.

Mr. McEvoy—Alternate sheets of foundation and combs. It is not profitable to have bees on full sheets of comb foundation.

Mr. Hall—For extracted honey hive on full sheets, every t me.

Ques. 9—Which is the best race?

All of them.

Mr. Smith—Judging from advertisements, the long-tongued.

Mr. Dickinson—Are we to understand that the long-tongued bees are a humbug?

The general opinion was that the long-tongued question had been stretched rather too far.

WEDNESDAY—MORNING SESSION—DEC. 4.

The session opened by the president calling upon Prof. Shutt, chemist of the Dominion Experimental Farm at Ottawa, to give the result of the tests conducted by them in connection with

The Specific Gravity of Honey.

Prof. Shutt said that some years ago some experiments were conducted by the Experimental Farm with comb foundation. In the discussion the question came up of the amount of water found in various samples of honey. There was no Canadian data, and in other books he found a variation of 10 to 15 percent of water. As a result of this Mr. Shutt desired to do some work in this direction, and the same was undertaken with the following results:

With the object of finding the percentage of water Mr. Shutt made a request for samples with which to work, yet no samples had been forwarded by the Ontario Bee-Keepers' Association, and the samples experimented on were from Mr. Fixter, of the Ottawa Experimental Apiary.

Mr. Shutt said that, greatly to his disappointment, he could not tell the members in convention assembled the percentage of water in normal honey. Honey is not a material collected by the bees, but the honey is nectar altered by the bees through chemical additions, a change similar to that which takes place in a portion of our digestive system. There is in honey two sugars closely related, the one sucrose, cane-sugar (dextrose), and another, levulose. This difference was detected by polarization. Results from chemical analysis had shown a great difference in the percentage of water in honey, but Mr. Shutt believed that this great difference was real to only a certain extent, and the great variability only seemed to be so. The work has been done by eminent men, and men of reputation. Why, then, the difference? In honey the portion which crystallizes is the dextrose, the levulose never crystallizing; the latter is also very sweet. Levulose is very liable to decompose, and this decomposition, taking place in drawing off the water, unless condensed, gives the appearance of an increased amount of water in the honey.

The samples taken were, uncapped honey, half-capped honey, and full capped honey.

Four lots were taken of each of the above, two lots covered with a glass stopper, and two with a cheese-cloth. One of each set was put in the honey-house and in the cellar, to test to what extent, it any, exposure to the atmosphere in the honey-house and the cellar influenced the percentage of water and flavor of the honey.

In applying heat to honey, even when the temperature is below boiling water, it decomposed the levulose as well as drove off the water. Therefore, the percentage of water calculated by such a method is unreliable.

Heating honey rapidly, there was less loss than if heated slowly.

Prof. Shutt then referred to the Bulletin of the Inland Revenue Department, showing that one man's work gave almost equal percentage of water, yet varies greatly from another chemist's. The uniform result was probably owing to the fact that each chemist put the samples under his hand through a similar process. In one case was found 10 percent, another 16 percent, another 27 percent, of water. He claimed the difference lay in the treatment of the samples, and Mr. Shutt felt inclined to believe the percentage of water was nearer 15 than 30.

After 48 hours' drying Mr. Shutt's results were 15 percent; after another day, 1 or 2 percent more; after another day, more or less, and so on indefinitely. This method was therefore of no use at 70 degrees, Centigrade, or 158 degrees, Fahrenheit; even the honey decomposed.

Another method was by taking the specific gravity, the percentage of dry matter being deducted from the honey. In this way, instead of 21 percent of water, he secured 17 and 16 percent, which seemed to indicate that even at 126 degrees, Fahrenheit, there was some decomposition.

By the application of heat at 126 degrees the percentage of water in various samples was: 23 by specific gravity, 19 percent; 20 by specific gravity, 15 percent; 22 by specific gravity, 17 percent; 26 by specific gravity, 21 percent; 21 by specific gravity, 15 percent. In the latter case there was 5 percent less water. He was not prepared to say which was more correct. Mr. Shutt, however, favored the specific gravity. But next year he expects to make further tests and at lower temperatures.

To confirm the theory that the levulose decomposed, Mr. Shutt mixed equal parts of dextrose and levulose and took the specific gravity; also applied heat.

At the temperature of boiling water, after 48 hours 10 percent of the levulose had decomposed. After 120 hours, 18 to 19 percent was lost. Next, a temperature three-quarters the heat of boiling was applied; after 24 hours 5 percent of loss was recorded.

Prof. Shutt intends to continue this work and find a definite way of determining the amount of water in honey.

As to general results, Mr. Shutt found that there was a general tendency of about 2 percent more water in the uncapped than in capped honey.

There is very little adulterated honey in Canada, the article used to adulterate being generally glucose. As to the difference between the honey from the honey-house and cellar, he wished a committee to decide. He believed the better way was to keep honey upstairs, not in the cellar.

In reply to a question Prof. Shutt said that Mr. Selwyn told him that, as to specific gravity, seasons of dryness of the atmosphere made a great difference.

A short address was then given on honey as a food.

Honey must be classed with saccharine food only. Foods contain the following: Protein or albumenoids; fat; starch and sugar; ash or mineral matter.

1st. Protein contains nitrogen, as the white of an egg, curds of milk, the gluten of wheat.

2d. Fat—this everyone knows.

3d. Starch and sugar—carbohydrates.

4th. Ash and mineral matter, which forms bone.

We require nitrogen to build up the broken-down and worn-out tissue; the others do not contain this element.

We obtain heat and energy from fats and sugars.

Where does honey come in? It produces heat and energy. It is not the food we eat but what we digest that is valuable. Honey is a food in a partially digested form, and in honey we are saved the expense of partially converting the food. Honey is used as a medicine.

For ages before Christ, honey was the only sugar known. Sugar from the sugar-cane was known to China and India 800 years B. C., but it had no commercial position for 1000 years after that.

Prof. Shutt did not think that honey was appreciated as it should be; it should be used more generally. More judicious advertising would be beneficial.

In liquifying honey it should be kept at 70 degrees, Centigrade, and not above. The essential oil is volatile; one should liquify at a low temperature.

Mr. Fixter, in explaining the selection of the samples, said:

The object I had in view in selecting the samples was to see if we could improve the quality. I therefore took three samples from July 1 to Aug. 5.

Did you extract some in September to get the specific gravity?

Mr. Fixter—No.

Mr. McEvoy—We believe when cool weather comes, the honey, though capped, is thinner.

Pres. Newton—Although Prof. Shutt has not obtained the results he desired, we have profited much by the address. I will appoint Messrs. Hall, Pickett and Emigh to report on the samples.

Report of Inspector of Apiaries.

During 1901 I visited bee-yards in the counties of Bruce, Grey, Perth, Oxford, Waterloo, Wellington, Wentworth, Halton, Peel, York, Ontario, and Simcoe.

I inspected 77 apiaries and found foul brood in 29 of them, and dead brood of other kinds in many others.

Some bee-keepers secured the comb from others who had lost many colonies of bees, and, not knowing that these combs were diseased, brought them home and put them into use, and thus spread the disease in their own apiaries.

When foul-brood matter dries down it glues itself fast to the lower side and bottom of the cells, and there it will remain just as long as the comb lasts, and in old, dark combs the stain-mark left in the cells from the disease is not yet noticed by those who never had any experience with foul brood.

It is when the disease becomes widely spread that the bee-keepers wake up to the fact that their colonies have foul brood. These mistakes, which have so often ended in big losses from bringing diseased combs into apiaries, should be a warning to bee-keepers not to deal much in old combs.

No bee-keeper would bring a diseased comb into his apiary if he knew that it contained foul brood, and the men who dispose of such combs don't know that they are diseased when they sell them.

I received many letters from bee-keepers asking me to visit their localities, and while inspecting there to stop with them. I was much pleased with the generous treatment which I received from every person, and in turn I felt in duty bound to help the people all I could in every possible way besides getting their apiaries cured of foul-brood, and I did so.

I am also pleased to say that nearly all of the largest and best-paying apiaries in the Province of Ontario are among the very many that I got perfectly cured of the disease years ago.

Wm. McEvoy.

Woodburn, Ont., Canada, Dec. 3, 1901.

Mr. Clarke thought it would be well to have a certificate of what had been done, and that the inspector had visited the apiaries, and the condition in which he left each apiary.

Mr. Enigh said that the Government hired Mr. McEvoy, and he reported to them.

Mr. Holtermann said that Mr. McEvoy had to give an account to the Government; it is not a question of his honesty, but in a business-like way he should give account, and this he did.

Mr. Evans said that the Ontario Government looked pretty closely after the finances, and when they passed a statement we might be sure all was right.

Mr. Gray asked to whom to apply for Mr. McEvoy's services?

Answer—The president.

President Newton—I think it would be well to abide more closely to the rule in this report in the future.

The Directors' report was given, and considered satisfactory.

WEDNESDAY—AFTERNOON SESSION.

The president in opening the session said he had great pleasure in calling upon Mr. Murus, Mayor of Woodstock.

The Mayor welcomed the Association and its members; he knew but little about this line of business but thought that more should understand something about bees. He paid the Association a high compliment as to the intelligent appearance of its members. He thought more could engage in the business in general, and especially in the vicinity of Woodstock. He trusted that they would soon be found again convening in the city.

In closing, he welcomed the Association on behalf of the citizens.

Pres. Newton in reply said that the Association was very much pleased to receive the welcome extended, as such a welcome had a tendency to make the members feel at home. On their behalf he thanked the Mayor for his presence and address.

John Fixter, of the Experimental Farm at Ottawa, then gave the following:

Experiments to Test Whether Bees Injure Sound Fruit.

For many years the question as to whether sound fruit was injured by honey bees has been under discussion, but last year special attention was drawn to this question by a lawsuit between a fruit-grower and a bee-keeper, the former claiming that his fruit had been seriously injured by the bees of his neighbor, while the bee-keeper brought evidence to show that not only was this not the case, but that it was impossible. The question was of so much interest to bee-keepers that the following experiments were undertaken to determine whether bees, even when deprived of food, would attack fruit placed within their reach. The results here given indicate that such is not the case, which merely confirms the conclusions arrived at many years ago.

On Sept. 7, 1901, when there was no honey to be gathered on plants outside, ripe fruit of four different kinds, viz., peaches, pears, plums and grapes were exposed in different places near the Experimental Farm Apiary, where it was easily accessible to the bees.

A. Inside the bee-hives.

B. On branches of trees in the apiary enclosure.

C. On shelves in a workshop, to which the bees had access through an open window.

Every care was taken that all the fruit used in this experiment should be perfectly sound.

A. Inside bee-hives: The fruit was exposed in three dif-

ferent conditions, (1) whole fruit without any treatment; (2) whole fruit that has been dipped in honey; (3) fruit which had been punctured in several places with the blade of a pen-knife.

Four colonies were selected for this experiment, all of about equal strength. Each of these colonies was in a hive upon which was placed a super divided in the middle by a partition. From two of the hives all the honey had been removed; in the two remaining hives five frames were left, each having considerable brood honey around it. The former two weighed, on an average, 27 pounds, the latter 34½ pounds. In each one of the four hives the whole specimens of fruit not dipped in honey were hung within three empty frames tied together as a rack. The whole specimens of fruit dipped in honey were placed in one compartment of a super, and the punctured specimens were placed in the other.

The bees began to work at once both upon the dipped and the punctured fruit. The former was cleaned thoroughly of honey during the first night; upon the punctured fruit the bees clustered, thereby sucking the juice through the punctures as long as they could obtain any liquid.

At the end of seven days all the fruit was carefully examined. The sound fruit was still uninjured in any way, but had the surface polished and shining as if the bees had been traveling it, trying to find some opening through the skin. The dipped fruit was in a like condition, quite sound, but every vestige of honey had disappeared. The punctured fruit was badly mutilated and worthless, and beneath each puncture was a cavity, and in some instances decay had set in.

The experiment was continued the following week, the undipped, sound fruit being left in the brood-chamber. The dipped fruit was given a new coating of honey and replaced in the super, and a fresh supply of punctured fruit was substituted for that which had been destroyed.

At the end of the second week, the condition of this fruit was entirely similar to that of the first lot.

For the third week fresh samples of fruit of all the above kinds were used, because some of the sound fruit had begun to decay; this fruit, however, had the skin unbroken, and in no case had the bees done any damage. The result was the same as before.

After the third week the bees belonging to the two hives which had been deprived of the honey appeared to be sluggish, and there were many dead bees about the entrances of the hives. These colonies had lived for the first week on the punctured fruit, and on the honey of the fruit which had been dipped.

As there were at that season few plants in flower from which they could gather nectar, these bees had died of starvation, notwithstanding the proximity of the ripe, juicy fruit. This supply of food, which they were urgently in need of, was separated from them only by the thin skin of the fruit, which, however, this evidence seems to prove they could not puncture, as they did not do so, although they kept crawling over it continually.

The mean weight of each of these two hives Sept. 7, when the experiment was begun, was 27 pounds. At the end of the experiment, four weeks later, each had lost 3½ pounds.

The mean weight of the two hives in each of which were left five frames with brood and honey, was, at the beginning of the experiment, 34½ pounds. The mean loss of each of these hives was 2¼ pounds.

B. Fruit exposed in the open air hung from the branches of a spruce tree in the apiary enclosure: In this experiment two sets of whole fruit were used, one being dipped in honey, the other punctured as before. The bees worked exactly as in the hives and with the same result.

C. Fruit exposed on shelves in a work-shop adjoining the honey-house: This, like the preceding experiment, consisted of dipped fruit and punctured fruit, although the bees did not work so freely inside the building as they did on the fruit hung outside on the trees and that in the hives; still, the results were practically the same in every case.

He had conducted experiments with the different sizes of hives, foundation and putting out bees.

In the matter of experimenting with fruit, Mr. Darling felt sure this experiment, and similar experiments conducted on the other side of the International line, would be of interest to bee-keepers and the public. As to Prof. Shutt's work he was surprised, yet not surprised, that there was the difficulty in detecting the percentage of water. He hoped Mr. Shutt would keep on and make a thorough investigation of the matter. As to practical experience in the apiary, he had no doubt all noticed that the grass becomes discolored at the entrance of the hive, no doubt from the fumes of formic acid from the

hive. He would endorse what Mr. Selwyn had said about the difference in the thickness of honey in certain seasons. The thin honey was not what the customers wish to purchase. Bee-keepers did not adulterate honey with water, but there was unripe honey put upon the market which destroys the market for good, thick, well-ripened honey.

Mr. Darling found that the longer the honey was left with the bees the riper and thicker it became.

Mr. Frith said this was a long-standing question, and of much importance. Many assertions were made, but they wanted evidence such as this. He was surprised that they had to admit that nectar did undergo some change in the hive.

Mr. Holtermann thought we should not let this statement pass; many have for years admitted that it does undergo some change.

Mr. Fixter asked if any one had trouble while picking fruit, or had they found bees working on sound fruit.

Mr. Evans—As a matter of fact, in seasons of scarcity the bees sometimes work on raspberry, but it is near the close of a season when berries are stunted and small; the bees do not sting the pickers unless they pinch them.

Pres. Newton—I think if raspberries are neglected and overripe they are attacked; not when ready for shipping.

Mr. McEvoy—I can endorse the president's statement.

Mr. Byer—I am convinced that bees will injure the raspberry even when not overripe.

Pres. Newton—I do not agree with Mr. Byer.

Mr. Chalmers—I agree with Mr. Byer.

Mr. Holtermann—I agree with Mr. Byer, but it is not often, and the bees help to fertilize the blossom, therefore doing more good than harm.

ELECTION OF OFFICERS—PLACE OF MEETING.

President—J. D. Evans; 1st Vice-President—James Armstrong; 2nd Vice-President—W. A. Chrysler; Secretary—Wm. Conse, Streetsville, Ont.; Treasurer—Martin Enigh. Directors—J. D. Evans, Jas. Armstrong, W. A. Chrysler, W. J. Brown, J. K. Darling, C. W. Post, A. Pickett, J. W. Sparling, M. B. Holmes, John Newton, F. A. Gemmill, Samuel Wood, and Prof. Harrison; Auditors: William Nolan and H. Sibbald; Inspector of Apiaries: William McEvoy; Assistant, F. A. Gemmill; Representative to Toronto Exhibition, A. Pickett; Western, J. F. Miller; Ottawa Exhibition, J. K. Darling; next place of meeting, Barrie, Ont.; Revising Committee, Messrs. Heise and Evans.

(Continued next week.)

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Historical—Dead Bees and Wintering.

1. Where and by whom was the first copy of the American Bee Journal printed? What date is the oldest number?

2. Is one quart of dead bees too much to indicate bad wintering, at the present date (Jan. 7), from 18 colonies?

PENN.

ANSWERS.—There lies before me a volume, whose title page reads as follows:

The American Bee Journal.

Edited by Samuel Wagner.

Volume 1—1861.

Published by

A. M. Spangler, Book and General Job Printer,
No. 25 North Sixth St., Philadelphia.

It was a monthly publication, the first number appearing January, 1861. There are 284 pages in the volume, about 24 pages each month. The printed surface on each page was a little more than a half that on the page of the present number—to be exact, four-sevenths. Comparing the volume for 1861 with that for 1901 (40 years later) the printed surface of the latter is a shade more than five times as much as the former. If the subscription price had been continued at the same rate in proportion to the printed surface, it would now be \$5.00 a year instead of \$1.00. Samuel Wagner, living at

York, Pa., the editor of the first volume, was a fine German scholar, and the first volume was and is especially valuable because of what is drawn from German success, and because of its containing the Dzierzon theory, with which every bee-keeper should be familiar if he would be up in his calling. No single volume of any bee-paper has been so valuable to me as Volume 1. of the American Bee Journal, and to this day I refer to it frequently.

2. No; I should say that is not at all a large quantity of dead bees up to Jan. 7.

Transferring and Swarming.

I have a colony of bees in a box-hive and I am going to transfer into a Danzenbaker hive in the spring. Will a swarm issue from them? and will it store any surplus honey during the season?

RHODE ISLAND.

ANSWER.—If you make no blunder in transferring, the colony ought to do about the same at swarming and storing honey as if it had not been transferred. Some, however, prefer to leave the colony undisturbed until it swarms, hiving the swarm in the new hive, then transferring about three weeks after swarming.

Danzenbaker vs. Langstroth Hive.

If the Danzenbaker hive is preferable to the Langstroth hive for the production of comb honey, are the closed-end frames an advantage? Wouldn't the bees stick propolis all over them so they could not be manipulated?

OHIO.

ANSWER.—I think closed-end frames ought to be better for wintering outdoors than open-end frames. But I found them so difficult to handle that I gave them up. Where propolis is not so plenty they would not be so bad, but if I had to use Danzenbaker hives I should prefer to live where there was no beelue.

Moving Bees a Long Distance.

I want to move 90 colonies of bees as far west as Omaha, Neb., by railroad. I will describe their condition and a plan that I have in mind for preparing them for the journey, and if, in your judgment, it is not complete, add what you think would make it so.

I expect to ship April 15 or 20. The bees are all in 8 and 10 frame St. Joe hives, on metal spacers, so the frames can not get misplaced sidewise. My plan is to put an extra strip on the bottom-board, making the space below the frames about $\frac{3}{4}$ inch, and close the entrance tight, and give them the same space above, with a strip across the top-bars at each end so they cannot shake, covering each with screen-wire, then with the lid or hive-cover off tier them up in the car. The frames are to run with the car, placing two strips of inch lumber between each tier, then fasten them securely so they cannot move. The distance is 382 miles. If they were not shut up over 48 hours would they get through without water?

ILLINOIS.

ANSWER.—It seems to me your plan hardly leaves anything to desire, so I have no suggestion to make. In April it hardly seems they ought to suffer for water if confined not more than 48 hours; still, it will not be a difficult thing to give each colony a small sponge or a rag filled with water.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

GENERAL ITEMS

Beginner's Experience with Bees.

The more I read the American Bee Journal the more I want to, hoping in this way to learn more about the little bees of which I know very little, although I have been keeping and handling them for five years.

When I captured my first swarm off some weeds at the end of a corn-row that I was cultivating, I thought I had performed a great feat. I also thought within a few years I would be a full-fledged bee-man. But I have found there are many things to learn about bee-keeping.

I kept this swarm in a salt-barrel (with a cross and support) the first season and winter. The following spring (having lots of hogs and only one barrel of bees) I traded a hog for a colony of bees in a deep box-hive, and an extra hive; then I transferred the old colony from the barrel to the box-hive. I did not like the hive, although the man I got them of said they were about as good as any made.

At this time I procured "A B C of Bee-Culture," and learned of the Langstroth hive, and at once sent for three of them, and I am using nothing else now.

I got along very nicely for a couple of years; then I had 13 colonies. I had been wintering them on the summer stands, but the winter of 1889-90 I lost eight of the 13 before the winter was half over. So I put the remaining five colonies in the cellar under the dining-room, as we had just completed a new house, and I had built a cellar large and roomy; I concluded it was a better place for the bees of Nebraska. Our cellar is 10 feet deep, 15 by 22, brick walls, cement floor, ceiling lathed and plastered, and entrance from the east porch. I take the window out and slat the hole and pack with straw. The mercury stands at 42 degrees until near spring or warm weather. I have never lost a colony in the cellar from any cause. So it is natural for me to advocate the cellar-wintering for bees.

The season of 1900 was so dry and hot here, or something, that my bees stored very little honey, and cast only one swarm from the five colonies.

The past season was a good one here. One colony of hybrids that did not swarm stored 96 pounds of comb honey, and another 80 pounds, which I thought was good.

I had one colony whose queen got crippled, losing a wing, and she must have been a superseded queen, because she laid nothing but drone-eggs, or all the brood was drone-brood from her eggs. Well, I tried for about three weeks to get them to start queen-cells by giving fresh frames of eggs and brood from other hives, but they would not. So some time in September I sent for a queen to put with them. Well, sir, Mr. York, those bees had become so indolent, or lazy, or something (I

"What Happened to Ted"

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x8 $\frac{1}{4}$ inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,

will let you name it), that they would not try to release the queen from the cage. So after about 50 hours of waiting I let her out of the cage, to go in among them, and everything seemed all right from that on. In a few days she began laying, and October being a fine month, by feeding I kept her laying all through the month, and I think they are all right for winter.

I fed granulated sugar syrup. And right here I would like to ask, Is there any danger of this granulating in the cells so hard that the bees cannot get it out?

W. H. ROOT.
Cedar Co., Nebr., Dec. 24.

[Yes, there is danger if you used no acid. If you feed as early as August or early in September, and use equal parts of sugar and water, the bees will so prepare the food that it will be all right without any acid. But if you feed as late as October and use as much water as sugar, there is danger that the bees will not succeed in evaporating the feed sufficiently; and possibly if they should get it thick enough they would not produce the chemical changes that prevent granulation. So if you must use syrup in October, take 2 pounds of water to 5 of sugar, and about the time the sugar is dissolved stir into it an even teaspoonful of tartaric acid for every 20 pounds of sugar, first dissolving the acid in a little water.—EDITOR.]

Wintering Bees—Arnica for Bee-Stings.

I have been a constant reader of the "Old Reliable" for the last three years—have read every issue very carefully—and noticed the many questions and their answers, and the opinion of different bee-men on the honey-bee question. I am well pleased to hear bee-men give their plans and opinions and new ideas for publication in the American Bee Journal, for it is in this way we all learn something new.

I winter my bees on the summer stands. I have what I call a winter-case, made five inches larger all around than the hive, and six inches higher, so as to admit a super on top of the hive. In September I place this winter-case over each hive and pack them well with chaff, putting a Hill's device over the frames, then a winter super—that is, a super without any slats across the bottom—then a piece of burlap followed by a thick, heavy cushion which fills the super, making four inches right over the cluster. Then I put on a cover on top of the super, then the cover on the winter-case, making all tight and warm. I have used this way of wintering for a number of years and have never lost a colony of bees, and we have some pretty cold weather here in Michigan.

My apiary consists of 13 colonies, as I live in the city and have not very much room. I keep the increase down and work for comb honey. As soon as my bees fly well in the spring I commence to feed; not because they are starving, but to stimulate them and start the queen to laying. Then when the honey-flow comes, which is white clover here, my bees are ready for work, for the hives are full of bees. If they choose to swarm I let them come out and cluster, then I set a new

hive on the old stand with six frames of full sheets of foundation, and a division-board on the outside, as the hives are all 8-frame. I then hive the swarm and cover them up until the next morning, when I take the frames out of the old hive and shake off almost all of the bees in front of the new hive, and if there is any unsealed brood I place that in another hive, leaving nothing but sealed brood in the old hive. Then I place a super on the new hive, and on the super I put a piece of window screen that just fits the sides of the hive. I then place the old hive on top of the super, making all tight so as to keep all the heat which rises from the lower hives. This keeps the brood warm, and soon all will be hatched out; then I shake them off the frames in front of the lower hive. When all are hatched out I take the hive off and keep the cover for other swarms. As soon as the flow stops I take out the two division-boards and put in two frames of worn-out combs. This gives the bees a chance to fill up for winter.

How often we hear the question asked, What is good for the bee-sting? But of all the answers that have been given in the bee-papers I failed to see the remedy that I have been using, and with success. I will give it here so if any one needs it next season he will have an opportunity to try it: Arnica. Simple, isn't it? Well, try it and be convinced. Simply remove the sting and apply the arnica; the pain stops, and the swelling stops. In 15 minutes you will not know that you had been stung. I have used it for several years.

L. D. CARRIER.

St. Joseph Co., Mich., Jan. 4.

Foul Brood—Queens—Candied Honey.

In renewing my subscription to the American Bee Journal I must say that I do not see how a bee-keeper can do without it, although at this time I can hardly class myself as a "bee-keeper." I did not keep mine. That dread disease, foul brood, or its nearest relative, whatever it is, has cleaned me out, and I gave up the fight. Sixty-five colonies last fall, and two colonies this fall, is my record. In five years I have lost over 250 colonies, and I now have come to the conclusion that it is of no use to attempt to keep bees in this locality, as a business, for several years to come, or not until the wild bees in the woods are also dead.

Colonies treated by the McEvoy plan last year (1900), developed the disease this year (1901), the larvæ dying before being capped over in most cases, but two colonies capped their brood before it died. They gave off the "glue-pot" odor, and the others did not.

Now I am looking for another location, and shall "try again," as I have retired from railroad work and aim to amuse myself with the pets I have loved so many years.

In regard to buying queens, I have bought half a bushel, or at least have a half bushel of old queen-cages, but very few I ever bought lasted one year. Of the bright yellow, 80 per cent died the first winter. I have bought queens from Texas to Michigan, and none gave the satisfaction that I got from queens

A Foster Stylographic PEN ...

This pen consists of a hard rubber holder, tapering to a round point, and writes as smoothly as a lead-pencil. The point and needle of the pen are made of platina, alloyed with iridium—substances of great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and do not leak or blot.

As they make a line of uniform width at all times they are unequaled for ruling purposes.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

BEST MANIFOLDING PEN ON THE MARKET.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

How to Get a "Foster" FREE.

Send TWO NEW SUBSCRIBERS to the American Bee Journal for one year, with \$2.00; or send \$1.90 for the Pen and your own subscription to the American Bee Journal for one year; or, for \$1.00 we will mail the pen alone. Address,

(Exact size of the Pen.) GEORGE W. YORK & CO.

of my own rearing. Still, I will buy again when I need them.

Now in regard to candied honey: For 20 years I have produced both comb and extracted. I have never seen candied honey, and have never had any of my extracted show even signs of candying, and have kept it for three years in glass and earthen vessels. When I am short of extracted and buy to fill out, I find the honey candied nearly to the top of the can. I wish some of the wise ones would tell the reason for this.

This American bottom (St. Clair Co., Ill.), is a good location for honey-production if free from disease, but without a State inspector I fear to risk it any more. Some bee-keepers do not know the disease (foul brood), and let weak or dead colonies be robbed out. Others who do not know allow the same thing, and deny having the disease. They go on spreading it by selling to anyone who will purchase. So the need of a State inspector becomes more apparent every day.

What has become of my old comrade, Hon. Ed. Whitcomb? I do not see him mentioned in the American Bee Journal any more. Wake him up please.

If I secure a suitable location you will probably hear from me again.

C. A. HAINES.

St. Clair Co., Ill., Dec. 20.

[Mr. Whitcomb will please consider himself called, and "wake up."—Ed.]

Long Tongues and Red Clover.

In the report of Prof. Gillette, as published in this journal recently, he expresses some doubt as to bees getting nectar from red clover, because the greatest tongue-reach does not exceed .23 inch, while red-clover tubes vary from .34 to .37 inch. To this Editor Root replies in Gleanings in Bee-Culture:

In regard to this last, I feel that Prof. Gillette has gathered a wrong impression, and certainly wrong in supposing that pollen may be the only thing sought by the bees. The red-clover corolla-tubes grown throughout the East, as I have measured them, in hundredths of an inch, vary all the way from .12 to .36 or .37 in length, the depth increasing from the outside to the center. In the rain-belt, at least, I am sure I am right for these measurements. What they may be in Colorado I am not able to say. As nearly as I can estimate, half of the tubes in an ordinary head of red clover come within the range of .20 and .22; so that the bees that have a tongue reach, no matter what their tongue length may be, will be able to gather from half of the tubes; and probably half of all the nectar in the head, as they get some out of the long tubes. That there is honey in these tubes is well known, a fact which can be easily demonstrated. All one has to do is to pull the tubes at the right season of the year, squeeze one between the thumb

SWEET CLOVER

And Several Other Clover Seeds.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

and finger, and a good-sized drop of nectar will issue from the end.

Nay, I have gone further. I have watched bees working on red clover, and I have repeatedly seen them extract all the nectar out of the shallow tubes, and draw it down in the long tubes to a point just equal to their reach. While the bees do, of course, gather some pollen from red clover, yet I think the fact is demonstrated beyond doubt that tons and tons of such honey is gathered, because there are times when nothing else is in bloom, and the bees will store in sections quantities of honey that tastes very much like the bumble-bee honey of our boyhood days.

On all other points I believe the Professor's conclusions are mainly correct, except that some bees have greater reaching powers, probably, than actual measurements will show. His tables show a variation in tongue reach in Italians from .15 to .22. It will be noticed that he says he had measured the tongues from red-clover bees, and also the tongues of those that were said *not* to work on that plant, and that he was "unable to find any difference in tongue length in favor of the clover workers." (The italics in this case are mine.) It would be interesting in this connection to know whether those same bees showed a difference in tongue reach; for, as the professor has very properly shown, there is a difference in tongue reach and tongue length, and the variation of the former is much greater than the latter.

It has been shown—indeed, I believe it is generally admitted—that some bees will gather much more honey from red clover than others. Whether there is a physical difference between them has not been proven so far; and, to speak frankly, it looks now as if tongue length certainly has nothing to do with it. Whether tongue reach has or not, will have to be determined by means of much more perfect glossometers than have yet been devised. I saw glossometers, because I am convinced that the rule plan of measuring (which I have hitherto advocated) is not altogether reliable. It gives an *idea*, but does not show what the bees will or can actually reach when alive.

"Bee-Fever."

DEAR FRIENDS:—I have been obliged to delay writing to you, as I have been "laid up for repairs." A tale hangs to this which I can best tell you by copying an extract from a letter that the partner of my joys and sorrows wrote to her sister. It may have interest for you, as you will see that you are clearly "accessory before the fact," and must bear your share of the penalty:

"Oh, good gracious! I must tell you of the new ailment that is afflicting Harry. You know what an enthusiast the dear fellow is in everything he touches, and how his geese are always swans. This time it is the bee-fever, to which typhoid is simple, and even yellow jack is less virulent. You cannot dream of such absolute absorption. Nothing is of interest unless it concerns bees. Just think, my sitting-room table is covered with bee books and magazines, which I must not move, as he runs in four hundred times a day to consult them and see (I reckon) if his

bees are working according to rule. Every little, miserable weed in the country near and far he has entered in a book—when it blooms, how long, and how good for bees, and his talk is bee, bee, bee, until I can hear the buzzing. I do believe he has a personal acquaintance with each one. I know he has with the queens, for they each have a name painted on their box: 'Yellow Rose of

to the house, and two men assisting him (I leave out what he was saying). I ran to him with, 'Oh, Harry, are you hurt? Are you injured, dear? Any bones broken?' I could see he was in much pain, but bless you, he gave me one of those high and mighty looks of his, and his lip curled up in scorn as he fairly yelled: 'Hurt! Bones broken! Injured! Why, woman, I tell

APIARY OF R. RODENBERGER, OF MILWAUKEE CO., WIS.
(See page 68.)

Texas,' 'Southland Queen,' 'The Lone Star,' etc., and if he does not talk to them I am confident they talk to him, for he can tell by their sounds just what they are doing.

"Some one from Texas sent him some queens, and his anxiety and expectation before they came, and while looking for them, was somewhat akin to what we experienced before the advent of another little stranger whom you know. But when they did come you never saw the like. 'Oh, mother, come look—oh, the beautiful things!—oh, how grand!' I had never seen a queen, and naturally I expected to see something gorgeous. I looked into the little box he was holding up to me and innocently asked (never dreaming of provoking him): 'Is that little brown thing the queen?' You ought to have seen the look of disgust and indignation I received. 'Little brown things! Why, woman, where are your eyes? She is two inches long and yellow as gold,' with which, after glaring at me, he marched out in the high sulks.

"Well, pretty soon he came back all smiles and good humor to tell me he had now introduced them. This seemed an unnecessary formality to go through with insects, I thought, but I did not dare to say anything. All he could do then, was to wait a week and see if they had 'took,' or something (may be it is like vaccination).

"At the end of the week here he comes for my embroidery scissors to cut off their legs or wings or something, and pretty soon I heard a terrible commotion at the barn, and a man came running to tell me he had dislocated his shoulder by a fall. I ran as fast as I could, and met the procession coming

you my queen is gone! What do you mean by talking of bones when I have lost my queen? Just like a woman!

"We got him to bed to find his shoulder was dislocated, and it has taken many weeks to get well. It seems his blessed queen got away and lit away up inside the barn, when he went climbing and clambering up after her, when something broke and gave him a terrible fall. It had no effect on the fever, for it is certainly as bad as ever, a case of 'ruling passion, strong in death.' For my part I feel and hear nothing but 'buz, buz, buz,' all day long. Do not be surprised if you hear of my 'swarming' any time."

Some people may think it was not in good taste for me to thus read my good wife's letter and then send it to others, but you see there is a moral in it. I wish to impress upon others the truth of the old adage that "listeners never hear any good of themselves;" besides, I need sympathy.—HONEY-BUG, in the Southland Queen.

Feeding Back.

J. E. Hand, who says he produced in the past season 2000 pounds of extra-fancy comb honey by feeding back, discusses the matter with a friend in Gleanings in Bee-Culture. Part of the conversation is as follows:

"What do you think of Mr. Doolittle's experience in feeding back?"

"I am not at all surprised at the results of his experiments. I have had about the same experience, and so will any one else who tries to feed back with a frame as deep as the one he uses. However, I consider his frame about

as well adapted to feeding back as it is to producing comb honey when gathered from the fields."

"Then you consider that a hive that is well suited to the production of comb honey is just as well suited to feeding back?"

"Yes, that is my experience exactly. Mr. Doolittle fed his bees 50 pounds of honey, and they only just got to building comb nicely, and then they struck and refused to do anything, after which he gave up the whole business in disgust, as almost every one else does who tries it."

"What do you think became of that 50 pounds of honey?"

"Well, I will tell you what I think became of it. You will notice he says he fed them about 15 pounds each, which they carried off during the day. At that rate it would take only a little over three days to carry off the 50 pounds. They were not building any comb; and as it takes three or four days of feeding to start comb-building there could be no place to store the feed except in the brood-chamber; and as his frame is 11 1/4 inches deep, there was plenty of room for it, or the queen might have been a poor one, and the bees simply crowded her out and filled up the brood-chamber. I have often found this the cause of a failure in feeding back. A good queen will compel the bees to move the honey out and give her room, while a poor one will be crowded out completely, and the brood-chamber crammed full of honey, after which the bees will work about as Mr. Doolittle says his did."

"Do your bees ever refuse to work in the feeders?"

"Well, not so bad as that; but there is a great difference in the working qualities of bees. Some will build comb faster, and cap their honey whiter. I keep a pedigree of these bees, and use them for feeding back. They are also likely to do better field-work. I had three colonies this year out of 50 that I could not make do satisfactory work. Two of them were poor comb-builders, and the other capped the honey so badly that it was not fit to sell. Those queens will lose their heads next spring."

"How much do you find it profitable to feed at a time?"

"I give them all they will take up in 12 hours if they are building comb; if not, I feed about a quart per day until comb-building is started nicely. My best colonies would take about 2 quarts every 12 hours."

"How long would they keep this up?"

"They kept it up this year from August to Sept. 25, when the weather became too cool for comb-building."

"What kind of hive do you consider the best suited to feeding back?"

"There is only one kind of hive that I know anything about that is at all suited to feeding back. It must have a very shallow frame, and must be capable of contraction horizontally so that the brood will be spread out evenly under the super. The Heddon is the only one that will do it."

G. B. Lewis Co., Watertown, Wis., are among those who believe in patronizing the advertising columns of the American Bee Journal. Hence we are glad to acknowledge the receipt of their neat catalog for 1902. It contains 48 pages and cover. See their advertisement on another page. In writing them, always mention the American Bee Journal, as it will help both them and us.

CONVENTION NOTICES.

Wisconsin—The Wisconsin State Bee-keepers' Association will hold its annual convention in the State Capitol, at Madison, Feb. 5 and 6, 1902. This promises to be a large convention. All are invited to attend. There will be excursion rates of 1 1/2 fare for the round-trip, good for all of the first week in February.
N. E. FRANCE, Pres. ADA L. PICKARD, Sec.

New York—The annual meeting of the New York State Association of Bee Keepers' Societies will be held in the parlors of the Kirkwood Hotel, Geneva, N. Y., Wednesday, Feb. 5, 1902, commencing at 10 a.m. All interested in bee-culture are cordially invited to be present. Subjects of importance are to be brought before this meeting, and it is desired to have a large representation of bee-keepers in attendance.
C. B. HOWARD, Sec., Romulus, N. Y.
W. F. MARKS, Pres.

Utah—The Utah State Bee-keepers' Association will hold its annual convention in the City and County Building, Salt Lake City, April 5, 1902, at 10 a.m. This promises to be an interesting convention. All are invited. It is desired to form an exchange for the protection and benefit of our bee-keepers. Come and aid a good cause. It is expected that every county will be represented.
J. B. FAGG, Sec.
E. S. LOVESY, Pres.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The honey market is of a slow nature with little change in price of any of the grades. Choice grades of white comb honey, 14 1/2 @ 15c; good to No. 1, 13 1/4 @ 14c; light ambers, 12 1/2 @ 13c; dark grades, including buckwheat, 10 @ 12c. Extracted, white, 5 1/2 @ 7c; amber, 5 1/4 @ 5 1/2c; dark, 5 @ 5 1/2c; the scale of prices varying according to flavor, body and package. Beeswax steady at 28c. R. A. BURNETT & Co.

CINCINNATI, Jan. 21.—The demand for honey is fair. Extracted honey is offered freely. Dark brings 5c; lighter, 5 1/2 @ 6c; fancy, 6 1/2 @ 7 1/2c. Comb, fancy, 15c; lower grades, 12 1/2 @ 13 1/2c.
C. H. W. WEBER.

ALBANY, N. Y., Jan. 22.—Honey market quiet and firm for all grades of comb honey, of which very light stock is on hand. White, fancy, 15c; No. 1, white, 14c; mixed, 13c; buckwheat, 13c. Extracted, white grades slow sale, and price uncertain. Straight buckwheat extracted scarce at 6c. Beeswax, 28 @ 30c. H. R. WRIGHT.

BOSTON, Jan. 20.—Strictly fancy comb honey in cartons, 15 1/2c; A No. 1, 15c; No. 1, 14 1/2c; very little No. 2 to offer; stock nominally running No. 1 and A No. 1. Extracted, light amber, 7 1/2c; amber, 7c; Florida honey, 6 1/2 @ 7c.

Our market continues somewhat dull in the demand for honey, while stocks are ample for the balance of the season, unless there should be a much larger demand than we at this moment anticipate.
BLAKE, SCOTT & LEE.

NEW YORK, Jan. 9.—Comb honey continues in good demand with supplies pretty well exhausted, and we quote: Fancy white, 15c; No. 1, 14c; No. 2, white, 13c; amber, 12c; dark, 10 @ 11c. Extracted dull with large supplies and quotations on large lots generally shaded in order to effect sales. We quote: White, 6 1/2 @ 7c; amber, 5 1/2 @ 6c; dark, 5 @ 5 1/2c. Beeswax firm and rather scarce at 28 @ 28 1/2c.

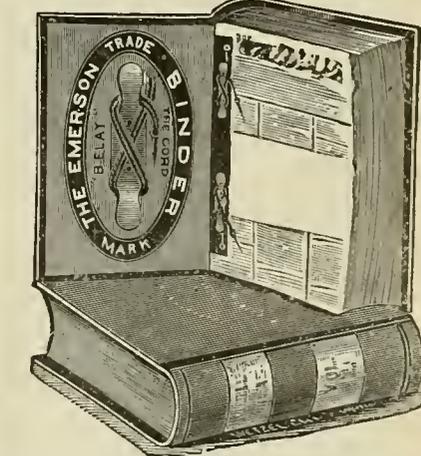

DETROIT, Dec. 20.—Fancy white comb honey, 14 @ 15c; No. 1, 13 @ 14c; no dark to quote. Extracted, white, 6 @ 7c. Beeswax, 25 @ 26c.
M. H. HUNT & SON.

SAN FRANCISCO, Jan. 15.—White comb, 11 @ 12 1/2 cents; amber, 8 @ 10c; dark, 6 @ 7 cents. Extracted, white, 5 1/2 @ 6c; light amber, 4 1/2 @ 5c; amber, 4 @ —. Beeswax, good to choice, light, 26 @ 28c; dark, 24 @ 25c.

There are no changes to record in quotations, but outside figures are more in accord with jobbing prices than with the views of wholesale buyers. The inquiry is light. Offerings are not heavy, however, either at this center or at interior producing points, and in consequence of dry weather the tendency of values is to more firmness.

The Emerson Binder.

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee

Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

"FACTS."

Root's Catalog Now Ready

It is a fact that Root's Catalog for 1902, the 91st edition, contains information valuable to EVERY bee-keeper, whether he has one colony or a thousand colonies. The catalog is ready for mailing, and will be sent free to all applicants. If you will give us the names and addresses of 10 or more bee-keepers, we will send you in addition our 40-page semi-monthly journal, GLEANINGS IN BEE-CULTURE, for 3 months free.

Root's Extractors

It's a fact that Root's Cowan Honey-Extractors are acknowledged by far the best extractors on the market. You will make a mistake if you take one represented to be "just as good." Our designs are the best, we use the best material, and our workmanship ship is unsurpassed. Insist on "Root's" Cowan.

Danz. Hive

It is a 'Fact' that the DANZENBAKER HIVE for Comb Honey, is acknowledged by ALL who have given it a fair trial, the best hive for comb honey.

Gives Best Yields

It is a fact that bee-keepers using the Danz. hive get better yields from this hive than any other hives in their yards.

Higher Price for Honey

It is also a fact that the honey in Danz. Sections generally sells for a higher price, and always finds a ready market. We have yet to learn of a bee-keeper having comb honey in Danz. sections who had to hold his honey because of a dull market.

Agencies

It is a fact that Root's Goods are in demand everywhere. For this reason we have agencies all over the United States and upward of 25 foreign countries. A full list of agents sent on application.

Low Freight Quick Delivery

It is a fact that we are able by these agencies to furnish our goods quickly, and at low cost of transportation.

Facts About Bees

"Facts About Bees," 7th edition, revised, is now ready. Full of information, and sent to any address for a 2 cent stamp, or free if you mention this paper.

E. R. ROOT, DR. C. C. MILLER.

EXECUTIVE COMMITTEE.

- ERNEST R. ROOT, President.
R. C. AIRIN, Vice-President.
DR. A. B. MASON, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

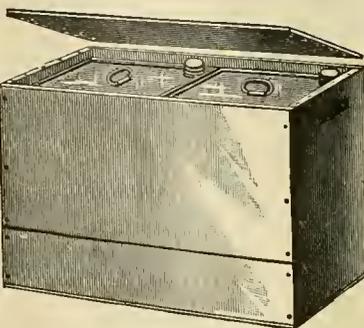

Alfalfa Honey-- 7 cents a pound in lots of 4 cans or more.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7 1/2 cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, 1/2 cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

* Editorial. *

Result of the "National" Election.

—We have received the result of the balloting for candidates in the election just held by the National Bee-Keepers' Association. The report of the committee is as follows:

TOLEDO, O., Jan. 27, 1902.

We, the undersigned, having this day counted the ballots cast for General Manager and three Directors of the National Bee-Keepers' Association, to fill the vacancies caused by the expiration of the terms of Eugene Seor as General Manager, and J. M. Hambaugh, Dr. C. C. Miller, and C. P. Dadant as Directors, find that 338 ballots have been cast; of which Eugene Seor received 172, the other 166 ballots being cast for 29 different members, the largest number of votes cast for any one of them being 33.

For Directors, J. M. Hambaugh received 180 votes, Dr. C. C. Miller, 232, and C. P. Dadant, 215 votes. The other votes were cast for 109 different members, the largest number cast for any one being 29.

We have also counted the votes cast for and against the proposed amendments of the Constitution, and find that 214 votes were cast for the first amendment, and 93 against it; and 263 votes were cast for the second amendment, and 47 against it.

Committee: A. B. MASON,
S. J. GRIGGS.

So all were re-elected. Congratulations to all the honored ones.

Dr. Mason, when sending us the foregoing report, quoted this sentence in his letter:

"Hardly any use to have any election, is it or so often?"

Then he added this comment, which we believe we agree with:

"ME, TOO. I feel now like giving the Constitution another whirl, and provide for electing all officers and changing the Constitution at our annual meeting. Other organizations do it. Our way is a nuisance. There were 30 different persons voted for for General Manager, and 109 for Directors in the recent election."

This is a matter worth thinking about. There is quite a little expense and work connected with a ballot by mail, and it is going to increase with the growth of the membership. The members better think about it and discuss it before the next annual meeting.

Propolis—which seems to be some kind of a preparation from propolis—is spoken of in very high terms in some of the foreign bee-papers. It is said to be a very healing application in wounds and sores, and it is also said that if one's hands are rubbed with it they will not be stung by the bees. An objection is that it is expensive. If it is really a good thing, Yankee ingenuity ought to succeed in getting it prepared so as to be sold at a moderate price.

"The Truth About Honey"—Mr. C. H. Dibbern, of Rock Island Co., Ill., writes as follows, Jan. 24:

EDITOR AMERICAN BEE JOURNAL:—I am greatly interested in your articles on "The Truth About Honey." I have been making some efforts along this line myself, and enclose one of my dodgers, that I furnish with each package of extracted honey I send out. The daily paper printing them kindly inserted the entire matter as an item of news, and it has helped my sales considerably.

I should think that in cases like the Chicago Tribune, a suit for damages by the National Bee-Keepers' Association would be in order. How do bee-keepers generally feel about it?

Yours truly,
C. H. DIBBERN.

As to bringing a suit for damages against the Chicago Tribune, we think it would be a hard matter to get at, though we do wish there might be some way to compel newspapers to stop publishing falsehoods about honey. You see, it is quite a little different when an industry or pursuit is libeled, from what would be the case if an individual or firm is libeled. The latter would be able to claim damages, but a pursuit like farming or bee-keeping could hardly have the same standing in court that a firm or individual would have. Of course, that is only our think. We are not experts in law.

Here is a copy of the wording of Mr. Dibbern's honey dodger or circular, which, by the way, is a good one:

Facts About Honey.

EXTRACTED HONEY is honey thrown out of the comb by means of the honey-extractor. It is simply HONEY without any wax, as in comb honey, and not some sort of "extract of honey" as many people suppose. The reason it is cheaper than comb honey, is that the combs are returned to the bees, to be refilled again and again, thus saving them the labor of building comb, and enabling them to send a much larger force into the fields. It is estimated that bees consume 15 to 20 pounds of honey to produce a pound of wax, and it can thus easily be seen that there is a great saving in returning the combs.

There has always been some prejudice against extracted honey, especially if granulated. People seem to fear that it is adulterated. If honey granulates (looks like lard) it is one of the best tests that it is pure. It is a fact that there is now very little adulterated honey in the market. The pure-food laws are so strict, and detection so easy, that no one can afford the risk, to say nothing about the dishonesty of adulterating it.

If honey is preferred liquid and clear place for a short time in a pan of hot (not boiling) water.

Honey bearing my labels is warranted *absolutely pure*, just as gathered by the bees from the fields. It is cheaper than comb honey, but just as good. You get as much for 10 cents as of comb honey for 15 or 20 cents, and you have left a jelly-glass worth 2 cents, instead of a worthless frame. My honey is filled in glasses while liquid, and left till it granulates, so it will not leak when hauled. It is fine. □ Try it. C. H. DIBBERN.

Strong vs. Weak Colonies for Winter.—Ulrich Gubler, in the Revue Internationale, says that the smaller the number of bees the greater burden upon each individual bee to keep up the heat. In a colony of 30,000 bees each bee will have only one-third as much heat to produce as in a colony of 10,000. So in the spring the bees of the weaker colony will be much more exhausted and fatigued than the others. Besides, a colony of 30,000 will consume much less than three colonies of 10,000 each.

Get a Text-Book on Bees.—That is sound advice to offer several times each year, because there are all the time, and especially at this time of the year, fresh additions to the readers of this journal. You may think you can get along and keep bees without a text-book. So you can. There are bee-keepers living to-day who began with neither a text-book nor a bee-paper, and they have made a success of bee-keeping. But their success would have been more rapid if they could have had access to the various good books and papers published to-day in the interest of bee-keeping, and you could not now induce them to do without such valuable printed helps.

The question is sometimes asked, "If I can afford to get only one, shall it be a text-book or a bee-paper?" This journal is anxious to get as many subscribers as possible, but if you *must* get along with only one, by all means let the paper go and get the text-book. In it you will find the things that every bee-keeper should have as foundation-stones of knowledge, and without which you will do more or less stumbling. If you have only a single colony of bees, the dollar or so that you pay for a text-book will be very likely to come back to you the first season. If you continue at the business, you will get back its value many times in the future.

Whatever else you get, or don't get, if you can get it without stealing, get a text-book on bee-keeping.

The Size and Place of Entrance being asked, Editor Gravenhorst of *Illustrierte Bienenzeitung* replies that it should be 3 or 4 inches wide, $\frac{3}{4}$ inch deep, and about 3 inches above the bottom-board or floor. He considers it bad to have the entrance clear down to the bottom-board, on account of the danger of having it clogged with dead bees. In this country the tendency is toward a larger entrance, and probably few entrances are to be found as far as 3 inches above the bottom-board. Undoubtedly there is an advantage in having the flight-hole so far above the floor that there is no danger of clogging

Commissioner Jones Explains.—In the *Modern Farmer* we find the following letter from Mr. Alfred H. Jones, the Illinois Pure Food Commissioner, explaining the Chicago Tribune's reported interview with him:

EDITOR MODERN FARMER:—

Your letter of the 16th ult., has been forwarded to me and I hasten to answer same, and in reply will state that I was not correctly reported in regard to the question of adulterating honey in the comb, and have corrected all mistaken notions that may have become circulated on account of the article in the Tribune in my Annual Report as the State Food Commissioner, just filed with the Governor, which will be published in the next few weeks.

I never thought of stating that honey-combs are manufactured out of paraffin and then filled out with glucose. On the contrary, Dr. E. N. Eaton, our State Analyst, as well as myself, have taken the position that the honey-cells made by the bees could not be successfully imitated so as to escape detection. In other words, that all the honey, or nearly so, that we have found to be adulterated in this State was strained honey, or honey in the comb, in which the walls of the comb had been broken by being thrown into some vessel, and then glucose mixed with the honey that had oozed out from the comb.

Thanking you for your kind letter, I am,
Very sincerely yours,

ALFRED H. JONES,
State Food Commissioner.

Commenting on the above, Editor Emerson T. Abbott, of the *Modern Farmer*, has this to say:

As soon as our attention was called to the articles which were being published claiming that Mr. Jones had made the statement that comb honey was manufactured by the use of paraffin and glucose, we wrote him to learn just what he did say, and received the above reply. It will be seen that his statements are a long way from those which the Chicago daily press put into his mouth. His explanation as to how the adulterated honey is produced is not as clear as we could wish, and in further elucidation of the matter we will say that the method of procedure is to take a good quality of honey-comb and cut it up into strips. A few of these strips are placed in a jar and glucose poured around them until the jar is full. This mixture is labeled, as a general thing, "Pure Honey," "Pure Clover Honey," or something of that kind. We have some on our desk now which is labeled, "Kellogg's Pure White Clover Honey, Medina, Ohio." We had one of these samples examined by an expert in Philadelphia, and he reported that it contained only 25 percent of honey. This fraud was perpetrated on the consumers by a firm in the State of Missouri who claim to be in a reputable business. We leave the reader to draw his own conclusions as to the honesty of such a mixture so labeled. If we could have our way every man who persists in placing such goods on the market would find himself in the pen with other frauds.

The other method of adulterating honey is by mixing glucose with pure liquid extracted honey. This covers all of the cases of adulteration which are found on the market, and the man who pretends to say in print that combs are manufactured out of paraffin, and then filled with glucose, and sold for pure honey, writes himself down as an ass or an ignoramus on this subject. He can take whichever horn of the dilemma he prefers.

To give this matter more weight, we desire to say that we are authorized by a majority of the Board of Directors of the National Bee-Keepers' Association to offer a reward of \$1,000 for a single pound of comb honey which has been so manufactured and does not appear as a fraud on its face.

Now, if some of these smart reporters want to secure a "scoop," here is their chance. Official announcement of this offer of a reward will be made in due time.

EMERSON TAYLOR ABBOTT.

We are exceedingly sorry that Commissioner Jones did not hasten to get a good, strong

denial over his own signature in the Chicago Tribune at the time the libelous matter appeared. He could very easily have compelled that paper to publish his correction, or stand a lawsuit on the matter, as, according to his letter in the *Modern Farmer*, The Tribune simply published a falsehood. In all probability the forthcoming report of the Pure Food Commissioner will have little attention from the daily newspaper press; and, besides, it is so long after the damage is done that it can be of little use in the way of counteracting the evil effects of the slander published by The Tribune.

Weekly Budget.

MR. A. F. FOOTE, of Mitchell Co., Iowa, wrote us Jan. 13, in the following exceedingly kindly strain:

EDITOR AMERICAN BEE JOURNAL:—

I have just read J. P. Blunk's item on pages 28 and 29. I am glad you let it "go in." I, too, say, "Let's have it"—the type-setting machine. I always try to keep a one-dollar bill on hand to send off in a letter when I wish. I have one now in the warm corner of my purse, that I would like to invest in, or towards, a type-setting machine for the American Bee Journal office in some way. Pay another year in advance, or better still, pay double price for the present year. It wouldn't be any more than the paper is worth to do that.

Anyhow, fix it up some way so we can have that type setting machine. Not that I object to the "girls"—especially the "cook"—working in the office occasionally, for it adds both dignity and refinement to the place to have them there—offices in general, I mean, of course.

Pass it along. My dollar is ready any time.
A. F. FOOTE.

We hardly know what to say to such a generous letter as the above. "It's so sudden," as the maiden said when her admirer popped the long-awaited-for and important question.

But, really, dear friends, if *all* who are now owing on their *back* subscription would just pay up and *also* pay for the year 1902, the type-setting machine could be bought and paid for at once. There would then be no need of the kind suggestion that all pay double-price, even if the American Bee Journal should be thought well worth \$2.00 a year.

It is a very hard matter to know just what to do about subscription credits. So many—surely the great majority—don't want their copies of the American Bee Journal discontinued at the end of the time paid for if not renewed on the minute. And we are glad to favor such by continuing to send it right along, believing them to be honest people who will not only appreciate the courtesy we have extended to them, but will soon pay up and in advance again.

Then, there are some who are willing to receive the Bee Journal right along after the time paid for expires, and when asked to pay for copies they have received, say they "didn't order it;" or "didn't want it;" or "you're a fool for sending it, without pay in advance;" or "when we want a paper continued we will say so"—and many other similar expressions. Certainly, after getting a copy or two beyond the time paid for, and not desiring it, any one could afford to be kind enough to spend one

cent for a postal card to ask us to discontinue sending the Journal. The copy or two received would be well worth the postal card used to send the notice.

We did not think to say so much on this subject when starting out, but perhaps it is just as well to place the matter fairly and squarely before our subscribers at this time. We want to please all our readers so far as we possibly can do so. We also want to feel that they will do the right thing by us. There should be a mutual feeling of honor and regard in this matter. From the many expressions of appreciation of the American Bee Journal received at this office, we know it is worth every cent of the dollar asked for a year's subscription—at least to the person who desires to make anything out of his bees and honey. If we did not believe that, we would be dishonest in accepting a dollar a year for it. Of course, if any one thinks it is not worth the dollar, it is his privilege to take some other bee-paper, or not any—just as he may choose. We would never wish to send the Bee Journal to any one who did not want it. But we do not know it is not wanted until we are so notified.

Now, we trust that all who are in arrears on their subscription will, the very day they read this, if possible, send the amount that is past due, and, if they can, add a dollar for 1902. We would be willing to work every night as well as every day for awhile, attending to such letters. We know we want to help you all by sending you a good bee-paper; and we believe you want to help us by paying for such paper. We have never yet run out of plans for improving the Bee Journal. The only trouble has been to get the necessary funds to carry out such plans. But we do not believe in begging in this matter. It is a clear-cut, business proposition. The American Bee Journal is worth one dollar a year to you or it is not. If it is not, we don't want you to keep on taking it. If it is worth the dollar a year to you, then why not pay it?

Let us be co-workers along the bee-keeping line, as well as friends and brothers.

MR. WARNER MILLS AND APIARY.—Mr. Mills, whose little apiary is pictured on the first page, wrote as follows when sending the photograph:

While you are publishing so much about bees, and showing up so many large apiaries from all parts of the country, I will send you a picture of a very small affair. I live in the center of a city of 140,000 inhabitants. I use Langstroth hives, make them myself, and love to work with the busy bee.

In my former home, Muskingum County, Ohio, I had more colonies than I can here in the city. I bought a colony of Italian bees from Adam Grimm, of Wisconsin, and changed my stock to good hybrids.

I had all the experience that a novice would have, that is at all ambitious. I am going slower now.

I read "The Bee-Keeper's Guide" and the American Bee Journal, and get enough honey for my family use, and a little for my friends.

I am a veteran of the Civil War, and do not have much to do but work with the bees.

WARNER MILLS.

PROF. A. J. COOK, writing us from Los Angeles Co., Calif., Jan. 22, said:

"We are having a very dry winter. It is very discouraging. We hope yet that rain will come in quantity."

It would be too bad if the honey crop should be short the coming season, just when California bee-keepers are ready to use their new honey-exchange organization.

Convention Proceedings.

Report of the Ontario Bee-Keepers' Convention, Held at Woodstock, Dec. 3, 4 and 5, 1901.

REPORTED BY R. F. HOLTERMANN.

(Continued from page 74.)

Prof. Shutt—We have just received a report from the committee to test the samples of honey, and in three cases out of four their judgment agrees with our chemical test of the quality of honey.

Mr. Darling moved that a vote of thanks be tendered to Prof. Shutt and Mr. Fixter, and through them to the Ottawa Government, for the services rendered to bee-keepers in their experimental work in the analysis of honey, etc. Carried by a standing vote.

TROUBLE WITH A HONEY-DEALER.

R. H. Smith then read a letter from a commission-house in London that sent out advertising and other matter, and he found the firm a fraud.

Mr. Craig said he regretted that the advertisement of the firm had appeared in the Canadian Bee Journal.

Mr. Nolan explained a transaction he had with the same firm; the promise of payment had not been kept, and a portion of his account was still unpaid.

Mr. Brown recommended the exposure of such men, and also that the editor of the Canadian Bee Journal take every precaution to see that parties were responsible before an advertisement is inserted.

R. T. Patterson, upon request, told how he was threatened with a suit for damages in connection with bee-keeping. After some discussion it was decided to leave the matter in the hands of the National Bee-Keepers' Association, of which Mr. Patterson is a member.

QUESTION DRAWER—MR. MILLER IN CHARGE.

Ques.—What is the best season of the year to introduce queens?

Ans.—During the harvest or directly after.

Mr. Chrysler—If this is done extra stores should be provided, as the young queen will rear much brood and draw on the stores.

Mr. Evans—In case of Italianizing, etc., would spring not be an advantage?

ONE-PIECE VS. FOUR-PIECE SECTIONS.

Ques.—Which are the better, one-piece or four-piece sections?

Ans.—Four-piece sections retain their shape better and are stronger for market.

Mr. Smith—Which is more generally used in Canada?

Mr. Craig—50 one-piece to one four-piece.

Mr. Chrysler—The best bee-keepers use four-piece.

Mr. Fixter—Do you not prefer the one-piece split top? We use this.

Mr. Hall—If you took much comb honey you would not advocate the one-piece section.

Mr. Holtermann—Mr. Chrysler is right. The question is not which is mostly used, but do the best comb-honey producers in Ontario use the one-piece section? They do not. They use the four-piece, and I strongly advocate it. There is less breakage with a hot-plate machine: a full sheet of foundation can be attached to the top-bar, and after that the section put together. I know of no machine in which this can be done with the one-piece section. When only a few sections are used, and the cost for the machine mentioned is too great, I believe in the one piece section with the split top-bar.

Mr. Pare—I use a brush with beeswax at the proper temperature—not too hot nor too cold. A block fits the section, and I can put them in very quickly after the section has been put together, and use a full sheet, too.

SMOKER-FUEL, LIGHTING, ETC.

Ques.—Which is the best smoker-fuel, and which is the best and quickest way of lighting?

Ans.—Cedar bark is advocated but it burns out too fast. For lighting, cotton saturated with saltpetre; light the cotton after drying.

A Member—Rotten basswood.

Pres. Newton—Planer-shavings. I throw a handful of grass on top.

Mr. Brown—I prefer rotten ash.

Mr. Armstrong—I use rotten elm, cedar bark and planer-shavings.

Mr. Holmes—Cedar bark.

Mr. Hall—Cedar bark.

Mr. McEvoy—If bees are very spunky, try dry June-grass.

Mr. Holtermann—Try compressed peat-fuel.

Mr. Fixter—Use an old bag rolled up.

PRICES OF HONEY—SHADE FOR BEES.

Ques.—Can we maintain the present better prices for honey, and how?

Ans.—Too heavy a question for me, but I believe the Guild will help.

Ques.—Which is the most advisable, natural shade or artificial, when necessary?

Ans.—I like the open spring, but later, shade; not being able to have both, I always place bees under trees.

Pres. Newton—Unless too dense, natural shade.

Mr. Fixter—I believe an apiary in the open is best. If the trees are high it is a great disadvantage for swarms.

Mr. Dickinson—Clip your queens' wings, then you do not need to climb trees.

Mr. McEvoy—I endorse Mr. Miller's statement.

Mr. Pare—I want bees in the open; they work longer.

Mr. Shaver—The same here.

Mr. Hall—My bees work from daylight to dark when there is honey to gather. They are under trees. What more can yours do?

Mr. Smith—I find as to working and results no difference between shade and the open.

Mr. Dickinson—Shelter on the north and west sides is wanted.

OUTDOOR WINTERING.

Ques.—In wintering outdoors is it advisable to pack bees before Nov. 1?

Ans.—I like by October 20.

Mr. Holtermann—I like them packed as soon as I get the brood-chamber ready. By early packing the bees cover the stores, and it is kept in better condition for them.

Mr. Chrysler—I like late packing: the bees learn to cluster during the cold nights.

Mr. Hall—We packed October 16, and I would sooner have done it October 1.

Mr. Shaver—I leave them until Nov. 1st or 10th.

Mr. Armstrong—Does Mr. Chrysler not find the hives moist if packed that late?

Mr. Chrysler—I did not notice.

Mr. Pare—The earlier the better.

EXTRACTED OR COMB HONEY.

Ques.—Which pays better, extracted honey at 9 cents a pound, or comb at \$1.80 per dozen?

Ans.—Comb.

Mr. McEvoy—It depends on the hive.

Mr. Shaver—9 cents for extracted pays best.

Mr. Hall—When not much help, comb honey can be prepared for previously and taken off after the flow. I can produce 80 pounds of comb honey to 100 pounds of extracted. If I can get \$1.60 I will produce no extracted.

Mr. Dickinson—Are seasons not getting shorter and more difficult to produce comb honey? It strikes me the wax should be considered. I have 200 pounds of wax: if I were producing comb honey I would not have had this.

Mr. Miller—True, but the margin more than counter-balances this.

Mr. Smith—At the price mentioned, section honey pays best. It depends on locality. In the south of Ontario comb honey can be produced to better advantage than in the north.

WEDNESDAY—EVENING SESSION.

Pres. Newton introduced the new president, Mr. Evans, who in a very clever manner thanked the Association for the honor conferred upon him. He took the position with diffidence, especially with the modest vice-president, who considered himself unfit for that position, advising the latter to cultivate more "brass" during the coming year. He was glad to see the good feeling and order maintained; they were more like Italians. (A voice added, "Long-tongued!")

He hoped that next year an increased number would attend at Barrie.

Pres. Evans then called for Mr. Hutchinson's paper on

How One Man, Alone, Managed 500 Colonies for Comb Honey, in Out-Apiaries.

I had hoped and expected to be with you at this convention, but, when at the Buffalo meeting, not dreaming of a conflict of dates, I promised to attend the meeting of the Minnesota State Bee-Keepers' Association, which is now in session. The Chicago convention, which I had hoped to attend, is also in session. Hoping that I may be with you next year, and that you may have a pleasant and profitable meeting this year, I will proceed to tell how one man, alone—Mr. Charles Koeppen—formerly of this place (Genesee Co., Mich.), but now in Virginia, managed 500 colonies for comb honey, in out-apiaries.

He bought bees and increased them, and built up to 500 colonies, under difficulties that would have discouraged an ordinary mortal. Almost his first experience was to buy 30 colonies for \$300, and seeing them die of foul brood the next year. He was green at the business, and did not know enough about the disease to recognize it. The bees were in chaff hives, and, by the way, he continued to use these hives as long as he was in Michigan. He disinfected them with a strong solution of carbolic acid: I don't know how strong it was, but he said it ate the splinters off the broom with which it was applied. I presume Mr. McEvoy would say that this precaution was unnecessary. Be that as it may, foul brood never developed in these hives since they were thus treated.

After getting some experience, and a few crops of honey, his enthusiasm and confidence became such that he bought bees largely, going into debt for some of them. Then poor seasons came on, and not only did the bees that were expected to pay for themselves fail to store any honey, but had to be fed both spring and fall. In one instance he fed the bees in the spring to keep them strong, and cared for them all during the summer, only to find they must be fed in the fall, and, rather than do this, he let them go back to the man of whom he bought them, losing his time and the spring feed. It was under such discouragement that he worked away and built up five out-apiaries of nearly 100 colonies each. Then came good seasons, and he was able to buy houses and lots and put money in the bank.

The wonderful thing about this is that he did all the work alone, with his own hands.

Briefly, his methods are as follows: He winters most of his bees out-of-doors, protecting them with chaff. He waits until as late as possible in the fall, sets the hives in a long row with boards at the back and front, and then packs the hives in chaff, putting two inches in front, three or four at the back, and five or six on top, covering all with shade-boards, covers or water-proof building-paper. Some of his colonies are in the chaff hives above mentioned, but he does not like them, as they are too expensive, and too bungling and heavy to handle to the best advantage.

In the spring the bees are looked over, stores equalized and all extra combs removed, the bees being crowded upon as few combs as possible. When the packing is removed, each alternate hive is moved ahead a little, and then in a few days the distance increased until the hives are sufficiently scattered. As soon as the bees are crowded for room, the combs are spread and empty combs put in the center. This is usually done for the first time just before the harvest from white clover. A week or ten days later the colonies are again gone over, and the combs of sealed brood in the center shifted to the outside, the outside combs, that are largely filled with honey, being moved to the center of the brood-nest. At the opening of the basswood flow the brood-nests are again overhauled, and this shifting process gone through with; but in many instances—in fact, in most instances—that is, if the colony is strong enough, two combs of bees and brood are taken away and used in starting a nucleus; their places, in the center of the brood-nest, being filled with empty combs. Each nucleus is furnished with a queen-cell, plenty of which will be found in overhauling the colonies. The empty combs that are placed in the center of the brood-nest at the last overhauling are usually filled, to a great extent, with honey; but, as soon as the flow begins to slack up, the honey will be removed and used in finishing up what sections may be on the hives. It is astonishing how a colony so treated will go on finishing up its sections after the flow from basswood is over.

With this management there is very little swarming, and, as the queens are clipped, the swarms always return, and usually the queens get back into their own hive. If they do not, the fact is shown at the next examination. Mr. Koeppen says that if he can get around and examine each colony as often as once a week, there is practically no swarming. Upon reaching an apiary, if there is not time enough to go over the whole number of colonies, the stronger ones are selected for that purpose.

Comparing one location with another, and one year with another, Mr. Koeppen believes that it is more profitable to keep not more than 50 colonies in a location. None of his apiaries are nearer each other than three miles. His principal honey-resources are white and alsike clovers, and basswood. One of his apiaries was located near a river bottom, and he often secured 25 pounds of surplus in the fall, from this yard, when nothing was secured from others.

During the past three years that he was in Michigan, he secured, on an average, each year, 20,000 pounds of comb honey.

His wife was a Virginia girl and she persuaded him to move to her old home, else I suppose he would still be piling up comb honey in Michigan.

W. Z. HUTCHINSON.

Pres. Evans—The subject is now open for discussion.

Mr. Hall—I am behind; I cannot do this. I am behind the times or too lazy. I cannot run 500 colonies alone. The paper is so vast I cannot take it in. Is it a dream?

Mr. Frith said he thought Ontario had produced nearly 40,000,000 pounds, valued at \$2,600,000.

Pres. Evans did not agree with Mr. Frith.

Mr. Dickinson—It is too much work for one man in Ontario.

Mr. Hall—I can manage 200 colonies when everything is ready in advance, and I can have a horse when I wish.

Mr. Miller—This paper was published four or five years ago in the Review, so it is no dream.

Mr. Holtermann—It seems to me utterly impractical; many matters not mentioned require attention.

A letter was read from Mr. Cogshall, regretting his inability to be present. A vote of thanks was tendered Mr. Hutchinson.

The convention then adjourned to a banquet of its members.

THURSDAY—MORNING SESSION.

The secretary then read a letter from the York Bee-Keepers' Association, showing that the following resolution had been passed, asking the Minister of Agriculture to secure the passage of an act to compel manufacturers of spraying implements, and druggists or others who sell spraying fixtures and mixtures, to label prominently all such implements and preparations with a warning not to spray fruit-trees while in bloom, as specified in the bill passed by the Legislative Assembly a few years ago, entitled "An Act for the Protection of Bees."

Mr. Byer read the following letter from Hon. John Dryden, Member of Agriculture, Ontario:

DEAR SIR:—I beg to acknowledge receipt of your letter of the 11th, drawing my attention to a resolution passed at a meeting of the York County Bee-Keepers' Association, asking for legislation to compel persons who sell implements and material used in spraying to label all such articles with a warning not to use them while fruit-trees are in bloom.

I think I appreciate fully the thought and desire of those who passed the resolution. I am not so sure, however, that it would accomplish much in the direction indicated. The present law is clear, and persons can be fined for violating it, yet it would appear from the resolution that, in the opinion of the members of your Association, it is not strictly observed. I would suggest that another statute would probably be treated in the same manner. It would be very difficult to reach all the parties who handle such goods, and I fear it would be suggested in the Legislature that the present law is quite efficient, and quite as likely to be observed as the one you suggest in addition. If in any particular section persons violate the law in the direction named, it would be easy to lay any information against them, when they would probably be fined for so doing. This would act as the best warning to all parties in the future in the particular locality.

My information leads me to say that, generally speaking, the law is pretty well observed, as it is of no practical utility to spray while the trees are in bloom; time and material are both wasted, and, when this is understood, there is no object in doing it at that time.

Yours very truly,
JOHN DRYDEN, *Member of Agriculture.*

Mr. Byer stated that in his vicinity they had not much trouble. He largely agreed with the views held by Mr. Dryden.

Pres. Evans thought that education went a long way. In his vicinity they had no trouble, the best fruit-growers recognizing that the honey-bee is their friend.

Mr. Byer related how a man in his vicinity offered to pay a bee-keeper if he would place bees on his farm to help fertilize the blossoms. There was a strong feeling to encourage bee-keeping in every possible way.

Mr. Conse told of a man who offered him not only room

to put his bees on his farm but a honey-house as long as he required it; and also to haul his bees a distance of 30 miles free of charge, so strongly was the man impressed with the value of bees as pollenizers of blossoms.

Mr. McEvoy gave the history of the Spraying Act.

A communication from Simcoe Association was read. At the annual meeting a resolution was passed, that the Association wishes the Ontario Bee-Keepers' Association to place permanent placards in public places with that portion of the Act with regard to *prevention of spraying fruit-trees while in bloom.*

QUESTION DRAWER—MR. BROWN ANSWERING.

Ques.—Should honey be strained or skimmed?

Ans.—I strain it.

Mr. McEvoy—Skim, always; say after two weeks.

Mr. Shaver—If exposed two weeks, will it not lose flavor?

Mr. McEvoy—Yes, a little, but if dead-ripe, not much.

Mr. Dickinson—I want honey strained through two cloths, one coarse and another finer.

Mr. Pare—The riper the honey, the less sediment.

Mr. Newton—I agree with Mr. Dickinson. At Buffalo they admired the clearness of Ontario honey.

Mr. Sibbald—it is useless to discuss this any. One should strain and skim.

Mr. Dickinson—There are bee-keepers out to learn and we want to teach them to strain.

James Armstrong—If you have to skim at all why not do away with the strainer?

Mr. Smith—I believe in skimming and straining, but there are lots who do not.

Mr. Fixter—One of the best bee-keepers in Russell county does not strain his honey.

Mr. McEvoy—A sediment settles.

A Member—What you skim off is pollen-grains.

Mr. Holtermann—Do not imagine that pollen will float. The specific gravity of this is greater than honey, as it will sink.

Pres. Evans—I strain honey, but do not skim.

The convention adjourned to meet next year in Barrie.

Contributed Articles.

Selling Comb Honey by the Case.

BY M. A. GILL.

I have read with interest what has been said about the (so-called) Colorado plan of selling honey by the case. I will say that there are some features about comb honey that puts it in the class with cased goods.

We buy our fruit, oysters, and canned vegetables, by the case, and they are retailed by the can, and we don't question whether they are *exactly* pints, quarts or pounds.

Again, if a case of comb honey has been so established that it is, we will say, two pounds short, it is not the fault of the producer, but the manufacturer who has established the size for us to use; however, it does something towards paying us for the trouble and tare on the package, and the great convenience of the goods pays the retailer for what he and the customer imagine as their loss. Most buyers never think of buying any other way than by the case in this section of the country.

The buyer to whom I sold my last car of comb honey the past season, on first seeing the honey, said:

"My people will insist on this honey weighing out 22 pounds per case."

"Very well," I said, "if they will pay me pro rata per pound what it weighs above 22 pounds per case."

"Oh, no," said he, "we don't care if it weighs 30 pounds."

I told him there was 1200 cases of honey, that there was a chisel and a pair of scales, and that he could examine to his heart's content; but that if he bought it, it would be by the case—at \$2.80 per case.

He bought the honey, and subsequently told me he weighed about 40 cases, and, that it weighed from 22½ to 24 pounds, net. Now he may think he bought by weight, but I think I sold by the case.

Again, it is not always convenient for us to weigh a car load of honey, but we always know it will weigh *so much*,

if we have graded it according to the rules of the State Association.

I have known one quite extensive buyer who would buy by the pound, then sell his light weights by the piece and his heavy by the pound. I conclude by this that *all* the virtues are not held by the buyers and dealers.

I insist again that the convenience of the package must, and does, pay the dealer and consumer for the ounce of honey they think they have lost, which, in fact, they have.

When I say the consumer has lost an ounce of honey I want it understood that his loss has not come through the producer, for when we say we want so much for 21 pounds or 22 pounds, we furnish that much. This is as far as our conscience goes—but to my certain knowledge too often the jobber sells what he has bought for 22 pounds as 24 pounds and the retailer sells the piece as 16 ounces if it is light, and by the pound if it overruns. So when the producers are accused of sharp dealing you will find we are not the only "pebbles on the beach."

Mr. Burnett says that after what he has written and said he looks for a lot of ignorance to be dispelled. I hope this is so, for it is always best to get rid of all the ignorance we can. But more surely in the future than in the past will Colorado's crop of comb honey move by the case than by the pound. We will see that it is done upon an equitable basis, but we will enjoy the same convenience as other producers of cased goods.

Boulder Co., Colo.

Extracting House on Wheels—Other Conveniences.

BY A. MOTTAZ.

Last summer, for the second season, I used my extracting house on wheels, with much satisfaction. Diameter 15 feet long by 8 feet wide, sides 6 feet high, roof round, made of 2 thicknesses of one-half inch boards with tarred building-paper between. Floor, inch flooring laid lengthwise on 2x4 resting on two sills 2x8, hay-rack fashion. Frame, 2x2 all around; cotton sheeting tacked on under, and one-half inch boards up and down.

The sills project behind to or 12 inches to receive on top a 2-inch plank for a door-step for convenience in going in and out, and also to rest one end of the plank on which is to run the wheel-barrow on when extracting.

Two single sash windows opposite each other, are on each side about four feet from the rear corner; and one in front to see to drive the team.

The wagon or running-gear is an old heavy wagon-gear with Electric steel wheels, 28 and 32 inches high.

The wheelbarrow's wheel is a cultivator iron wheel; the barrow's frame rests on two blocks 5 or 6 inches higher than the wheel's axle; it has long legs in proportion so as to stand about level; the object is to have it on a level with the extracting table in the house, so as to be able to roll it right on the platform, which lies loose on the barrow's frame, and having castor wheels underneath. I have two platforms: when the full one (they hold two hives each) is extracted, it is

HONEY-WAGON OF A. MOTTAZ.

A. MOTTAZ IN HIS APIARY.

rolled on one end of the table to make room for the full one, and then exchanged for it on the barrow.

The extractor, a four-frame Cowan, stands in the middle of the house, on one side, and the straining one-half barrel tub in one front corner, and the cans at the other end and alongside of the house.

I am careful to drive to the nearest and most convenient and level place to the hives. This is kept in mind when placing the hives, and whenever possible I stop on ground having an incline away from the apiary so as to be able to run the house away by hand. When this is impossible we use a rope 100 feet long, and also sheet covers on the horses. We have to use the rope only occasionally.

The house and furniture with 1000 to 1200 pounds of honey make a good load on ordinary good roads.

We are promptly ready for work on arriving. I usually ride alone in the house, my help (usually three), coming and returning in a top buggy. My daughter and two neighbor girls prove first-class help, both to do the work expeditiously and in fixing the house both at starting and finishing.

We extracted last summer about 18,000 pounds in all, including about 1000 pounds of comb honey, from some 200 colonies, spring count; but 60 colonies had been transferred in the spring.

I have quite an extensive retail trade, to the stores in pint Mason jars, and to private customers in pails and in bulk. This will use six or seven thousand pounds. This trade increases every year.

LONG-TONGUED BEES.

I have just read with interest Prof. C. P. Gillette's article on long-tongued bees. I desire to emphasize his remark, that besides long-tongue there is to consider the individual energy, gumption, or get there, of the bees. Let me illustrate: I have two horses, one is smaller than the other, some older, somewhat stiff, and 15 years old. That horse is very greedy whenever he happens to be cast about for finding something to eat. When hitched up double or single, and reined up, he turns his head on one side, braces his legs in some odd way, and reaches the shortest grass, if only there is any at all. Let him loose in a yard, tight must be the barn and crib indeed if he cannot get something to eat. His neck, or nose, or teeth, are no longer, rather shorter, than most horses, but I believe that if he were put with 99 others in a barren, starved place, in all likelihood he would outlive all the others.

Also, I have some 18 cattle; last fall, when the pasture began to fail, two of them after having fed the grass underneath the lower wire, finally pushed their way entirely through the fence into a clover field. I then put the whole herd into it. Well, the next day the same two energetic cows again pushed their way into a corn-field adjoining, and kept finding plenty of feed. Now is it not so with bees? Will not a bee or a colony of bees with tongues two or three, even four one-hundredths less long tongue, but having ten one-hundredths more energy or greediness and know-how-to-get-there, surpass merely long-tongued bees?

I do not deprecate breeding for long tongues, for this, coupled with the other (and it can certainly be) cannot help proving extra good gatherers.

By the way, I have had working for me a carpenter, a tall fellow, probably six feet and 2 inches, or more. Many times I have seen him reach up to drive a nail high above his head, and apparently above the length of his arm. I would think he is too short by 1, 2, 3, or 4 inches, but every time he would stretch arms, body or legs, or all together, and reach to his nail. He is the only carpenter I ever saw do that. I often thought that he could always stretch or reach another inch higher. All this comes from some characteristics of both the body and brain, or instinct when in animals or insects.

La Salle Co., Ill.

The Truth About Honey—Encouraging Words.

BY C. P. DADANT.

It sometimes seems rather discouraging to see so many false stories pass current about the nature of honey and the adulteration of it, and yet when we look back upon the conditions which the apiarist has had to meet in this country, and upon what he is meeting in the Old World, there are many things that give us encouragement.

When the honey-extractor was first invented by a European apiarist, Hruschka, there was no practical way to separate honey from the comb. Good honey could be secured only by straining the nicest combs, taking good care not to mix the old combs with the new, or to get combs in which any pollen was stored. The average "strained" honey was taken out by heating, and was cloudy, dark, and mixed with all sorts of objectionable things, of which the least disagreeable was the pollen. So those who knew honey in the liquid state, knew only this ugly mixture, and I can recall dozens of instances, in the early '70's, when the consumer would flatly say: "No, sir; that isn't honey. I know honey when I see it. That's sugar syrup that you are trying to palm on us for honey." Then would come a description of honey as the man had seen it: "No, you can't put any of your stuff on me; my dad used to keep bees when I was a boy, and such nice buckwheat honey he used to get; but it was not like that, it was darker. That is altogether too light-colored for honey. None of your sugar for me."

But the worst man to "rub in" the slander was an old fellow who thought he could not eat honey: "No, sir; I can't eat honey; pure honey makes me sick; but I can eat Dadant's honey; it is just right for me; it don't make me sick. I don't know what they make it out of, but probably good sugar."

And so it went for years, and the argument and assertion had to be taken over and over, that the honey was "honey" and nothing else, and that if it was nice, that was a quality and not a fault. For years it was out of the question to get the papers to quote "extracted honey" at all, and they insisted on the word "strained."

Some of my readers will probably say that it is very much that way yet, in many places. That is true, yet the average commission man and the average grocer are quite likely to be informed on the question of honey, and you do not have to begin at the beginning and inform even the educated man—the man of good sense—and every day you meet people who already know the actual facts, and help you to argue your case.

Again, even, if our chemists have done us some harm by repeating stories—for fun or out of ignorance, which is hardly excusable in learned men—we now have chemists who really take hold of the true interests of the pursuit, and their work goes a long way towards helping both ourselves and the consumers. Mr. Eaton, the chemist in charge of honey tests at Chicago, has undoubtedly done work which will bear fruits. The National Bee-Keepers' Association, on the strength of his tests, has begun a work of reform which is showing practical results among the adulterators. For years—yes, for 30 years—we have seen a fraud perpetrated upon the public by dishonest dealers who passed glucose for pure honey, helped in this work by the consumers themselves, who, out of their ignorance, were distrustful of the pure article and disliked granulated honey. Lately, I must say that I have examined a number of samples of such of the stuff as used to be sold openly as honey, and in every case I have found it to be labeled "Imitation HONEY," with the disreputable word in small letters of course; but with such labeling there is no need of any one being deceived in what they buy, and I believe that the success achieved is to be credited to the work of Mr. Eaton. There has been enough done to frighten the adulterators in many cases. It is without doubt that there must be a great deal of adulteration yet, but it is getting timid. It feels that

the truth is becoming known, and as we progress the true article will stand a better show every day.

The sale of honey, in my experience, has undergone an evolution which is remarkable. In 1870 one had to drum, and drum, and repeat the history of honey over and over again, with each customer. A few years later the sale had already made some progress, but there was still a chance for the consumer to be deceived, even if he tried hard to become informed. To-day the average man knows what he buys, and the average grocer cannot readily be deceived. True, there are all sorts of incredible stories running about, and it is a real shame that daily newspapers should lend themselves to such humbugs; but the average newspaper is not above relating a big ghost story, or a sea-monster tale, and they (it is sad to say) expect to keep alive by sensational reports. It will take many and many a day to teach the truth to the World, but each day brings a little change and sooner or later the truth will stand supreme. It is very much easier to sell honey now than 30 years ago; it is even easier to sell it than it was ten years ago, and since the new methods are still in their infancy, we must not get discouraged, for it is a slow thing to educate the masses.

Let us never spare a chance to inform the people, to threaten and frighten the adulterators, and we may readily expect that success will crown our efforts. I think it would be well to keep our National Bee-Keepers' Association after the adulterators, and to publish, whenever practicable, all we know about good, true, honest honey. Hancock Co., Ill.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

FORCED SWARMING.

That Colorado plan of forced swarming—sections with full foundation above and only starters below—that's a plan which it will certainly do to watch with interest. Probably a poor plan for a lean locality. And fat locations which have a capricious way of withholding or misplacing the honey-shower may vote it a vexation. Page 798.

AGE OF LARVAE USED IN QUEEN-REARING.

For patient, persistent work in a good cause, and against venerable lies with strong backers, Dr. Miller deserves a medal. Few more honorable forms of intellectual doing good can be found on this globe than just that kind of work. But, ah, me, how the brickbats do fly, in the benevolent chap's direction, sometimes! The bees' choice of 28 young larvæ to only 1 too old larva is a triumph for a valuable truth. In reasonable probability that one was chosen only because lots of bees that wanted to work at that kind of work couldn't readily get at the limited space where the younger larvæ could be had. The ordinary removal of a queen from a full colony would not bring such conditions. It was a serious dilemma that most of the bee-keeping world were in—learn methods unendurably fussy, else not do anything at all at the propagation of their *very best* stock—and Dr. Miller has removed that dilemma. Page 798.

DISAGREEMENT OF LONG-TONGUE DOCTORS.

While I was talking long tongues I failed to notice one sad disagreement between the doctors. Prof. Gillette finds the amount of the variation one-twelfth, while Mr. Rankin finds it one-third of the tongue's length. The former rather seems to infer from the small relative variation that the whole effort is hopeless. The larger relative variation would stimulate us to hope that still larger ones could easily be produced when once Intelligence takes the thing in hand. Pages 789 and 794.

FEEDING BOILED FOUL-BROODY HONEY PROHIBITED.

So (in the laboratory) foul brood has been made to grow after two hours' boiling of the honey? And practically the average bee-man will reproduce the disease in so large a proportion of the trials that the best inspectors now totally forbid all attempts to disinfect and feed foul-broody honey. This is somewhat of a change from former ideas and teachings. Page 789.

THE SELF-WATERING EUCALYPTUS TREE.

I have read with interest many items about the eucalyptus in California; knew it was specially adapted to dry climates, but somehow I never before got hold of the idea that it watered itself by condensing water on the leaves at night. Oft good-sized puddles on the ground, eh? A Yankee trick among trees—even if the trees don't come from Yankee-land, but from the antipodes. Howsoever, a Bakersfield Californian at my hand never heard of this, although eucalyptus is plenty there—don't think the puddles would appear where the nights are as dewless and dry as in the Kern River valley. Almost any tree *might* make a puddle when a dense, dripping fog comes up—or when the air is saturated, and the night sky clear. Page 807.

DISCARDED HIVE-COVERS.

"I have hundreds of discarded covers of all descriptions lying around." Mr. Bartz, we are not all of us in that condition outwardly, but most of us are in that way inwardly—unsatisfied as to cover. Alas, I fear for your cover, also! Depends for its water-turning powers wholly on muslin and paint—and the slope a mere trifle. 'Specks that in most yards it, too, would soon be chalked, "Discarded." Page 811.

EXCHANGING QUEENS.

To introduce three "superior" queens and lose 400 pounds of honey by it. Well, that's just one of the little incidents in our efforts to climb. Many of us don't know how good our own bees are. And only a small "lunk" of sympathy can we deal out to such an experienced old chap as Wm. Stolley. But the case is decidedly sad when a beginner with 25 really superior queens kills them all off and introduces 25 which are scarcely half as efficient. Still, our efforts to climb should not be left off altogether. It is to be regretted that public competitions in the actual work of different strains of bees are so troublesome and so rare. Page 824.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

GOOD-BYE.

When our good friend and editor, Mr. York, asked me to attempt this department I was no less surprised than startled. I had never "sawed such wood." It would be an entirely new field. Could I do it acceptably? Would my usual duties permit the time? Would my strength prove equal to the added task?

I have a brother whom I have always regarded as almost an ideal man. The fact that he is my brother may have influence to effect the opinion. It certainly did in that I know him so thoroughly. He says he has always regretted that he had not a larger family even to number ten or twelve. Possibly the possession of two splendid boys gave him this longing for still better things. Surely, to give to one's country and the world ten stalwart children, true, vigorous, God-fearing, is a privilege that any of us might well covet.

My lot was like my brother's, though better; for while I had but two children, one was a daughter, and so I have always felt, and do now feel, much sympathy with my brother's longing. I would like a large family; indeed, as teacher, I have always had a large family, and to-day I can count my boys and girls by the hundreds. The thought that he may have done something to lighten the loads, and sweeten the lives of these foster children, is what makes the profession of the teacher so full of pleasure and inspiration.

The thought of the larger family—the great, big family that would be instantly born to me as editor of "The Home Circle" department of the "Old Reliable," I must say came to me as a most toothsome morsel. It would be a precious privilege to share with them all my pleasures in the home, the children, the home pets, the flowers, the neighbors, and the thousand daily experiences that make this earth so delightful and this life so worth living. I could but say, "I will try it." I have never regretted the decision. I come each week, though often wearied and over-tasked, to this part of my full life's work, with only thoughts of pleasure. I really felt that I came to a great home

which was full of those who sympathized with each other, and were in kindly sympathy with me; of those who were kindly tolerant of each other, and so would be charitable with me even though I might stumble on to the wrong thought or unsuitable suggestion. I have meant to give my best, and only good things. That I have always been so happy as to realize my desires, I am not at all certain is true. We can hardly expect to be so privileged even in matters of much less importance and influence in this world of imperfections. I am assured of some success, in the very kind, and, I fear, undeserved words of appreciation and approval that have come to me from numerous members of the dear home circle. It has indeed been a labor of love.

I believe no country is above its average homes. I believe more depends upon the sanctity of the home in making a grand, stalwart nation, than on aught else. So, to-day, it is my proud hope that I may have said some word, dropped some hint, quickened some good purpose, that has worked to make some home truer and better. Surely, if what two have written me—that they always read "The Home Circle" article first, and are always helped by it, is at all shared by many others, then am I glad and happy.

It was no pleasure, then, to write the letter that would sever this connection, and strike from our dear old American Bee Journal "The Home Circle" department. Other duties take precedence, and I am constrained to say, Good-by.

I still hope that the idea may not be given up, but that it may fall into other and abler hands.

We often hear doubts as to the perpetuity of our country. People say, "No republic has lasted, so ours will cease." We do not believe it. Yet there are serious dangers that should make all of us serious and thoughtful: The terrible social evil, the horrid saloon, the labor problem, unequal taxation. What will dominate these evils and preserve us as a nation? A quick, active conscience. The recent election in New York City shows that we have the conscience. If in New York City, then surely in the country at large. If we would make safe our country's future we must all do our little part towards arousing and strengthening the conscience of our people.

When can, and must, this work be done? Surely, as we all agree, in our homes. If our homes are all that they should be, then our Government will feel the quickening, and we shall continue to bless the world.

The greater problems which of late have come upon us make it all the more important that the public pulse as to righteousness be quickened. It seems a great thing, this raising of our whole people to a higher plane; it should make us all feel a higher dignity and a greater self-respect, that in our own beloved homes, where the influence will be reflex, and will react beneficently upon us, we may do our part in this glorious work.

It is my best hope, and my fervent prayer, that I may have done a little in these "Home Circle" articles to bless the homes and enrich their spirit. I come to the last word, "Good-by," with only sorrow, regretting that the pleasant relation might not have continued; and wishing that our limitations were not so obvious.

A. J. Cook.

[Perhaps a few words from us might not be amiss, right here. Prof. Cook had an opportunity to do writing for which he could command much higher pay than we felt we could afford to give him, and so we thought he should not sacrifice his good opportunity in order to continue this department. We know his home circle contributions have been greatly appreciated by nearly all our readers.

Of course, the department will be missed, and yet we will use the space thus vacated in a way that will be both helpful and profitable to all.

But, after all, the great majority of those who subscribe for the American Bee Journal do so for the information it contains on practical bee-keeping. We could not hope, within its few pages, to compete with the many rich and varied home magazines that are published to-day. And almost every family has such magazines, as they are so fine and so cheap. So when Prof. Cook decided that he could not continue at the price he was receiving, and that we could afford to pay him for the work, we concluded to devote the space and money to matter we are certain will be appreciated by our readers. It may be more nice pictures, more splendid contributed articles, and more of some other good things.

Of course, Prof. Cook will continue, as heretofore, to give to the American Bee Journal his best articles along the line of bee-keeping. We have several such on hand now. So our readers are not going to lose him, after all.—EDITOR.]

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Starting in Bee-Keeping.

I am a bee-keeper and have a mother and myself to support.

1. Do you think it would be advisable for one to start with six or eight colonies of bees?

2. Would it be necessary to have a large piece of ground?

ILLINOIS.

ANSWERS.—1. Unless you have some money to throw away, don't think of beginning with so large a number as 6 or 8 colonies. First experiment with not more than 2 colonies, and find out whether you can make a success of the business. You may be well fitted for the business, and you may not. Only trial will tell. If you think of undertaking bee-keeping, get a text-book first thing (you can get one at the office of the American Bee Journal), and familiarize yourself with its contents between this and the time for bees to fly in the spring. The study of a text-book and the reading of a bee-paper, together with practice upon one or two colonies, will start you on the road to successful bee-keeping if there is in you the right material for a bee-keeper.

2. No, a large piece of ground is not necessary. You can get along with not more than 10 square feet of ground for each colony. Some bee-keepers in cities have had no other place for bees than a flat roof.

Finding Queens—Knowing Bees are Not Queenless—Preserving Caged Queen Above a Normal Colony.

1. A queen is found by searching each frame in the hive, of course. But it is something easier that I would like to do. I tried three or four times last fall to catch the queen of a certain hive; I was sure she was there, since I saw the eggs and larvæ. I could never get at her, so I gave it up in disgust. Now, there are various devices to catch rats, mice, flies, etc., why not invent a queen-catcher? I move that a premium be proposed to award the inventor of the best queen-catcher.

2. When we see the eggs or larvæ anywhere in the hive we know that a queen is there. But there are times when the queen stops laying, as in October, generally. Well, now, that is just the time we want to be sure that each colony is provided with a good queen. Don't say, examine carefully each frame, etc. I want to dispense as much as possible with such manipulations. Is there any means of knowing for sure that her majesty is at home, without entering the house? I will relate my experience:

Last fall I had two queens to spare, so I went to a hive which I suspected to be without a queen. I put her majesty in a little cage with perforated zinc, and placed the cage in a little box above the frame, with a glass, so as to watch the actions of the bees. They came to see the queen, entered the queen's apartments, seemed to feed her, and by and by lots of bees came and filled the box, so I concluded they were without a queen.

I went to another colony, and repeated the same trick; the bees came, but only in small numbers; after two or three days, they did not seem to care much for that queen; only 8 or 10 were with her. I was surprised that they seemed to treat her kindly, and to feed her. But thinking that they possibly had a queen down below, I removed the caged queen. Afterwards, being a little perplexed about that colony, I went to the trouble of examining every frame. I found no queen, no queen-cell, eggs, no larvæ, no pollen stored, except one frame full of pollen. I feel I should have risked to liberate the proposed queen, but I did not and gave up in despair. Next march I will know, I suppose.

Now, if you veterans have any trick to be sure about the presence of a queen, we novices would be very glad to know of it.

3. Can a caged queen be preserved above a normal colony?

The reason for asking is, that having tried my caged queen (with queen-excluding zinc) over several colonies, I found that (at least in October) the bees did not seem to molest the queen, at least for the two or three days that I allowed them access to her. Having one not-disposed-of queen, I thought I would risk her, in a very small cage, with excluding zinc, above the frames. But, after about a week, when I went to examine my queen, I found her dead. Was the cage too close? Or was there any other reason for starving that queen? I don't know. Queen-breeders ought to know more about it, and if they do I should like to know.

MONTREAL.

ANSWERS.—1. Don't you think a good queen-catcher is already invented? Strain the bees through excluder zinc, and the workers will go through, leaving the queen and drones. One way is to have a queen-excluding honey-board fastened to the bottom of a hive-body. Set this on the top of a hive that contains a frame of brood, then shake all the bees into the strainer. It is a rare thing, however, that it is necessary to resort to anything of the kind. It sometimes happens that you may look over the combs for an hour without finding the queen, and I confess to you that I don't know why. It may be that the queen is hid somewhere in a cell; it may be that she is in some corner of the hive, off the combs entirely. So if you do not find her the second time looking over the combs it is economy to shut up the hive and leave it half an hour or more before attempting further search.

2. I'll tell you a trick worth two of finding whether a queen is present after she has stopped laying. It is to find whether eggs are present before it is time for her to stop laying. If eggs are present in September I don't care to know anything more about it till the next spring. I may mention incidentally that you may often find in September sealed brood and eggs but no unsealed brood. It seems that the queen continues laying for some time after the bees cease nourishing the brood.

3. I have kept a good many laying queens caged over a normal colony, sometimes several in one hive, and I am not sure that I ever lost any of them. But at least in one case, when half a dozen queens were caged over a colony, the reigning, free queen was killed. But these caged queens were in wire-cloth cages; and if I understand you correctly, yours were in cages of excluder-zinc. I should expect to have frequent loss of queens in such a cage. You ask if the cage was too close. I don't suppose that had anything to do with it. I have had queens by the hundred caged in small wire-cloth cages for ten days at a time without loss, and if your cage had been larger the result would probably have been the same. It is possible that cool weather may have had something to do with the case; also the place where the queen was. If she were on top of the frames and the weather cool, the cluster would shrink away from her

and she would be deserted, even if no other queens were in the hive.

Improving the Stock Preventing Bees from Flying In Winter.

The climate of northwestern Washington is not just perfect for bees. The summers are rather cool, very seldom getting above 90 degrees in the heat of the day, and quite cool morning and evening, with much cloudy, rainy weather. Bees swarm very little, not more than 25 percent at the most, according to my experience. The winters are mild, usually. The bees fly nearly every day, so far this winter, and they consume a great deal of honey. I lost some last winter from starvation before I knew it. The most experienced bee-man that I know in this country says that Italians do not do as well as black bees; they do not rush out and get chilled in a cool wind or caught in a shower of rain, as much as the Italians.

1. I wish to improve my bees all I can, and would like to know what strain to breed, Italians, blacks, Carniolans, or what?

2. I also wish to know what I can do to keep the bees from flying so much through the winter. There have been times when the roof of the shed and the ground were fairly covered with chilled bees, and when they were apparently dead, if we picked them up and warmed them in the kitchen they would revive and fly to the hive. The colonies get weak from loss of chilled bees, then a cold snap in February ends them. I expect to lose several colonies out of my 40 before spring.

WASHINGTON.

ANSWERS.—1. I'm afraid I can't tell any more about it than you can. The testimony of your experienced bee-friend looks in the direction of blacks being better than Italians. If blacks winter better, and if they store as much as Italians, then the blacks are preferable. But wintering alone should not decide the question. If you could have a fair test of the two kinds side by side for a series of years you could more easily decide. Suppose you had ten black colonies and ten Italians to start with. Give them the same treatment, and the lot that at the end of the series of years has given the most honey for the whole time may be voted the best. You will understand that if there were no winter losses of the blacks and some loss of the Italians that it might be that the Italians might store enough more than the blacks to make up for more than the winter loss. And again they might not.

2. You may do something toward preventing the bees from flying out by shading their entrances. If you will watch the matter you will find that a colony in the shade will not fly out so soon as one into whose entrance the rays of the sun are shining. Place in front of the entrance a board, or boards, of sufficient size to darken pretty thoroughly the entrance.

MAIL BOX TESTS.
Tender-hearted men should not serve on the committee. Each member should be furnished with a heavy club and a dose of nerve tonic. Before knocking the samples all over the hall, instruct janitors where to ship the remains of those that fall. If there is more than one survivor, it is a sign you are not hard hitters. Write to-day for description and prices.

GENERAL ITEMS

A Good Year with the Bees.

I am recovering slowly from the effects of the runaway I had last February. I was able to do the most of the work in the apiary. My bees (145 colonies, spring count) did very nicely the past season. I have sold over \$900 worth of honey, and over \$500 worth of bees, within one year, and have about 100 colonies left.

Our last Minnesota bee-keepers' convention, at Minneapolis, was a success—the best we ever had.
C. THEILMANN.
Wabasha Co., Minn., Dec. 30.

Dealing with Misrepresentations.

Are not persons liable to prosecutions for damage who publish damaging reports against any business where there is no truth in them? If one should publish in the papers that Mr. A. or B. was in the habit of mixing sand with his sugar and thereby injuring his trade, is he not liable for damage? Or of a miller, that he was mixing shorts with the best brands of his flour, by which his sales were greatly reduced, could not that miller maintain an action in court for damage? Again, if such person were to make a general charge against the whole class of millers

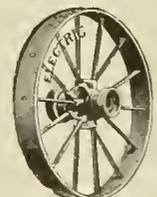

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well if they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.
See honey-offers on page 82.

(that they were all doing the same thing), and there was not a car-load of No. 1 flour in Chicago, and in consequence all their first-class flour was to remain on hand, or be sold at a reduced price, or not sold at all, is the damage any less? It seems to me that if an action could be sustained against such lying persons, and an example made of them, it would have the effect to close forever the mouths of such characters. Besides, the evidence brought out in such a trial, and published, would be a good educator.

There are samples of honey on the market in this city. One sample is labeled, "Adulterated." That perhaps is all right, and yet there is an effort to deceive as there are good-sized pieces of comb in it. Why that should be there unless to deceive I don't see, when it might be left out without trouble. The other sample is put up by a Mr. Lamon, and warranted pure. Perhaps it is, but why it should not candy I don't know. I can't keep mine from candying. J. C. ARMSTRONG, Marshall Co., Iowa, Jan. 18.

[It certainly looks as if you had made a pretty good case, but the workings of law are sometimes mysterious. If Mr. A. is falsely accused of sanding his sugar an action would lie, and it seems as if the case would be still worse if he accused a larger number, say all the men who were selling sugar. But would the law so consider it?—EDITOR.]

Successful Shipping of Bees.

I packed and shipped my goods from here on New Year's day, and put in the car my 40 colonies of bees. They arrived here on the morning of the 4th in fine shape. The supers were on, full of dry leaves. One super got loose and let a few bees out, but a little smoke soon settled them.

Yesterday was very warm and pleasant, and they had a fine cleansing flight and I could see no signs of any combs being broken down.

This is my first experience in shipping bees, and I think I have been very fortunate, especially so as I had the car packed full, and had the hives packed three deep in the center of the car.

I could not be contented here without my bees and the American Bee Journal.

H. W. CONGOON,
 Monona Co., Iowa, Jan. 7.

Colony from a Bee-Tree.

Three years ago I cut down a tree and lived the colony of bees. I packed them in leaves that winter, and they came through in fine shape. They swarmed twice, which made me three colonies, and last season I increased to nine, and got 300 pounds of comb honey in sections.

This year I allowed them to swarm, and sold 8 colonies, and 288 pounds of honey at 15 cents. Besides, I have five 24-section supers on hand.

I have had but little time to look after my bees as I have been away the most of the time.

H. A. DICKER,
 Cass Co., Iowa, Dec. 28.

Some North Carolina Honey-Plants.

I will give a list of the many honey-yielding flowers of our section, in the order in which they come. First in the spring, ground ivy, then soft maple, buckeye-tree, peach, cherry and plum trees; apples of all sorts; sugar-maple, wild-cherry, blackberry, red and black raspberries, all yielding some honey.

Then comes the poplar bloom about the first of June, yielding a real harvest for the bees, white clover beginning to yield, also red and alsike clover, beginning to bloom. Spring-sowed buckwheat comes about the same time; linden about the first of July, when there is another harvest for man and bees. There is not much bloom of any note through August. September brings another real harvest with the fall asters, golden-rod, Spanish-needles, smart-weed, and many others too tedious to name.

A. J. MCBRIDE,
 Watauga Co., N. C., Dec. 23.

Swarming All Around.

My bees did splendidly this year. I had 12 colonies, spring count, and had only three swarms, but I caught nine swarms while plowing corn. I caught five in one day and plowed four acres. I thought that was pretty good for a clod-hopper.

My 12 colonies averaged 147 pounds of comb honey to the colony, and my 12 new swarms stored about 30 pounds each. I had

Please mention Bee Journal when writing

The New Catalog of Prairie State Incubator Co., which we have just received, is probably the handsomest piece of printing ever put out by any firm in the interest of the poultry industry. It is a large volume, pages 8 1/2 x 11 1/2, printed in two colors throughout, with several handsome colored inserts and more than 50 full-page groups, showing scenes on poultry farms throughout the entire country. Besides this there are numerous smaller illustrations. More than 1000 photographs were taken for this book. A full description is given of the Prairie State Incubators and Brooders, and a complete record of their show-record. It is, all in all, a handsome book—a good book—about a good machine built by a good company, which we can most heartily recommend to all our readers. Another attractive thing about the catalog is, that while it cost probably \$15,000 to print the first edition, a copy will be sent free to anyone interested in poultry. Write to Prairie State Incubator Co., Homer City, Pa., and please mention the American Bee Journal when writing.

to acres of buckwheat that they did well on, and some white and sweet clover which was good.

By the way, there is some talk about red clover queens. I had if red clover does not grow too rank the bees will work on it more or less every year—at least they do here. The bees worked more on the corn tassels than I ever saw them do before.

There were lots of bees flying around this year. One man had a swarm go into his chimney; another man had one in a five gallon oil-can; and another in an old cook-stove in an out-house. I found several bee trees along the river.

H. GILBERT.
Jasper Co., Iowa, Jan. 1.

Poorest Season in 10 Years.

This has been the poorest season for 10 years in this locality. We did not secure any summer honey and very little fall honey. I began with 5 colonies, spring count, and secured 110 pounds of extracted honey, an average of 28 pounds to the colony.

Bees were put into winter quarters in fair condition, and the weather so far has been very favorable for good wintering.

I received and introduced a queen all right last summer. I had the colony shut down in the brood-chamber, and as there was a small amount of honey coming in I was endeavoring to get some new combs built. While manipulating them late one evening in a hurry, the queen in some mysterious way was left on top of the honey-board, and the hive closed, and you may imagine my regret when I opened the hive the next time.

So much for hasty work.
J. WILEY MOUNTJOY.
Anderson Co., Ky., Jan. 6.

Another Poor Season.

The past was another poor season for bees in this locality. The weather was very unfavorable during the spring and fruit blooming; white clover was good but did not last long. Nearly the only honey we got was in the fall from smartweed.

We are having spring weather here now; bees are flying, and are carrying out the dead ones.

Otoe Co., Nebr., Jan. 6.
D. E. EVERS.

One Season's Report.

I began bee-keeping in the fall of 1900 by buying one colony in a box-hive, which wintered in the cellar and was taken out in good condition in the spring. I increased to four colonies and secured a surplus of 12 pounds of section honey per colony, spring count. They are now in winter quarters in good condition, with plenty of stores without feeding.

I transferred the old colony from the box-hive to an 8-frame Langstroth, and also hived the swarms in 8-frame hives.

The main honey-flow here is from milkweed and white clover.

L. V. RICKETTS.
Whitman Co., Wash., Dec. 27.

A Young Bee-Keeper's Report.

Last spring I started a very small colony of bees, I should judge about 10 dozen bees. I got a hive and made 8 frames but only gave them 2 frames. I then gave them 2 queen-cells and in three days the queen was hatched, and in 21 days the hive had an increase of some more bees. Soon it had quite a few more bees so I gave them another frame.

One day my father looked in, and made fun of me, but I did not care. When he saw I was interested in my small lot he fixed them up for me so they looked like bees to him.

Of course they did not store enough honey to winter them, but you know a greenhorn can make a fortune in his mind if he does not make it outright. When winter came I put them in the cellar along with some more.

One day last summer we had 8 swarms in one day. Two of them went to the woods, but my sister and brother followed them. My sister was 14 and my brother 8. They followed them about a mile over creeks, hills and through brush, when the bees took a rest, and so did their followers. My father and I then took a hive and went to get them, but it being a very warm day made it bad for us. We got about one-third of them in the hive and then we left the hive on the hillside, but we went home and in the evening we undertook the task of going and bringing the hive home. All the bees had gone in excepting a quart. We left them and Pa carried the hive home on his shoulder. When we arrived home he looked as though he had been boat-

To make cows pay, use Sharples Cream Separators. Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

riding and the boat had capsized. It being a good season we were well paid, for this swarm filled 140 sections.

One day, about a month later, myself and my sister and brother were out in the woods digging ginseng, and we came to the place where the swarm had settled. I spoke of a quart remaining; well, those bees had built two pieces of comb about five inches wide and nine inches long on the ground. How or why they remained I do not know, but I got the honey and bees and brought them home.

We have 150 colonies of bees, of which 59 are in the cellar and 91 are on the winter stands, and both lots are doing nicely. The past season we got 13,000 pound of honey, and sold the most of it within 20 miles of home, and could have sold twice as much.

I sent some to Washington, D. C., and some was taken to New Mexico, so you see we have quite a large trade of our own.

I am 13 years old. FRED BANKER. Brown Co., Minn., Jan. 12.

A Beginner's Report.

I became interested in bees by reading the columns on bees in the agricultural papers. Last fall I ordered the "A B C of Bee-Culture," a smoker, and some other fixtures, without having a single colony of bees. I read the book, and made a few 8 and 10 frame Langstroth hives last winter. About the last of February I bought a colony of black bees in a box-hive from a neighbor, and later three colonies of Italian bees in 8-frame dovetailed hives from a bee-keeper 20 miles away. On the first of May I transferred the black bees into a Simplicity hive.

My bees did well considering the poor season, increasing to 16 colonies, and producing considerable honey. They averaged about 20 pounds per colony from goldenrod and asters in October.

In August I subscribed for the American Bee Journal, and received a red clover queen, which I successfully introduced to the only colony of blacks I had. While the weather was warm, the last of October, I packed them up snug for winter.

I think this a fine locality for bees, there being an abundance of sourwood, white clover and poplar, and in the fall many fields are fairly white with asters. There are a great many minor plants, such as catnip, sumac, horsemint, goldenrod, etc. C. L. SAMS. Madison Co., N. C., Dec. 23.

Hoping for Better Things.

The last two years have been poor, with only one swarm with an average of 30 colonies in the two years, and not enough honey for family use. But I am hopeful the next will be better. JAMES COE. Van Buren Co., Iowa, Jan. 2.

Loss from Spraying in Bloom.

I have lost most of my bees by people spraying orchards while in full bloom last spring. We had to force them to stop spraying, some of them saying they would rather pay their fine than stop the pump. We walked them out of their orchards, but they "laid out" lots of our bees before we knew they were doing that kind of work. C. H. LAKE. Wayne Co., N. Y., Dec. 27.

Bees Did Well.

My bees did excellently well last year. From 8 colonies I extracted close to 600 pounds of as nice honey as I ever took from them, but it is slow sale here. I keep my bees as near the yellow stock as I can, and I think it pays big. Nearly all my queens were superseded in August; I cannot say why, because they were nearly all young. A. J. FREEMAN. Neosho Co., Kans., Jan. 9.

Report for 1901—Spring Feeding.

I am one of the small bee-keepers. I started in last spring with 10 colonies and had only two swarms. I took from 8 hives about 1200 pounds of comb, and as nice as I ever saw. We had a fine yield of white clover in this part of the country, and the aster crop can't be beat.

I have my bees on the summer stands with plenty to live on, though I see them bring out quite a lot of dead bees, when it is warm enough to fly. I am afraid they will be very weak in the spring. About what time should I commence to feed them? Some Golden queens that I got last sum-

mer are hustlers, and don't want to be disturbed much; if they are I find it out, as they are not much of cowards, and they do gather honey when there is any to get.

C. M. KIMBROUGH.

Giles Co., Tenn., Jan. 14.

[If, as you say, they have plenty to live on, don't feed them at all. But you may mean they have plenty for the winter and not enough to last till nectar yields again. In that case feed as soon as weather is warm enough for them to fly freely, and give them an abundance to last till they can gather again. There is more danger of too little than of too much. You will be surprised to see how rapidly they use up stores when breeding gets under full way in the spring.—EDITOR.]

Outlook "A Dry Year."

I have 160 colonies of bees, increased from 90 last year, and produced 9 tons of extracted honey. The outlook is "dry year again." When California bee-keepers begin to "pat themselves on the back" over a good year, they must also prepare to face a dry one. It is a "streak of lean and a streak of fat" with us. A. B. BLAND. Los Angeles Co., Calif., Jan. 8.

Wintering Bees—A Correction.

I wish to correct one statement in "An Old Timer's Methods," on pages 45 and 46. I do not want it to go out that I put a board in the rabbets on top of the super and place that on top of bees, leaving the whole super space open above the bees, as I was made to say, for that would be reckless. But I cut a board to fit inside the super to rest on the tins, as do the section-holders, making only a bee-space above the frames; then another board is put in the rabbets, then a ventilated cover, and the job is done. It has worked well with me for some time. J. W. C. GRAY. Piatt Co., Ill.

A Good Report.

My bees produced about \$800 worth of honey this year. I sold all of it for 14 and 15 cents per pound. It was nearly all white clover honey. My bees are in good shape for wintering, and all in the cellar. I have over 100 colonies. C. W. ANDERSON. Bureau Co., Ill., Dec. 30.

Small Honey Crop.

The honey crop was very small here this year on account of drouth, but the bees went into winter quarters in good condition.

LEWIS LLOYD, JR. Columbia Co., Wis., Dec. 30.

Did Fairly Well on White Clover.

Bees did fairly well the first of the season on white clover, then the drouth set in and they stopped very suddenly. They stored some rather dark honey in the fall, but I don't know where they got it. They seem in good condition for wintering.

We have had quite a cold snap, 12 degrees below zero, with 4 inches of snow. It was 50 degrees above zero yesterday, and bees were out. T. Q. GARMAN. Gentry Co., Mo., Dec. 31.

Fears Heavy Winter Loss.

My crop of extracted honey this year was 6000 pounds, from 100 colonies, spring count. I am wintering 90 colonies in chaff hives, and they seem to be all right so far, but I fear there will be heavy loss this winter on account of their not rearing any young bees since September.

F. B. FARRINGTON. Clayton Co., Iowa, Dec. 18.

A Swarming Experience.

July 15, 1900, as I was at work with a shovel-plow hilling up potatoes, I saw a swarm of bees coming straight towards the horse and me, perhaps 20 or 30 rods off. I tried to hurry the horse on, but she stood still until the bees were all around us in no time. I went to try to unhitch the horse, and in doing so she switched her tail, which took my hat off. In an instant the bees were all over my head and the horse was off to the

barn with the plow. When she got to the barn-door the plow caught in the sill, and the horse broke away. When I got home the horse was in the barn, and my head was covered with dead bees, as I had rubbed it all the way home. I first took a pail of the coldest water I could get, and bathed my face and head. I went and served the horse the same way after I got home. There were three stings taken from over one eye. My head was very sore for days. Geo. Hodges. Allegany Co., N. Y., Dec. 26.

Seem to be Wintering Well.

My bees seem to be wintering well so far. I put them into the cellar about Nov. 20. I have 120 colonies. This has been a poor year for honey, basswood being the main crop. SAM SEVERSON, Clark Co., Wis., Dec. 26.

Results of the First Season.

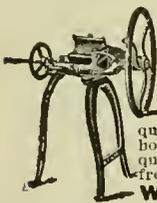

My bees are wintering on the summer stands in double-walled cases with chaff cushions on top of the hives, with plenty of honey. I started last spring with two colonies in box-hives that I bought; they cast four large swarms, and one of the swarms produced 80 pounds of honey, another 41 pounds, and the other two later filled up their hives well for winter. F. McBRIDE, Hardin Co., Ohio., Dec. 27.

No Fall Honey.

I had no fall surplus honey this year; white clover was cut short by the drouth, and we had only about half a crop of it. Bees are doing nicely in their winter quarters. They were out prospecting a few days ago. They had gathered plenty for winter stores. D. C. McLEOD, Christian Co., Ill., Dec. 30.

It Pays to Read.

I cannot dispense with the old stand-by, so I renew my subscription. I had the promise of two new names, and I find at the last minute they do not think they will need it. Well, the old adage says, "Where ignorance is bliss, 'tis folly to be wise." My old Journal will have to go the rounds of the neighborhood as usual, I suppose. But I will make them see the need of it another season, if I have success with my bees. They do not believe that what I read materially aids my success in securing large yields. It is "all in the location," you know. JOHN W. LYELL, Washoe Co., Nev., Dec. 28.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The honey market is of a slow nature with little change in price of any of the grades. Choice grades of white comb honey, 14 1/2 @ 15c; good to No. 1, 13 1/2 @ 14c; light ambers, 12 1/2 @ 13c; dark grades, including buckwheat, 10 @ 12c. Extracted, white, 5 1/2 @ 7c; amber, 5 1/4 @ 5 1/2 c; dark, 5 @ 5 1/4 c; the scale of prices varying according to flavor, body and package. Beeswax steady at 28c. R. A. BURNETT & Co.

CINCINNATI, Jan. 21.—The demand for honey is fair. Extracted honey is offered freely. Dark brings 5c; lighter, 5 1/2 @ 6c; fancy, 6 1/2 @ 7 1/2 c. Comb, fancy, 15c; lower grades, 12 1/2 @ 13 1/4 c.
C. H. W. WRBER.

ALBANY, N. Y., Jan. 22.—Honey market quiet and firm for all grades of comb honey, of which very light stock is on hand. White, fancy, 15c; No. 1, white, 14c; mixed, 13c; buckwheat, 13c. Extracted, white grades slow sale, and price uncertain. Straight buckwheat extracted scarce at 6c. Beeswax, 28 @ 30c. H. R. WRIGHT.

BOSTON, Jan. 20.—Strictly fancy comb honey in cartons, 15 1/2 c; A No. 1, 15c; No. 1, 14 1/2 c; very little No. 2 to offer; stock nominally running No. 1 and A No. 1. Extracted, light amber, 7 1/2 c; amber, 7c; Florida honey, 6 1/2 @ 7c.

Our market continues somewhat dull in the demand for honey, while stocks are ample for the balance of the season, unless there should be a much larger demand than we at this moment anticipate. BLAKE, SCOTT & LEE.

NEW YORK, Jan. 9.—Comb honey continues in good demand with supplies pretty well exhausted, and we quote: Fancy white, 15c; No. 1, 14c; No. 2, white, 13c; amber, 12c; dark, 10 @ 11c. Extracted dull with large supplies and quotations on large lots generally shaded in order to effect sales. We quote: White, 6 1/2 @ 7c; amber, 5 1/2 @ 6c; dark, 5 @ 5 1/2 c. Beeswax firm and rather scarce at 28 @ 28 1/2 c.
HILDRETH & SEGBLEN.

DETROIT, Dec. 20.—Fancy white comb honey, 14 @ 15c; No. 1, 13 @ 14c; no dark to quote. Extracted, white, 6 @ 7c. Beeswax, 25 @ 26c.
M. H. HUNT & SON.

SAN FRANCISCO, Jan. 22.—White comb, 11 @ 12 1/2 cents; amber, 8 @ 10c; dark, 6 @ 7 cents. Extracted, white, 5 1/2 @ 6c; light amber, 4 1/2 @ 5c; amber, 4 @ —. Beeswax, good to choice, light, 26 @ 28c; dark, 24 @ 25c.

Market continues quiet, but is tolerably firm, particularly for choice to select. Spot stocks are of rather small volume, and there are no evidences of much being left in the interior. There is some probability of prices hardening slightly during the next few months, particularly if the spring trade proves to be of good average proportions.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak, which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey-jars.

"FACTS."

Root's Catalog Now Ready

It is a fact that Root's Catalog for 1902, the 91st edition, contains information valuable to EVERY bee-keeper, whether he has one colony or a thousand colonies. The catalog is ready for mailing, and will be sent free to all applicants. If you will give us the names and addresses of 10 or more bee-keepers, we will send you in addition our 40-page semi-monthly journal, GLEANINGS IN BEE-CULTURE, for 3 months free.

Root's Extractors

It's a fact that Root's Cowan Honey-Extractors are acknowledged by far the best extractors on the market. You will make a mistake if you take one represented to be "just as good." Our designs are the best, we use the best material, and our workmanship ship is unsurpassed. Insist on "Root's" Cowan.

Danz. Hive

It is a "Fact" that the DANZENBAKER HIVE for Comb Honey, is acknowledged by ALL who have given it a fair trial, the best hive for comb honey.

Gives Best Yields

It is a fact that bee-keepers using the Danz. hive get better yields from this hive than any other hives in their yards.

Higher Price for Honey

It is also a fact that the honey in Danz. Sections generally sells for a higher price, and always finds a ready market. We have yet to earn of a bee-keeper having comb honey in Danz. sections who had to hold his honey because of a dull market.

Agencies

It is a fact that Root's Goods are in demand everywhere. For this reason we have agencies all over the United States and upward of 25 foreign countries. A full list of agents sent on application.

Low Freight Quick Delivery

It is a fact that we are able by these agencies to furnish our goods quickly, and at low cost of transportation.

Facts About Bees

"Facts About Bees," 7th edition, revised, is now ready. Full of information, and sent to any address for a 2 cent stamp or free if you mention this paper.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

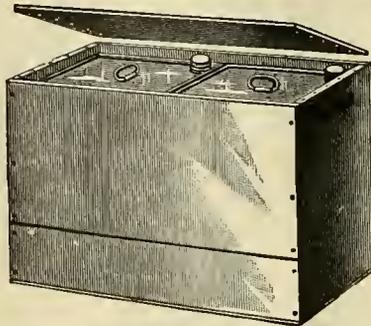

Alfalfa Honey--7 cents a pound in lots of 4 cans or more.

BEST
Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelities," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER
IN AMERICA

42d YEAR.

CHICAGO, ILL., FEBRUARY 13, 1902.

No. 7.

* Editorial. *

The Wisconsin Convention was held last week Wednesday and Thursday. There was a fair attendance and a good meeting. All the officers were re-elected, and they are as follows:

President, N. E. France; vice-president, Jacob Huffman; secretary, Ada L. Pickard; and treasurer, Harry Lathrop.

Next week we will have more to say about it, and later we expect to publish a short report of the proceedings, including the papers that were read.

"Somny" on Adulteration.—Somnambulist opens up his January contribution to the Progressive Bee-Keeper by saying:

"One's faith in humanity as well as one's reliance on one's own senses receive a very distinct shock on opening the American Bee Journal for Dec. 5."

After some racy comments upon the Chicago Tribune article and cartoon, he says:

In this famous or infamous article, as bee-keepers are apt to brand it, one complainant says, "I know of no place in Chicago where one can purchase a pound of pure honey." Poor Chicago! Little "one hoss" Missouri towns can beat that.

Proceeding then to quote that genuine honey may be told by the brown coloring, he comments:

What a fine excuse for a "little more sleep, a little more slumber" along about the time to remove supers; what a grand inducement to the extra-fancy comb-honey producers!

After years of contriving and weeks of hustling to secure unblemished sections, only to be assured that they are not genuine! Too bad!

What a vast amount of maneuvering, and how many sleepless nights might have been saved had this information but reached us years ago. On the other hand, what a crumb of comfort is this knowledge to the slovenly, go-easy bee-keeper. The company of anti-section scrapers may confidently expect new recruits, for if the brown coloring around the cells is an indication of genuineness, the same coupled with a propolis-debauded section would constitute a surety.

After a perusal of the Tribune article it will be hard for some bee-keepers to believe that the "world moves."

Watering Bees in Winter is little practiced in this country. In Germany some bee-keepers consider it very important, while others think it needless if not injurious. Editor Weippl, of *Illustrierte Monatsblätter*, says both are right. If the bees have honey that is candied, thick, or tough, they may

suffer without water. If their honey is late-gathered, or such as contains a fair proportion of water, then water is superfluous. The water in honey varies from 10 to 25 percent. If there is 18 percent or more, that is all the water the bees need, even in the time when breeding begins. Besides, the bees understand how to increase the supply of water. Outside of the cluster they uncap more honey than is needed for immediate use, and this attracts moisture from the atmosphere. But if the honey be candied or thick, then water in sufficient degree is not attracted from the atmosphere.

The Robber Spotted.—A peasant came one day to the Cadi to complain that his hives had been robbed. "Come to me to-morrow with your neighbor," said the Cadi. Next day at the appointed hour, the peasant appeared with a number of the villagers.

"Imbecile!" said the Cadi; "didn't you know any better than to bring all these worthy people here? Don't you see that the man that robbed your hive has yet a cluster of bees on his turban?" At this one of the men quickly put his hand to his turban, and—was arrested on the spot.—Prak. Wegweiser.

A Honey-Lie Correction.—Mr. Newton Bawn, of Iowa, has kindly sent us a clipping written by Mr. J. S. Triggs, who, unfortunately, helped to keep in circulation the old lie about the manufacture of comb honey. The correction is as follows:

ARTIFICIAL COMB HONEY.

A short time ago we incidentally referred to the manufacture of bogus comb honey, and, judging from the many letters we received, we made a mistake in assuming that any such honey is made, or could possibly be made, and so our readers will please understand that there is no such fraud practiced, and that we never said there was. The bee-men unite in saying that it is a mechanical impossibility to make an artificial comb, fill it with an adulterated sweet and so to seal up the cells that such fraud could not be readily detected.

At the same time, we have before us the statement of an expert of the Agricultural Department at Washington—Mr. Chas. Saylor, of Des Moines, Ia.—in which he refers to this matter as though such bogus product were actually being made. The bee-men can now go for him, and convince him as they have us, that he is in error.

The item which drew forth the criticism was prompted, not so much by what we had read and heard of this fraud, as by the character and quality of a lot of honey which we bought about that time. Assuming that this lot of honey was the pure-quill product of the bees, we wonder what the moral condition of the members of the hive must have been to have produced such an abomination, when it looked so very tempting. They must surely have been foragers on strange grounds and eaters of forbidden fruits—revellers among

the bloom of skunk cabbage, henbane and rag-weed, distillers of the nectar from malignant and deadly types of the vegetable kingdom. Maybe their queen was dead, or the regular workers on a strike and the drones tried their hand. Anyhow, not knowing that the bees made that honey, the poetic sentiment with which we have always invested the bee is knocked into smithereens, and, hereafter, it, like the ox or the pig, is of the earth, earthy.

Undoubtedly, Mr. Triggs got hold of some rank honey—perhaps some sour, spoiled honey. Of course, all pure comb honey is not of the finest flavor, as any one knows who is at all familiar with honey. But just because a certain honey does not suit one's palate, or is rank from any cause, that is no good reason for saying that it was manufactured by machinery, etc.

We think we'll turn over the Mr. Chas. Saylor mentioned, to Mr. Benton, of the Department of Agriculture, and give him the bee-keepers' full permission to "sail into" him in the way he deserves.

Carbon Bisulphid as an Insecticide is the title of Farmers' Bulletin No. 145 sent out by the U. S. Department of Agriculture. Carbon bisulphid has come into prominence among bee-keepers as an insecticide superior to sulphur, having along with its other claims for recognition the very important one that it destroys eggs as well as wax-worms. This bulletin is probably the best thing of the kind in existence, and it will be well for those interested in the matter to obtain a free copy from Washington.

The following description of its liquid properties is interesting and instructive:

The liquid is one-fourth heavier than water, its specific gravity being 1.29 at the freezing temperature of water. It is very volatile, evaporating with great rapidity when freely exposed to the air. The rapidity of evaporation depends mainly upon the area of the evaporating surface and the temperature of the liquid and the air. It may be retarded by mixing the liquid with various substances, and is wholly prevented by covering the surface of the carbon bisulphid with a layer of water, which, being lighter, floats easily on top, just as kerosene does upon water. The rapid evaporation of the liquid takes up a large amount of heat. If a little be poured upon the hand, a burning sensation will be experienced, which, however, is due, not to a burning, but to a cooling process, as may be perceived by touching the spot with the other hand. No harm need be feared from getting it upon the skin.

When perfectly pure the liquid has an acid taste and a rather sweetish, not unpleasant, ethereal odor, quite similar to that of ether or chloroform. Pure carbon bisulphid is completely volatile, and will not injure or stain the finest fabrics. Even when poured directly upon food-stuffs their edibility is not at all impaired, and all trace of the odor disappears quickly upon free and full exposure to the air. The ordinary commercial article,

however, has a slightly yellowish tinge due to its impurities, which also gives it a rank, fetid odor that is extremely obnoxious. These impurities add to its poisonous qualities. When the impure article is used, some slight residue may be left after the evaporation of the liquid. For this reason this grade will stain goods, and it should not be poured upon food-stuffs, though its vapor will do them no harm.

Liquid carbon bisulphid is not at all explosive, so there need be no fear of handling it, provided the cans are perfectly tight. It is best kept in an out-house where there is no fire and where it is dry, so that the cans will not rust and allow the vapors to escape through leaks. The liquid boils at 115 degrees F., but a few degrees higher than the temperature of the human body. One volume of the liquid is said to give 375 volumes of vapor upon evaporation.

As a vapor, it is 2.63 times as heavy as air, and so can be poured from one glass to another almost like water. Understanding its weight, it will easily be understood why it is directed to have the vessel containing the liquid *above* the combs to be disinfected, and that the vapor will be more dense at the bottom. The first effect of inhaling the vapor is giddiness, and upon the first feeling of giddiness if one immediately gets to the open air to breathe, the ill effects will soon pass off, while death may ensue if the vapor is inhaled for a sufficient length of time. If one should desire to remain in a room with the vapor a few minutes it may be safely done by resorting to the following device:

A large paper bag (20 quarts or more) is tied tightly around a short piece of tubing of glass, rubber, or metal, inserted in its mouth. When inflated, the bag contains sufficient air to enable one to respire into it for several minutes without discomfort. Being very light, it can be carried by the tube in the mouth, thus leaving the hands free for any work desired.

Of course it is understood that the vapor must be confined to be effective, and the amount of vapor needed depends much upon the closeness with which it is confined. One pound of liquid bisulphid to each 1000 cubic feet of space, which is equivalent to 1 part of vapor to 90 parts of air, will, if the vapor be properly confined, destroy insect life in a few seconds, and the same result will follow in 75 minutes if there be one part of vapor to 254 parts of air. The weaker the vapor the longer the time required.

"Carbon bisulphid is put up in tight tin cans or iron drums holding from 1 to 50 pounds. It may be purchased in small quantities of any druggist, at from 25 to 35 cents per pound;" and at a very much less price by the quantity from wholesale dealers or manufacturers.

To destroy ants with this drug, trace the ants to their nests, make one or more holes in the nest with a stick or iron bar, pour into each hole 1 or 2 ounces of the liquid, and then close the hole immediately by stepping on it.

It should be emphasized that bisulphid of carbon is a dangerous explosive if the least spark of fire should touch it.

Working for Wax and Honey.—A. Maujean gives in the *Revue Eclectique* a plan by which he gets a crop of extracted honey and a considerable quantity of wax, which he thinks costs him nothing. His extracting-combs are spaced 1 $\frac{3}{4}$ inches from center to center, and are left in the hive till sealed over. Then they are cut down to 1 inch in thickness, yielding considerable wax.

Weekly Budget.

OUT OF No. 1.—Unfortunately we have run out of the first number of the Bee Journal for this year, dated Jan. 2. We wonder if some of our readers, who do not preserve them for binding, would not like to send us that copy. If so we will send them in exchange a copy of the song, "Buckwheat Cakes and Honey," if those who return to us that number of the Bee Journal will write their name and address with pencil on the first page before wrapping for mailing.

MR. GEO. W. BRODBECK, of Los Angeles Co., Calif., wrote us Jan. 25, as follows, when sending a short report of the recent California convention:

"California bee-keepers have been apprehensive of another dry year, as the rainfall up to the present has been below the average, and up to two days ago we had no rain for over two months. The past 24 hours, though, has brought us a fall of 1.32 inches, with a prospect of more, consequently we feel somewhat relieved."

IDAHO ORGANIZED.—We learn from Mr. E. F. Atwater, that the Idaho State Bee-keepers' Association was organized at Parma, Jan. 18, with the following officers: President, F. R. Fouch; vice-president, W. F. Schull; general manager, E. F. Atwater; secretary, Miss B. M. Petersen. Membership fee, \$1.00 a year.

Success to the new Idaho Association.

MR. FRED W. MUTH, of Cincinnati, Ohio, gave us a pleasant call last week. He had been on a business trip to Wisconsin. The firm of Fred W. Muth & Co. has dissolved partnership, and hereafter it will be "The Fred W. Muth Co.," an incorporated concern, with an authorized capital stock of \$10,000, about a third of it being fully paid up. Mr. Muth himself will manage the business, which means that it will be well managed. Handling bee-keepers' supplies and honey will be the business of the new firm, as it was of the old one. Their prospects are exceedingly bright. We wish them all success, which they will certainly have, as they are pushers for business.

"THE TRUTH ABOUT HONEY" is being published in various newspapers throughout the land. The first to come to our desk containing the Chicago Association committee's report was the Wood County Reporter, of Grand Rapids, Wis.

The next we received was Agricultural Advertising, the sparkling monthly that unfortunately published Mr. John M. Stahl's foolish paragraph on manufactured comb honey, which we reprinted on page 803 (1901). In addition to giving "The Truth About Honey" in full, Agricultural Advertising had this editorial utterance, which shows that its heart is still in the proper place:

Agricultural Advertising has received a score or more protests from honey-producers the country over who object to the strictures laid upon the honey-trade in a paper read before the National Agricultural Press League

and printed in the November Agricultural Advertising.

Agricultural Advertising takes off its hat and apologizes to the wardens of the busy bee. Personally they are the salt of the earth, and we believe they never made a pound of artificial comb honey in all their days.

THE AMERICAN GROCER—the leading periodical devoted to the grocery trade—in its issue for Jan. 29, had an illustrated article written by Mr. W. P. Root, an employee of the A. I. Root Co., counteracting the effect of the manufactured-honey misrepresentation, and trying to set the grocers right on the subject of comb honey. It was well done. Every bee-keeper or other person who can influence the publisher of any paper to give the truth about comb honey to its readers will be doing a good thing.

MR. W. A. PRYAL, of Alameda Co., Calif., wrote us as follows, Jan. 21:

"The weather around Christmas was as fine as any summer weather we ever had in this State, with the exception that some of the mornings were a trifle sharp. But the weather was just grand.

We are having nice rains at last. Crops are in splendid condition here, and the prospects are good for an abundant harvest."

Mr. Pryal also wrote us that his oldest sister, "Ella," died Christmas morning, lastly of pneumonia. She was a very bright person, a teacher of a dozen years' service, a gifted artist in coloring, and withal a beautiful character. Mr. Pryal will have the sympathy of all in his bereavement.

THE CHICAGO DAILY NEWS.—After reading that the Daily News had published "The Truth About Honey," as mentioned on page 51, a subscriber to the Bee Journal wrote us as follows:

"I am glad to see your good report of the Daily News. I think I will subscribe for it when my time is out on another Chicago daily paper. Why should the News not get some fresh subscribers from bee-keepers on the strength of its attitude toward them?"

We believe that bee-keepers should patronize the papers that treat them right. Editor Smith, of the Chicago Daily News, would no doubt be pleased to hear from the bee-keepers, not only with their subscriptions for his paper, but a letter of encouragement and thanks for his treatment of them would be appreciated. The editor of a daily newspaper has no easy job, especially the editor that wants to do the right thing.

NOT A "FLING."—One of our valued readers says this in a private letter:

"I am sorry you made that fling at 'the editors who enjoy showing themselves off in their own papers.'"

Why, bless you, that wasn't intended as a "fling," at all, unless it was a fling at ourselves as well. Wasn't *our own* picture in the American Bee Journal last spring or summer, in connection with two other bee-paper editors? And, once upon a time, we had a reproduction of our homely pliz shown inside of a bee-veil, and used it in connection with the word "Editorial" at the head of that department. But, say, we hope our readers forgave us at the time, and have not laid it up against us. We must admit it wasn't a modest thing for us to do, and we promised ourselves we wouldn't do it again. But, then, we do and say lots of things that afterward we find would better have been left undone and unsaid. But we are not perfect yet. Are you, dear reader?

The Buffalo Convention.

Report of the Proceedings of the Thirty-Second Annual Convention of the National Bee-Keepers' Association, held at Buffalo, New York, Sept. 10, 11 and 12, 1901.

(Continued from page 23.)

The Relation of Bees to the Orchard.

I will discuss the subject, under three heads:

First, Bees and the monilia fungus;
Second, Bees and pear-blight.
Third, Bees as pollenizers.

Bees are certainly intimately connected with the orchard, both in health and disease. Taking up the first subject, I think I can give you something new. It is probably the least important of the three matters which I shall take up, but it is the newest. I am quite well satisfied from observations made during the early part of the present summer that bees are largely responsible for the rapid distribution of the peach and plum rot fungus. They are not the only culprits connected with that distribution. Wasps and soldier-bugs and several other puncturing insects are also concerned in the matter, and the wasps and the puncturing insects the ones which usually make the openings, especially in perfectly sound fruit. However, bees rapidly follow in the punctures by other insects. In June and July hundreds and thousands of bees may be seen swarming over the early-ripening peaches and Japanese plums, and in going over rotten fruit they carry the spores into the wounds made by the wasps and soldier-bugs, and into weather-cracks. The peaches cracked open badly by the wet weather this year. Oldmixon was the worst in Maryland, but even varieties like Elberta make a great many weather-cracks. Into these cracks the bees penetrated. They even ate large holes in the fruit. I have seen a hole large enough to hold three bees inside of it, and even on gathering the fruit, they were so busily engaged that they were still at work inside the hole.

I have endeavored to follow up this subject a little more closely, and tried to find out how much the monilia fungus could spread without the aid of bees, and investigation showed that it was able to spread without the aid of insects: in other words, it does blow by the wind, and gets about in that way. I covered trees with mosquito-netting, and also branches, and thought perhaps I might be able to prevent the spread of monilia with mosquito-net protection, but was not able to do so entirely. I somewhat reduced it, however, showing that the bees are active agents in the distribution of monilia.

Taking up the second subject of bees and pear-blight, we may say that bees are very active agents in the distribution of pear-blight. In order to understand fully, however, the exact part that bees do play in the distribution of pear-blight, it will be necessary to go

very briefly over some other points concerning this disease, and to give, in fact, the life-history of the pear-blight bacillus through the year.

In the first place, we have three methods by which the pear-blight germ enters the tree: First, through the blossoms, resulting in what is commonly called blossom-blight, to distinguish it from the other methods of communication of the disease; second, through the tender tips of growing twigs; but either blossom-blight or twig-blight may run down on the limbs and trunk; and, third, blight may enter directly into the fleshy bark of young trees.

The latter is comparatively a rare method, in fact by far the greater number of infections are directly through the blossom.

Now, of course, it is only in blossom-blight that the honey-bee is concerned, and furthermore, all insects which visit the pear and apple blossoms and quince blossoms are more or less concerned in the matter of distribution on the blossoms. I may say also that other insects than the honey-bee are largely instrumental in the distribution of pear-blight on the twigs, and we have scarcely been able to find a direct, normal method of introduction of the disease in the twigs without the introduction of some mechanical or insect puncture. Beginning with the spring of the year, the disease breaks out on the blossoms. Ordinarily, trees do not have the blight very badly until they come into bloom, and this, as I said before, is mostly due to its distribution by bees and other insects which visit the flowers and are the main factors. The pear-blossom is a very open one and is very extensively visited by a whole list of insects. I started out to get a list of insects which visit pear-blossoms, but when I reached the number of forty, I gave it up. Nearly all the flying insects—the bee being most active of all, but even beetles and wasps, and occasionally even a humming-bird (the latter of course not being insect)—visited the pear-blossoms and carried the disease along.

The blight begins on the blossoms in early spring; then during the summer we may have twig-blight clear into September. The disease runs down on the twigs, and in the great majority of cases dies out. The disease works in the bark and as a rule finds the tree, at some time during the late spring and summer, a little too dry and tough for it to take hold of, and it dies out. Occasionally infections, however, keep running down on the twigs, get into the fleshy bark, and keep on working slowly till fall. After this season of the year, the trees are so moist that those germs will not dry out but will

live over winter, resulting in what I call "hold-over blight." It stands zero weather perfectly. In the spring, those hold-over cases start off when root pressure begins and when the tree is forced full of sap. In some instances in the South, very active changes go on in these hold-over cases during mild winter weather, but in the Northern States they don't have time to do much damage. The virus runs out on the sides of the tree and drops down. I saw some very fine cases in the mountains of Virginia last spring. The flies and wasps and other insects swarm on the exuding sap, and as the blossoms open they fly from that to the opening blossoms and start the infection for the next year.

Bloom-blight, then blight running on the branches, then hold-over blight, then re-infection next spring on the blossoms. When it is started on the blossoms, it is carried like fire. Now, as I started to say a moment ago, you would like to have the authentic proof that the bees carry pear-blight. I worked long and patiently on this problem for three or four years. In the first place, the great abundance of blossom-blight leads to a suspicion, at least, that we have here some normal, effective method of distribution. There is some regular way about it, and we shall see what that method is. In the second place, the disease begins in the nectaries. The germs of the pear-blight are found growing and multiplying in this nectar. I determined this mostly by artificial infection. By taking pure cultures of the pear-blight germ and touching the nectary with a camel's hair brush, I started the pear-blight off. It requires no puncture. It is the only point on the tree where the germs enter normally without a puncture. The nectar has no shield or cuticle over it to keep out the germs.

Now my first acquaintance with this relationship of bees to pear-blight came about something like this: When I had succeeded in isolating the pear-blight germ, I immediately tested the validity of my cultures by a series of experiments with a camel's-hair brush on some blossoms, and I inoculated and labeled a number of blossoms around the lower part of a pear-tree on the Agricultural Department grounds at Washington. I spent a good deal of time actually watching those blossoms growing, and of course here came the bees right in front of me, and as the germs began to grow in the nectaries, they began to visit my infected blossoms, and I saw them fly from these over the trees to the other blossoms. I captured two bees, caught them in the act of visiting the infected blossoms, and taking them into the laboratory made plate cultures by the method in which we ordinarily isolate bacteria, and succeeded beautifully in isolating pear-blight germs from the mouth-parts of the bees.

In other words, we actually caught the bees in the act, and this was repeated a number of times and in different parts of the country. Now it seems as though we had matters pretty well proven. My trees that I had infected came down beautifully with pear-blight. The clusters all came down which I had infected and labeled, and a large number of others all around the tree.

The question then was as to what

other methods of distribution the pear-blight germ might have, and I set about with quite an elaborate series of experiments, to find out the truth of the matter. The main question was whether the pear-blight germ was carried by the wind. If it could be blown by the wind, it would not make any difference whether the bees carried it or not, but it was not blown by the wind, it became a matter of considerable importance. So, having gone through one spring in Washington, I moved up to western New York and passed through another spring the same year.

A gentleman near Brockport, N. Y., very kindly turned over a small orchard to me in which I could start a small, artificial epidemic of pear-blight. We inoculated about 6 or 8 trees, and about eight or ten small branches on each tree. Before inoculating them, I covered a large portion of the tree with bags of various density, mosquito-netting, cheese-cloth and paper, reasoning that by covering the trees with mosquito-netting, if the disease is blown by the wind it would certainly blow through the mosquito-netting and appear under the bags.

The disease gradually spread from my centers of infection, but in no case did the disease get through the mosquito-netting, although a large percentage of the clusters broke down, on the trees that were infected, outside of the mosquito-netting. We inoculated blight in the bags and kept it in: we inoculated it outside, and kept it out.

Now, in further support of the view that I have taken that pear-blight is not borne by the wind, we have two important facts: The first is that pear-blight virus is always a sticky mass, which cannot be blown by the wind. It is a gummy material that can readily be carried by anything that touches it, but not by the wind. The second fact is that the pear-blight germs on drying rapidly die. In ordinary orchard conditions, a few days after the twig dries out the germs die. So that pear-blight germs are not lying around promiscuously. We have no evidence whatever that we can get infection in any other

way. So I think you will be willing to accept my proposition, that bees are active agents in carrying pear-blight on blossoms, and that the blight is not carried by the wind.

Now we have been giving the honey-bee such a bad record that it is with great pleasure that I turn to another phase of this subject. Very early in this work, the question came up in my mind, if the honey-bee was doing this unfortunate work, what was its function on the blossoms? The question came up, Are our pear-blossoms of such a nature that they required this insect fertilization by the bees? So I started out to determine the relationship between the bees and the fertilization of the blossom. The result was a long series of experiments lasting over three years.

On account of the limited time, I shall have to state very briefly the results of this pollenization work. In the first place it came out that most of our pears, as a result of careful hand-pollination on tests, are sterile to their own pollen. Cross-pollination is characteristic of our orchard fruits. It is perhaps not true of peaches and quinces, but as far as apples and pears are concerned, cross-pollination is a necessity.

By trying a large number of experiments, I concluded that insects were the largest agents in cross-pollination. The blossom of the pear is not of the type of wind-fertilized blossoms, but is distinctly of the insect-fertilized type. Now this matter is so complicated that it will be impossible, in the short time at my disposal, to go into the details of fertilization. To make the story short, we may say that from the biological standpoint, the bees are doing their normal, natural work in visiting the pear and apple blossoms. The blossoms are for the bees to pollinate, are developed by insects, and the insects have been developed in correlation to them. It is a normal, biological process, the visiting of orchard fruit-blossoms by bees. The bees are there performing their proper function.

Now the question is, Is the honey-

bee to be looked upon as useful or as injurious? Do its beneficial effects equal its injurious effects? When there is no pear-blight about, it is easily decided in favor of the usefulness of the bee, but when there is an outbreak of blight, it is a rather hard question to decide.

There are no doubt times when pear-blight is rampant in an orchard, when it would be better not to have the honey-bee or any other insect in there until the blight is past. On the other hand, from the standpoint of the bee-keeper, it can be said that in most cases wild bees and other insects would do a large part of the work, both good and bad, without the honey-bee, so that we could not get rid of the infection of the blight even if we do dispense with the presence of the bee.

I feel satisfied that in the Eastern United States the honey-bee must be looked upon as a useful element in the orchard. I have an apiary in my own orchard. The people in California have had some terrific outbreaks of pear-blight and are very much concerned over the matter, and they have reached the conclusion that they can dispense with the honey-bee as an orchard pollinizer; that their Bartlett pears will set all the fruit that is necessary, without insect fertilization. I have never investigated the subject in California. My only knowledge of the case is due to my observation of California fruits. There are so many seedless Bartlett pears from California that it looks as if they were necessarily self-pollinated, and there may possibly be some truth in their views that their pears will set without cross-pollination. In that case, it moves the thing a little against the bee, and if pear-blight is rampant in an orchard, it would certainly be desirable—at times at least—not to have bees about.

In conclusion, I may say that I have had just barely to touch upon matters of extreme importance that should require an evening for their discussion, but I am prepared to defend my propositions by further explanation, if you find it necessary. M. B. WAITE.

Report of the California Bee-Keepers' Association.

BY GEO. W. BRODBECK.

The echoes of the last step of the departing delegates of the California State Bee-Keepers' Association is faintly passing away, but we trust that the work accomplished and the inspiration engendered will result in the beginning of a new era in the honey-industry of this great State long to be remembered.

The announced meeting was for Jan. 15 and 16, which met in the Chamber of Commerce, in Los Angeles. Pres. G. S. Stubblefield presided, with J. F. McIntyre as secretary.

To the wide-awake and intelligent bee-keeper it has been evident for some time that we had reached a critical period in the history of our industry, and while space will not permit me to define the conditions that confront us, to the observant reader and the California bee-keeper this undoubtedly will not be necessary. Recognizing the prevailing conditions and the danger ahead, the bee-keepers of Southern California met last October and organized a temporary association for the purpose of co-operating in marketing their product, along the lines and methods so successfully demonstrated by the California fruit-growers.

A Central organization was effected, which selected a board of nine directors, composed as follows: G. S. Stubblefield, W. T. Richardson, M. H. Mendleson, G. W. Brodbeck, E. A. Honey, F. M. McNay, H. C. Williamson, D. A. Wheeler, and W. W. Bliss.

The object of this was initiatory to the organization of local associations wherever bee-keepers were disposed to do so. This previous action resulted in the presentation of the project to the members assembled at this annual session, it being the principal theme of the meeting. Mr. A. H. Naftzger, President of the Southern California Fruit Exchange; Prof. A. R. Sorague of the California Fruit-Growers' Association, and W. B. Chambling, the father of the exchange system in California—all presented their views and practical experience in relation to this subject, urging upon the bee-keepers the necessity of organization as the only means of the disposal of their surplus product.

Prof. Cook followed with an urgent appeal for immediate action, the result of which was the selection of the following committee: Prof. A. J. Cook, J. F. McIntyre, and F. McNay, with power to select others to aid in the organization of local associations in every county and section.

The Redlands bee-keepers have been the first to fling their banner to the breeze, with the selection of H. C. Williamson as president. When these local associations are completed they will be asked to select a delegate to meet in Los Angeles for the purpose of organizing a permanent Central Exchange, composed of a specified number of directors of their own selection, and who will then supervise and conduct the business of the local associations with the prospective plan for the utilization of the selling agency of the fruit-growers.

The election of officers for the ensuing year resulted as follows: G. S. Stubblefield, president; J. F. McIntyre, Ven-

tura, secretary and treasurer. Executive Committee: F. Mc Nay, Allen Barnett, T. F. Arundell. Vice-Presidents: Geo. W. Brodbeck, for Los Angeles County; H. E. Wilder, for Riverside County; Major G. F. Merriam, for San Diego; M. H. Mendleson, for Ventura; H. C. Williamson, for San Bernardino; E. A. Honey, for Orange; and Delos Wood, for Santa Barbara County.

Appropriate resolutions in memory of Robert Wilkin, R. Touchton, and J. R. Crow, were presented, followed by touching remarks by Prof. Cook and others.

The genial face of "Rambler" Martin was missing, with many inquiries in regard to his Cuban projects.

The following 11 members represented 9000 colonies of bees: J. F. McIntyre, M. H. Mendleson, Emerson Bros., G. F. Merriam, J. McClure, W. B. Whittaker, Dr. D. W. Edwards, Delos Wood, T. F. Arundell, T. O. Andrews, and L. T. Andrews.

The amendment to the constitution increasing the membership fee to one dollar was carried, thus entitling one to membership in the State Association and in the National Association; 48 names will thus be enrolled on the latter, so look out for California!

After a harmonious and interesting session, on motion and considerate action of Mrs. J. F. McIntyre, the Association adjourned to meet next December, during the meeting of the Southern California Teachers' Association, thus securing the benefit of reduced railroad rates.

The Tent-Canvas and Tin Hive-Cover.

BY T. F. BINGHAM.

The tent-apiary probably solves the much-written-about hive-cover. Bee-keepers need not be told that material from trees which grows by its ability to absorb water from the air and earth does not lose its affinity for water even years after seasoning, when atmosphere or other conditions favor absorption.

It is practically useless to try to keep bee-hives from sympathizing with the air surrounding, and within them, either in a dry or damp climate.

With the present high price of good lumber, economic considerations would not seem to justify further experiments with wooden hive-covers. No hive is complete without an outside cover that will protect the hive proper against heat and rain. Painted wood costs more if of choice and valuable kinds than tin, and is of no comparative value. This was one of the factors leading up to the canvas tents in the photograph. Lightness, however, was the great incentive to their adoption.

That my apiary has had no other covers than the tin top and canvas sides since leaving the cellar last April is evidence that it can be used.

It may be further observed that such tents are a great pleasure in handling when necessary; they weigh not more than four pounds, and are very easy to manipulate. Of course, my hives are not like any others in use, but any hive having a tin top and a narrow curtain around it to fall down over the sides would do away with all warping features so much written about.

The interior of my hives are practically solid and would stand the out exposure as well as any, but I use the outside arrangement because I think it pays. The top or roof is an unplanned pine board 1 inch thick and 17 inches square. The tin roof is formed at the sides like a square tin pan, by turning down the edges $1\frac{1}{2}$ inches on all four sides. This tin is fastened to the board with nails driven through the rim into the edge of the board. The tent-cloth I use is the common tent-cloth used in tents for hunters, etc. It is split in two lengthwise and cut into pieces long enough to go loosely around the hive, and sewed together so as to form a tube or bag with open ends. It is fastened into or on the cover with strips of lath long enough to make good corners. This lath secures a shallow chamber across the top of the hive $\frac{3}{8}$ inch high—dead-air space.

A frame of lath or pieces the length of each side is fastened to the lower edge of the canvas, so it will drop

loosely over the interior or main hive. No paint is required if the tin is good enough so it will not rust. If the tin receives a coat of oil every spring it won't rust, and will not absorb the sun's heat.

It seems strange that some of those bee-keepers that have had trouble with combs melting down in the sun have not tried unpainted tin for a roof, or even sides of tin. Tin does not absorb much heat from the sun. It is a thousand times better than any painted wood or iron. A tin-covered hive would not only be moisture proof, but sun proof, and about as cheap as choice lumber.

Clare Co., Mich., Dec. 9, 1901.

No-Drip Shipping-Cases—How to Prepare Them.

BY C. DAVENPORT.

A bee-keeper who was at my place in 1900, when I was putting no-drip shipping-cases together, said I could put two together in less time than he could one. He considered these cases a great nuisance on account of the time it took him to make the paper tray and nail in the cleats or strips the right distance apart in the bottom. If the paper is heavy enough it can be shaped into a tray over a board in the way that has before been described. But with the kind of paper that has been sent out with some of these cases of late, it will not, after being formed around the board, stay in shape long enough to place it in the case. This can be overcome by using a wet or damp cloth to press and form the paper around the board. But I now practice a much quicker and easier way. I have a board of such size that it will just easily fit down inside the cases, the corners on the lower side are slightly rounded and made very smooth and the sharp edge of the whole corners are made smooth with fine sand-paper. The corners, except slightly on the bottom side, are not cut off—simply smoothed. Insignificant as the details may appear they are important.

To put the paper in a case I lay a sheet down on the table and lay the board, rounded corners down, on the top of it so the paper will project evenly all around it. I then raise the paper up and hold it tightly against each end of the board. The paper and board are now placed over the case, and with the board the paper is pressed down to the bottom of the case. These trays can in this manner be placed in very rapidly, and no matter what kind of paper is used it will stay in position. Simple as this seems, there is a knack about it, as some who may spoil a few dozen sheets of paper and spend a few hours' time in learning will be ready to acknowledge.

To nail the strips the right distance apart in the bottom, I use two strips the length of the case, these being marked to show where the center cleats should be nailed. I first nail in the two end cleats, then place in the center ones, and then lay in the two long strips on top of them, one on each side, and the marks on these show just where the center cleats should be nailed. A very short-handled hammer makes the nailing of these much easier, as does starting the nails or staples in the cleats before they are placed in the case.

PUTTING UP SECTIONS OF HONEY FOR THE HOME RETAIL TRADE.

The visitor mentioned was also interested in the way I put up section honey for retail trade. I have for many years sold several thousand pounds of honey each season in small amounts. Part of this is sold at the apiary to people who call for it, and part of it is carried to customers who reside in towns near my home, many of the latter taking a whole case of comb honey each fall, and where a full case is taken I usually furnish a tight and convenient case to keep it in. But at the house and in town a good deal is sold to persons who buy but a few sections at a time, and to furnish a regular case for a few sections is of course out of the question, and sections are, unless one knows how, very difficult to wrap and tie up in paper so the honey will not get broken and mashed up when it is carried for a number of miles over rough country roads.

The way I first did to insure these small lots carrying safely was to take as many sections as might be ordered and set them up close and evenly together on a table, then over their tops I would lay a thin piece of wood—usually a discarded separator—then very small wire nails would be driven down through these thin strips on top into the section; 3 nails were driven through into each section, the whole then turned bottom side up and another strip nailed on the bottom side in the same way. These separators, or whatever might be used, were then trimmed or cut off

even with the sections, which could now be wrapped up in paper to keep out dust. If the package was kept right side up the sections would carry as well and as safely as they would in a case.

I practiced this plan for a number of years before making what might be called skeleton crates to pack small lots in. Aside from the work of making them, which is small, the cost of these crates is insignificant. The end-pieces were made out of cheap lumber one or one-half inch thick—it did not matter which—and were just the size of the outside measurement of the sections to be put in them. For instance, with standard sections these end-pieces would be $4\frac{1}{4}$ inches square. All the bottom or sides there were to these crates was one piece $1\frac{1}{2}$ or 2 inches wide. I generally used pieces of common building lath. The bottom piece was nailed on so it would be in the center, and the side pieces were also nailed at about the center of each side, and no top was used, unless it was to go an unusually long distance, then another piece of lath was nailed over the top after the sections were placed in.

I used to make these crates of various lengths, to hold from 3 to 12 sections. I also used these crates for years, their advantage over the plan first described, being that after the crates were made it was quicker and easier to put the honey in safe shape to be carried, for all there was to do was to put the sections in a crate, and then tie up the whole in paper, the same as one would any package. But the method I now practice is far superior to either of these. Sections of honey can be done up simply with twine and paper so it will carry practically as safely, and any where, as it would in a regular case.

Before describing how this is done I wish to say that I did not discover how to do it—the man who showed me how to do up sections in this way was one who came to the apiary to buy a few sections, and it may be of interest to some to know that I made him a present of a 24-pound case of fancy clover honey, and the next fall I sent him another case. I tell this because it shows what I think of the plan.

Suppose we want to tie up 12 sections; a stout piece of twine is laid on a table, and six sections are set on top of it up close to each other, so the string will be under the center of each. The sections should of course be exactly even with each other. The string is now brought up over the center of the tops and six sections tied together. The only secret of success about this method is to use strong twine and tie them together *tight*. Six more sections are tied together in the same way. The two rows are then set close together and a string tied around the outside of the whole. This last string should be tied so it will be about at the center, or midway between the top and bottom of the sections. If only six sections or less were to be done up, after being tied as first described, the first string should be tied around this one row.

If the sections of honey have been produced without using separators, care should be taken to select some for the ends, one side of which the comb did not come out quite even with the wood, or the strings would mar and damage the outer face of the end section.

I have known sections tied up in lots of twelve in this way to be carried 20 miles over rough roads and without a section moving out of place.

Smaller lots of one row done up this way are practically as safe to carry as one solid section of the same size would be. Southern Minnesota.

Bees and Grapes, and Shooting Birds.

BY "OLD GRIMES."

Well, Mr. Editor, there is that John Hardscabble with his picture and his broad-brimmed hat, and that good old smile in the American Bee-Keeper, and just as natural and good looking (not handsome, by any means) as when he and I were boys together. John always had that sunburst look on his face, and so happy.

But I never thought John would take to bee-keeping and religion. Bee-keeping is surely a new wrinkle, and as to religion and being a deacon, why, John, how did you get in, anyway? It is surprising.

Well, Mr. Editor, when John was married to his first wife he lived neighbor to me, and a right happy couple were they. A nice little wife, a nice little farm, and all paid for, and that meant a great deal in those days, didn't it, John?

Well, John had a little vineyard, too, and we came near

having a quarrel over it. You see, John came over to my house one morning rather hot in the face, and, said he, "See here, Mr. Grimes, your bees are eating up all our grapes." "Do tell," said I, "but, John, let's not get hot about it; let's go over and see about it."

And what do you think we found? About five bees on his hundred vines.

"Why, John," said I, "it will take those five bees a long time to eat up all of those grapes."

"Why, Grimes," said he, "just look at this whole cluster—every grape full of punctures."

"But, John, you do not believe that a few bees made those big holes, do you? You just watch out early in the morning and you will find that the linnets and other birds are puncturing your grapes; and, of course, when the juice begins to run, the bees go for it, and I am surprised that there are not more bees here."

My explanation looked so reasonable that John cooled down considerably, and said he would watch out for those linnets. John was an honest chap, and in a few days he came over and said, "Brother Grimes, I will have to give up; there are more birds than bees after my grapes, and now I am going to shoot the pesky things."

For the next week or two, or until the grapes were harvested, there was a shot-gun fusillade over at John's every morning.

I knew it would do no good to talk to him while in his destructive mood, but after the grapes were all off to market I went over one evening and we had a talk.

I said, "John, how did you come out with your grapes, birds, and the shot-gun?"

"All right, I guess," said John. "I shot an everlasting number of linnets, orioles and sich."

"And, John, you missed some, I suppose?"

"Yes, we can't hit every time. Yes, yes; but I did not go to see how many."

"John, how much did you get for your grapes?"

"Well, times are awful dull, and there is a big crop of grapes, and prices are low, so I got only 3 cents for them."

"Now, John, do you think if the birds had been let alone they would have destroyed 100 pounds of grapes?"

"Well, neighbor Grimes, that is a hard question to answer; but the fact is, it does not seem as though they would."

"And now, John, how much ammunition did you use?"

"Why, goodness, I had not thought of that; I guess I used about \$3 worth."

"And, John Hardscabble, in order to save \$3 worth of grapes you fired away \$3 worth of powder and shot. You furthermore killed some of our best friends. Then, you know the Bible says that you must give the birds a portion of the crop, it is by right theirs."

"Why, neighbor Grimes, I never thought of it in that way. I do not believe I will fool away any more ammunition that way."

"You see, John, I had some experience in that line myself. You know king-birds catch bees, and I shot lots of them around my apiary. One year I was afraid they might catch my young queens when on their wedding-flight. But, after all, nobody has ever proved that they catch queen-bees; besides, my queens mate now just as well when there are numerous king-birds as they did when I used the gun. I really think a few king-birds do very little harm to a large apiary, and for every bee they catch I have no doubt they catch some other insect that is not the friend of man."

But now, John Hardscabble—I suppose I ought to call you deacon but it sounds so queer—I am glad to know that you are prospering, but until I hear from you I shall wonder and wonder how you happened to take up bee-keeping.

And then, deacon in a church—you must have *fallen* in, John.

Introducing Queens with Tobacco-Smoke—Other Important Matters.

BY FRANCISCO BROWN.

There is something wrong with the tobacco method of introducing queens as mentioned in the Colorado convention report, on page 601 (1901). I have introduced a great many queens with tobacco-smoke, and have yet to lose my first one. Last season I introduced 40 that came in three shipments by mail, three to five days en route, and were introduced to various conditions of colonies, some just made

queenless to five hours, others queenless three, four or five days, while there were seven or eight colonies that had been queenless several weeks. Some colonies were very strong, some very weak, and all grades of bees from the crossiest hybrids to pure Italians and blacks. I speak particularly of this lot as they were received during an extended honey-dearth, when all colonies in the apiaries (there were three apiaries of about 100 colonies each that the queens were distributed among) were worked up to the robbing pitch, and one to two hours' work at a time was all one could do before robbers forced a stop.

The queens were introduced just at dark, by first going around and smoking the colonies to which they were introduced, with a few puffs of tobacco-smoke in the entrance; the cover was removed, another puff given, and the queen run down on the combs followed with a puff of smoke, and the hive closed. Fifteen to 20 minutes later I went around and gave each colony two or three more puffs of tobacco-smoke in at the entrance.

This is the Henry Alley method, and has been in use 30 years. I used it fully 15 years ago. Mr. Alley uses a tin-tube smoker especially adapted for the business. I use a common Bingham smoker, starting fire with dry rotten wood, filling the box well up, and then drop in about a table-spoonful of Bull Durham smoking tobacco, and shake it down among the wood well. If there are many queens to introduce, add more tobacco when the odor of the first gets weak.

I am well aware that much has been said on this subject, but its value is worth repeating. Queens cost money. From an extensive acquaintance among bee-keepers I know a great many queens are lost in introducing them. The usual candy-cage method (shipping-cage method, I should say) is far from being any where near a universal success.

LONG-TONGUE BEES THE AIM.

Mr. Gill considers long-tongue bees (in the same paper) to be the aim. Right you are, Mr. Gill, or at least if not long-tongued there is some factor we do not understand. One of the largest yields of honey I ever had, and the largest by nearly double of any in the whole yard (and three yards), was from a colony whose queen kept only five or six Langstroth frames full of brood, say 30,000 cells of brood. There were plenty of other colonies in the yards that had 10 to 12 solid frames of brood for weeks, but when it came to the honey crop they gave only 80 to 120 pounds each, while the one colony, singled out above, gave 240 pounds of comb honey.

Each year for three years that one colony has given 50 to 100 pounds more honey than the general run of good colonies. The one pity is that the queen will not transmit her extra qualities to her daughters, notwithstanding a number of trials. They are hybrid-Italian crossed with extra blacks or Carniolans, are not robbers and so don't steal, but are honest gatherers.

On three occasions I have removed the queen with a frame of brood to another colony and introduced a pure Italian queen, thus I know that the bees live longer than the average. Who can tell why this is?

BREEDING BEES FOR HONEY-PRODUCING QUALITIES.

For years we have been told to pick out our best colony to breed from—the one that gave the biggest yields. And what have we got in most instances as the results? Just what we might have known we should get if we had stopped to study it out—a lot of colonies with all varieties of yields, from zero up to big yields; no uniformity except it came by a fortunate chance.

The gist of the matter is, breed from a queen that comes only from good, average yielding stock, and that transmits a uniformity to her daughters; then breed from those daughters that show a general uniformity of good, average yields, and go upward by degrees, not by one leap.

I must confess that I have been led astray by the false idea of breeding from the extra-big-yielding colony, and as a result I have continually to be culling out worthless queens that run so far below the general average yield as some of their sisters go above it. We cull out the poor ones and then think next year surely we will have all good ones to start with—we shall be on the upward tendency—but, lo, when new queens come on to replace the old ones or by swarming, we have the same old trouble—lots of them gone backwards.

In a small apiary of a dozen or two colonies it does

not show much, but take it in a large apiary, and several apiaries combined, the sporting back is too plainly seen.

What is the remedy nearest to hand? Record-books and pedigreed queens. We may not be able to know about the drones—it may not be needed so much—but we *must* know that a queen will transmit her qualities *uniformly* good, let them be only a good average for a starting-point.

Pedigrees should be sworn to, and breeders should be required to furnish queens that give a *general* uniformity of results.

Diek, Tom and Harry rearing and shipping queens has certainly deteriorated the quality of the bees in many an apiary throughout the land. There are many good, responsible breeders that can soon furnish a record and pedigree of their stock, and we should patronize them. Florida.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

SELLING HONEY BY THE CASE VS. WEIGHT.

Suppose Burnett & Co. buy 2100 pounds of honey. It arrives—weight short—and they go before a jury to recover their rights. We have a general idea of what their chances would be. Now suppose again: They buy 100 *cases* of honey, to be cased according to Colorado rules. When it arrives, short just as many pounds as the other lot was, would they stand as well before the jury? I suspect there are many jurors that would say: "Things must not be drawn too fine in this rough-and-tumble world. These commission chaps bought 100 cases and got 100 cases. Let 'em be satisfied." My suspicion may be wrong—but if it is, it is valid all the same, providing the commission men share it. They will not favor a change which they *think* damages their legal standing. It would be nice to save the long and fussy job of finding the exact weight, in each case of a car-load of honey—but—. 'Spects there'll have to be an "Honesty Department" in each bee-paper, and every bee-man a subscriber first. Pages 819 and 822.

FOUL BROOD IN MICHIGAN.

For 402 foul-broody colonies to be scattered through 206 apiaries appears quite singular. Looks as if the disease in Michigan had taken a sudden and rapid march in all directions; and as if but few apiaries had been infected more than a few months. Why thus, if so? One would expect 206 infected apiaries to yield at least a thousand infected colonies.

The general ignorance of apicultural needs and rights comes in very badly here. Clean out the disease in your locality and directly you are in bad odor, and accused of being a bad neighbor. Not only those who had a few neglected bees, but those who didn't have any bees, side against you. Page 823.

GLOSSOMETER FOR MEASURING TONGUES.

While every one is thinking and talking long tongues, some supply firm ought to offer Cook's Glossometer for sale. Still I think it has weak points which some future instrument may remedy. A mere smearing of sweet will quickly become too thick for the best satisfaction. Also, if you will observe *very closely* a bee's ligula operating in a state of nature, I think that you will join me in saying that the bee values, and perhaps decidedly needs, some surface to one side of which the finger-like ligula tip can be flipped against—one smooth surface at right angles and extreme distance not being favorable. Too much like picking up distant grains of wheat with the tip of your finger. We are too prone to forget that the bee cannot *suck* honey exactly as a boy would suck cider through a straw—has to coax it up some other way. Page 4.

ACORNS AND QUEEN-CELLS.

Many of our Pin Oak and Yellow Oak acorns are no bigger than a queen-cell, dear Boss. You just quit now from leaning across the ocean and punching your Australian

brother with the "shooting-stick!" Perchance some of your own "subs." need punching more. Page 3.

A CO-OPERATIVE UNION AMONG BEE-KEEPERS.

Wish I could second Prof. Cook's desire that the farmers form a co-operative union (trust, under a mild name) and get better prices. Can't do it. If farmers form a trust political men now engaged in trying to bring the great trust evil under control, will get right out from under, and all hopeful opposition to extortion will collapse. Just now the people are being helplessly scooped of multi-millions on their coal and their sugar and their oil and their transportation. This done for no service or reason at all except the conscienceless power of the scoopers. Flour, and everything else necessary to life, is likely to suffer in the same way unless help is found quickly. The trust method, I freely grant, is a millennial method; but the Millennium is not here yet. Leaving your watch and money on a post by the roadside will be all right in the Millennium—won't do now. Combines could be wholly beneficent—at present sure not to be.

A second reason why I cannot do it, is that the farmers themselves are not up to the moral level that would be required to make it safe. Next to flour the potato is civilized man's food. Owing to a short crop it is expected that people will pay twice the usual price for potatoes for the next five months. A trust with all the supply under control would easily get three prices instead of two. It would be simply and flatly wicked to do it; but it would be done, and the average farmer would approve. Alas, it's only when somebody else takes *his dollars* for no reason except the brutal power to take them, that the average man can see any sin in devouring! Page 4.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Running an Apiary with But Little Increase.

1. I wish to run my apiary with but little increase. What would be your plan to that end?

2. I had thought of destroying most of the queens about the time basswood comes in bloom; then about the time queen-cells are ready to hatch destroy all but one. Then the progeny of this new queen would be ready for the fall flow. Then, again, I had thought instead of killing, caging her. If I do that and put her cage between the frames, would the worker-bees feed her?

3. If I do that, would they start queen-cells with a view of superseding her?

4. If in either case, either killing or caging, would the bees be likely to fill the combs with honey as they hatch out?
IOWA.

ANSWERS—1. I hardly know how to answer your question. There are so many different plans and combinations of plans, some of which would be best under some circumstances and some under others. One plan that I followed with much satisfaction, so long as I had some one on hand at all times to watch for swarms, was a plan originating, so far as I know, with G. M. Doolittle. When a swarm issues, cage the clipped queen and put her in the hive. About 5 days after the issuing of the swarm destroy all queen-cells, or at least all sealed cells. Ten days after the issuing of the swarm destroy all queen-cells and liberate the queen. In that way you can prevent increase entirely, if you so desire, and I got good crops by it.

2. The first plan you mention might work all right, but it would be well to go slow till you know. Unless you are unusually good at finding queen-cells you would miss a cell in a good many cases, then out would come a swarm with a virgin queen. Possibly a modification of the plan might suit you. After removing the queen, wait till the first young queen hatches, which you will know by listening for her piping in the evening, beginning to listen 10 or 12 days after removing the queen. The next morning after hearing the piping, destroy all cells, paying no attention to the young queen. That ought to end all swarming and the plan would have the ad-

vantage over your plan, that you would be sure of your queen hatching all right, and you would be likely to average a better queen than if you arbitrarily chose one of the cells. The caging plan you mention I tried, but it was not satisfactory with me. I think others have liked it better.

3. When the queen is caged, you may count that the bees will almost certainly start queen-cells.

4. Yes, to a large extent.

Honey on Foundation—New-Style Section.

1. Is it the usual thing that comb-foundation honey sells for 5 cents a pound less than that made without foundation, as D. H. Metcalf says on page 59?

2. What is the new style of section that he tells about, in which bees will build combs more true and perfect than with foundation furnished them?
SUBSCRIBER.

ANSWERS.—1. I think that the usual thing is that comb honey built upon foundation will sell for more than that without foundation. It is possible some one may have used brood foundation, or done something else to make his honey unacceptable, but as a rule I think that the highest prices are obtained by those who use foundation.

2. I don't know; and I am skeptical about bees building more true and perfect without foundation than with it.

Early Detection of Foul Brood.

1. Proceeding on the McEvoy plan of curing foul brood, are the bees confined while they are kept on the "starters" the first four days, or are they allowed to fly at their will?

2. How can one detect the disease in its incipient state? It seems to me that it would be difficult for an amateur to detect it until it had made a considerable progress. For instance, if only a few of the larvae in a full comb of brood are affected, one might have a big job to find them. I will need to be on the lookout as soon as the hot weather comes, for the development of the disease among my bees, and what I feel I am not fully posted on is the method of detecting its appearance. If I can get informed on these two points I feel confident the disease will not get much of a start in my apiary.
OHIO.

ANSWERS.—1. They are not confined. If they were to be confined, there would be instructions to that effect given with the treatment.

2. You are right; it is not only difficult to detect the disease in its incipient state, but impossible. You'll have to wait till the larvae are very much dead.

Hand-Fertilization of Queens.

Inclosed you will find a paragraph that I copied from a report of Nelson W. McLain, apicultural agent of the Department of Agriculture, who made experiments with bees at Aurora, Ill., in 1885. I have looked through other reports of the Department of later years but could not find anything further on this subject, which, if it is practical, would be a great thing for bee-keepers.

If you think this is worth publishing in the American Bee Journal, you are at liberty to do so. It might lead to further experiments among the younger bee-keepers, who might make a success of it.

In Mr. McLain's report he tells of experiments made in trying to fertilize the larva, and also when the queen is just hatched, but he met with no success, except in the latter case, which you will find in the inclosed article.

I hope to hear more on the subject through the Bee Journal.
MINNESOTA.

The paragraph from Mr. McLain's report reads as follows:

When the virgin queen was 6 days old orgasm occurred, and on the evening of the seventh day we removed her from the hive and placed drops of the male sperm upon the vulva as she was held back downwards, by gently grasping the thorax between the thumb and finger. The instant the male sperm was pressed from the testes and seminal sack of a mature drone upon the excited and distended vulva, it was curious to observe the effect. The action of the abdomen and vulva resembled that of young birds while being fed. There was the reaching up after the seminal fluid, and an action of the parts resembling the opening of the mouth and swallowing food. As much seminal fluid as could be obtained, by the imperfect method employed, from three or four drones, was utilized and readily absorbed by the queen, after which her wings were clipped, and she was dropped on a frame covered with bees and returned to the hive, and the bees were liberated. Up to this time her appearance and actions were those of a

virgin queen. The next morning, 12 hours after exposure to the seminal fluid, her abdomen was distended, and her appearance and actions in all respects were those common to fertile, laying queens. She was moving about slowly over the combs, and peering into the cells, and in 24 hours afterwards she had 400 or 500 eggs. In due time the worker-larvæ appeared, and at this date (November 13) worker bees in considerable numbers are being hatched. We then reared two queens from the eggs laid by this artificially fecundated queen, in queenless colonies, and as soon as they were hatched I clipped their wings, and when orgasm appeared they were treated as before described, and in three days one laid a few eggs in worker-cells. The other has the appearance and action of a fertile queen, but has laid no eggs, and the lateness of the season forbids advantageous continuance of the experiments.

ANSWER.—The success claimed by N. W. McLain in fertilizing a queen by hand was well known in bee-keeping circles, and the fact that the thing has never been repeated by him or any one else, in all these 16 years or more, gives some ground for the belief that no such success was ever attained. He reports success in three cases. If you should succeed three times, do you think you would then drop the matter entirely?

Perhaps Suffering From Bee-Paralysis.

My 6 colonies of bees are all dying out, apparently, of a disease with which I am not at all acquainted. A bee will come out of the hive, and other bees will gather around it, and seem to trim it. There is no show of anger by any of them, but sometimes a strong bee will rise and fly off with one of those diseased bees, but which is sometimes able to fly very well. Thousands seem to die daily. Can you tell me the cause, and remedy?

ANSWER.—Most likely the trouble is bee-paralysis, which subject please look up in your text-book. Unfortunately, you will not get a great deal of comfort from such consultation, for many remedies have been given, some of them vaulted as sure cures, but further trial has not confirmed the belief in their efficacy. The fact is that in many cases the disease disappears of itself, and then whatever remedy was used has the credit of the cure. While the disease is generally of so little

consequence in the North that it need not give any uneasiness, in the South it is sometimes very destructive. Among the remedies offered are changing the queen; spraying the combs with salt water, or a solution of carbolic acid and water; and transposing the colony. The last named is one of the latest offered, and it is just possible it might be worth while to try it. Simply let the diseased colony change places with a strong, healthy one. The "A B C of Bee-Culture," while saying "we know of no reliable cure," gives the transposition treatment and says:

"The rationale of the treatment seems to be that the bees of the ordinary colony having bee-paralysis are too much discouraged to remove the sick; as a consequence, the source of infection—that is, the swelled, shiny bees—are allowed to crawl through the hive at will. But when the colonies are transposed, the healthy, vigorous bees of the sound colony carry the diseased bees entirely away from the hive. The sick and dying being removed the colony recovers."

Prevention of Increase.

I have 25 colonies of bees that I run for section honey. I don't want any increase, and will not have any empty hives for the swarms that may issue. How should I manage them to get best results? What should I do with the swarms? Would I gain anything by uniting two colonies in one hive, in the spring, thereby having some hives for the swarms?

ANSWER—I don't know enough to say for certain what plan will bring the best results. Here's one plan that might be worth trying: Have all queens clipped, and when a swarm issues remove or kill the old queen. A week later begin listening each evening for the piping of the young queen. When you hear her piping, go the next morning to the hive and destroy all queen-cells, paying no attention to the young queen. Two weeks later look to see if brood is present, and if not give them a queen.

Yes, it might be well to unite in the spring any that are not tolerably strong.

Is It Wise to Guess at Results when you may be absolutely sure about it!

If the eggs are good and you put them in a **Reliable Incubator** and follow instructions, you are sure to get a satisfactory hatch. If you put the chicks into a **RELIABLE BROODER** you will raise every one that could be raised in any other way. Our **20TH CENTURY POULTRY BOOK** tells why and a hundred other things every poultry owner should know. Sent for 10 cents. We have 115 yards of thoroughbred poultry.

Reliable Incubator and Brooder Co., Box B 2 Quincy, Ills.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well if they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 98.

GENERAL ITEMS

Report for 1901.

I commenced last spring with nineteen colonies of bees, secured 1715 pounds of extracted honey, and a quantity of comb honey. It is all sold, and I received over \$165.00 for it.

I have twenty-eight colonies packed for winter. I use the 8-frame dovetailed hive.

HERBERT FREAS.
Lincoln Co., Ont., Canada, Jan. 15.

Bee-Business Almost a Failure.

The last two years the bee-business has been almost an entire failure, some having lost all their bees. My bees went into winter quarters in bad shape, but I hope now to get the most of them through.

Bees did not work on the alfalfa last summer, as it was so very dry that it did not even bloom very much excepting on bottom land.

I hope we will have a good honey-flow the coming year.

I have been a constant reader of the American Bee Journal for years, and could hardly get along without it. H. H. MCGUCIN.
Jewel Co., Kans., Jan. 13.

Buckwheat and Locust--The Jouncer

I have been waiting before reporting on a piece of buckwheat planted in 1900, to see what that planted May 22, 1901, would do. It came into bloom July 9, and bees were getting both pollen and honey from it in great shape. Mustard, clover, motherwort, catnip and all of our honey-plants were in full bloom, and it looked to me as if a great many writers were mistaken in what they have said in regard to buckwheat yielding no nectar when planted early.

We usually have nothing for bees to work on from about July 20 to August 15, and

To make cows pay, use Sharples Cream Separators. Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

Stone Bruise.

This is a dangerous disease among Rural Mail Boxes. If the box is light weight, or has (cast) iron in its blood, the disease often proves fatal. Even when the victim pulls through it will have a pock-marked appearance. The **STEEL PLATE MAIL BOX** is perfectly immune to this disease. Made only by the **BOND STEEL POST CO., ADRIAN, MICH.**

S.W. Cor. Front & Walnut Sts. CINCINNATI, O
Please mention Bee Journal when writing

if a crop of buckwheat can be made to fill the shortage I am satisfied it is a paying investment.

Compare with the "A B C of Bee Culture," page 50, Doolittle's note 44; also note page 197, in regard to locust.

In this locality there are three varieties, common, honey, and one that I do not know by what name it is designated. I have observed closely for three years, and following is the result: Two years strong colonies gave some surplus, and the other year it sounded like a swarm in every tree, but no surplus honey.

The jouncer solves one of my most difficult problems, and on plain sections it gives me as good results as Mr. Davenport gets on extracting supers. Many thanks to him and the American Bee Journal. L. C. SALSBURY. Bradford Co., Pa.

Finally Made the Bees Pay.

During the past season I was able, through the advice and instruction received through the columns of the American Bee Journal, to make the bees pay for the first time in my experience.

I started with 3 colonies last spring and have 5 that are very heavy now, and 1 that is pretty light.

I placed them in an unused bedroom over a cold room in the south-east corner of the house. They seemed all right when I looked in the first of the week, so I did not disturb them any more than I was obliged to, in order to get some books needed. HOWARD H. HOUSE. Oneida Co., N. Y., Jan 20.

Good Yield—Honey-Dew for Stores.

I saw an item recently that spoke of bees supporting a hired man in the hayfield at \$1.75 per day. I had a prime swarm of black bees which came out June 7, 1901, and on June 8 I put on sections enough to hold 64 pounds of honey, and in just 9 days from the day I put them on I looked at them and found in every one of them was ready to take off, and so I took them away completed and in good shape. I think they did fairly well.

I have kept bees for a number of years and have had success with them, for this reason. I never lost a colony in winter, indoors or outdoors, so I think I have been successful. This winter I expect to lose them all, on account of the honey-dew that they have to winter on.

A. H. CHESLEY. Carroll Co., N. H., Jan. 20.

Report of 2 Acres of Buckwheat.

It was planted May 24, 1900, and bloomed July 10. Nectar first showed in the hives to any extent July 23.

Brood-rearing was certainly stimulated up to July 28. They at no time worked on blossoms after 11 a. m.; on that date they worked until 1 p. m.

The buckwheat on July 28 was loaded quite well.

August 6 the bees worked on it every day, but at no time after 11 a. m., and it is now about through blooming. No honey showed in the supers but considerable in the hives.

On August 6, there were 10 acres of buckwheat in full bloom about one-half mile from here and bees were putting honey from there into the supers. This seems to me to prove that it pays to plant buckwheat for bees. Fortunately, I was able to harvest quite a nice crop of the grain, but this is not the case usually, as rain fell several times very opportunely, and a few days more of the hot, dry weather would have entirely spoiled it.

L. C. SALSBURY. Bradford Co., Pa.

"The Bee in Law."

On pages 11 and 12, I noticed the finding of R. D. Fisher, i. e., "The Bee in Law." That finding appears strange, indeed. It would seem to me that if a person obtained a license to cut down a tree and take either tree or bees from the owner of the land, that should be sufficient, as against a third party. Why, a farmer might as well sell a fat steer out at pasture to a third party, as the owner of the land to sell a bee-tree to a third party. You do not give just what the statute in New York State provides, but I gather from what you have hoiled down in the matter that Mr. Fisher, or anybody in authority there, can rule just as they think fit, according to their own personal ideas.

The law in the Province of Ontario is laid down by act of Parliament, and the judge would have to base his findings accordingly. Bees living in a state of freedom in Ontario

shall be the property of the person discovering them whether he is or is not the proprietor of the land on which they have established themselves. But in event of his not being the owner of the land he would be obliged to compensate the owner for all or any damage he would cause the owner of the land in removing said bees. **W. J. BROWN.** Ontario, Canada.

[So long as law-makers are fallible beings there is a likelihood of laws more or less fallible. The most that the bee-papers can do is to try to tell what the laws are.—EDITOR.]

Bees Wintering Nicely.

My 240 colonies are wintering nicely, and are very rich in stores. We extracted 7 barrels—about 4,000 pounds—last year to 1 1/2 barrels the previous year. Last year was exceedingly dry, probably the driest I have ever seen in my 40 years' residence here. **EMIL BAXTER.** Hancock Co., Ill., Jan. 20.

Wintering Well.

The bees appear to be doing very well in the cellar, where they were put Dec. 10. It was so very dry last fall that I don't expect much white clover the coming summer, as last year's clover burned out. **L. HIGHBARGER.** Ogle Co., Ill., Jan. 20.

Treating Foul and Black Brood.

I will tell how we treated foul and black brood the past season with the best results. We had about 50 colonies which had the disease in all stages, and, after thinking the matter over, decided to try a way of our own.

The first thing was to get them strong by uniting and otherwise before the honey-flow was on; then when the honey was coming in fast we took an old hive where the bees had died of foul brood and cut out all of the combs, scraped the frames as well as we could, then put in 2-inch starters for the brood-nest.

Next, going to the hive we wished to treat, we first smoked, then lightly jarred the bees so as to get them to load, as we think it best that all bees carry as much honey to the new hive as possible. We then moved the old hive away a few feet, front or back, set the new hive with the starters and a super of drawn sections in its place, then shake the bees out before it and let them run in, being careful that none of the young bees go into another hive, and the work is done.

The reason for it being a success, is, the loaded bees at once store above all foul honey in drawn combs, and commence to clean house, and, as there is no comb below, if there is any honey on the hive or frames it also goes above. I omitted to say there should be an excluder between sections and brood-nest.

Now if the flow should stop before the super is filled and capped, it should come off, otherwise we have a good super of honey and the bees never stop work. Out of 50 colonies so treated the disease did not appear again.

This year (1901) has not been a good one for bee-keepers around here, but we are hoping 1902 will be better. **W. J. STEWART.** Utah Co., Utah.

A Swarming Experience.

During the season of 1900 I secured 1400 pounds of honey from 14 colonies, spring count, and 19 swarms, several of which I sold during the season. Then I expected great things for the honey season of 1901, but early in the spring wet weather set in and continued until about July 1, at which time, instead of having my honey crop taken and sold as usual, my bees were just about ready to go to work in the supers, and in this country it was said of old that bees could not build comb after July 10, and as I have always found it necessary to leave plenty of honey in the hive after this time, on which the bees might winter, my feelings may be imagined when after two to three fair days my bees began to swarm, which was a large one, and put it in place of the parent colony. (It was hived on starters of foundation only). I then went to the parent hive, lifted off the extracting super, placed it with bees and empty combs on the newly-hived swarm with a queen-excluder between. Well, it soon looked as if every bee in the apiary had become deranged, for there would be two or three swarms in the air at one time. I hived some, dumped some on the ground in front of the hives from which they came,

and some I let go. So after a few days they settled down to business, and I was soon as much surprised at the way they carried honey and built comb as I was at the way they had conducted themselves in their stampede.

But that first swarm which I treated as I said before, gathered at least twice the amount of honey gathered by any other colony.

After July 3, I averaged about 40 pounds, of as nice honey per colony as I ever saw. It was basswood, the season having been such that it did not bloom as early as usual.

I am putting forth every effort to improve my bees by selection, have been rearing drones from select queens, as well as queens from select mothers, and had fair success the past season in mating my queens with these drones.

R. L. DAVIS.

Tazewell Co., Va., Dec. 9.

Bee-Keeping in Southern Ohio.

I will try to give the readers of the American Bee Journal a short description of Southern Ohio, mostly applicable to Pike, Highland and Adams Counties. We have a great deal of land here, in fact it is piled up in great, big piles, some of the hills being from 300 to 450 feet high, and extending many times for 25 or 30 miles. The valleys are usually not over a mile and a half wide, and many are only a few hundred feet wide. The valleys are rich, being fair grazing and farming land. The hills are heavily timbered, and are the finest fruit land in the State. The hill land is very rocky, and fairly productive on the north side, while the south side is mainly a barren, slaty soil, covered by scrub-oaks and huckleberry bushes.

In the forest trees the bees find a fine pasture. First the red maple, usually about March 20, and three varieties of willows, red-bud, poplar, dogwood and sassafras coming in just after fruit-bloom. In May, and sometimes a little sooner, we get wild strawberry bloom, raspberry and blackberry, of which we have hundreds of acres, especially of the blackberry; sugar-maple, chestnut, sourwood, basswood and buckeye. Add to that white clover, motherwort, catnip, hoarhound, huttonbush, wild mustard, milkweed, ironweed, smartweed, water-lily, golden-rod and asters, and you have a partial list of the honey-plants. I could name probably 50 more and leave out all the wild flowers, of which there is a great number. Yet you could ride for miles and not see even a box-hive. The man that has 20 colonies in any kind of old boxes is considered a great bee-man.

My 18 colonies have a range of miles of hills and dales. Here the Italian bee rules. It came about in this way: Some 15 years ago a Mr. Legg engaged in apiculture to the extent of 100 colonies; he became interested in politics, was elected county treasurer, defaulted the county some \$17,000, and later took up his residence at Columbus, Ohio, for six years. The bees being neglected they sent out many swarms which went to the woods, and did for the black bees what politics had done for their keeper. Motto: Let good enough alone. Now it would be impossible to find a colony of black bees, and you seldom see a single black bee. Bee-trees have as fine Italian bees as you wish to see.

Land is cheap in the hills—can be bought for a song, almost—\$3 to \$10 per acre; while land in the valleys would cost from \$30 to \$60 per acre. We would be glad to welcome some good, reliable, up-to-date bee-man, for a fellow gets awfully lonesome. If a colony dies from any cause, even queenlessness, and you ask any box-hive, old-fashioned bee-man what ailed them, he would say that worms got in the *skep*, the bees took the cholera, and froze to death. They never read a bee-paper, saying that it does not pay to keep more than enough for seed. But they say they know how to catch a sucker.

One of those fellows approached me one day in the spring of 1900, and told me that he had two good colonies of bees for sale cheap. I told him I knew nothing about bees, and could do nothing with them. He said he could tell me about them and he would teach me. I told him I might trade him a watch (it was plated and the plating was about all off). Well, we went to look at the bees. I took shelter behind an apple-tree, and he walked bravely up. It was a nice, spring day, just right for bees to get a hustle on themselves. One colony was sending out several bees, and the other had one or two crawling around the entrance. I remarked that they were weak. "No, those fellows are rich; they do not have to work unless they feel like it." Well, that looked a little bit reasonable, so I bit.

The fellow helped me carry them that night to my vineyard, and I went to bed that night dreaming of tons of honey. I was satisfied that I had two extreme classes of

honey-bees, viz.: one aristocratic, New York 400—they were so rich they only worked when they pleased; the other colony poor, and not so far up socially, and had to work like the rest of us clodhoppers.

In a few days my "millionaires" began to act as if they were suffering from sore feet; and as the great bee-man had told me of the great store of luxuries they owned, I naturally supposed they had the gout. In a few days they had gone the way of all the world.

Well, I had caught the germ of bee-fever. Later I bought four good colonies in movable-frame hives, and a man promised to loan me a bee-book if I would return it. I went four miles after it and it proved to be a bee-supply catalogue for 1891. I returned the "book" and it was snugly stored away for future use. Pike Co., Ohio, Jan. 14. J. M. WEST.

Carbolineum Paint—A Warning.

A word of warning as to Carbolineum may save some sad experience. For outside paint it is altogether out of the question, for the stuff will never dry, and all bees that touch it while the sun shines on it must surely die.

For bottom-boards, paint the under side, and do it a long time before they are to be used. Reversible bottoms, of course, cannot be painted with it.

Three years ago I painted some hen-roosts with it on the under side, and it killed all the lice in the entire hen-house. It also filled the building with such horrid fumes that the chickens' lives were endangered, and they had to remain outdoors all day. The vapor that arose from the stuff caused the skin on my face to peel, and almost blinded me for two days. The nasty smell is still on the wood after three years.

But still, carbolineum may have its uses in the apiary; for instance, it may be effective in destroying the bee-moth. The way to do it is to paint a hive-bottom with it, and place over it a hive-body with infected combs inside, and cover with glass; then place in the hot sun, and fumes that rise ought to burn the faces clean off of the old worms.

If carbolineum is handled in the sunshine without wearing a face-mask, the handler will certainly have reason to regret it. Dupage Co., Ill. T. FLUEGGE.

Bees and Ants.

Many of our bee-keepers do not seem to realize the importance of the danger that ants are to their bees. I note what our mutual friend, Mr. Hasty, says in reply to Mr. Working (see page 9). Yes, they will not only grapple with and destroy the queen, but if they are present in immense numbers they will destroy every living bee in the hive; and they will also carry away the honey, leaving the combs as light and dry as if they were robbed by wasps or other bees.

I remember visiting an apiary of over 60 colonies that were badly troubled with small black-brown ants about three-sixteenths of an inch long; they destroyed several colonies, among them being a colony in a 10-frame, 3-story Langstroth hive containing 12 to 15 frames of brood, and over 100 pounds of honey, and from 90 to 100 thousand bees, and the ants invaded the hives in such vast numbers that they destroyed the bees and completely cleaned out the hive in 21 days.

Mr. Hasty says the number of species of ants is immense, which is true. There are white, black, brown and red ants, and in size they range from about one-sixteenth to seven-eighths of an inch. As far as their destructive effects are concerned their size does not count like their numbers; thus a quart of small ants are more destructive than a gallon of large ones; besides, it is much easier to find and destroy large ones than the small ones.

Mr. Hasty also says that bees show anger when multitudes of little ants, too small to grapple with, get scattered among them. He could have said with equal truth that the bees are in a terror of fright when the hive is full of small ants.

I have opened hives where there were many times more ants than bees, and the bees in their frantic efforts to get away from the ants that followed them would rush against the others. I saw large numbers of ants grapple the bees by the legs or body, and, as they scarcely let go when they fasten themselves on anything, the bees rise and fly off with the ants; and as they seldom, if ever, live to return, and as it often happens that the ants are much more numerous than the bees, a small colony of bees is soon cleaned out, and the ants have a picnic carrying off the honey.

After about 15 years of experience with this ant-pest, I find that when a supply of water is available so that the soil can be kept continually wet, the eggs will rot and they can

thus be killed out. Great quantities can be destroyed with coal-oil, fire, boiling water, or with pails of sweetened water or with poisoned honey or sugar. When it is found impossible to keep them down by the above methods, the bees can be protected by using three small trestles, about 7 feet apart. Take two long 2x4 scantlings, brace them, then place as many hives as the stand will hold; then paint a two-inch ring around the trestle legs with a mixture of two-thirds of lard to one-third of coal-tar. If it dries too quickly add a little more lard. The ants will not go over it if it is kept soft and sticky; apply it from about the first of April until the middle of June, as the ants will not be troublesome after that date, as a rule.

The honey and irrigating water prospects for the coming season appear to be bright in some portions of the State; but in many parts of the State at present the indications are not flattering. There is very little snow in the hills; however, it is not too late for snow.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey-jars.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 7.—Hope of February bringing a good demand for honey is so far disappointing. The weather is extremely cold, yet this should not curtail the demand, for honey is a cold-weather luxury, and to most people more inviting when cold than when it is hot. Perhaps one of the causes (for there are many) was the holding back of the crop by producers in the early autumn, on the supposition that the yield was light taking the country as a whole; the result was consumers reasoned that it was going to be scarce and substituted other things in lieu thereof. Comb is freely offered with prices weak at 14@15c for choice to fancy; 13@14c for No. 1; 11@12c for amber and buckwheat. Extracted slow at former prices. Beeswax strong at 29c. R. A. BURNETT & Co.

ALBANY, N. Y., Feb. 7.—Honey market firm for all grades of comb honey, of which there is a very light stock here. White comb is selling at 15@16c; No. 2, 14@15c; buckwheat and amber, 13@14c. Extracted slow at 6@7c for white; but buckwheat extracted is selling best at 6 cents. Beeswax scarce, 28@30c. H. R. WRIGHT.

CINCINNATI, Feb. 7.—The honey market has been rather dull this year. Comb honey is selling fairly, and brings as follows: White clover, 15c; lower grades from 12@14c. Extracted honey sells very slow, the lower grades bringing 5@6c, and fancy, 6 1/2@7c. Beeswax, 28@30c. C. H. W. WEBER.

BOSTON, Jan. 20.—Strictly fancy comb honey in cartons, 15 1/2c; A No. 1, 15c; No. 1, 14 1/2c; very little No. 2 to offer; stock nominally running No. 1 and A No. 1. Extracted, light amber, 7 1/2c; amber, 7c; Florida honey, 6 1/2@7c.

Our market continues somewhat dull in the demand for honey, while stocks are ample for the balance of the season, unless there should be a much larger demand than we at this moment anticipate. BLAKE, SCOTT & LEE.

NEW YORK, Feb. 8.—There has been very little movement of late in comb honey, and while there is no buckwheat on the market to amount to anything, there is sufficient quantity of the different grades of white honey. The demand having been slow of late, prices have had a downward tendency and are likely to remain so during the spring.

We quote: Fancy white, 14c, and exceptionally fine stock at perhaps 15c; No. 1 white at 13c; amber at 11@12c. Extracted remains dull at unchanged prices. Arrivals of late are quite plentiful of all the different grades. Beeswax firm at 28@28 1/2c. HILDRETH & SEGELKEN.

SAN FRANCISCO, Jan. 22.—White comb, 11@12 1/2 cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5 1/2@6c; light amber, 4 1/2@5c; amber, 4@— Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Market continues quiet, but is tolerably firm, particularly for choice to select. Spot stocks are of rather small volume, and there are no evidences of much being left in the interior. There is some probability of prices hardening slightly during the next few months, particularly if the spring trade proves to be of good average proportions.

WANTED 150 COLONIES OF BEES in March or April. State kind of hive and general conditions; also lowest cash price. Address, **G. E. P.,** Care American Bee Journal, 6Atf 144 & 146 Erie Street, CHICAGO, ILL.

Notice.—On another page of this issue of our paper will be found the advertisement of the Watkins Medical Company, of Winona, Minn. These people are the sole owners and manufacturers of the famous Watkins Remedies. These remedies are not new and untried preparations, for they have been upon the market and in daily use over a very large section of the country for the past 34 years. We do not doubt but that many of our readers are perfectly familiar with and are now using the Watkins Remedies. They have stood the most rigid test of all these years and are more popular with the people to day than ever before. This could not be true but for the fact that the remedies are made upon honor and sold on their merits. The responsibility of the Watkins Medical Company is entirely beyond question. Ask your banker, any reputable business man, or refer to Bradstreet and Dunn's Commercial Reports. Write them for a free copy of their Home Doctor and Cook Book. This will serve to acquaint you with these people and gives at the same time valuable information, weather forecasts, cooking recipes, etc. Address the J. R. Watkins Medical Co., 10 Liberty St., Winona, Minn., and please mention this journal.

We have a Large Stock on hand and can ship promptly.

"FACTS."

Root's Catalog Now Ready

It is a fact that Root's Catalog for 1902, the 91st edition, contains information valuable to EVERY bee-keeper, whether he has one colony or a thousand colonies. The catalog is ready for mailing, and will be sent free to all applicants. If you will give us the names and addresses of 10 or more bee-keepers, we will send you in addition our 40-page semi monthly journal, GLEANINGS IN BEE-CULTURE, for 3 months free.

Root's Extractors

It's a fact that Root's Cowan Honey-Extractors are acknowledged by far the best extractors on the market. You will make a mistake if you take one represented to be "just as good." Our designs are the best, we use the best material, and our workmanship ship is unsurpassed. Insist on "Root's" Cowan.

Danz. Hive

It is a 'Fact' that the DANZENBAKER HIVE for Comb Honey, is acknowledged by ALL who have given it a fair trial, the best hive for comb honey.

Gives Best Yields

It is a fact that bee-keepers using the Danz. hive get better yield from this hive than any other hives in their yards.

Higher Price for Honey

It is also a fact that the honey in Danz. Sections generally sells for a higher price, and always finds a ready market. We have yet to earn of a bee-keeper having comb honey in Danz. sections who had to hold his honey because of a dull market.

Agencies

It is a fact that Root's Goods are in demand everywhere. For this reason we have agencies all over the United States and upward of 25 foreign countries. A full list of agents sent on application.

Low Freight Quick Delivery

It is a fact that we are able by these agencies to furnish our goods quickly, and at low cost of transportation.

Facts About Bees

"Facts About Bees," 7th edition, revised, is now ready. Full of information, and sent to any address for a 2 cent stamp or free if you mention this paper.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.

Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

Please mention Bee Journal
when writing advertisers.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 7.—Hope of February bringing a good demand for honey is so far disappointing. The weather is extremely cold, yet this should not curtail the demand, for honey is a cold-weather luxury, and to most people more inviting when cold than when it is hot. Perhaps one of the causes (for there are many) was the holding back of the crop by producers in the early autumn, on the supposition that the yield was light taking the country as a whole; the result was consumers reasoned that it was going to be scarce and substituted other things in lieu thereof. Comb is freely offered with prices weak at 14@15c for choice to fancy; 13@14c for No. 1; 11@12c for amber and buckwheat. Extracted slow at former prices. Beeswax strong at 29c. R. A. BURNETT & CO.

ALBANY, N. Y., Feb. 7.—Honey market firm for all grades of comb honey, of which there is a very light stock here. White comb is selling at 15@16c; No. 2, 14@15c; buckwheat and amber, 13@14c. Extracted slow at 6@7c for white; but buckwheat extracted is selling best at 6 cents. Beeswax scarce, 28@30c. H. R. WRIGHT.

CINCINNATI, Feb. 7.—The honey market has been rather dull this year. Comb honey is selling fairly, and brings as follows: White clover, 15c; lower grades from 12@14c. Extracted honey sells very slow, the lower grades bringing 5@6c, and fancy, 6½@7½c. Beeswax, 28@30c. C. H. W. WEBER.

BOSTON, Jan. 20.—Strictly fancy comb honey in cartons, 15½c; A No. 1, 15c; No. 1, 14½c; very little No. 2 to offer; stock nominally running No. 1 and A No. 1. Extracted, light amber, 7½c; amber, 7c; Florida honey, 6½@7c.

Our market continues somewhat dull in the demand for honey, while stocks are ample for the balance of the season, unless there should be a much larger demand than we at this moment anticipate. BLAKE, SCOTT & LEE.

NEW YORK, Feb. 8.—There has been very little movement of late in comb honey, and while there is no buckwheat on the market to amount to anything, there is sufficient quantity of the different grades of white honey. The demand having been slow of late, prices have had a downward tendency and are likely to remain so during the spring.

We quote: Fancy white, 14c, and exceptionally fine stock at perhaps 15c; No. 1 white at 13c; amber at 11@12c. Extracted remains dull at unchanged prices. Arrivals of late are quite plentiful of all the different grades. Beeswax firm at 28@28½c. HILDRETH & SOBLEN.

SAN FRANCISCO, Feb. 5.—White comb, 11@12½ cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5½@6c; light amber, 4½@5c; amber, 4@—. Beeswax, good to choice, light, 26@28c; dark, 24@25c.

There is not much offering in this center from either first or second hands. The market is firm at the quotations, although business is of a light order. To purchase freely, higher prices than are warranted as quotations would very likely have to be paid.

CONVENTION NOTICE.

Utah.—The Utah State Bee-Keepers' Association will hold its annual convention in the City and County Building, Salt Lake City, April 5, 1902, at 10 a.m. This promises to be an interesting convention. All are invited. It is desired to form an exchange for the protection and benefit of our bee-keepers. Come and aid a good cause. It is expected that every county will be represented. J. B. FAGG, Sec.

E. S. LOVESY, Pres.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well if they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 98.

ESTABLISHED IN
1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER
IN AMERICA

42d YEAR.

CHICAGO, ILL., FEBRUARY 20, 1902.

No. 8.

* Editorial. *

"The Truth About Honey" was referred by the Chicago Tribune, as we reported recently in these columns. But in its issue of Feb. 4 we find the following, being a contribution from a California correspondent:

Honey-Comb Is Not Imitated.

WAX FOUNDATION FOR THE CELLS IS THE ONLY ASSISTANCE MAN GIVES THE BEES.

California's honey crop for 1901 was 2,208,000 pounds. This was gathered by about one-half the usual number of bees and from small, favored localities. With the number of bees now in the State, should the conditions be favorable, the output this year will be in excess of 5,000,000 pounds. In consequence, we are interested in all that advances or injures the industry. The Tribune printed an interview in which it was said that artificial comb honey was now both made and sold. This statement is running like a prairie fire, and, unless its correction is as emphatic and public as the assertion, will work great injury to the honey-producer.

Bee-keepers use what is known as "comb foundation." This is a thin sheet of pure wax, with the impressions of the base of the cells impressed on the same. This is used to direct the course of the bees in comb-building. Beyond this "base" man has not been able to go. There is not to-day, and never has been, a pound of complete comb honey made by man or machinery. I will give \$1,000 for a pound so manufactured.

E. H. SCHAEFFLE.

This is good as far as it goes, but how much better it would have been had the editor of The Tribune written his own correction, and promptly admitted that he published an interview that was a great damage to an honorable industry, and that he regretted it exceedingly, hastened to make the correction as prominent as was the misrepresentation, etc. But even editors are human, as we know from experience, and perhaps too much should not be expected of them—especially of the editors of some partisan daily newspapers who are so accustomed to painting things in wrong colors that they are practically color-blind when it comes to the question of right and wrong. And to admit that they had been unjust to any one or any thing—why, that would be unthinkable to them!

But let us be thankful that there are many editors of daily papers that are all right.

Do Robber-Bees Sting?—It is well known that sometimes robbing goes on quietly with little appearance of anything but friendly feeling between the robbing and robbed, and it is equally true that sometimes a

very lively struggle is seen. In that struggle, when there is a clinch between one of the robbers and one of the defenders, it is plain to be seen that the defender is not joking, the number of dead and dying bees often bearing evidence of the desperate earnestness of the struggle; but it is not so easy to say whether in a warfare of that kind the two bees are each trying to sting. So good an authority as Rauschenfels says they are. Perhaps he is right. Yet it is certainly true that when a robber-bee is grabbed by the leg or wing, there is never any appearance of resistance, only an effort to escape. Is it not possible that when two bees have a closer grip, that still the only effort of the robber is to get away? The movements are so lively, the bees tumbling and rolling in all directions to such a degree that it is not easy to see what is going on.

If one had a case of robbing in which the robbers were blacks at work upon an Italian colony, or vice versa, then something might be decided in the matter. For if in the heap of slain none but bees showing the color of the robbers were to be found, then it might be concluded that robbers do not sting; whereas, if both kinds were among the slain it would be proof that the efforts of the apprehended robbers were something more than to get away. Perhaps some one can report a decisive case.

Honey-Recipes.—The following, taken from the British Bee Journal, are translated from Le Rucher Belge:

DIGESTIVE LOZENGES can be made by melting in a bain-marie 3 oz. of pure gelatine in 3 oz. of water; then add carefully, while stirring thoroughly, $\frac{1}{2}$ lb. of honey previously warmed. When well incorporated add a little cochineal and five or six drops to every 3 oz. of English essence of peppermint. This is then run into lozenge moulds or thinly on a plate, dried in the cool, cut into shapes, and finished drying for eight hours in a dry place.

A HEALING BALSAM, really valuable in case of wounds or injuries to the skin, is prepared in the same way in a bain-marie:—Take of wax from the cell cappings 1 oz.; of fresh propolis, 2 oz.; of the finest honey, 7 oz. After all is well mixed pass through a close cloth, and press out well; replace in the bain-marie; add a little cochineal and a few drops of essence of lavender; then beat the mixture well with a fork, and fill into small pots, which fasten down closely.

Stimulative Feeding is spoken of more frequently in European journals than in this country, and is perhaps practiced more in Europe than here, yet it is spoken of there as a two-edged sword, and one with which it is not wise for beginners to meddle. The Rocky Mountain Bee Journal having designated as a "fossil" a man who should say that "spring

feeding for stimulation of brood rearing was not only unprofitable, but detrimental to the bees," the editor of The American Bee-keeper, while agreeing that, "if discreetly done, stimulative feeding in the spring repays the cost and trouble handsomely," expresses himself somewhat emphatically in the following words:

We believe ourself that in other than expert hands it is a most dangerous procedure, and should not be recommended to the inexperienced manipulator. There is no part of apian work in which the skill of a master hand becomes more imperative than in the practice of stimulative feeding in the spring.

It may as well be clearly understood that whatever good or bad results there may be in the hands of those of long experience, stimulative feeding is a very safe thing for beginners to let entirely alone.

Stingless Bees of Mexico.—We lately received the following about the little stingless bees that are found in Old Mexico:

EDITOR AMERICAN BEE JOURNAL:—

By this mail we send three pieces of honey-comb, and a few very small bees. These are the smallest bees we have ever seen; they are very plentiful here. There are other kinds of stingless bees here, one kind nearly as large as the Italian, and very nicely marked, but the bands are of a very dark yellow, and the body of a greyish color. They are very queer, and they usually build in a log, with an opening just large enough for one bee to go in or out at a time; the door-keeper pops back out of the way when another bee wishes to go in or out.

We have just imported some Italian bees from Texas, and have been expecting to see them "go for" the stingless bees we have, but so far they have not bothered them, for the reason, I suspect, that our honey-flow has been on every since they came.

We have no German or Italian bees within 300 miles, so far as we know, so this ought to be a pretty good place to rear queens. Mr. Doolittle, no doubt, would be in his glory here rearing queens.

We received our bees about two months ago, and they are building up finely; this morning I saw a few drones, and plenty of drone-brood. The tops of the combs are getting white, which, according to some of the bee-papers I have been reading, is a sign that honey is coming in. We got the bees to pollinize our coffee-trees, as well as cocoa, vanilla, and other fruit-trees.

Our chief work down here is the planting of rubber and coffee, with side crops of corn and beans. We have produced between 8,000 and 10,000 bushels of corn as a side crop, and hope to save several hundred bags of beans within the next 60 days. The food of the Indians is beans and corn, so we feed them with home-grown food.

However, I started to tell you about the little bees, or rather to ask you to name the little things, as you will see they are smaller than the smallest house-flies, and just as harmless. What are they called? To what class of bee do they belong?

We have an ant here, too, that gathers honey, and if you care to have a sample I will

be glad to send you some by friends who are coming here in 10 or 15 days, and will soon return to the "Windy City."

Yours truly,

MEXICAN MUTUAL PLANTERS COMPANY.

Yes, we would be pleased to see the honey-gathering ant.

We wish to thank you for the samples of comb and small, stingless bees. Such have often been mentioned in the American Bee Journal in the years gone by. We will forward the sample to Prof. Cook, and ask him to report on them. The cells seem to have no bottoms, as the brood runs clear through the comb, capped at both ends. Queer, isn't it? And the bees—well, they are about as large as two or three ordinary pin-heads with little wings? They are very interesting, indeed.

Parsley Honey.—The following clipping has been received at this office:

The honey that bees gather from parsley is likely to make man feel very ill indeed. Probably that honey does not disagree with the collector, or it may occasionally be gathered and placed with the rest by mistake. There is just the chance that it is done for purposes of revenge by one member of the community who considers himself aggrieved and vents his spite on his fellows.

There are not many places in which parsley is raised in large quantity, and still fewer are the places where it is allowed to blossom in sufficient quantity to allow an appreciable quantity of honey to be gathered from it. So one is led to wonder how it was ever found out that parsley honey was such an objectionable thing. "There is just the chance" that the whole thing is as much in the realm of romance as the idea in the last sentence of the clipping seems to be.

Weekly Budget.

THE WISCONSIN CONVENTION.—It has been our privilege as well as pleasure to attend three or four meetings of the Wisconsin Beekeepers' Association. Bee-keepers are pretty much alike the country over, we believe. Especially the ones that attend conventions. They are a jolly set of people. And clean, too—with but very few exceptions. We do not remember hearing an ungentlemanly word during the two days' sessions, either outside or inside the convention room. Take beekeepers as a class, and we believe they average higher in almost every way than do those in many other pursuits.

But we didn't start out to tell how wonderfully good all bee-keepers are. Not at all, for we have discovered several specimens that are otherwise. But the black sheep will show up occasionally. We'll have to get Mr. Hutchinson to ask Stock-Breeder Simpson to explain how it happened. Perhaps he can account for it.

Pres. France is a good hustler. He knows Wisconsin and its bee-keepers to a dot. And they know him, and like him. And well they may. He is simply tireless in his devotion to Wisconsin bee-keeping. He succeeds, too. He gets what he goes after. And sometimes he gets what he doesn't go after—the presidency of the Association, for instance.

Then there is Vice-President Hoffman. He is a big help in a convention. Keeps the discussions moving. To have a Wisconsin convention without his genial presence would seem strange, indeed. So it would if Messrs. Wilcox, Pierce, Gross and others remained at home.

And Miss Pickard, the secretary. But, hold on; an old married man like the writer perhaps would better tread rather lightly here. Suppose we simply say that she is all right in every way, and just let it go at that. Now, certainly, not many could find much fault with that, could they? But we will say that she is a thoroughly practical "bee-keeperess"—"und vergessen sie das nicht."

Harry Lathrop, the treasurer, is almost too well known to need any introduction. For years he has been a contributor on bees to the Wisconsin Agriculturist. He's a railroad station agent, too. That seems to be a pretty good business to combine with bee-keeping—at least in his case. "Harry" produces very nice comb honey, and is a good bee-keeper, of course.

Oh, yes, there is at least one really and truly honest bee-keeper in Madison. Now, don't go and say we said there is only one honest bee-keeper there. That wouldn't be true. But, listen to this: As far back as 1878 there was a Wisconsin State Bee-keepers' Association. And they had "money to burn," it seems. At any rate, when the association disbanded there was \$7.00 remaining in the treasury. And the selfsame \$7.00—yes, the very same bills—was turned over to Pres. France at the recent meeting. Think of hanging on to \$7.00 for a quarter of a century, and then turning it over to the proper authorities! Wonder why it wasn't handed in long ago? And yet the convention didn't adjourn at once, and all go out and "blow it in" in some "jollificating" and questionable way. No, sir, bee-keepers at conventions are all straight. At least they are in Wisconsin. And the samples we have seen as far away as California seem to be ditto. And almost without a single individual exception this is true of every bee-keepers' convention we have ever attended.

Pres. France says the majority of the bee-keepers are working toward the production of extracted honey. Less swarming, less work, and more honey and money. But the best producers are death on the chaps that extract unripe honey to put on the market. And they ought to be. The bee-keeper that puts unripe honey on the market ought to be—well, he ought to be forced to earn an honest living in some way, and not rob the consumer and also damage the market for good honey.

There were some good papers read by Mr. Hoffman, Miss Pickard, Mr. Fox and C. H. Pierce. We will publish them later. It is surprising how much some people know about successful bee-keeping, but have to be pressed or squeezed in order to get the information out of them. At the convention is where they can sometimes be compelled to "let out." So it often happens that the quietest member could, if he only would, give the most and best instruction to the rest of the crowd.

Perhaps we'd better leave the rest for the secretary to tell. But the trouble is, she's inclined to be rather backward in coming forward with a full report of the proceedings. We just believe she could write out a very

complete report of all that was said and done. But will she? We'll await her answer.

Miss S. E. WOODCOCK, of Cook Co., Ill., when renewing her subscription for another year in advance, wrote thus appreciatively of the American Bee Journal: "I find it both instructive and entertaining, and enjoy it and my bees immensely."

HON. EUGENE SECOR, now a member of the Iowa Legislature, in session at Des Moines, has introduced a bill on the subject of pure food. This is his first experience in Iowa's General Assembly, and he says that he finds "the session so far very pleasant, with plenty of work."

THE APIARY OF A. FRASER is shown on the first page this week. The following accompanied the photograph:

I may say in connection with the picture I sent, that I have been keeping bees 10 years, and am satisfied with the business. Last year I had a trifle better than half a crop. I would like to get some of those big crops that I read about people getting in Illinois, Nebraska, etc. I do not mean the Western country.

I started with one colony and have had varying success. I have 151 colonies in the cellar, which is 20 less than the number I put away last year.

I think the American Bee Journal is all right. A. FRAZER.

MR. R. A. BURNETT, of R. A. Burnett & Co., took a trip to the East recently, and on Feb. 7 wrote us:

"My trip in the East was very agreeable. I visited the honey-dealers in Philadelphia, New York, and Buffalo, where they seem to have stock enough to carry them along, if not some to spare."

We understand that there is quite a good deal of honey yet in the country—a number of carloads of extracted. Seems to us some tried to have bee-keepers believe, last fall, that the crop of 1901 was very short, and advised holding for higher prices. We still think our advice was all right—to sell if as good prices as those of 1900 could be secured.

MR. WM. A. SELSER, of Philadelphia, wrote as follows, Feb. 6:

I expect to leave this week for a tour of Texas, Arizona and California, in the interest of the pure-food law now before Congress from a chemical, scientific standpoint in order to get samples direct from the bees of all flows of nectar that produce a dextrose action with a levulose reaction, that makes some adulterated honey hard to prove before a jury, when the said honey has been adulterated by the packers with inverted sucrose. I think when I return I will be able to prove adulteration sufficient to any jury, no matter how much it has been doctored chemically. I hope to return in about two months.

My dear mother passed away last week, and our home is so very sad without her.

WM. A. SELSER.

Mr. Selser is a honey expert, and no one we know of is better prepared to undertake the work assigned him in the interest of pure honey.

We had the pleasure of meeting Mr. Selser's mother when attending the Philadelphia convention 2 or 3 years ago. She was indeed a lovely character, as are all good mothers. Our sympathy, as well as that of all who know Mr. Selser, goes out to him in his sorrow.

Convention Proceedings.

Report of the Colorado Bee-Keepers' Convention held in Denver, Nov. 18, 19 and 20, 1901.

BY D. W. WORKING, SEC'Y.

In making this report of the proceedings of the annual meeting of the Colorado State Bee-Keepers' Association, I assume that the readers of the American Bee Journal are not interested in many of the business matters that were of importance to the members at the time; also, that much of the discussion would be of interest to so few Journal readers that it is better to omit at least those parts that seem to have only a local application. So, while the Journal will have opportunity to publish all the papers, the editor will not be required to use his blue pencil to any great extent in marking out profitless matter.

The first paper of the session was on grading honey; and as it was written with the Colorado grading rules as a text, it seems well to print those rules in connection with the paper. They follow:

COMB HONEY RULES.

No. 1—Sections to be well filled and capped, honey white or slightly amber, comb white and not projecting beyond the wood, wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, with a minimum weight of not less than 20 pounds for any single case; cases of half-separated honey to average not less than 21¾ pounds net per case of 24 sections, with a minimum weight of 20¾ pounds for any single case; cases of unseparated honey to average not less than 22½ pounds net per case of 24 sections, with a minimum weight of 21½ pounds for any single case.

No. 2—Includes all amber honey of a pronounced tinge, and all white and amber honey not included in No. 1; to be fairly well sealed, uncapped cells not to exceed fifty in number exclusive of the outside row, wood to be well cleaned; cases of separated honey to average not less than 18 pounds net per case of 24 sections; cases of half-separated honey to average not less than 19 pounds net per case of 24 sections; cases of unseparated honey to average not less than 20 pounds net per case of 24 sections.

EXTRACTED HONEY RULES.

Extracted honey shall be classified as white and amber, shall weigh twelve pounds per gallon, shall be perfectly free from particles of wax, and shall always be marketed in new cans. All rendered honey, whether obtained by solar heat or otherwise, shall be classed as strained honey and not as extracted.

RECOMMENDATIONS.

It is recommended to sell all cull honey around home as much as possible; to grade only in daylight, near a window; to use the standard 4¼x4¼x1¾ inch section and the 24-pound double-tier shipping-case, in order to have uniformity in loading cars; to stamp all cases of No. 1 honey with the owner's name above the handholes; to mark all cases of No. 2 honey with two dashes in the handholes at each end of the case, and with no other marks whatsoever; to use no second-hand cases for No. 1 and No. 2 honey; to pack all sections with paper below and above, and in double-tier cases to put a sheet of paper between the tiers; to store comb honey in a warm, dry place, protected from flies and dust; and to haul carefully, well protected from dust and rain.

Grading Honey.

The subject assigned me by your committee is so important that I had hoped it would be handled by older members with more practical experience. I shall speak of comb honey only.

The grading of comb honey is so closely related to the entire field of production that I shall not attempt to write a comprehensive article. Assuming that we have a first-class article in the house, the question is grading for color, beauty of build, and weight, so as to get the best returns for the product.

The first essential of grading I believe to be honesty of purpose; but an attempt to grade by any of the established rules has always brought me many difficulties. I believe we, on the Western Slope, have grades of amber honey that are not found on the east side, and the term "slightly amber" in the Colorado grading rules was a constant source of trouble to me in attempting to follow those rules. We have a decided amber grade of honey that always has clean white cappings, and all buyers have taken it as No. 1 honey when buying by weight; and yet I fear our rules would make it No. 2.

Up to the past season I have been making a case of honey of even color and allowing buyers to grade it; and

after convincing them of honest, careful packing, I have been very much pleased with their liberality in grading cases. The past summer I tried to grade by the Colorado rules, and sold by the case for the first time, getting a substantial advance in price over former sales. And I will say that careful work in producing, care in cleaning and packing, with or without rules for No. 1 and No. 2, will bring good rewards for the labor expended. But I was especially impressed with the value of weighing cases, being able to guarantee weights and sell by the case. J. S. BRUCE.

F. L. Thompson—In regard to the uncertainty of including the amber comb honey of the Western Slope, those grading rules were worded for the very purpose of including the first part of their second flow in No. 1. The only honey of theirs which would be excluded from No. 1, according to its color, is that capped in the latter part of August and in September.

T. Lyle—Every man is his own grader. He should have absolute uniformity in any one case, and face it with fair and honorable samples of that case. I don't see how we can make rules that will be observed. He should use well-made shipping-cases, uniformly packed, and, above all, should have his comb honey well ripened. We had a tilt here last year on that last item; hence I wish to say that this year again I received 25 to 40 cents more for my cases than did my neighbors. Of course, there is a great deal in always selling in the same city for some period.

V. Devinny—What's the use of making rules for me? I have to call in my wife to decide the color of the combs, and many times she can not come. Many are color-blind, and do not wish to acknowledge it.

Summary of the Recent Discussions on Breeding.

In one of the recent articles on breeding the following quotation from Darwin was made:

"If selection consisted merely in separating some very distinct variety, and breeding from it, the principle would be so obvious as hardly to be worth notice; but its importance consists in the great effect produced by the accumulation in one direction, during successive generations, of differences absolutely inappreciable by the uneducated eye—differences which I for one have vainly attempted to appreciate. Not one man in a thousand has accuracy of eye and judgment sufficient to become an eminent breeder. If gifted with these qualities, and he studies his subject for years, and devotes his lifetime to it with indomitable perseverance, he will succeed, and may make great improvements; if he wants any of these qualities, he will assuredly fail."

Under these circumstances, some will doubtless inquire why the common bee-keeper should pay any attention to this subject at all. I answer, for the same reason that every person who buys hay should know what good hay is, and where to get it, though he may not be competent to raise it himself. If I have 150 colonies, and re-queen them with such superior stock that they average five pounds apiece more than they otherwise would, that is a gain of 750 pounds, and I have the same stock for next year. That result is worth a good deal of study and thought to secure whether one selects his own queens or selects the man that sells him the queens. Our queen-rearers, moreover, depend largely on the bee-papers and conventions for suggestive ideas, and we should see to it that they get them by providing for the continuance of this discussion, though it may not affect our personal bee-work.

The starting-point of the present discussion on breeding in the Eastern papers was the following vigorous language by Mr. A. C. Miller, in the Bee-Keepers' Review for last March:

"The authors of our text-books, and the editors of our journals [look out], appear to be grievously ignorant of the laws of heredity, and of such authors as Darwin, Huxley, Hæckel, Spencer, and a host of other biological authors. Now, if our instructors are thus ignorant, what wonder that the rank and file do not advance in scientific queen-breeding? . . . Is it any wonder we do not get ahead? Bah! Scientific queen-breeding, forsooth; 'breeding queens,' 'golden breeders,' etc. Rot."

In the same article he also said: "Crossing tends to cause variation. The male varies more than the female. The male is the stronger element in begetting offspring. . . . Under such conditions it is little less than marvelous that we have made the progress which we have. As I view it, the only thing we have done, actually accomplished, is to cause the bee to vary. Variation, once started, seems to run riot unless fixed by scientific breeding-in. For example of this, look

at the pedigrees of noted trotting-horses."

In another article in *Gleanings*, he said: "The use of the terms 'choice bred,' 'straight golden breeders,' 'breeding-queens,' etc., implies that the person claiming to have such stock has produced it according to the well-recognized laws of breeding; that for many years the ancestry of this stock was pure and potent, and that these 'breeders' will produce offspring which, when properly mated, will maintain the same traits as their parents, with virtually no variation. Just how many queen-rearers care to affirm that for their stock?"

"Thoroughbred" is not 'crossbred,' as any high-class stock-raiser will testify. Thorough breeding is cautious, careful, scientific in-breeding (do not confound this with in-and-in breeding); and when alien blood is introduced the result can never be foretold with certainty, the chances being toward atavism, the reverting to a previous type."

"It is high time we began to be scientific in our work. The haphazard, guess-at-it rule-o'-thumb ways have prevailed altogether too long. We shall injure ourselves, and be held accountable by those who follow us, if, knowing, we do not set about to overcome the evils."

These extracts indicate, in general, that those who rear queens are ignorant of matters of great importance in breeding queens. Let us now turn to the utterances of one of the foremost queen-rearers, and judge for ourselves whether he and others do all they might in selecting the ancestors of those queens which they are undoubtedly competent to rear. Mr. G. M. Doolittle says in the *American Bee Journal*:

"A yield of from 60 to 80 pounds of comb honey from red clover this year, with little or nothing 20 years ago, proves that I have not labored entirely in vain." In the *American Bee-Keeper* he sets forth his ideas thus: "We often hear bee-keepers say, 'If all the colonies had been as good as No. 12 (No. 45, or some other number, as the case may be), I should have had several hundred, if not thousand, more pounds of honey than I secured this year.' Well, the question is, why not have all the colonies in the apiary as good as No. 12? We may not accomplish all we would like to in one year, but by superseding all the poorer queens in the apiary by those reared from No. 12, we certainly shall be advancing our apiary up the scale toward No. 12's yield. This is what I have been working for during the past 30 years, and it gives me pleasure to say that my colonies average very much more nearly alike in their yields, and the average yield per colony is much higher in proportion to the yield of nectar from the nectar-bearing flora, than it was when I commenced."

It is evident from this quotation that one who is an authority on queen-rearing recommends no other principle than that of breeding from the queen that did best in one particular year. He says nothing about the fact that a queen whose own colony is good may be weak in the power to transmit her excellence. That he has made progress by simply going on the assumption that "like produces like" is precisely what we should expect; for among the numerous best queens in a long period of years, some, at least, would have the power of transmitting their qualities with little loss. But the question is, Would he not have done better still to breed only from the potent queens than to breed from all the freaks without discrimination? We must conclude, therefore, that Mr. Miller's reference to "haphazard, rule-o'-thumb ways" of queen-rearers in selecting queens is justified, no matter how skillful they may be in the rearing itself.

Mr. Doolittle has, it is true, attempted to parry the criticism of his neglect to select according to the laws of breeding, by referring to the difficulty of mating with desired drones. In this very important matter of selecting queens whose progeny is uniform, that excuse has very little force, for queens can always be selected, even if we never could select drones. The conclusion is unavoidable that, with all the disadvantages connected with the choice of drones, our queen-rearers have not applied the science of breeding as they could have done.

But let us consider just what this matter of difficulty in selecting drones amounts to. On page 681 (1901) of the *American Bee Journal* Mr. Doolittle gives four plans for mating queens with desired drones. Of one of his plans—that of having his queen-mating nuclei in a locality isolated five miles or more from all other bees—he remarks: "The queens will, as a rule, be all mated with the desired drones." (Right here I wish to say that there are plenty of locations in Colorado and Utah that have the advantage of daily mails, and I have no doubt also all over the West and Southwest, where we can be absolutely sure there are no outside drones, for the reason that there is nothing in the

surrounding country to support bees.) Of another plan, that of carrying the drone colony and the nuclei into the cellar until after four o'clock, or when other drones cease to fly, feeding them a little warm diluted sweet just before setting out, and setting them so as to face the western sun, he remarks: "Queens and drones will fly something as they usually do in the early afternoon, and the results will prove quite satisfactory." It seems, then, that when sufficient labor and care are taken, queens can be mated with drones from some particular queen; and in one of the other plans Mr. Doolittle hand-picks his drones, thus narrowing the choice still further. There appears to be no reason why this hand-picking process should not be applied to any such plan. Now, this attention and labor may not be commercially profitable on a large scale, when a man makes his bread and butter from queen-rearing. I do not know about that. But it is clear that we can select both sides in breeding bees to almost as great a degree as in breeding Jersey cattle or Leghorn chickens, the only differences being that the queen herself does not gather honey as a cow gives milk, and that we can judge somewhat more by the external appearance of a bull than we can at present from the appearance of a drone. But these are minor considerations, for ancestry—of which we may be equally sure in bees and cattle if we are willing to take the trouble—counts for more than individual traits as a guarantee that those traits will be transmitted. And when the desired object is the establishment of a new strain of stock a good deal of attention and labor are required in any case.

Mr. Adrian Getaz, in the *American Bee Journal*, lays much stress on the fact that Nature has been thousands of years developing hardiness and honey-gathering qualities, so it is reasonable to suppose the limit has been nearly reached, if not altogether. He says that those qualities in animals which we have succeeded in improving were completely undeveloped in nature. The trouble with this statement is that it isn't so. Even a Mexican wild hog has some value for meat; and when we consider milk-producing qualities, which are a pretty good parallel to honey-producing qualities, we see how fallacious the idea is. Nature has been developing milk-producing qualities for millions of years, but nature never would have developed a strain of cows every one of which gives several times as much milk as the calf requires; nor does nature need to concern herself with producing bees that will gather much more honey than suffices for winter stores. Nature has done nothing whatever to test the full capacity of bees for gathering honey. So it is with hardiness. Both white and black men belong to the same species; but nature has not made the black capable of resisting pulmonary diseases, nor the white man capable of resisting malarial fevers. But if each had developed in the other's quarter of the globe, can we doubt the result, according to the law of the survival of the fittest? The fallacy of the idea consists in assuming that nature's tests are always the most complete possible. They are not; they are of all degrees.

We have, therefore, no sound reasons for believing that the breeding of bees, and their possible improvement, present such insuperable difficulties as to differentiate them from all other stock. But what about the science of breeding in general? Is it easy or hard, slow or fast? On this point Mr. C. P. Dadant says in the *American Bee Journal*: "Those who have persistently worked for years—for a lifetime—to secure the change desired in breeds of horses, pigs, cows, chickens, and, in fact, in the improvement of any domestic animals, or plants, or trees, those men know how little can be accomplished in a single man's life. . . . But nevertheless it would be wrong to discourage those who try, for they are certainly on the right road. . . . That we can succeed, sooner or later, is evident, if we consider what has been done in other lines."

Thus the question arises, Is it well for honey-producers to undertake a work of such magnitude, when they already have enough to do? Even the consideration of the strenuous requirements of rearing alone, without reference to breeding, has led Mr. J. H. Martin, in *Gleanings*, to recommend that a certain number of bee-keepers in a given locality turn their queen-rearing over to an expert in that line of work, each bee-keeper to contribute his best stock, and to agree to take a certain number of queens per annum, so that, having a large and definite number of queens to rear, the expert could rear them both cheaply and profitably. In this manner the queens used by the bee-keepers would be only one remove from the original; whereas, by our present method of rearing several generations of queens from one

breeding-queen to start with, and letting them mate with promiscuous drones, the best blood is too much diluted. Mrs. Barber, in the Rocky Mountain Bee Journal, emphatically endorses that plan, saying that she does not believe queen-breeders produce honey enough to give their bees a chance to show what they are; but if each bee-keeper furnished a few of the best queens of his whole apiary, that would be securing stock whose working capacity had been tested.

This plan is alluded to in the Review by Mr. F. B. Simpson, a breeder of trotting horses and Jersey cows, who has recently turned his attention to bees, and is writing a series of articles, not yet completed, for the Review, on the application of the principles of stock-breeding to bees. Mr. Simpson would prefer to follow a plan which would give the breeder a chance to establish a business and reputation for himself, and outline the system he would follow. He would have over a hundred full colonies in addition to nuclei in his own apiary, and would contract with bee-keepers in his vicinity for the privilege of re-queening 500 additional colonies, the queens to remain his property, for the purpose of testing the honey-producing qualities of the bees of the queens furnished. He would start with six of the best queens procurable, as unrelated as possible, using each queen in turn as a drone-mother with the others as queen-mothers, thus getting thirty combinations of blood for testing. In ensuing years just enough new queens would be purchased to avoid in-breeding, to which he is opposed. This is but the gist of his plan, which should be read in full in the August Review to be understood.

On the subject of in-breeding, by the way, I find opposing views in the various articles. Mr. A. C. Miller, already quoted, says: "Variation once started seems to run riot unless fixed by scientific breeding-in;" and after pointing out that inbreeding intensifies characteristics, whether good or bad, his conclusion is—"Select properly, and it is your greatest helper; select poorly, and it is your greatest enemy."

Mr. H. L. Jeffrey, in *Gleanings*, says the worth of a blooded animal is in his ability to stamp the blood qualities, and refers to Mercury, the famous Jersey bull, for whose services \$75 were offered, 23 of whose 32 ancestors were descended from one pair.

Mr. J. H. Gerbracht says in *Gleanings*: "There is not in existence to-day a single strain of unusual superiority of either cattle, hogs, or chickens, in which this principle has not been employed to secure a fixed type; and after this has been done, the fixed type can be maintained only by the most careful and scientific line-breeding. Crosses between different strains produce just the same unreliability and tendency to degeneration as crosses of distinct breeds do, except in the few cases in which, either by accident or the exercise of the most unusual good judgment, the two strains happen to 'nick' well. In cattle and swine breeding, the infusion of one-eighth new blood is considered enough to affect whatever ill effects close inbreeding may produce, the idea being to use the least possible amount to maintain the vigor and stamina, with as little disturbance of characteristics and type as possible; and the success of the breeder depends to a great extent on his ability to do this accurately. In poultry breeding, he says inbreeding and line-breeding are the only ways by which any fixity of type can be secured, and while the results are sometimes only good to look at, yet the best laying and most vigorous growing stock we have to-day is from this same line-breeding.

George Shiber, a breeder of carrier-pigeons, says in the *American Bee Journal*, "Most of the leading pigeon fliers inbreed; of course this can not be carried on indefinitely; new blood has to be added, gradually, say, a quarter, an eighth, or a sixteenth. It is an old saying, if you inbreed stock it would soon decline or weaken. It is undoubtedly true; but the breeder unmercifully culls his stock." He refers to a pigeon of his own, from stock bred as closely as possible, that flew 250 miles in seven hours over the Alleghany Mountains. He thinks that if, for illustration, two queens were chosen whose bees were long-tongued, but of different strains, one to be a drone-mother and the other a queen-mother, that but few of the resulting strain would be as good as their parents, judging by the experience of the breeders of other stock.

On the other hand, Mr. Simpson urges that nature never inbreeds unless compelled to; that, when it takes an animal several years to mature, there is an incentive to inbreeding, in securing uniformity without loss of time, and frequently inbreeding is resorted to just because no unre-

lated individuals are at hand; but neither of these reasons holds good with bees, for a vast number of generations can be reared in a short time, and an unlimited number of unrelated individuals of equal value procured; that while inbreeding of Jersey cattle has procured results in milk, they are very nervous, undersized, subject to disease and great mortality, and deficient in bringing forth living young; that the fact that Jerseys abound in renowned ancestors makes it impossible to say whether certain results were due to successful inbreeding or successful selection independent of inbreeding; that in trotting-horses the real cause of prepotency is skillful selection and not inbreeding, which is incidental and seldom close; that from personal observations he is led to believe that close inbreeding in trotting-horses is a total failure, with some exceptions of parents of especial vigor; that inbreeding is resorted to mainly to get some one or a few qualities, and this result is attained at the expense of other qualities; that nowadays the best racing horses are also the best all-round horses, because it has been found unwise to breed for speed alone; and he suggests that the best bee is the best all-round bee.

It is certainly an interesting and valuable fact that a practical breeder of trotting-horses and Jersey cattle declares against inbreeding, and prefers the difficulties of cross-breeding, by which it is very much harder to obtain a fixed type. But we have not yet been accurately informed whether the unsuccessful results from inbreeding are more numerous, or more prevalent, or of a worse character on the whole, than the unsuccessful results from outcrossing. Perhaps the exact information is unavailable. We should remember that it is not a mark of superior intelligence, but rather the contrary, for inexperienced persons invariably to take one side or the other in disputed questions. I suggest, therefore, that we keep an open mind on this subject, and reserve judgment. We wish to breed both for vigor of constitution and for permanency of type; and if we fail in either one, we have not succeeded in breeding.

The next question is, What principles, in addition to the well-known principle, "like produces like," should govern our selection of breeding stock, in order that we should be up-to-date in applying to bees all that we can supply of the knowledge gained by breeding other animals? Mr. Simpson has so far given us but one article on that subject, besides the one on inbreeding, and so, after summarizing that article and a few general principles laid down by Mr. Miller, I shall be obliged to leave the subject in an incomplete state, as the bee-papers have not yet finished it. Mr. Simpson takes up the popular fallacy of breeding from the queen whose bees produce the most honey. That trait by no means indicates that that queen has a special power of transmitting her own qualities, but rather the reverse, for the very fact that she is out of the ordinary indicates that she does not belong to a uniform strain, and that her daughters are not likely to be like her. The majority have for years bred from the least uniform, hoping to obtain uniformity, thus sacrificing blood for individuality. The proper queens to breed from are those which produce the highest proportion of daughters above the average. In fact the less the increase of average with which we are satisfied, the more certain are we to maintain it. He would prefer to select on a basis of five or ten pounds' increase over the parents' averages, if the colonies were kept as nearly as possible in like conditions, avoiding manipulation. A queen should pass through one winter and one honey crop before he would do any selecting. In buying the original queens, their previous honey-yield would cut no figure, and only their daughters' yields would be used as the basis in considering an increase of yield. In getting additional queens for new blood, he would prefer to get a dozen untested queens early enough to select a breeder from them after one winter and a honey-flow. His breeders should do their duty as queens in full-sized hives, so that he could from year to year compare their yield with other queens, and so that he could judge of their longevity under normal conditions.

Further, even if one breeding-queen produced daughters all of which gave a yield of 150 pounds each, he would not select one of them for a breeder to depend upon, because it would be too great an increase to be maintained. Daughters would be reared from one of them, but only as an experiment outside of his system, and none would be used in the system until they proved able to transmit hereditary uniformity. His breeders would themselves be good average queens, but not the best as queens, because he estimates the power to produce like offspring as very much higher than

mere individual excellence. His rule would be to breed from the most consistent representative of the best and most uniform blood.

The general principles which Mr. Miller lays down are as follows: "Domestication of animals causes variation, since variation is always brought about by a change of conditions. Food, shelter, freedom from fear and from the struggle to exist, are the changed conditions which follow domestication. The variation produced by them in sheep, hogs, fowls, and cattle, is very great; and by taking advantage of those variations, and selecting parents having certain characteristics, man has produced wonderful results. But the conditions of existence which surround the bee can not be materially changed; hence, we have a harder task to perform. Nevertheless, there is encouragement in the fact that the bee has begun to vary. This is the first great step. The next is to increase that tendency, and then guide it in the desired directions. These results may be accomplished by breeding together those types that more nearly approach our ideal."

"The successful stock breeder is he with the truest and highest ideal, and who is able to detect and select those animals most nearly approaching it. To select thus he must know the internal as well as the external anatomy of the animals he is breeding; must know their habits, tendencies, and ancestry. The men who have achieved greatness in this line have been wide readers, deep thinkers, and close observers."

We may sum up the important inferences to be drawn from the whole discussion so far, as follows:

1. There are no reasons for supposing that any essential difference exists between the breeding of bees and the breeding of other stock.

2. Drones can be selected, to the extent that we can be sure that a queen mates with some of the drones from a particular queen.

3. Queens should not be selected for breeding because their colonies are above the average. Such queens should only be experimented with, to find out whether any one or more of their descendants will transmit their traits uniformly.

4. Those queens should be selected for general breeding purposes whose ancestors have been uniformly good for several generations back, and whose own colonies are fairly good.

5. Every bee-keeper should study to acquire a theoretical knowledge of breeding, in order that he may improve his stock, and consequently his honey crop and his profits, by being able to discriminate between the pretensions of those upon whom he relies for breeding-stock.

6. A professional honey-producer should not waste any time in breeding a strain of his own, if there is any reasonable chance of procuring a good strain from one who makes a specialty of breeding.

7. Bee-keepers should plan to co-operate in furnishing their best queens to breeders for further tests.

F. L. THOMPSON.

Mr. Deviny—It seems that the whole aim of breeding now is to increase the length of the tongue. Why should not the wing be increased to correspond with the tongue, so that the bee can carry the bigger loads? Some of the finest race-horses have come from "chance seedlings," so to speak.

Mr. Gill—There is no danger of a bee loading up too much, for it can hold just so much and no more. But there is something in that matter of wing-power. Too much can be done to establish one quality to the detriment of the constitution. We want bees of strong wing-power, long-lived, and of good constitution.

W. Z. Hutchinson—We are not sure that all bees have the same-sized honey-sacs. I spent half a day with Mr. Simpson in measuring the capacity and tongue-length of bees. To measure the tongue-length, he uses very small glass tubes, half an inch long, closed at one end, and filled with honey. The tubes are filled with honey by first inserting a wire, plunging in honey, and withdrawing the wire. Then the open end of the tube is applied to the wire-cloth of the cage in which the bee is, and the length to which the honey is withdrawn shows the tongue-reach of that bee—perhaps 20-100 of an inch. To measure the capacity of the honey-sac, he uses a long tube, open at both ends. Some bees would take out an inch and a quarter of honey, some an inch, and some an inch and a half. All those bees had been kept without food, so that their honey-sacs were empty. I agree with Mr. Gill that we should not breed for one thing. We want hardiness as well.

Mr. Harris—We should encourage every line of investigation. Things have come down from one generation to another. We must take time. Everything can not be done at once.

Mr. Lytle—Two things stand in the way of the improvement of queens. We need some means by which queens can reach buyers in as good condition as they leave the breeders. We also need a set of men who are willing to experiment enough to make a good stock. You have to reach down into your pockets to get good results.

(To be continued.)

Selling Honey by Weight or Case—Which is Better?

BY F. GREINER.

I find the people I have to deal with are very loth buying honey by the case. In buying anything we all want to know what we are getting. Even grain must hold out weight or we are not willing to pay the specified price. If I guarantee the number of pounds each case of honey contains, and the cases fall not short, then no objection could be raised against my selling by the case.

I am using but one size of sections, but when casing I find there is always some difference in the weight of the filled sections. When well filled they weigh a full pound; but others scantily filled scarcely weigh three-fourths of a pound. The quality of this light-weight honey may be exactly as good—how, then, ought I to case it in order to sell my honey by the case, and do justice to the buyer and myself?

My practice has been to select sections of uniform weight (quality of honey to be the same) and case by themselves' weigh each case carefully and note the net weight on the cover, not necessarily in a conspicuous manner except when desired by the purchaser. In thus casing there would sometimes be a difference of 6 pounds between the heaviest cases and the lightest ones. By interchanging sections the two cases could be evened up so that each would weigh 21 pounds (24 sections to the case); but the retailer would then not sell them by the piece alike, but would have to sell them by weight, which would be a good deal of trouble to him.

It is a well established custom by the retailers of honey to sell by the piece, and for that reason sections ought to run uniformly throughout a case, throughout the whole lot, if possible. However, many of us cannot produce honey of the desirable uniformity, although we aim to do so. Perhaps our stock of bees consists of poor workers, or our management may be faulty; possibly our location is not the best and we can only obtain very low yields, the honey coming very slow and in spurts. Whatever the reason may be, our honey here lacks uniformity, and I notice that this location is not the only one producing such honey. If we were always blessed with bountiful honey-yields, say 50 pounds per colony, spring count, I think we could produce more uniform honey; but as it is, we cannot or don't.

Now, as stated before, the retailers want to sell by the piece—we want to sell by the piece ourselves when retailing—and it is a great help if all sections in a case are so uniform that any one of the 24 is a fair representative of the other 23. With the net weight marked on each case it is an easy matter to figure out what a section costs at a certain figure per pound; a section of another case may have to be sold for a trifle more or less, according to the weight of the whole 24. On the whole, it is less complicated if the sections contained in a case are uniform, than if the cases all averaged uniformly in weight, but sections in these cases were not uniform. It is very true, it would be better if not only the sections in each case were uniform but also all cases among themselves. But if I had to case my honey in this manner, a great deal of it would not be suitable for casing at all. The over-weight sections would have to be rejected, also the light-weight sections. In a liberal mood I might let the heavy weighters go in with those of the desired weight, but then, someone would get more than he paid for, and I would not get my just dues.

It would be an injustice even if the producer was willing to stand it.

I observe the Root Company is very careful to buy by weight only, and I fail to see why this system should not be good. To sell by weight is practical and entirely satisfactory. Each party knows what he is selling, each what he is buying. If the Colorado people sell by the case, but guarantee each case to weigh 21 pounds or any other number of pounds, then they practically do sell by weight and not by the case.

What is the motive, any way, to lump off our honey? Is it to take advantage of the purchaser? I cannot see any justice in selling honey by the case regardless of weight.

Ontario Co., N. Y.

Damp Bee-Cellars and Safe Wintering of Bees.

BY G. M. DOOLITTLE.

A correspondent writes thus: "My bee-cellar seems very damp, so much so that the floor is quite sticky, and the moisture has collected in drops on the overhead wall. The bees, however, appear very quiet, and, as far as I can judge are doing well so far. Will this dampness do any particular harm, or accumulate to a sufficient extent to injure the bees before it is time to put them out in the spring? Please give us your views on this matter in the American Bee Journal."

I am glad to have the correspondent say that his bees "appear very quiet," for quietness is the essential quality for safe wintering, for with it always comes the least consumption of stores, and with a minimum consumption of stores comes the least possible exhausted vitality and the greatest longevity during the spring and early summer days. Under such circumstances I have had individual bees by the thousand, in one colony, live from the first of September till July 1st of the following year, or for a period of ten months, this being known by a change of queens on or about the tenth of the preceding August.

Now, I wish to say to each and every one, that, so long as bees are quiet, no matter where they are—whether in the cellar, in a room above ground, or on the summer stand—they are wintering in the best possible condition, and should be left undisturbed, no matter if the place where they are is dripping wet, or so dry that you may fear the bees are suffering from want of water.

Many seem to suppose that a cellar in which bees are wintering should appear absolutely dry in all of its parts, and, if it does not, or shows a condition of things similar to that described by our correspondent, they become fearful of the final results, often taking the bees out too early in the spring, or putting them into another cellar or room which exhibits more dryness. Allow me to say once more, "Don't touch them as long as they are quiet, until the time of putting out comes, no matter what all or any of the other conditions may be.

From all the experience of the past I am convinced that the temperature of the bee-repository has more to do with safe wintering than any other one thing, and especially is this the case where the repository is affected with dampness as is the one our correspondent describes. Should the temperature in such a repository sink to near or quite the freezing point, it will be found that the bees will no longer be quiet, but will become uneasy, and go to roaring, and running out of their hives, should such a temperature continue long; but if the temperature can be kept from 44 degrees to 48 degrees, all things will continue as they were when he reported, unless some disturbing element enters in beside the moisture.

As I was in my bee-cellar a day or two ago, perhaps I can better illustrate what I wish to say by telling how I found things there January 12, 1902; and as far as I could see the bees were wintering unusually well. I found the temperature at 46, and the overhead wall very damp, so much so that the water was running down the flag-stones which formed the roof, from the condensation of moisture on them. Then the sawdust on the floor, the farthest from the doors, was so wet that I could nearly squeeze water out of it, while near the door end it is barely moist enough to be pliable to the hand. This sawdust has a flour-sack full added to it every two or three weeks, so as to keep the dying bees from molding or being mashed on the floor, and the reason for going in on January 12 was to add another sack full.

The moisture which runs down from the stone roof is caught by the mason-work walls, and as the top of these

slopes out and away from the inside of the cellar, it is carried to the outside of the wall rather than staying inside. Some may call this cellar absolutely wet, but such is not the case, for the hives and all about them (they do not touch the wall or the floor of the cellar) appears as dry as in summer, and will so long as the colony of bees remains alive inside. But should any colony die, then the combs and honey take on moisture very similar to the flagging; and if any colony should die very soon after being put in, the combs would become quite moldy by the time the bees should be put out; but as I have not lost an average of two per cent in this cellar during the past 12 years, it is very few combs indeed that have become thus wet and moldy.

Perhaps some of the readers of the American Bee Journal would like to know how the bees appear. They are so quiet that often I stand with a lighted candle in front of a colony, holding the candle within 12 to 15 inches of the bees for two or three minutes, and I could not see that a single bee moved at all; but a little breath from my mouth upon them at the end of this time, will make them all raise their abdomens and thrust out their stings; and if I continue after this to stay longer, they will soon begin to crawl about and some of those coming from the inside of the cluster attempt to fly to the light. Some of the stronger colonies have nearly as many bees hanging below the combs as it would take to make a fairly good after-swarm, while the weaker ones show only the points to their abdomens standing out all along in rows between the bottoms of the combs; and if very light in bees a few are up so far on the combs that no bees are seen from the bottom of the hive.

For cellar-wintering I like the Dr. Miller bottom-board very much, as it catches the most of the dead bees, as well as to allow ample space for the stronger colonies to hang below the combs all they desire, besides giving full and ample ventilation, from the bottom, for all the wants of the bees. Then, to any lover of bees, these bottom-boards give a chance to see the clusters whenever said lover enters the cellar, and where a colony clusters below the combs, or in the shape of those first and second described above, it is something so enchanting to look upon, that it becomes almost bewitching, and it is with reluctance that I leave the cellar every time I go in.

The viewing of a cluster having from two to three quarts of bees hanging below the combs—something like a swarm in June, all perfectly motionless, and each bee lapping over its neighbor like rows of shingles on a roof, right in the center of the winter, with the mercury from 10 to 20 degrees below zero outside—is a sight to make one feel very cheery, and that is apt to give almost any one what is called a "bee-fever." In fact, I find that I have a touch of that disease myself, whenever I go into the bee-cellar, although I have kept bees now over 32 years.

Onondaga Co., N. Y., Jan. 17.

The Honey Crop of 1901—Marketing, Etc.

BY B. A. HADSELL.

The following clipping is taken from one of the best agricultural papers in the United States:

MARKETING HONEY THROUGH DIRECT SALE.

It is the commission man selling the lowest who does the business and who establishes the price of our products. The honest commission man—the one who would get full value—is not in it. He is at the mercy of the most unscrupulous member of the craft, and we are no better than their slaves. I want you to understand me, and I will repeat—It is the commission man who sells the lowest who establishes the price.

Stop selling honey through commission men, and then see what the dealers who will buy for cash will pay. If they cannot get our goods on commission they must pay cash. Having money invested in it, then and not till then, will they try and sustain prices. I have asked many city dealers of whom they purchased their farm produce and they invariably said through commission houses, and gave for their reason that they could in that way buy cheaper than of the farmer. I remember one instance in particular, where the dealer, with a knowing wink and laugh, said he would rather let the commission man settle with the farmer, and then his conscience would be clear.

W. F. MARKS.

The above explains why we do not receive a fair price

for our honey. Untruthful and unfair means are resorted to in controlling the press, by which prices are depressed and producers encouraged to sell. To illustrate: I am the regular correspondent for one of the largest farm papers in the United States for the county which produces nearly all the honey shipped out of Arizona; and I am one of the largest producers of honey in the Territory. Recently an article appeared in the paper I represent, headed from my Territory, but no name signed to it, evidently written and paid for by some Eastern commission man who never saw Arizona. He had it headed, "Big crop of honey in Arizona;" and went on to say that the conditions had been favorable, and that the bee-men had harvested a big crop from desert flowers and cactus fruit and bloom, and gave the average yield at four times its actual amount. The entire article was a false statement. I sent a reply, giving the exact report of the amount produced, correcting his false statements, and saying that the desert flowers had started four times the past three years and had dried up without bloom or seed, and I doubted if there was seed left to sprout again; and that I never saw cactus honey.

Supply and demand have nothing to do with it. Early in the season, before the crop was harvested, Arizona bee-keepers received letters from commission men, all quoting the same low prices, telling us of the big crops and foreign competition. One who had been handling our honey before was bolder than the rest and went on to say that our brother bee-keepers in Cuba were offering to lay down honey in Chicago at 3 cents, and we would have to meet this foreign competition or hold our honey. This was too much for an alfalfa bee-keeper to stand. The commission man got a reply that we had no 3-cent honey, and that when the Cuban bee-keeper packed his honey on burrows from the interior to the coast, and shipped it to New York and paid 20 cents a gallon duty, then shipped it to Chicago and paid him his commission, we would advise our brother bee-keeper to send a cargo of bananas along to pay expenses.

On page 643 (1901) a Chicago commission man tells us that Colorado, Nevada, and Utah are finding that there is not the demand from the East that has existed, and are beginning to get anxious about marketing their honey. That is just what those letters and false articles were sent out for, and it is that which has unsettled the market and held back buyers from buying his supply. As usual, the local merchants, and even the farmers, have refused to buy their usual can of honey, all quoting the big California, Cuban, or other foreign crops; unwilling to pay even a reduced price. He says that when we know the facts we will be governed accordingly. Yes, the facts are not allowed to go to press, as in my case, and won't be until this year's crop is sold. He goes on to try to convince us that it will do us good to have these false reports sent out, but we know better, and want the truth.

Can't the National Bee-Keepers' Association stop such adulteration of the press?
Maricopa Co., Ariz.

[This article was received early last December, but became mislaid, else it would have appeared sooner. But it has not lost its value by reason of the delay.—EDITOR.]

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

SMALL LOTS OF HONEY ON COMMISSION.

One would reasonably imagine that 100 pounds of honey would be too small a lot to ship to the commission man. Poor guide, that imagination, it seems. Mr. Doolittle has an experience 23 years' long on just that point; and he finds that such little lots *always* turn out more profitably than big ones. Let's mark it down. Page 6.

SPRAYING FRUIT-BLOOM.

The valuable paper of Prof. Beach, of Geneva, N. Y., on the red-hot subject of poisoning our bees—well, we want the scientists to hurry up, so as to have not quite so many may-be-sos and may-be-nots. The fact that hitting *all* the blossoms soon after they open will destroy all the young

fruit, appears to be one of the best things to give our pomological neighbors. As for the rest, perhaps an appeal to their sense of justice may be worth while. To destroy fungi and kill insects by the *only practical means* does not greatly offend the public sense of justice, even if some minor interests do suffer. But it does offend the public sense of justice to spread injuriously poison, just for the sake of thinning out the fruit. What would be thought of the farmer who thinned his corn by shooting shot through it—and peppered his neighbors' cows? It might also be worth while to say: Do you want the strong, first blooms all killed, and only laggards and side blooms left to furnish your crop of fruit? Interesting to see that Prof. Beach classes apple pollen as one of the kinds not well adapted to floating on the wind, and therefore specially depend on insects. Pages 7 to 9.

GETTING HONEY FROM BOX-HIVES.

It is not merely a few pounds but several hundred pounds of honey that are involved, page 10. If Dr. Miller will be patient with my know-it-all style, I wish to protest his answer to the man who wants to close out 20 box-hives. *Don't* melt chunk honey, except to close out the remainders. If the man will properly sort over his combs, and then proceed by crushing and draining in a warm place, he may just as well have from one-third to two-thirds of his honey of excellent quality as to half spoil it. As it is not the necessary heat that does the major part of the mischief, care in that respect will not make the honey good. The harm comes from contact between hot honey and dirt, and contact between hot honey and pollen and propolis. Most cappings and most combs have more or less propolis on or in them—and dirt also. Combs with masses of pollen in them are likely to make trouble even without melting, and would better be left for a second lot.

INCREASE OUT OF LOW-GRADE HONEY.

Where a man wants both honey and increase, and operates two locations, it's just the cunning thing to make the increase in the location where low-grade honey comes in during the time when bees incline to boom. Rather dark honey with off flavors will make up into bees as well as any. S. Q. Conkley suggests this for us on page 13.

BEE-KEEPING IN RUSSIA.

And so in Russia, when their bees all kick up their heels and die, they go 2,800 miles and buy a lot more. That's all right. And, the world over, what a cosmopolitan the bee is, in this little matter of taking sudden leave of her keeper and slipping through the shady gates! And the juice-producing bug, who puts the gates ajar, he's a cosmopolitan also, it seems. Some of our people would give up if they lost 500 colonies at one lick. Pages 18 and 20.

COLD-WATER HIVE-PAINT.

That cold-water hive-paint, page 20 and elsewhere; we are all anxious to see it. If water will wash it on, why won't it wash it off?

BEES NECESSARY TO THE FRUIT-GROWER.

This department does not run to quotations much; but it puts in gladly and fully this one from H. W. Collingwood. It's not likely to be printed too many times. Glad so weighty a man as the editor of the Rural New-Yorker said it, and not one of the smaller fry—and not a bee-man of any sort:

"With all his proud dominion over the lower forces of nature, man cannot produce the finest and most perfect fruits without the help of his friend, the bee. That, I believe, will be the conclusion of every fruit-grower who will really study the question." Page 20.

MASCULINE PRONOUNS FOR WORKER-BEES.

I laugh to see that Editor Collingwood's masculine pronouns applied to the bee, a big lot of them, got into the American Bee Journal without being checked out. While nobody's listening let me make a horrible confession. I mostly use masculines for the bee, too (or would, if I had my sweet will) but the Editor *she* won't let 'em go through. —[And Editor Collingwood wouldn't have succeeded in getting them through, either, had it not been that there were so many of them in his paper. And, besides, he is not a bee-keeper. We expect bee-keepers to call things apianian by their right names, as they are supposed to know better. A *he* woman would never get into the American Bee Journal, even if a Collingwood or a Hasty would try it on.—EDITOR.]

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marango, Ill.

Do Bees Build Cells Full Depth Before Putting Honey into Them.

On page 44, Sarah J. Griffith says of her bees: "They made a lot of comb in the sections in the fall, but could not get honey to fill them, so I will have nearly a hundred to commence with in the spring, the most of them full of comb." Is it a common thing for bees to fill sections with comb before putting any honey in them? SUBSCRIBER.

ANSWER.—I do not believe that bees ever filled a section with empty comb. They build comb no faster than it is needed, and the probability is that if the sections in question had been taken off earlier they would have had honey in them. Being left on the hive after the harvest was over, the bees carried the honey down into the brood-chamber.

Sowing Sweet Clover.

1. With the idea of sowing sweet clover for bee-pasture I had plowed up last fall about three acres of land. The soil is sandy and poor, being run out and too impoverished to farm profitably. There was no sod to speak of, the land having grown up in weeds. Now, would it be wise to sow the seed on the rough-plowed land, and harrow over, covering deeply? or would it be a better plan to level the land by harrowing first, and then sow the seed and cover by a second harrowing?

2. What is the difference, if any, between the white and yellow varieties of sweet clover in the matter of honey-production and time of bloom? NEW BRUNSWICK.

ANSWERS.—1. I believe I would sow pretty heavily without first harrowing. That will give seeds at different depths, some of it pretty deep, whereas if you harrow first none of it will be very deep, and if you should have the experience I once had it might all heave the first winter. Very hard ground seems to be best, and if not hard it is probably best to sow deep.

2. I don't know the difference in honey-production, but if I remember rightly, there is about two to four weeks' difference in the time of bloom, the yellow being the earlier.

Moving Bees on the Cars.

I have accepted the pastorate of a church here and have rented my berry farm in Iowa. I intend to ship my bees here in the spring when I move my family. The time of moving will depend somewhat on how soon it will be safe to move the bees.

1. Will it be safe to take them from the cellar and ship them 200 miles by cars before they have had a flight in the spring? I put 22 colonies into the cellar and they seem to be in good condition when I examined them the first of January.

2. If they are prepared for shipment with a wire-cloth screen on top of the hive in place of a cover, and the entrance securely fastened up, will they be all right?

3. Would it be safe to ship them in a car with a horse, cow, and household goods?

This is a town on the Mississippi 40 miles northwest of Minneapolis. There are but few bees kept here. There is considerable basswood along the river, and I think it will be a good location for bees. MINNESOTA.

ANSWERS.—1. They may stand the journey a great deal better after having a spring flight.

2. Yes, wire-cloth covering the whole top will give them all the air needed, even if the entrance be hermetically sealed. But it will be all right, too, to have the entrance closed with wire-cloth.

3. Yes, animals and other goods in the car will do no hurt, so that everything is so firmly in place that there is no danger

of collision between the bees and anything else. There must be no possibility of anything being shoved against the hives, and the hives must be fastened in place so they can not move. It will be a simple matter to pack the hives if there is enough room so that each hive can be placed on the floor of the car. All you need to do is to nail cleats of inch stuff on the floor so the hives cannot move, having the hives placed so the frames run parallel with the rails. Most likely, however, there will be so little room that the hives will have to be piled on top of one another. In that case, of course, it will not do to set one hive directly on another so as to cover up the wire-cloth. One way to do is to fasten two strips across the hives, on which to set the next hives. Unless the weather is quite cool it will be a good thing to have in each hive a sponge or rag filled with water.

The "Golden" Comb-Honey System—10-Frame vs. 8-Frame Hives.

1. What is the "Golden" plan or system, mentioned on page 57, for production of comb honey?

2. Can a 10-frame hive be used as successfully as an 8-frame hive for comb honey? and under what circumstances? JERSEYMAN.

ANSWERS.—1. It would take up too much room to answer here your question in full, but it may be found in the American Bee Journal for 1899, pages 34, 66, and 97. On page 57 (this year) to which you refer, Mr. Hartzell inquires why the five men named did not accept his proposition, and then says it was prejudice, although when he made the proposition he declared that he believed them all to be honorable and unbiased. His proposition was that they should each buy a hive from Mr. Golden, and test it, and if it proved unsatisfactory Mr. Hartzell would buy the hive from them. That would give them no pay for their time and trouble except what they might get from the gain in the system. Evidently they had not enough faith in that gain to be willing to make the test, even if it cost them nothing to make that test.

2. Yes, I am sure that good crops of comb honey can be obtained from 10-frame hives, for I have obtained them myself. I used 10-frame hives for years, and I am not sure but I got just as good crops as with 8-frame hives. But the work in handling hives and supers was very much heavier. I don't know that any great difference in circumstances would call for one more than another, unless it be that 10-frame hives require stronger colonies to start storing than are absolutely necessary in 8-frame hives.

Moving Bees on a Bobsled—Preventing Swarming—Facing Hives.

1. In moving bees about the first of March, that are packed with four inches of chaff all around and on top, would you smoke them before loading them on the bobsled, or handle them as quietly as possible without smoke? Would smoking do more harm than the excitement of jarring, etc., without, in case they did not have a flight within a couple of weeks? I wish to move them about three miles.

2. I want to run part of the apiary for extracted honey next season. If, on approach of the honey-flow, I take three or four combs pretty well filled with sealed brood, and place in an upper story, finishing out with empty combs or frames filled with foundation, and fill in the lower hive where brood was taken from with empty combs, would it work all right, and be likely to keep down swarming? I shall use queen-excluders between the hives.

3. Will bees do as well, and gather as much honey, with hive entrances facing north as they will with entrances to the south or southeast, especially if hives are under trees? NEW YORK.

ANSWERS.—1. By all means avoid the use of smoke as much as possible. If you can fasten the bees in the hive without smoke, there will certainly be no need of smoking them afterward. The smoking and jarring will do more harm than the jarring alone.

2. It will work well, and there will be less likelihood of swarming, but if you go the whole figure, as many bee-keepers do, and put all the brood above, leaving only empty frames or combs below, you may like it still better, as in that case you are practically free from swarming.

3. That question has been discussed a good deal, and opinions differ. It is doubtful that you will find a very marked difference.

Did Well Last Season.

My bees did well last season, but I do not know how they will come out in the spring as it has been so very cold and dry during the winter, but they are in good condition now.

I am the only bee-keeper that takes any reading at all, but the others run after me to take care of their bees, and want it done for friendship's sake. It seems as if I could not get along without the Journal.

JOSEPH A. LEWIS.

Navajo Co., Ariz., Jan. 23.

More Rain Expected.

We had a fine rain here in Orange county—about 3 inches up in the mountain—last week. It is cloudy to-day, and we will have some more rain soon. The sage is starting finely, from which the bees will gather the water-white honey next spring, if we have later rains.

I sold 5 tons of honey last year for 4 and 4½ cents per pound. There is no market for honey here. I have 200 colonies of bees in good condition, almost all Italians. I run two apiaries 4½ miles apart, 100 colonies in each apiary.

F. S. BUCHHEIM.

Orange Co., Calif., Feb. 3.

Poor Season for Bees.

The weather has been so very dry the past season that the bees barely lived, and gave scarcely any surplus, except a hundred pounds or so, taken from brood-nest where they had too many combs for wintering, which was extracted. Our extracted honey has sold better candied than in the liquid form the past few years. The grocer can then dish it out on his little trays or butter-dishes just as he does butter or lard, and it is not so daubly to handle as when in the liquid form.

MRS. L. C. AXTELL.

Warren Co., Ill., Jan. 30.

Working on Red Clover.

Bees are wintering splendidly so far. To this date I have not lost a colony. I look forward to a successful year, for the white clover in this vicinity was excellent when winter set in, and the red clover is in good shape so far. I am convinced that the latter clover was the source from which the bulk of the honey came here. For the last two years the bees have been working well on red clover in this vicinity.

CHAUNCEY REYNOLDS.

Sandusky Co., Ohio, Feb. 1.

A Woman's Report—Propolis.

Seeing so many reports in the American Bee Journal of many apiaries and honey crops induces me to try and describe our success among bees.

Our apiary is situated about 8 miles east and a little south of Longmont, and in a real, good locality. But the country is nearly filled up with bees, and more coming in.

My husband ran about 200 colonies last year, and got 700 cases of 24 sections in a case, and only about 200 pounds of extracted honey. We did a great deal better than a good many bee-men in this part of the country. It would have been a great deal better if we had had more moisture from July on through the fall.

This year we intend to run about 300 colonies. Bees are selling here for \$5 to \$7 per colony.

The bees gather nearly all the honey from sweet clover, alfalfa and Rocky Mountain beplant.

Can you tell us about the sale of propolis or bee-glue, whether there is any demand for it, and how we shall prepare it for market?

Rather Risky Business,

this buying untried incubators in these days of the perfectly working and surprisingly simple

Reliable Incubators and Brooders,

where every fertile egg means a strong healthy chick. Guaranteed to do the work and do it as it has never been done before. The 20th Century Poultry Book ought to be in every chickenman's house. Also tell us how to separate the wax from the bee-glue.—[So far as we know, there is no sale for propolis. Error.]

We have about 150 colonies at home fixed for winter, by putting chaff in an empty super over each brood-chamber.

We have had a very nice winter, bees flying all month up to this last week, when it became real cold. **Mrs. J. H. TAYLOR,** Weld Co., Colo., Jan. 26.

'Way Down in "Egypt."

I was down in Illinois at my old home place, in "Egypt." I have been away for 25 years. As far as bee-culture is concerned there has been no change even in 60 years. The same old log or board gums are used, and honey taken out from the top in chunks, either at night or when the weather was so cold the bees could not fly. I saw no one that took any care of their bees, and very few will keep bees, as they say it is too much trouble, and the moths are too bad.

I had sent a few cases down there before I went, and one man that had a few bees and was peddling honey as black as tar, said the honey I sent down was not made by the bees; that the bees never made it so even and so white as that was. He declared it was all manufactured, and warned the folks not to eat it. There was no one that I talked with that was afraid of it.

I was in Alexander, Union and Williamson Counties, Illinois, and saw but few bees.

W. G. LINDZA,

Boulder, Colo., Jan. 29.

Advertise the Truth About Honey.

Now about those big lies that are going the rounds of the press in regard to comb honey. It really looks discouraging when an editor can find room to publish falsehoods to injure a class of honest producers, yet when furnished with the truth cannot give it room. Now I want to suggest that the National Association take the matter up. Surely, it is of enough importance, as it affects all honey-producers everywhere.

My suggestion is this: Let the Association buy space in suitable papers, paying advertising rates, if necessary, in order to furnish the consumers with the truth about the matter, and head off the big lies. It seems to me some of the money could be used to good advantage thus. **W. G. GATHRIGHT,** Donna Ana Co., New Mex.

Reports of the Parma Convention.

The annual meeting of the Parma Bee-keepers' Association met in Parma, Ida., at 10 a.m. Jan 18, 1902, with a large attendance, Pres. Brush being in the chair. In the discussions many interesting points were brought out, some referring 8-frames. Some having large hives claimed 45 Danz. sections of comb honey could be produced in the same time it took 8-frame colonies to produce 24 sections. Reversible bottom-boards were generally preferred.

After a basket dinner the following officers were elected: Mrs. Mitchell, president; F. R. Fouch and H. M. Ruddock, secretaries.

We shall try in the future to get better rates on honey, from transportation companies. The Chantry feeder for stimulating breeding was shown, and its use illustrated by E. F.

Is this Monopoly?
Lots of lies have been told about the Rural Mail Box business. Here are the facts. There are 14 approved boxes and with the makers it is "everybody for himself and the devil take the hindmost." We plead guilty to getting the lion's share of the business, simply because our box has such "winning way." Write us and learn about it.
BOND STEEL POST CO., ADRIAN, MICH.

Please mention Bee Journal when writing.

Atwater. This feeder is cheap, easily made, and one of the best feeders in existence. Mr. Atwater followed this by a short talk on queen-rearing, and the importance of rearing our own queens from the best stock obtainable.

A State Association was also formed, its purpose being to protect the bee-keepers of the State, and to keep diseased colonies of bees from being shipped. We also have a bee-inspector for foul-brood, etc.

This section of the country is full of bees, and short pasture will soon be the next drawback.
H. M. RUDDOCK, Sec.
Canyon Co., Ida.

The Boston Honey Market.

There is a good opportunity for honest honey-producers to cultivate a market in Boston and vicinity. Not a quarter the honey is consumed that should be.

I have seen some very fancy white comb honey there and have had occasion to sample different lots, but so far I have not found any equal to our Aroostook clover and whitewood honey. I suppose it is there, but there is considerable honey on the market that is fine in appearance but lacks that fine flavor found in honey from more northern latitudes.

O. B. GRIFFIN.
Aroostook Co., Maine, Feb. 13.

White Clover May Not Do Much.

We have about 600 colonies of bees for the coming season, but fear that white clover will not do much the coming season, as the past summer was so dry that the greater part of it was killed out; however, we have two chances for a crop, as our bees are all located where heartsease is plentiful and yields fully half our surplus, as well as furnishing a bountiful supply of excellent food for winter.

The past three years have been very satisfactory to us.
FRANK COVERDALE.
Jackson Co., Iowa, Jan. 31.

An Old Bee-Keeper.

Last spring I had 5 colonies and now have 12 (if they come through all right) without boxes on.

I took off last year something over 400 pounds of extracted honey, worth here 12 cents per pound.

I am not able to do any heavy work, but I think I can do a little and put in the time more satisfactorily than to be idle. I am nearing my 76th year.

We have a quantity of honey-locust, and a lot of linden, which lasts quite a while; also white clover, then white sweet clover along the roadsides. I still like to work at bee-keeping rather than be idle.

GEORGE McCULLOUGH.
Page Co., Iowa, Feb. 3.

Hauling Bees with Open Hive-Entrances.

A case is reported in Gleanings in Bee-Culture as having been successfully accomplished by Adin Stone. While it might not be wise for most persons to try such a thing, it is well enough to know what can be done. He says:

I had about one mile to move, and about as many hives as I could place on a lumber-wagon as they sat in the apiary. I loaded them in as they sat, first using the smoker to drive the bees inside. I hitched a horse to the load and drove to my destination; unhitching the horse from the wagon, I waited until morning, when I put them on their stands. These were full colonies in eight-frame hives, Hoffman self-spacing frames, loose bottom-boards, 1/4-inch entrance full width of both

ends of hives. All of them were left open as they stood when at work in the apiary. I moved on a lumber-wagon without springs, over a stony road, and through a small village, in daylight, between 6 and 7 o'clock p.m.

I don't advise anybody, nor claim this as the proper way to handle bees; but I tell you what I did successfully. Not a person was stung, nor any trouble whatever came from the bees. Of course, they came outside and clustered on the hives. I walked and drove the horse (not a very steady one either.)

I found the same principle to work in this case as in handling bees in hives or hiving swarms. When thoroughly alarmed, and filled with honey, the bees attended to their own business and troubled nobody. I am satisfied I could have driven for miles with them.

I can not say that this plan will always work. It did that time and season, between spring and summer. Some new honey was coming in at the time.

Importance of Fresh Air in Bee-Cellars.

It will be remembered that in the winter of 1900-01 Editor Root reported wintering 50 colonies in an inside cellar—a room within a room—with great success. This winter the experiment is repeated on a larger scale, and Mr. Root seems somewhat enthusiastic over it. He also had a cellar constructed at an out-apiary. When it is remembered that he has heretofore been very successful in out-door wintering, and has for the most part been rather an advocate of that kind of wintering, his advocacy of indoor wintering is all the more striking. He seems somewhat vehement in insisting upon the importance of plenty of pure air, for which belief he no doubt has the very best grounds. He reports:

There are 200 colonies of them, and they are wintering finely. To all appearances they are doing as well as the 50 colonies did a year ago; and these, it will be remembered, came through without the loss of a colony, and scarcely any dead bees on the floor. During warm nights, when the air is sultry, we open the door opening into the outer cellar, and just opposite this door is a window leading to the outside. The cool, fresh air pours in all night, and then before daylight comes on the door is closed. We have tried keeping the door shut every night running for three or four days, but the bees get uneasy and begin to roar. This goes to show that an infusion of fresh air from outdoors and a constant supply of it *all the time*, day and night, from the outer cellar having ten times the cubic capacity of the room in which the bees are, is important.

Yes, indeed, I am becoming more and more convinced that plenty of fresh air in indoor wintering is one of the prime essentials, and variation in temperature is only secondary. Why, the mercury in our bee-room last year, where the bees wintered so perfectly, moved up and down all the way from 38 to 60, and noise—there was a constant banging and slamming, and yet you will remember I kept those bees in till about the middle of May. The dead ones had never been swept up, and yet you *could almost* walk across that cellar without stepping on one. When we remembered that it is considered good wintering indoors, even if the cellar is completely covered with dead bees, the results I have mentioned are all the more remarkable.

The bees in the out-yard cellar are not doing quite so well, for the reason that a street-railway company have two or three times filled our drain, causing the water to back up. But we are sure of this, that Bingham's idea of ventilation through a shaft 20 inches square, going from the roof of the building above, is all right.

I believe bee-keepers have been making a great mistake in their house-bee-cellars by not giving the bees fresh air, and lots of it.

WHEN ACCIDENTS HAPPEN
and you never know just when that will be—it's very convenient to have at hand a good, reliable, dependable remedy, like

Watkins' Vegetable Anodyne Liniment.

A burn, a bruise, a frost bite, a cut or a sprain, an attack of rheumatism, cholera morbus, cramps, diarrhoea, flux, sore throat, mumps or diphtheria do not admit of experimenting. You want something to help you, and you want it right away. Why not, then, keep on hand a really reliable remedy, so as to have it by you when you need it?

Watkins' Liniment, for internal and external use, for man and beast, has been for 40 years the best standard household remedy known to medical science. It has peculiar penetrating qualities, and gets at the root of the trouble as does no other liniment.

Watkins' Vegetable Anodyne Liniment is sold by our traveling salesmen through the country. If our agent has not called on you, send us your name and address at once, and we will see that you are promptly supplied. Price \$1.00 and your money back if it isn't the best liniment you ever used.

Do You Produce Comb Honey?

Here is something that will interest you.

"The Danzenbaker Hive I think will take precedence over all others. I am delighted with it, as it is simple, and easily manipulated."

R. H. PEPWORTH, Pietermaritzburg, Natal, South Africa.

Nov. 30, 1901.

If you buy the Danz. hive you will find a ready market for your honey. Comb honey in Danz. sections has never yet been held because of "little demand."

EXTRACTED HONEY!

You will need good hives, smokers, knives, and most of all, a good honey-extractor. Root's Cowan Rapid Reversible Extractors are used everywhere, and always acknowledged to be the best. Be sure to get one of our make.

BEESWAX?

You should have the best wax-extractors, else large quantities of wax will be left in the refuse. See what one extensive and practical bee-keeper says of the ROOT-GERMAN STEAM WAX-PRESS:

For over 20 years past I have had to render up old combs or cappings in larger or smaller quantities, and my experience has been extensive, for I have tried faithfully almost every known method to get all the wax out, but have never succeeded to my satisfaction until recently. I got of you a German wax-press, that comes nearer accomplishing that object than any thing I have ever tried. I am more than satisfied with it, for, if used according to directions, there is little if any wax left in the refuse. Any one used to the old methods will be astonished at the results obtained. In this press you have given those in need of it the best thing, to my mind, you have ever brought out, and I really believe all who try it will pronounce it a real treasure. There are other points of advantage that I could mention, one of which is its perfect safety—no boiling over and setting fire to every thing, and it can be left alone without care for quite a time, and every thing can be kept neat and clean, and it occupies very little room. E. T. FLANAGAN. Belleville, Ill., Dec. 12.

Root's goods are for sale everywhere. See list of jobbers and agents in the January bee-journals. A full list of local agents sent you on request. We will also send you a little book, "Facts About Bees," describing the Danz. hive, and our catalog, on request.

WANTED.—Beeswax. Price, 23c cash or 30c in trade for pure average beeswax, delivered here. We want also a car of white sage extracted honey, also large lots of WHITE COMB HONEY in DANZ. sections.

THE A. I. ROOT CO., MEDINA, OHIO, U. S. A.

GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL., are headquarters for ROOT'S BEE-KEEPERS' SUPPLIES IN CHICAGO. Send to them for their free Catalog.

FORTY-SECOND YEAR
No. 9.

WEEKLY

APIARY OF J. WARREN SHERMAN, OF SUFFOLK CO., N. Y.
(See page 132.)

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

National Bee-Keepers' Association

OBJECTS:

- To promote and protect the interests of its members.
- To prevent the adulteration of honey.
- To prosecute dishonest honey-dealers.

BOARD OF DIRECTORS.

E. WHITCOMB,	THOS. G. NEWMAN,
W. Z. HUTCHINSON,	G. M. DOOLITTLE,
A. I. ROOT,	W. F. MARKS,
E. T. ABBOTT,	J. M. HAMBAUGH,
P. H. ELWOOD,	C. P. DADANT,
E. R. ROOT,	DR. C. C. MILLER.

EXECUTIVE COMMITTEE.

W. Z. HUTCHINSON, President.
OREL L. HERSHISER, Vice-President.
DR. A. B. MASON, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.

Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

Please mention Bee Journal when writing advertisers.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 18.—There has been a decline in the market on comb honey of one cent per pound since the month came in. Best grades of white now slow at 14c; sales chiefly at 13½c with some Western choice at 13c; no buckwheat comb offered, and other dark grades are meeting with little attention, prices ranging from 9@12c. Extracted is steady, white, 5½@7c, according to quality and what it is gathered from; amber, 5¼@5¾c; off grades at 5c. Beeswax wanted at 30c. R. A. BURNETT & Co.

ALBANY, N. Y., Feb. 7.—Honey market firm for all grades of comb honey, of which there is a very light stock here. White comb is selling at 15@16c; No. 2, 14@15c; buckwheat and amber, 13@14c. Extracted slow at 6@7c for white; but buckwheat extracted is selling best at 6 cents. Beeswax scarce, 28@30c. H. R. WRIGHT.

CINCINNATI, Feb. 7.—The honey market has been rather dull this year. Comb honey is selling fairly, and brings as follows: White clover, 15c; lower grades from 12@14c. Extracted honey sells very slow, the lower grades bringing 5@6c, and fancy, 6½@7½c. Beeswax, 28@30c. C. H. W. WEBER.

BOSTON, Jan. 20.—Strictly fancy comb honey in cartons, 15½c; A No. 1, 15c; No. 1, 14½c; very little No. 2 to offer; stock nominally running No. 1 and A No. 1. Extracted, light amber, 7½c; amber, 7c; Florida honey, 6½@7c.

Our market continues somewhat dull in the demand for honey, while stocks are ample for the balance of the season, unless there should be a much larger demand than we at this moment anticipate. BLAKE, SCOTT & LEE.

NEW YORK, Feb. 8.—There has been very little movement of late in comb honey, and while there is no buckwheat on the market to amount to anything, there is sufficient quantity of the different grades of white honey. The demand having been slow of late, prices have had a downward tendency and are likely to remain so during the spring.

We quote: Fancy white, 14c, and exceptionally fine stock at perhaps 15c; No. 1 white at 13c; amber at 11@12c. Extracted remains dull at unchanged prices. Arrivals of late are quite plentiful of all the different grades. Beeswax firm at 28@28½c. HILDRETH & SEIGELKEN.

SAN FRANCISCO, Feb. 12.—White comb, 11@12½ cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5½@6c; light amber, 4½@5c; amber, 4@—, Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Considering the limited quantities offering there is a fair trade in progress, both for shipment and local account. Quotable values are without change, but market is moderately firm at the prevailing figures.

CONVENTION NOTICES.

Utah.—The Utah State Bee-Keepers' Association will hold its annual convention in the City and County Building, Salt Lake City, April 5, 1902, at 10 a.m. This promises to be an interesting convention. All are invited. It is desired to form an exchange for the protection and benefit of our bee-keepers. Come and aid a good cause. It is expected that every county will be represented. J. B. FAGG, Sec.

E. S. LOVESY, Pres.

New Jersey.—Several of our progressive States have one or two bee-keepers' associations, and New Jersey should be able to place one to her credit with several hundred active bee-men. If time was ever opportune for an association, with a membership of several hundred, that time is now. The New Jersey Bee-Keepers' Association was organized January 11, 1902. The next regular meeting will take place Saturday, March 1, at the office of Mr. J. B. M. Cook, 62 Cortlandt Street, New York City. Every bee-keeper is most cordially invited to be present. It does not matter whether you own a half-dozen colonies of bees or a hundred dozen, you are welcome to join us in a cause that you know is worthy of advancement. From present indications will be held at Trenton next Fall, during the State Fair, at which place almost every person in our State who is interested in rural pursuits is generally found. Crawford, N. J. GEORGE N. WANSER, Sec.

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., FEBRUARY 27, 1902.

No. 9.

* Editorial. *

That Libel on Comb Honey.—It is very disheartening to know that there are indications of a decline in the demand for comb honey in some of the prominent markets as a result of falsehoods for which there can be no excuse. There are, however, some encouraging features as well. There seems to be an activity on the part of bee-keepers in demanding attention to the truth that was hardly known in the years gone by when Prof. Wiley made his unfortunate false step. Possibly as a result from this, but from whatever cause, there seems a more general inclination on the part of the public press to do the fair thing by bee-keepers in the way of retracting errors and publishing truth. True, that inclination is by no means universal; but that could hardly be expected.

Among the papers that have shown a disposition to give space ungrudgingly to have wrongs righted may be mentioned two very influential journals in their respective spheres—the National Stockman and Farmer, and the American Grocer. The Stockman is a well-known authority in the agricultural world, and has published a plain and full discussion of the matter which seems to be written in as strong terms as were at the command of Dr. C. C. Miller. The American Grocer, with its prestige of years' circulation in the grocery trade, devotes half of one of its large pages to an article headed, "A Great Damage to the Grocery Trade," written by W. P. Root, the "Stenog" of Gleanings. Mr. Root indignantly denies that there was any seecrey about the production of honey, gives a cut of a comb foundation machine and a frame having foundation fastened into it, and shows that artificial comb honey can have no possible existence.

Let the good work go on, and let bee-keepers everywhere continue their efforts with the local press to have the truth placed before the public.

Improvement of Stock still holds the floor as a live topic. G. M. Doolittle discusses the matter conversationally in Gleanings in Bee-Culture, and among other things says:

A score or more years ago I began to turn my attention to this matter, and soon adopted the following plans: At the close of each honey season I struck an average of the number of pounds of surplus honey produced by the whole apiary; and then all the colonies which did not come up to this average were marked. These colonies were united, either

in the fall or spring, with others, which had produced an average amount, or above, if such uniting was deemed advisable, through colonies light in bees or scarcity of honey. If all were not disposed of in this way (of course I always destroyed the poorest queen and retained the other), I superseded the inferior queens by those reared from colonies known to have produced the very largest amount.

He emphasizes the importance of keeping a careful record of each colony, and says:

Prolificness, length of life of the workers, whiteness of cappings, wintering quantities, etc., are all looked after, and all queens at all times are reared, as far as possible, from those giving the highest number of points along all these lines, and in this way any apiary can be kept steadily improving instead of holding its own or retrograding.

Insurance for Bee-Keepers is a topic of some prominence in the British Bee Journal nowadays, and enthusiasm is shown over the prospect of carrying out the scheme. The object of the scheme is for the purpose "of insuring bee-keepers against loss from damage done by their bees." That raises the question whether there is not more damage done by bees in England than in this country.

Rambler's Big Scheme.—Rambler is nothing if not a schemer, and now he has a new scheme in Gleanings in Bee-Culture, which is nothing less than the idea of getting a large amount of capital invested in bees, and the business so managed as to be largely freed from the element of uncertainty. This he thinks might be done by having the same company own bees in a number of different localities widely separated, in which case a failure in one locality might be more than balanced by a big harvest in another. One might need some study before deciding that the plan could succeed even on paper.

All Help to Raise the Standard.—It may be thought by some that those who are laboring for the improvement of their stock of bees are not at all dependent upon others, and that a few leaders working together may raise the standard for the whole country. While a single person may do much to raise the standard, if the matter is looked at in the right light it will be seen that so long as we can not control the fecundation of queens the most obscure bee-keeper in the land may have a certain degree of influence toward preventing that raising. For drones reared by him may have their evil effect upon the character of colonies two, three, or more miles away, and these again in a diminishing degree upon colonies still farther out, and so on. Is it not for the general good to have all interested in the work?

Changing Locations.—When one reads about localities that are paradises for bee-keepers, there is very likely to be some feeling of dissatisfaction with one's present location; but if an actual change is made it is not always an improvement. Both sides of a story are not always fully told, even if nothing but the truth is told on the one side. Here are some very sensible words spoken by J. E. Hand, in Gleanings in Bee-Culture:

There are a great number of things to be considered in changing to a new location. I have been in some of these paradises, and there are other things to be desired besides securing a large crop of honey. Many of these places are far from market; and unless bee-keepers have an organization to protect themselves, they are at the mercy of speculators who will buy their product at their own price because they cannot ship it themselves; and then most of these locations are already overstocked, and strangers will meet with anything but a hearty welcome. A good, accessible market, with a fair to poor honey-yield, is more desirable than a good crop that is practically inaccessible to market. This past season has decided that, for me, the proper solution of this problem rests in improved methods, careful management, and in developing the resources already at hand.

Improvement of Bees.—Arthur C. Miller says in the American Beekeeper:

Well, until we find some feasible way of controlling the mating of the queens there is but little we can do in the way of improvement. We can select for our propagating stock those colonies which seem to possess the greatest number of desirable qualities; we can suppress the drones of all other colonies. We can use the utmost pains and care to rear strong, vigorous drones and queens.

Some would hardly agree that doing thus much was doing "but little." At any rate, if all bee-keepers would only do so much as to see that their increase was made from their best stock instead of the usual way of having the most increase from those most given to swarming, it would make a very appreciable difference in the general character of stock throughout the country.

A Law Against Box-Hives is advocated in Gleanings in Bee-Culture by J. M. Hambaugh. At first glance it would appear arbitrary and unreasonable to prevent a man from keeping his bees in any kind of a hive he chose, but after reading what Mr. Hambaugh says about the difficulty of detecting disease in hives from which the frames can not be lifted, the unreasonableness does not appear so clear. He says in part:

Foul brood, black brood, and all the diseases known in the category can fester and thrive in these old non-movable-comb hives, so far as the efforts of the inspectors are concerned, from observations that can be gained in the brood-chamber, and so the non-progres-

sive, slipshod bee-keeper can thus hug an adder, not only to sting himself, but also his neighbors, who are powerless to help themselves under existing conditions.

Now, I am sure, the picture is not overdrawn, and I look upon it as an absolute necessity in behalf of the best interests of the careless bee-keeper, as well as the protection of the progressive apiarist, to enact a State law making it obligatory on each and every bee-keeper to put his bees upon movable combs, so that they may be accessible for investigation and manipulation. It would be doing no one an injustice, but instituting a righteous defense against the common enemy to the bee-keeping fraternity, and raising the industry to a higher degree of progress.

I also believe it is very essential that a law be passed compelling every one, under penalty of a fine, to obtain a certificate from a lawfully appointed inspector, certifying that his or her bees are healthy, and free from all infectious diseases, before he can be at liberty to move them from one locality to another; and when bees are imported from an adjoining State that has no laws of a like nature it should be the duty of the owner of said bees, under penalty of the law, to have, at once, said bees inspected.

The Double Cover is strongly advocated for the sake of having something warmer in winter and cooler in summer than the single-board cover, but L. O. Westcott objects, in *Gleanings in Bee-Culture*, that the space in the double cover furnishes too convenient a place for ants to have their nests. He says it is very annoying to have them crawl over your hands, biting like little bull-dogs. In the region of Chicago there is some trouble with double covers, but not enough to overbalance the advantages. The objection would be removed if the covers were made so tight that no ant could get in, and this would make the covers warmer in winter. Editor Root says there is made one style of double cover that is guaranteed to be ant-proof.

Super Foundation in the Brood-Chamber.—W. T. Stephenson, in *Gleanings in Bee-Culture*, reports success in getting brood-combs built out on thin and extra-thin foundation. This was Weed foundation. When other foundation was used it would warp and fall down after the cells were $\frac{1}{4}$ inch deep. But it requires a great deal of attention to make a success in the brood-chamber with such thin foundation, and perhaps it is economy for most of us to use the heavier. Editor Root has in mind exceedingly thin foundation with No. 40 wire incorporated in it to make it substantial.

Weekly Budget.

"A CENTER SHOT" is what Stenog in *Gleanings* calls the following remark in this Journal:

"The Tribune thus admits that it had room to publish lies about honey, but it has not the space to allow the truth to appear about it!"

Mr. T. B. BLOW, who formerly conducted extensive hive-works in England, and who made a visit to this country a few years ago, has married Shoko Koyake, of Kyoto, Japan, and has settled down as a good Japanese citizen. So says the *British Bee Journal*.

HON. E. WHITCOMB, of Saline Co., Nebr., has been spending a month in southern Louisiana. He is a member of the Board of Directors of the National Bee-Keepers' Association. Somehow he has been very quiet for a long time, keeping his apicultural "light hid under a bushel," as it were. Perhaps he needs contact with chief Geronimo and his band of Indian warriors to get him warmed up. "Uncle Whitcomb" is "right at home" with Indians and bees.

Referring to his trip to the Southland, he has this to say:

Down in Louisiana they have all the birds that we have in summer; there are plenty of opossum and coon, quail, rabbits and squirrels, and the ducks are so thick that it is almost wicked to kill them—great, big canvas-backs and greenhead mallards. It may be that I did not hunt any! I returned weighing 14 pounds more than when I went, and Mrs. Whitcomb exceeded that by several pounds. I did not see any ice while I was gone, and found on my return that the cold weather pinched me considerable, yet "There's no place like home."

MRS. J. B. AUSMUS, the wife of one our esteemed readers, died Jan. 24, 1902, being sick only about a week from pneumonia fever. She was a faithful Christian, and member of the Methodist church. These partings must come to us all sometime. No matter what any of us may think of the future, we cannot get away from the fact that the messenger Death will call at each of our doors some day. And there will be sorrowing ones left behind. Then what comfort to the bereaved ones to feel that there may be a reunion sometime, over on "the other side."

A SPANISH BEE JOURNAL, or at least a Spanish department of five and a half pages, is the latest thing in the American Bee-keeper. "H. E. Hill, Editor, *El American Bee-keeper*" is easy reading; beyond that it would be easier reading if printed in English. "Abeja" seems to be frequently mentioned. If that is some Spanish bee-disease, Editor Hill would have been kinder not to have introduced it into this country.

MR. F. W. L. SLADEN VISITS DOOLITTLE.—Mr. Sladen, who made a visit to this country not long ago, is one of England's prominent bee-keepers, and the following items are clipped from an account in the *British Bee Journal* of his visit to Mr. G. M. Doolittle:

"He had an unusually powerful voice. His thoughts and words flowed so rapidly that I had some difficulty in keeping pace with them, and sometimes of comprehending his meaning. He was, however, exceedingly explicit whenever I requested him to repeat anything he had said. The first thing we did was to look at his bees. Mr. Doolittle took a small piece of touchwood and, fixing it on to the end of a wire skewer, set it well alight. He then dropped it into his Corneil smoker with some more pieces of the same material, and, armed with this and two bee-hats, we sallied forth to the bees. Mr. Doolittle has about 90 colonies of bees. He uses a small, square frame, the "Gallup," measuring $11\frac{1}{4} \times 11\frac{1}{4}$, and he spaces with his fingers. For sections he seems to prefer a four-piece tall section, the size of which is $3\frac{1}{4}$ inches by $5\frac{3}{8}$ inches.

"The sections were placed in a hanging frame, and tin separators were attached to the frame. Mr. Doolittle gave me a message for British bee-keepers, which I will repeat here while I remember it. 'If you tell them nothing else from me,' he said, 'impress on

them the importance of having a full force of working bees in the field at the right time.'

"Mr. Doolittle was most kind in explaining to me all kinds of appliances and methods; he showed me the little room where he did all his writing, the walls of which were well decorated with a large number of newspaper cuttings. The four hours or so I spent with him passed like a moment, and the sun was already getting low when he wished me good-bye."

Did not Mr. Doolittle in his modesty fail to say anything about any out-apiary to be added to the number of those 90 colonies?

MR. A. B. COOK, familiarly known as "Bert" Cook, the son of Prof. A. J. Cook, is coming into prominence in Michigan, the State in which his father was so prominent in years gone by. He has been honored with the position of president of the Michigan State Association of Farmers' Clubs.

THE LONE STAR APIARIST has made its first bow to Texas and other bee-keepers, edited by Louis Scholl. In one respect it has made a stride such as is usually made later on. It has merged into it the *Southland Queen*, which merging was accomplished before the first number was off the press, indeed before the first number was fully on the press. Success to the "Lone(some) Star."

MR. J. WARREN SHERMAN AND APIARY are shown on the first page this week. When sending the pictures he wrote as follows:

I send a picture of my apiary, my sisters, and my children. It is hard work to get a picture of the apiary as it is too shady. The lower picture is the apiary. The house on the right is the honey-house and house-apiary, and is used for queen-rearing exclusively; it contains 26 colonies of bees.

I commenced bee-keeping four years ago, by catching a stray swarm that came to a friend of mine, and was hived in a soap-box. I transferred them to an 8-frame Langstroth hive, and have been using that kind of a hive ever since.

My average yield of honey in 1901 was 60 pounds per colony, of comb and extracted, as I run for both.

You can see by the picture that it is rightly named, "Shady Nook Apiary," although this picture was taken in the winter.

The upper picture shows my two sisters on the right and my three daughters on the left. They are interested in bee-keeping, too. This picture shows only one hive in the background, the rest being too much in the shade.

J. WARREN SHERMAN.

MRS. E. H. STEWART, of Niagara Falls South, Ont., passed away, Feb. 8, after suffering about 4 weeks with the bursting of a blood-vessel in the brain. She was 41 years and 5 months old—just in her prime. Mrs. York and the writer met Mrs. Stewart the first time at the World's Fair convention, and liked her so well. She seemed such a good and true little woman. Then, when at the Buffalo convention, several years ago, she invited Dr. Miller and us to her little home in Ontario, after the convention. We spent the night there and in the morning she and Mr. Stewart took us to see Niagara Falls—the first time we had beheld that great wonder.

But Mrs. Stewart is gone. She was a consistent Christian, loved and beloved. Her husband and children remain to mourn her untimely death, but also to live so that when their time shall have come to leave this world, they will go to meet the "little mother" in that "Better Land."

Convention Proceedings.

(Continued from page 120.)

Report of the Colorado Bee-Keepers' Convention held in Denver, Nov. 18, 19 and 20, 1901.

BY D. W. WORKING, SEC'Y.

Advice to Beginners.

As relates to bee-culture, the world of mankind is divided into two distinct classes, between which the line of demarkation is strongly and sharply drawn. One class possesses natural qualifications that render its members capable of handling bees with both pleasure and profit. The other class is so constituted by nature that its members are foredoomed to failure, and at best would achieve but an indifferent success should they embark in the business of raising bees and producing honey. Only a few people in each community belong to the former class; while in the latter class may be reckoned the balance of the human family, comprising, by inconceivable odds, the major fraction of the race. There is no absolutely fixed rule by which these classes may be differentiated, but there are a few guide-boards that help to point the way toward probable success or failure.

This was to be a paper of advice to beginners; but I feel that it will be incomplete, and fail of its intended mission, if it is not also a paper of advice to those who ought not to begin. As the latter class far outnumbers the former, I propose to dispose of it in advance, and hang out a few danger signals that no one of ordinary comprehension can fail to interpret.

It is a mistaken idea that bee-culture is a lazy man's road to wealth and affluence. It requires hard study, hard work, and unceasing activity the year around to be successful. The same amount of capital, brains, and energy, invested in any other occupation would yield as good or better returns. If love of ease and the luxuries that gold will buy are the overmastering passions of your life, do not seek bee-culture as a means of gratifying them, as failure all around would be the inevitable result.

If you have other business that absorbs your time to such an extent that you can not devote the time and study to bee-culture necessary to conduct it along scientific lines—in other words, if you can only make it a side-issue—then most emphatically do I advise you to let it alone. While bee-culture sometimes combines profitably with horticulture, poultry culture, and other rural or semi-rural pursuits, still I believe that specialism in any one of these occupations will yield the best financial returns.

Unless you can accustom yourself to being stung, it will be useless for you to embark in the bee-business. It is possible to put on a rigging that is sting-proof, but no practical apiarist would think for a moment of working in such toggerly. Stings are unavoidably of daily occurrence when working in the apiary; at least that is my experience, and one can become so accustomed to them as to become almost immune from their effects. On the other hand, a great many people suffer intolerably from even one sting. To such, apiculture offers very little inducement as an occupation, no matter how dearly they may otherwise love the work, or its results.

To revert now to the advice to beginners, I wish to preface what I may say under this heading by saying that I do not pose as a sage, or lay claim to the wisdom that will allow me to speak authoritatively upon any subject connected with bee-culture. I am only a beginner myself, in the investigation and pursuit of scientific bee-culture, and would much rather this subject had been assigned to some one riper in judgment and older in experience.

We will assume that our would-be beginner is naturally qualified for the occupation of an apiarist and is desirous of entering upon it as a life work. My first advice to you would be to procure a good text-book on bee-culture and subscribe at once for as many of the leading bee-journals as the state of your exchequer will permit. Do this right away, and study them until next spring. That will enable you to master thoroughly the theory of modern bee-keeping,

queen rearing, grading and marketing honey, etc. What you now lack is the practical experience, and that is, by long odds, the biggest and hardest lesson you will have to learn. The best way to gain this experience is to apprentice yourself to some practical apiarist. Learn all that he can teach you, and when competent to manage an apiary alone you can begin to think about embarking in the business upon your own account.

On the other hand, if you desire to enter into the business at once for yourself, after having spent the winter in study and preparation, at the beginning of spring purchase not to exceed five or six colonies of bees. Be sure they are Italian bees and that they are in movable comb hives and on standard Hoffman-Langstroth frames. Read your books and journals and manage your bees according to the directions they will give you. In all cases do all the work yourself. Seek the advice, if you like, of older bee-keepers, but do not employ them to do any of the work for you. You need the experience, and you may be certain that you can not get it vicariously, or in the sweat of some other man's brow. Follow the beaten path that has led others to success. When you have made a success along that line, there will be time enough then for you to diverge in search of other and better methods.

Perhaps I should be more specific. I would advise you to produce comb honey. This year and for several years past extracted honey has ruled low in price, and the tendency is for it to go still lower. Comb honey finds a readier sale, is more profitable, and requires less work to produce. I would recommend that you use the 8-frame hive with the standard 24-pound super, using scalloped $4\frac{1}{4} \times 4\frac{1}{4}$ sections. Unless you are a good mechanic and have some machine tools, it will hardly pay you to make your own hives. Better buy them anyhow for a year or two, and in all cases buy your inside hive furniture. Home made frames and section-holders are more of a nuisance than you will be able to realize until you have stocked your apiary with them.

Procure at the outset a good strain of Italian bees, or, better still, purchase them of some successful apiarist of your acquaintance, as he will be pretty apt to have good stock. Pay no attention to flaming advertisements of long-tongued queens, superior stock, etc., until you have made a success with the common stock. The so-called superior stock doubtless possesses merit, but it will not pay for you to bother with it until you have at least mastered the common branches of apiculture.

Your half-dozen colonies will increase just about as fast as it will be safe for you to enlarge your operations. One thing, especially, you must guard against is your enthusiasm. That will rise like an ocean tide at the harvest of your first crop of honey, and you will want to buy all of your neighbors' bees and then some more; but don't do it. You will reap disaster if you do. Grow into it, and you will come out all right.

And, lastly, I want to advise you, as your first duty, to join your State bee-keepers' association; and when your honey crop becomes too large to dispose of at home, join the Honey-Producers' Association and market your honey co-operatively through that channel.

I want to impress upon you the advantage and necessity of co-operating with your fellow bee-keepers in every possible way. Bee-keepers must co-operate with each other in every way that can revert to their mutual advantage, or get left. That is the naked truth of the matter, tersely stated. Co-operation is the great fact of the Twentieth Century. It is the beginning of a better, juster, and more Christian civilization. It behooves us as bee-keepers to fall in line, and thus be in accord with the spirit of the New Time.

H. C. MOREHOUSE.

Mr Devinney—It is one thing to join the Association, and another to attend. I think the attendance is more important than the joining. I object to advising beginners to start with the 8-frame hive. That size requires particular attention to make it a success.

H. Rauchfuss—Why advise beginners to buy Italian bees?

Mr. Morehouse—Because for all purposes they are the best race of bees.

H. Rauchfuss—My experience is that the Italians are the crossst bees, especially those with four or five bands. I advise Carniolans.

Mr. Lytle—I object to the advice to buy bees without regard to the stock bought. I should not want my neighbors to buy worse stock than I have. I don't want to be served

as I have been by the importation of inferior stock. It is a nuisance and a serious menace. Get an expert to buy for you. At the same time, I think a man in the business is a chump to sell good stock. Superior stock counts as much in bees as in horses and cattle.

Levi Booth—If all bee-keepers were like you, where would beginners buy?

Mr. Lytle—There are persons who make a business of selling good stock. I do not.

Mr. Gill—We have a very good strain of bees in Colorado. Many of our bee-keepers have bought queens of the best stock. Beginners would do just as well to buy at home.

F. H. C. Krueger—I think the paper an excellent one. As your stock increases, get knowledge. I commenced many years ago in a small way. I think I was the first to write to the American Bee Journal that there are sometimes two queens in a hive. Start small; feel your way along; then make a business of it. If you want to farm and take care of bees, too, you can not make it a success.

D. A. McLean—If nobody must commence the bee-business unless he makes it an entire occupation, and yet must commence with a few colonies, how is he going to live? It is not right to say no one must keep bees unless he does not make it a side-issue. Two-thirds of the members present make bees a side-issue, and yet are good bee-keepers, and I know some who make money out of it as a side-issue.

Mr. Harris—I think the paper an excellent one. We all make errors. I would say, don't rush in and think you are going to make money. Work carefully. Experiment. Then enlarge. I think we should always lend a helping hand to those starting in.

B. F. Hastings—I think it well enough to tell our ideas to those already in the business; but to have a lot more jumping into the same occupation is not good business.

W. L. Hawley—I think it is a good paper. I don't care how much book-learning you have; without practical experience it comes to nothing. The advice to beginners always ought to be, Attach yourself to a practical man.

A Good Honey-House.

With the assignment of this topic came a note saying it was desired to embrace a combined workshop and honey-house to be constructed at moderate cost. This last requirement carries limitations not always easily overcome.

If the bee-keeper is expert with tools, as all should be, one large item of cost can be saved; but if he is not, it is simply a question of cost of materials and labor. Of the materials costing the least, good adobes, well laid and plastered outside and in, furnish a thoroughly serviceable building, and in many ways desirable. Grout and concrete are also good and not very expensive to make. Still, I suppose, wood will be used in the greater number of cases, and therefore I shall speak more fully of it as a material for such purposes.

My experience does not cause me to look with much favor upon makeshifts. It is better to avoid them where possible, as they are the dearest in the long run; and few can plan out really good devices of that character. Instead, use good materials, exact workmanship, and then care well for the structure.

I will not try to outline a plan and specifications for such a building in this article, because conditions may demand variations and individuality be a controlling factor, but rather note the things which, to me, seem necessary in all such buildings.

And, first, make a good foundation, either of stone, concrete, or brick, so carefully built that not a crack or crevice remains to allow the entrance of any pest. The floor joists should be made straight or slightly crowned, and be built into the foundation wall, which should be carried up flush with the top of these joists. The upper ends of the joists should be notched to receive a 2x4 sill flush with the upper edges of these joists and the outer line of the framework of the building; and upon this sill erect the frame of the building. I should have this frame of 2x4 lumber, machine dressed on all sides to size, the studding spaced to receive a super easily between them. Over all secure horizontally two layers of good building-paper, the inner one smooth calendered, well lapped, and inner edges pasted down snugly. Side up with good quality drop-siding, carried up flush with top edge of rafters. Cover over the paper on rafters with sheeting, and finish roof with a good grade of shingles. No cornice is needed. The rafters will project the same

as if a cornice was designed. The roof sheeting will extend over these projecting ends and at the ends of the building, giving sufficient cornice effect.

I can not impress upon you too forcibly the need of a good floor. It should be strong, firm, and of such lumber as will wear smooth, and should be covered as occasion requires with some good floor-dressing. Nothing will pay you so well as a floor that can readily be kept clean. In fact, I am convinced that where sections are cleaned or extracting done, a floor covered with sheet-metal well nailed down would be very desirable. If there is anything that to me seems more necessary than another in bee-keeping, it is cleanliness, and nothing more disgusting than the floors of some honey-houses. I would really not care to eat honey coming from such places.

I suppose you will want me to tell how much room I would want for, say, a 200-colony apiary. Well, a 12x14 foot work-room, an 8x12 foot extracting-room or section-cleaning room, and a 12x30 foot storage-room.

Of course you will have doors and windows and roof-peak ventilators screened and provided with bee-escapes to suit the needs of the building.

In presenting this paper, I do not feel that all has been said, but rather that it may be the basis of a discussion drawing forth from others the good features they have for years, perhaps, practiced.

T. LYTLE.

Mr. Thompson—Probably 49 out of 50 of those who build honey-houses make them too small. In this paper the dimensions given seem to be about right.

Mr. Foster—How may we get the room warm enough to keep the honey from candying?

Mr. Aikin—Those who handle large amounts of honey must protect themselves against fire. When I look at the size of the check when I have to pay insurance, it makes me feel that if I had to do it again, I should want a fire-proof house. The insurance bill would go a long way towards paying the extra cost. It is also important to facilitate labor and cut off extra labor. A few hours now and then in the course of years amounts to a large sum. The running expenses eat up the profits, not the permanent ones.

Mr. Lytle—It was required of me, in writing my paper, to describe a honey-house of moderate cost. Fire-proof structures are always very expensive.

Abnormal Swarming.

It seems to me that there is something like the irony of Fate in the fact that I have been chosen to write a paper on this subject—abnormal swarming. If there is one thing that I know less about than any other thing connected with the management of bees, I think it is how to control excessive swarming in a profitable and satisfactory manner.

Until last year I should very confidently have said that there would be no excessive swarming if bees were properly managed, and that swarming could be controlled by a proper use of half-depth Hoffman frames used with sections. Our method was to put on a super of those small extracting frames near the close of the season when we took off sections, letting the bees fill and keep them over winter. Just before alfalfa bloom, or when the bees began to get crowded, we raised the small super and put sections between it and the brood-chamber, being careful to have the queen below. The bees usually go to work at once in the sections and continue to work as long as the honey-flow continues. We seldom have more swarms than we want, and get good honey crops, while our neighbors have trouble in getting the bees started in sections and have excessive swarming as hot weather comes on.

Last year, however, was an exceptionally hot and dry season, and the honey-flow was scant and slow. The bees simply went crazy, and when I raised the extracting supers and put in the sections they just made the queen-cells on the brood in the upper story, and left without beginning on the sections at all. We began as usual, hiving swarms on starters in a new hive on the old stand, but usually the swarms would come out again the next day. Sometimes they would loaf in the hive two or three days, gnawing off the starters, but doing nothing else. Sometimes a little comb would be built, a few eggs deposited and queen-cells started, and the swarm would come out again.

We tried hiving on old combs and on full sheets of foundation, but got no better results than with starters. I exhausted my ingenuity, patience, and resources in trying to satisfy them. Near the end of the season I began killing every queen that came out the second time and giving her bees either a newly hatched queen or a frame of brood with

a good queen-cell the next day after the old queen was destroyed. This, I think, is the best plan, except for one disadvantage. I have found that in excessive swarming there is always a great deal of excitement among the bees, and that more than half of the young queens are lost before they begin to lay.

The next plan was to cage the old queen when she came out with the swarm, and keep her caged for a few days. Usually the bees will go to work when she is liberated—at least mine did—but to this day I can't say positively that caging the queen made them go to work. They may have been just ready to get over their swarming fit, and might have gone to work soon any way. I did not try that until late in the season; but if I ever have another experience like last year's I shall depend upon hiving swarms on starters on the old stand with a caged queen. In a small apiary I should kill old queens and give cells or newly-hatched queens, but in a large apiary the loss is too great, as not more than one in three of the young queens will get to laying.

We have all our bees in shade now, and believe that we shall have less trouble. My home apiary is in a nice grove, and last year when nearly all the other bees were crazy we had but little more than the usual swarming there. The apiary at the Kramer place was in sunshine most of the day, and we only had three colonies that did not swarm at all at that place, and all the rest of them swarmed from once to half a dozen times each. This year we have not had as many swarms as we wanted, but about the same amount of honey—a short crop in both cases.

I regret very much that I have so little to offer upon this subject, as I think it is a very important one, and would be pleased to help much more than I have been able to do.

MRS. A. J. BARBER.

Mr. Lytle—The paper is chiefly valuable as showing the probable reason of excessive swarming. The remedy is plainly pointed out in the same paper. My hives are covered with shade-boards, and I have no trouble with excessive swarming.

H. Rauehuss—I do not know how to prevent excessive swarming except with a special system. Shade will not prevent it.

Mr. Gill—I want my bees out in the sun. My bees do not swarm any worse in the sun than in the shade. If you get an abnormally scant flow, bees will swarm in the shade as well as in the sun. If you give ample ventilation the bees will do as well in the sun.

J. B. Adams—Part of my home apiary is in the shade, and 50 or 60 hives are in the sun. When it gets hot, I raise the covers of these.

Mr. Aikin—Heat is an important agency in producing the swarming fever, but there are other conditions. If the conditions are such that the bees commence gathering honey and keep straight on storing it in the super, it will surprise you how little swarming there will be.

Mr. Hawley—I run for extracted honey. I had excessive swarming one year—sometimes 10 or 12 to 15 swarms in the air at one time. The following year there was a heavy flow, and two bee-yards acted differently. I can draw no conclusions.

When to Produce Extracted Honey.

One of the first things to be considered in the production of comb or extracted honey is the market. To produce comb honey profitably when the market is distant, it must be handled in car-load quantities, or the local freight rates will take up a large part of the profits. This is not so necessary with extracted honey. But for the same returns on the capital invested, extracted honey must be produced in larger quantities, which requires a larger equipment and more extensive preparation.

For instance, when comb honey ranges in price from 12 to 15 cents, and extracted from 5 to 8 cents, the producer of extracted honey must have enough more colonies and enough better averages to make up the difference in price. This requires a larger outlay of capital, more time in getting the outfit established, and the ability to run the business on a larger scale.

If there is a home demand for extracted honey, or if one can be worked up, it may be profitable to produce it on a smaller scale. Often it can be profitably combined with comb-honey production.

If the first and last flows are dark honey, it would be well to have these extracted from special combs, while the white flow could be stored in sections. In this way the extracting

supers can be used to coax the bees into the supers early in the spring, and at the close of the flow put them on where sections would not be likely to be properly finished.

It seems probable that in the future, comb-honey production will surpass that of extracted honey. Imitations are so common, and the production of comb-honey is increasing so fast, that extracted honey is likely to give place largely to comb-honey as a table article. This will lead those who can produce a fine, white quality to become comb-honey producers, leaving those who produce the darker grades to supply the candy factories and bakeries.

At present, in our vicinity, it would be almost impossible to run for extracted honey profitably, on account of the prevalence of foul brood, which would be very likely to be spread broadcast over the yard by the changing of combs to different hives.

A. F. FOSTER.

Mr. Lytle—The time to produce extracted honey is when it pays to produce it. When to produce it exclusively is another question. In every yard it will pay to produce a certain amount of it. I have used a section of a Heddon hive at the beginning of the season for an extracting super. It relieves the brood-chamber of the excess honey.

I have thus taken 10 or 15 pounds when the scale again showed only 5 pounds, showing that quite a quantity had been moved up from below, thus giving the queen more room to lay. Then I put on foundation for comb honey later. It is a very slight cost and a great gain. If the colony is at all weak, the same reasons hold good; it gives the queen opportunity to lay freely until the colony becomes strong enough for comb honey. Each one should determine for himself what course to pursue according to the conditions.

Mr. Krueger—I don't agree that people will more and more like comb honey better than extracted. When I began selling extracted, I had hard work to sell it. But I did sell it. If we sell the people pure, unadulterated extracted honey, they will like it better than comb honey. This year I had less than enough to supply the demand. The smallest amount I sell is half a gallon. Under my present circumstances, I would not think of selling comb honey. If I had 100 colonies, I might run 50 for extracted and 50 for comb. I don't believe extracted is used less from year to year; I believe it is used more from year to year. Extracted honey when granulated is all right, but what are you going to do with comb honey when it candies?

The Interests of Isolated Bee-Keepers.

There are many bee-keepers in this State, I suppose, who, like myself, live in localities remote from towns and railroad lines, and therefore find little opportunity to exchange ideas on bee-topics with the bee-men of their county, and who are in a measure handicapped in conducting their business, from the buying of supplies to the marketing of their crops, because of this isolation. And possibly for the reason that I am a representative of this class it has become my privilege to state to this convention my ideas as to how our interests might be best served.

There can be little doubt that our condition admits of improvement, or that it would be improved could we but feel certain as to just what our best interests are, and then act accordingly. Most of us keep bees for profit, if not, indeed, as the sole means of income; and of course our aim is to produce large crops of honey at the least cost of production. Our next aim is to place it upon the market in such manner and at such a time as to command the very best prices at the least possible cost to us.

To accomplish these results we must endeavor to come into full possession of the latest and most approved methods of management, together with a complete understanding of what our market requires in the way of package and grading. And we must likewise seek to keep informed on the best figures obtainable, not alone on the honey which we have to sell, but also on all supplies which we may need for the season. In addition to this, we should keep our weather-eye trimmed on matters calling for legislation—such as the question of spraying, of foul-brood, of adulteration, and perhaps others, lest our indifference in this connection prove to be a source of serious consequences to us in time to come.

Such, then, are our requirements and our duties, if we are to achieve the greatest success financially; and anything which will aid us in obtaining desired information or necessary legislation must be regarded as furthering our very best interests.

Now, it will be noticed that the factors necessary to the success of isolated bee-keepers are essentially the same the State over, be it at Denver or at Grand Junction; and it

follows, therefore, that whatever affects our vital interests as bee-keepers in your section or my section will do the same in any section. In other words our interests are identical. They should be mutual. We should grasp the idea firmly, that our individual actions, isolated as we are, may affect bee-men all over the State, and that their acts in turn do even more certainly affect us. I believe the interests of isolated bee-keepers demand a general recognition of these facts. When we once learn to appreciate that we, in common with other bee-keepers of the State, have substantially the same subjects to master, the same difficulties to surmount, and the same dangers to guard against, then it will be easy to see the benefits which will come to us through organization.

Good bee-literature is undoubtedly invaluable to every one who keeps bees; but information which is elicited through the asking and answering of questions, and the exchanging of ideas upon the spot, can not be well gleaned from books or papers. Besides, knowledge so acquired usually "sticks" better than so-called book-knowledge.

Again, object-lessons, such, for instance, as the display of a lot of comb honey properly cased and graded as the market requires, would come within the province of a bee-keepers' meeting and, according to my ideas, would impart more real information on the matter of grading in one day than illustrations and descriptions could in a year. Let us not fail to consider fully the importance of the educational feature of such organization; for it must be remembered that it is at the point of production that bee-keepers will have to make their last stand when excessive demands are made upon them.

Organization offers to isolated bee-keepers possibilities of obtaining their supplies at reasonable prices. The price which we must pay for these hinges largely upon the quantity we can use. Quantity regulates the first cost, and it also determines the freight-rates. If we can order a car direct from the factory or from the manufacturer's agents, and then divide the same among us, we will be gainers thereby to the amount of at least one profit, plus reduced freight-rates. If you will take the time to figure it out, you will see that there is a considerable saving in it.

Through organization, and to my way of thinking, through that alone, can we hope to keep the price of honey somewhere near its true level. To those who have not experienced the helping influence of our State organization, I would say: Try for yourselves. Who in our ranks has not felt himself at sea regarding the market value of his product when the opportunity to sell has presented itself? Would you not have welcomed valuable information on the state of the honey crop and the honey market at such times? Or, would you not be pleased to think that your crop, together with the crops of your neighbors, could be handled for you to the very best advantage to yourselves at the least cost to each producer?

To many of us these are comparatively new ideas, and we can not be expected to lay aside our old methods at once; but this grand plan of organization will bear our careful investigation.

I have yet one other advantage to mention, which would be ours through organizing our forces thoroughly. It is in the matter of securing desirable legislation. Bee-men, like dairymen or stock-breeders, require helpful legislation. To secure the same, our legislators must be convinced by us that we actually need it, and that there are enough of us to make it worth while bothering, anyway. Should a single bee-keeper, or even a dozen, apply for the enactment of a certain law, the law in all probability would never be enacted. Should an organization of several hundred men back up the same application, we would probably receive what we asked for. If a law—let us say the law on spraying fruit-trees—is being violated, and some isolated bee-keeper enters complaint, he may or he may not make his voice heard. Very likely not. But let the organization of which he is a member take a hand in the case, and we may expect to see the wheels of justice begin to turn forthwith.

In every case where individual effort can be of avail, organized effort will effect more; and where individuals are helpless, there we may behold the power of organization. All bee-keepers need the help which a strong union is able to give, but none need it more than those who are laboring under the disadvantages of isolation.

Brethren, our interests certainly need attention. Let us take them under consideration.

Bee-Keeping as a Business—Good Advice.

BY C. P. DADANT.

"Does bee-keeping pay as a business? and would you advise a young man to go into it as such? Where can I get a practical knowledge of the business from an experienced man? My experience is limited to the care of a few colonies on the farm.—R. M. BLACK."

It is rather an unpleasant task to give advice to a young man as to what he should do. Much of the success of an individual depends upon his aptitudes, his tastes, his education, and men are not always found in the business which is best adapted to their inclinations. Many a poor mechanic might have made a good farmer, and many an unsuccessful farmer might have made a good business man, if only his opportunities had been different. So, in the question, "Does bee-keeping pay as a business?" the aptitudes of the man must be considered. But if the question is asked, "Can bee-keeping be made to pay as a business *if properly managed?*" the answer could be given in the affirmative by many successful bee-keepers.

Our location is not a very good one for bees, and yet we have often said that the average annual yield of a colony of bees has usually been with us about 50 pounds. The last ten years would probably somewhat lower this average, which had been more than made in the ten previous years, for the past few years have been very unfortunate, owing to the almost total absence of white clover in the pastures and roadsides in this part of the country. But this condition of affairs will certainly not last, unless there is a positive change in the climatic conditions of the Mississippi Valley, and a steady recrudescence of drouths, in which case not only the culture of bees but most other agricultural pursuits would suffer greatly.

I said that 50 pounds per colony would be a good average. This is counted as a low estimate by many apiarists living in favored regions. In many parts of Wisconsin, Michigan and New York, as well as in the new States, such as Colorado, the average of yield by colonies in the hands of progressive bee-keepers I believe to be above 50 pounds per colony. In California it is perhaps several times that amount, but the low price of honey there in good seasons would counterbalance the larger crops.

Counting on an average of 50 pounds, the net price of honey that is secured by the producers in an all-around business is certainly not less than 8 cents per pound, net of packages, cost of boxing, etc. This makes a probable profit of \$4 per colony, spring count.

This estimate is taken in a general way. It is impossible to make an absolutely reliable estimate of any farm crop, and the bees are not an exception to this. But if we take the reports of wheat acreage and number of bushels reported, we will come to a very fair knowledge of the entire crop of the wheat-producing farms, and, in the same way, the product of the bee is very nearly estimated.

A practical apiarist who makes bee-culture his business can easily take care of 200 colonies of bees in producing comb honey, and of twice that number, or more, in the production of extracted honey. And if he is wide awake, and does not manufacture his own hives, and manages to take a little cheap help at the opening of the season, he may be able to teach school during the winter, for five or six months, at least, during the time when the bees are not busy. An occasional Saturday will be sufficient to keep informed as to the condition of the apiary, whether wintered in the cellar or on the summer stands.

If the man "grows" with his business, the outlay need not be very great, as the original cost of a few colonies of bees and that of the empty hives is a very unimportant capital. An industrious man will rear his own queens, and may even rear some for sale. Then he may sell a few bees, a colony here and there. The careful saving of all the broken pieces of comb, burr-combs, drone-combs, and cappings, ought very nearly to pay for what comb foundation is needed. There are very few lines of business—except perhaps chicken raising—where so few implements are needed. But poultry-raising is not to be compared to bee-culture. The fowls need constant attention. They have

to be fed daily. The bees feed themselves, except in unfortunate cases.

And yet there are many drawbacks—winter losses, spring dwindling, wet seasons. Our grandfathers used to count the bee-moth among the drawbacks. We have outgrown that. But foul-brood seems to be more prevalent than formerly, though I must say that personally I have never seen a case of it. But the worst drawback of all comes from the possible neglect, or greediness, of the apiarist. Of all lines of stock-raising none requires more careful watching than bee-culture. "Know what is to be done, and do it in time," is the most important motto of a successful apiarist.

But if you do not love to care for little things—to go into details, to watch the bees at work and keep an eye on their actions; if, above all, you are afraid of your bees, and cannot find pleasure in opening a hive full of bees and taking it to pieces for examination or for show; if you do not care to read a bee-book and get informed on the exact habits of these toilers, you would best keep out of bee-keeping.

My advice to a beginner who wants to become practical would be to go slowly. If he can find a position with a bee-keeper, who can give him a season or two of practice, this would be of great value. But such positions are hard to find. If you have to gain your information on your own responsibility, have a dozen colonies, more or less, and try to increase their numbers by following the methods most recommended in the books. A few years will give you more information on how successful you can be with bees than could be imparted in a dozen articles on the subject.

Hamilton Co., Ill.

Those Interesting Questions, Again.

BY F. GREINER.

Contributing a mite to answering the interesting questions, as on page 69, I wish to say the following:

HONEY FROM CAPPINGS.

To remove honey, which will not run out, from the cappings, if it is desirable to use said honey for culinary purposes, about as good a way as I know of is to place the cappings containing the honey in a can and warm the mass by gentle heat, or better by placing the can with contents inside a larger can with some water in it, and then setting both on a hot stove. The wax will melt, the honey separate and go to the bottom; the latter will be but slightly impaired as to quality.

If the cappings are run through the solar wax-extractor, as Mr. Doolittle advises, the honey gained will usually not be of good color or flavor without the solar extractor was perfectly clean, and the sheet of iron in the bottom of it is tinned. A solar wax-extractor that has been used for the purpose intended is not fit any more to produce honey for the table. It is all right for feeding or for making vinegar. If wanted for vinegar-making I would prefer to soak the cappings in warm water and wash the honey out of them. This is the way I always treat cappings after being drained. A press could probably be used to squeeze this cheese dry, but ordinary ripe honey is too thick to be squeezed out of cappings by simple pressure.

PLACING COMBS IN THE EXTRACTOR.

On account of its stickiness and heavy body, honey can not be as perfectly extracted from a comb in horizontal position as when placed in vertical position, as in our present extractors. The principle would be all right. As an illustration: Take a glass in your hand filled with water. Whirl around on your heels. The water in the glass, pressing against its side, will come up and out of it and fly away from the central shaft—a perpendicular line through the heel and the head of the operator. If a small tube was substituted, open at the bottom and small enough so adhesion and atmospheric pressure would keep the water in the tube, the operation would force the water down and out. In other words, the liquid would have to go up in one case and down in the other. It would have to go in the direction where it finds no resistance. Theoretically, a honey-comb could be emptied when placed horizontally in the extractor, as the questioner proposes. The idea of constructing extractors on this principle is not at all a new one. I think the Roots have tested it.

If it was desirable to extract the honey in its raw state, before any of it was sealed over, it might be an

advantage to use that kind of an extractor. Whole supers could be placed into the extractor without loosening a wedge or touching a comb and the honey could be nearly all thrown out; it would not matter so much whether the honey did come out of the cells perfectly or not, as it would not be lost. However, this method would necessitate extracting the same supers every two, three or four days, and this would mean a great deal of work, freeing supers from bees, taking them to the honey-house and returning again so often. However, it is not desirable to extract unripe honey, and I think on this account the whole idea of constructing extractors on such a plan as the question proposes is impractical, and has no future.

CHOOSING A LOCATION FOR BEE-KEEPING.

As to choosing a location, from what I have seen and can learn, good locations for bee-keeping may be found in nearly all States. The difficulty will be to single them out without actually trying them. One cannot safely judge a location by one year's test, either. My home yard, for instance, gave me, in 1881, nearly 100 pounds of surplus comb-honey; in 1885 about 70 pounds. During the rest of the years the crop has seldom averaged over 30 pounds in a single year, and many a time only half of that. One would have been badly fooled to judge my location by the years 1881 and 1885; and if he had pitched his tent here, depending on bee-keeping for a living, he would not have much money in his pocket.

On the other hand, if he should have hit such a location as Mr. Doolittle has, or if he had his ability to make the bees "shell out" the honey like Doolittle's bees have done, he would not know what to do with all the money. He would have to be very liberal and extravagant indeed to spend it.

To illustrate further how difficult it is to select a good location, I want to say: My two out yards within 5 miles of my home yard—one of them lies in the same valley as home yard—average nearly double what the latter does (and put me in a position at least to live); I cannot understand why the yields in these out yards are so much higher, for the flora seems to be the same in all of them.

In Colorado and some other States it might be easier to select a location without making a mistake.

Ontario Co., N. Y.

The Mating of Queens in Confinement.

BY W. E. FLOWER.

I wish the bee-papers would devote a little more space to the matter of mating queens in confinement, as I firmly believe it to be the keynote to the whole problem of successful breeding of bees. It is useless to talk about breeding horses, cattle, sheep, swine, dogs and all other "mammals" in which the fetus is developed within the dam. Principles or rules which apply to them do not, cannot, and will not, apply to the hen or to the honey-bee, for the simple reason that there is no union of circulation between the egg and the hen. The egg is hermetically sealed and passes out, and the first pulsation in the heart of the chicken may take place a hundred miles away from the hen.

The same may be said of the bee—there is no union of circulation between the queen and the egg, but some rules that apply to the hen do not apply to the bee. A virgin pullet will lay, but her eggs will not hatch; a virgin queen will lay, and her eggs will hatch, but produce drones only; and in my humble opinion (mind I don't make the assertion, simply give it as my opinion), if these drones can be utilized they are destined to become a very potent factor in producing a strain of bees that will "git up an git," and gather in the honey. Parthenogenesis exists in the bee but not in horses, cattle, sheep, swine or poultry, hence it is a factor that must be taken into account when mating queens for certain results.

I have had nearly 40 years' experience in breeding thoroughbred fowls, and have had some prize-winners in your gone by. I believe in inbreeding to fix points and characteristics or types, and in careful and judicious selection of strong, healthy, vigorous breeding-stock to maintain vigor and stamina of the breed. Darwin says that the "progeny of a first cross always reverts to one or the other of the original ancestors;" hence when we introduce new blood into a strain of fowls we run the risk of getting a lot of scrubs, because all the faults that have existed in the parent stock

on both sides for generations past are bound to crop out in their progeny.

I believe this to be the case with bees, hence I want to be able to control the mating of my queens so that I may be able to practice inbreeding, and prevent undesirable crosses.

Some one once asked Abraham Lincoln how long a man's legs ought to be, and he replied, "They ought to be long enough to reach from his body to the ground." I don't take much stock in long-tongued bees; might as well choose a long-tongued woman for a good housekeeper.

Montgomery Co., Pa.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

THE COMPLETED SCORE-CARD.

The completed score-card on page 24 *still might* provoke objections on one or more points. I think there is sometimes seen bark-louse honey, too nauseous of flavor to be eaten at all, that would score high according to the card, if not actually take 100. No place in the whole eight items where good or bad taste could come in! Still, this blemish is more apparent than real. Honey that isn't *good*, very seldom gets offered for a prize. Very likely it's the best way practically not to require judges to cut into sections.

HONEY-VINEGAR VS. OTHER "VINEGARS."

Between the vile competition of "cost-nothing" pyroligneous acid and the honest competition of cider-vinegar, honey-vinegar droops, it seems. Rough in me to kick it when it's down—but truth and death seem to have scant respect for Marquis of Queensbury rules.

"The liquid thus obtained will not appear very clean." Page 25.

Yes, indeed; me believes *us*. Twentieth century will hardly get out before it will find the public saying they don't want to eat vinegar made from such dirty slop. May be the going-to-be public and myself are fussy. But say, melt the cappings, lift off the resulting cake (to be melted over again of course—for you'll be astonished to see how dirty it is) and use the black honey below for bee-feed. If you want honey-vinegar, take some clean, sound honey and make it.

KILLING YOUNG SWEET CLOVER.

Interesting to see that cutting, followed by a dry spell, does sometimes kill young sweet clover. Alas, that that "sometimes" fails so seldom when I want it to die in my strawberry patch!

OPTIMISM PROF. COOK'S "ISM."

Prof. Cook, you hardly needed to tell us that optimism was your "ism." I wonder if you have sufficiently meditated the evil of optimism right or wrong—always—through thick and thin. Pardon the suggestion. How sorely the world needs a few more persons who are neither optimists nor pessimists, but capable of seeing with clear, uncolored eyes both modest good and sneaking evil! Between the pull and the haul of the optimist and the pessimist it seems at times as if all mankind were being divided into two self-neutralizing parties. Nothing so bad but half mankind will excuse it; and nothing so good but t'other half will condemn it. O that young students, and young people everywhere who are in the formative period of life, might realize the importance of not making themselves *partisans* in this important matter! But we won't call Prof. Cook a *professional* optimist, eternally proud of his profession—not unless he commands us to. Page 27.

MELTOSE AND ITS MAKERS.

How pleasant it is (though oft a bit humiliating) to find people very much more reasonable than we smelt them to be! This anent meltose and its makers. Not the "cunning little feet" that gathered honey but the "cunning little thief." The words which stirred our dander were partly inadvertent, and the firm are willing to them. Do us no harm to be civil on our side. On careful and repeated

tastings of meltose—while not falling head and ears in love with it—I gave up a previous bad opinion. Had guessed it was best commercial glucose sweetened up with something. It appears to be a thing of itself, and tolerably good. Presumably safe for invalids, which honey usually is, but sometimes is not. Not seductive enough, either in look or taste, to travel very far outside of the clientage of the health-food establishments—and so not likely to do us any harm whatever. Pages 28 and 67.

FEEDING BEES IN THE OPEN AIR.

If you wanted to feed 100 colonies in the open air the chances are you would be "all at sea" about the minimum of feeding space required. Glad to see so competent authority as the Atchleys on record that 10 feet by 18 inches will do. Page 31.

THE QUEEN'S STING AND THE LAMB'S TAIL.

Mr. B. Hamlin-Harris, if the queen facilitates laying, by reciprocating her sting, may not the wagging of the lamb's tail facilitate getting the milk? Page 35.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Moving Bees 20 Miles.

1. How can I move my bees 20 miles over a rough country road? I want them to be in their new home the first of June. The road is quite rough, and over three mountains. Can I haul them on a wagon on boards?

2. I would like to take them as early as I can. When is the best time, in warm or cold weather? Will it be safe to move them in this way? WEST VIRGINIA.

ANSWERS—1. Yes, fasten them in place so they cannot slide around, and they can be safely taken. Look up back numbers of this journal, especially within the past few weeks, and you will find some information on the subject.

2. In the spring, when it is neither too hot nor too cold, is the best time. If the weather is freezing, the combs are brittle and will break in hauling. If too warm there is danger of the bees smothering, and if ventilation is lacking the combs may be broken down because too soft.

Moved Bees Uneasy in the Cellar.

What should I do with my bees? I have had them in the cellar about 30 days, they having been expressed 120 miles by train. The temperature of the cellar is 38 degrees inside, and about 5 outside. The bees do not seem to rest easy, flying and crawling continually. The hives have a solid board on the bottom, and I have lifted the board a little on the top. I have the cellar perfectly dark, and the hives on 2x4 planks, and about 2 feet off the ground. There are about 200 dead bees lying around. ILLINOIS.

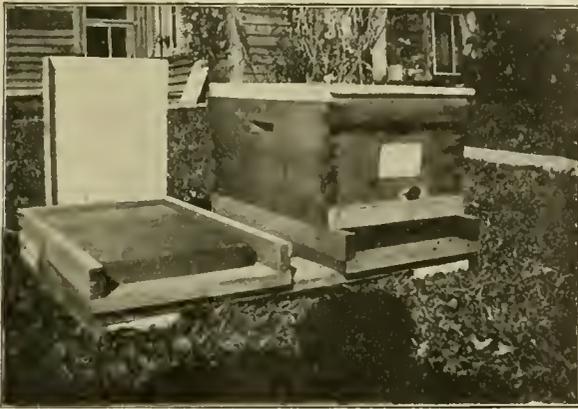

ANSWER.—It was expecting a good deal from the bees to give them a ride of 120 miles in the middle of winter, to put them directly in the cellar without flight, and then ask them to be good. The 20 dead bees in 30 days is a very small number if there are 50 colonies, and nothing to be alarmed about if there were only 200. I'm afraid there may be more dead bees on the floor of the hive. The thing for you to do is to do what you can in the matter of temperature and ventilation. If your thermometer is at all reliable, your cellar is too cold. If there are colonies enough to make it worth while, a coal-stove would be the thing to raise the temperature to 50 degrees or more, and then let it settle and stay at about 45 degrees. But don't use an oil-stove with nothing in the way of a chimney to carry out the smoke or gas. If you have only two or three colonies, you can help matters at least a little by taking into the cellar hot stones or jugs of boiling hot water *corked tight*. You can lay hot bricks on the covers of hives, or you can remove the covers and put old carpets or cloths of any kind over the

frames and then hot bricks on these. As to ventilation, it may be that it is all right, and it may not. If the air of the cellar smells foul and close, try to clear it up. Remove decaying vegetables if any are present. Open the inside door and let the air from upstairs go into the cellar. If you cannot do this in daylight because of the bees coming up, do it at night. It may be that opening an inside door will do all that is needed to bring up the temperature.

The Dr. Miller Hive Bottom-Board.

On page 70, Mr. Doolittle describes the Dr. Miller bottom-board, but his description hardly tallies with the picture there given. Which is right? And how is the bottom-board made? SUBSCRIBER.

ANSWER.—Mr. Doolittle is usually very careful to make no incorrect statements, and the present case is no exception. Mr. Doolittle describes the bottom-board as I used it for years, and it is no little gratification to me to know that a man of such experience and judgment has given it his approval. The reversible feature was the valuable thing about it, allowing a deep space in winter and as shallow one in summer. The reversing necessitated lifting the hive every time, which I consider a small cost for the advantage. But I thought it would be better if I could change to the shallower space in summer

without the lifting. So I devised a false bottom to fill up the space in summer, making the expense more and the labor less.

In the picture you see at the left a bottom-board with the false bottom in it, ready for summer use. For winter all that is necessary is to slide out the false bottom, and you have the space two inches deep. Back of this bottom-board, standing up, is another false bottom, showing the under side, but the light upon it was so strong that at the right hand side there is nothing clearly defined about it.

Now, as to the making: The bottom board is a plain box 2 inches deep, and open at one end. It is made of six pieces of $\frac{7}{8}$ stuff; two pieces $22\frac{1}{2} \times 2$, one piece $12\frac{1}{2} \times 2$, and three pieces $13\frac{3}{4} \times 7\frac{1}{2}$. The outside dimensions of the false bottom are $18\frac{1}{4} \times 11 \times 1\frac{1}{2}$. It is constructed of two pieces $18\frac{1}{4} \times 1\frac{1}{4} \times \frac{1}{2}$, one piece $10 \times 1\frac{1}{4} \times \frac{1}{2}$, and two pieces $11 \times 9\frac{1}{8} \times \frac{1}{4}$. You see, it is made on the same general plan as the bottom-board, only smaller and much lighter. When in use, the closed end of the false bottom is toward the entrance.

While talking about the picture I may as well tell you a little more about it. The hive that you see has its entrance closed ready for hauling. A piece of wirecloth folded over the ends and bottom is placed against the entrance and held there by a piece of lath with a nail at each end, and usually another nail in the middle driven through the lath into the front of the hive. The stand on which the hive is placed carries double and is a very simple affair. It is made of common fence-boards 6 inches wide. Two pieces 32 inches long are nailed upon two other pieces or cleats 24 inches long. That's all. Of course the longer pieces are uppermost.

Sticking Comb to Separators—8 or 10 Frames.

1. I had some trouble about the bees sticking honey to the slat separators. What is the reason? I believe I left it on too long; still, that ought not to make much difference, or else they did not have room to store it.

2. Which do you think will be the best to use, the 10-frame or the 8-frame hive? Of course there will be more bees and larger swarms in the 10-frame, and it will take more to feed them through the winter, but I thought they would winter better, the larger body together. What is your experience? INDIANA.

ANSWERS.—1. Being too much crowded may have caused the bees to build the sections to the separators. Sometimes, however, they do it without being too much crowded, and I hardly know why.

2. Your own experience in the matter is a great deal, and if you found 10-frame hives best, stick to them. They certainly do not require so close watching for safe wintering as do the 8-frame hives.

New Swarm Rearing a Queen.

When a colony swarms, if I catch the queen and kill her, and give the swarm a frame of young brood and eggs from a select queen, will they rear a queen? ILLINOIS.

ANSWER.—I don't know. If you should kill the queen immediately upon hiving the swarm or before hiving it, there would be a probability that the swarm would desert the brood and return to the old hive. If it was a second swarm there might be more than one queen. If, however, you should wait perhaps 24 hours before removing the queen, you would have a pretty sure thing of it. But if you try the plan it is not very likely you will follow it up, for the colony will be badly reduced before any new "fielders" appear on the scene.

Preparing Bees for Moving, Etc.

1. My brother and I have 65 colonies to move about the first of March. We would like to have your advice as to the best way to prepare them to move.

We will move them to northeast Missouri. Is that a good country for bees? IOWA.

ANSWERS.—1. Specific instructions for preparation can hardly be given without knowing just what kind of hives you have. You will, however, besides the information you can get in your text-book, get some instructions from answers given in this department in late numbers. It may be repeated here, that the chief thing is to have the bees securely fastened in the hives with provision for abundant ventilation, by having top of the hive covered with wire-cloth or otherwise, and then to have the hives firmly fastened so they cannot move about in hauling, with the frames running parallel with the rails on a railroad, and parallel with the axles on a wagon.

2. I don't know about the particular localities in that region.

Filling T Supers with Sections.

I see you speak of filling supers with empty sections and then putting in the T tins. I fasten the T tins to the bottom of the super. Is that the best way? OHIO.

ANSWER.—I prefer to have the T tins loose, for the sake of having it easier to take out the sections. The super is reversed and the contents pushed out, T tins and all. Then it is an easy thing to lift the tins from their places, after which the sections can be separated. But "filling supers and then putting in the T tins" hardly gives the right impression, for it might be understood that the 24 sections were put in the super and then the T tins were put in, which would be impossible. The first row of sections is put in one end of the super, then a T tin is slipped under this first row of sections, and a T tin is in like manner put under the second and third row. In filling the super it is not left on an exactly flat surface, but little strips are bailed to the surface in such a way as to raise the sections an eighth or a quarter of an inch, which gives plenty of room to slip the T tin under the sections. Then when the super is lifted from the board the sections settle down in their places.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Our New Catalog,

describing and listing the finest line of **BEE-KEEPERS' SUPPLIES** in the world, is ready. If you have not been receiving a copy annually, send us your name and address and one will be mailed you **FREE**

Bees Wintering Nicely.

I have 85 colonies of bees, and put them in the winter house Nov. 27; they were in good condition. I think they are wintering nicely. I got about 1/3 of a crop of honey last season. Scott Co., Iowa, Feb. 7. **E. R. WRIGHT.**

A Profitable Pleasure.

I keep only a few colonies of bees, more for pleasure than anything else, and to pay me for the good time I had with them last summer they gave me 1,000 pounds of fine honey (comb and extracted). This was from 13 colonies, spring count, with an increase to 22, that are now in the cellar in good condition. The American Bee Journal is all right, and I am not afraid to promise that as long as I keep bees I will have the Bee Journal also, because I am sure I could not get along without it and keep bees. So you can be sure it is a welcome visitor to me every time.
C. E. LEMON.

Chisago Co., Minn., Feb. 7.

For the Type-Setting Machine.

Here goes a dollar for 1902, and as soon as that type-setting machine is ready I will send another, or more, if needed. It is a blank proposition, and, commencing at the "Foot" of the ladder, let us, like the Irishman, average up until the machine is a reality. Brother bee-keepers, the bugle sounds. Fall in line!
GEO. FERGUSON.
Rock Island Co., Ill.

Bee Books and Papers.

The advice to the bee-keeper who cannot afford to buy a text-book and at the same time subscribe for a bee-paper (page 83) is all wrong, in my experience. I have read all the apian text-books published in America, and, if I had to do without all the text-books, or have one bee-paper, I would take the paper; but I would want to select the paper. A bee-keeper who cannot afford one good book, and a bee-paper besides, is indeed a very poor bee-keeper in more ways than one.
M. D. ANDES.

Sullivan Co., Tenn., Feb. 7.

An Experience with Bees.

My bees did fairly well last season, 20 colonies averaging about 40 pounds each, all housed in winter-cases with 35 pounds of stores each. For the past 4 years I have been quite studious in bee-keeping, reading text-books and bee-papers as well. Though unlike most others in the beginning, it was not the love I had for the bees—more selfish, perhaps. Four years ago I visited my brother John, living in Maryland. I was suffering terribly with rheumatism, and had been suffering for years with paralysis in my right leg. Well, I complained so much my brother said (laughingly), get some bees. Speaking more seriously, I concluded it could do no harm, if I could endure the stings. "Well," said he, "there is something to learn about bees that you may not enjoy—bee-culture has recently become a science; you

ELECTRIC Handy Farm Wagons

make the work easier for both the man and team. The tires being wide they do not cut into the ground; the labor of loading is reduced many times, because of the short lift. They are equipped with our famous Electric Steel Wheels, either straight or stagger spokes. Wheels any height from 24 to 60 inches. White hickory axles, steel hounds. Guaranteed to carry 4000 lbs. Why not get started right by putting in one of these wagons. We make our steel wheels to fit any wagon. Write for the catalog. It is free. ELECTRIC WHEEL CO., BOX 16, QUINCY, ILL.

must read and think, to become proficient." He reached up and took down an old, greasy "Manual" written by Prof. A. J. Cook in 1876. He then handed me another "Manual of the Apiary," scientific. Well, that called me back to when I was persuaded by our old medicine man to study medicine. I was in my sixth year, the Doctor was 56; he searched around and found an old Comley's spelling book, and turned to the word "baker." I could only master one syllable. He said, "My good boy, you will make a doctor but you must follow instructions." In the past four years I have been following instructions pretty well; however, with the hundreds of stings received I have become immune to the sting.

I want to say right here that I believe that one man can handle bees as well as another (all things being equal) or, in other words, I do not think bees know their keeper from any other person. I have frequent demonstrations to convince me of that fact. You must know your bees, and not your bees know you; there is no mystery about that.

Every farmer could keep 2 or more colonies profitably in frame hives; box-hives and black bees will soon be a thing of the past. I have the 8-frame Simplicity hive, and Italian bees. I hope soon to present you with a picture of my apiary.

I desire to say, briefly, that since I have been so infatuated with apiculture, the fever has raged so incessantly that it has crowded out all symptoms of rheumatism. Now, I do not want to be misunderstood; I do not say it was bee-stings or enthusiasm; I do say it must have been one or the other. Daviess Co., Ky., Jan. 4. J. M. HALL.

Report of the Past Season.

The honey crop from my bees last season was far from promising on white clover, and a total failure on sweet clover and buckwheat. I got only 600 pounds of salable honey from 35 colonies. We will hope for a better crop this year. CHAS. LUEBKE.

Rock Co., Wis., Feb. 3.

Snow-Storm in New York.

We are having a terrible snow-storm to-day; the roads will be impassible to-morrow, I expect. Our bees in the cellar seem to be in good shape.

The State (N. Y.) Bee-Keepers' society is to meet tomorrow, but I don't see any way of getting to Geneva, only 30 miles away, so I will have to stay at home. F. GREINER.

Ontario Co., N. Y., Feb. 2.

P. S.—The snow-storm raging Sunday continued until Monday night. Our roads are blockaded; we received no mail, and none went out.

Wintering All Right.

We have had very cold weather the last month, but the bees are wintering all right, as far as I have been able to tell. I have been experimenting some with out-of-door wintering, and they are all right yet.

I cannot get along with my bees without the "Old Reliable;" I read it every week. A. W. ATRERSON.

Jasper Co., Mo., Feb. 8.

Wintering Well—A Good Swarm.

The bees are, as usual, wintering comfortably on their summer-stands. Since the introduction of the tight-frame hive into the apiary, uniform success and most gratifying results have been obtained.

The honey-yield last season was abundant. I had one prime swarm, which issued from a 32-frame hive. It was hived on 16 frames, a number of which were wired, and had the least sign of a starter. Those that the bees wanted for brood they built up with worker-cells, but those they reserved for honey they built up in drone-cells; a super was also added at the same time, which they filled in about

To make cows pay, use Sharples Cream Separators. Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

Low Rates to the Northwest.

Beginning March 1st, and every day thereafter during the months of March and April, 1912, the Great Northern Railway will sell one-way second-class settlers' tickets at very low rates to almost all points on its main line west of St. Paul and Minneapolis. Low rates will also be made in connection with the Great Northern, from Chicago.

The rate from St. Paul, Minneapolis and other Eastern terminals, to Montana points is from \$15 to \$20; to points in Washington, \$22.50 to \$25. The rates from Chicago to Montana points is from \$25 to \$30, and the highest rate to points in Washington is \$33. Equally low rates will be made to other stations reached by the Great Northern Railway and its connections.

The journey must begin on the day of sale of ticket, and tickets will be good for stop-over ten days or less at points on the Great Northern Railway west of and including Harve, Mont.

This is the best opportunity that has ever been offered to parties who wish to investigate the many advantages offered them in the great Northwest. Information about Great Northern country is given by the Agent of Great Northern Railway, or those desirous of ascertaining just what opportunities are offered there can secure full information in reference to land, climate, crops, etc., by writing to Max Bass, G. I. A., 220 S. Clark St., Chicago, or to F. I. Whitney, G. P. & T. A. Great Northern Railway, St. Paul, Minn.

J. R. Watkins

THIS IS J. R. WATKINS,

the president and founder of the J. R. Watkins Medical Company, Winona, Minn., U. S. A., the proprietors of the world famous

Watkins' Remedies.

You will find this picture of Mr. Watkins and his signature as above on every label, wrapper, carton and package of Watkins' Remedies. It is the trade mark—the stamp which marks the genuine from the spurious and worthless. Some unscrupulous men will attempt to sell you other preparations for the genuine Watkins' Remedies. They will declare that others, which they are trying to sell, are "just as good" as Watkins' Remedies. In order that you may not be deceived we put on the picture and this signature to protect you from fraud. Always insist upon the genuine, with the portrait and signature of J. R. Watkins, as above. Take no others, for no others are so good as the original and only Watkins' Remedies.

Free! Free! Free!

We mail free to any address "Watkins' Home Doctor," an illustrated book of 100 pages, the finest of the kind ever printed, containing much valuable information, interesting, instructive and humorous reading matter, astronomical calculations, weather forecasts, first-class cooking recipes, and matter relating to farm and home; in short, something for every member of the family, old or young.

Almost a Lifetime—If one were to count the manufacturers who have been in business continuously for a generation they would be found comparatively few in number, and yet among them would be that old and well known house, the Elkhart Carriage & Harness Manufacturing Company, of Elkhart, Ind., whose ad appears in this issue. This concern has been in business for twenty-nine years and during all that time has been selling direct to the consumer at lower prices than many factories charge dealers. The great saving effected by dealing with this advertiser is at once apparent. Their line of vehicles and harness is larger than ever. It embraces many patterns shown at the Pan-American Exposition, where the Elkhart people not only exhibited against some factories noted for their high prices but carried off honors, too. Their new catalog presents the complete line, and a copy will be sent free to any one who mentions this paper in writing. Address, Elkhart Carriage & Harness Manufacturing Company, Elkhart, Ind., and please mention the American Bee Journal when writing.

three days. What seems to be noteworthy about this swarm is, that the queen was reared late in the fall, in an observation hive in which she passed the winter on the summer stand. The hive was wrapped in a heavy woolen blanket, but they breathed the air as it came along, which was at times about 20 degrees below zero. However, they came through the winter in good shape, but were set out under the trees too early, and many died from the effects of cold, as the space between the glass was only $1\frac{1}{2}$ inches, and the height sufficient to admit three frames.

Wishing to give this young queen a fair chance, I put her together with her bees and brood, into a hive, and added 13 frames containing some stores, and set this hive in the place of another. Being thus encouraged and assisted by the additional force of field-bees, she was able, some time in July, to lead out the large swarm as above noted.

B. J. CHRYSOSTOM.

St. Joseph Co., Ind., Jan. 17.

A Report—Golden Italians.

The bee season of the past summer was very good here, the bees doing very well. Mine averaged 40 pounds to the colony. The honey was as clear as any I ever saw. I took some off that I could hold up to the light and see clear through it. I could put my hand a little way off on the other side of a section and could look through and see it. The honey has a fine body to it. I left it on the hives, and that was what gave it the body; it was "boiled down" more.

I have transferred a good many bees for other people, besides my own, and I have come across all kinds of gums and boxes, of all sizes and shapes, and my experience is that the 10-frame would be better.

I have tried the golden Italians but they do not winter well, as far as I know anything about them; and in view of what others say who have tried them, they do not stand the winter as well as the hybrids.

I enjoy reading in the Journal what people in other States have to say about bees and the honey crop.

CHARLES ELLIS.

Newton Co., Ind., Jan. 28.

Winter in Texas.

My bees are all doing well so far this winter, and I hope all will come out "right side up" in the spring.

We have been having some of the coldest and most disagreeable weather the past two weeks that I have ever seen in Texas, and I have been here 32 years.

R. P. DAVIES, M. D.

Lamar Co., Texas, Feb. 9.

Condition of Bees in Winter.

We are having a pretty steady, cold winter here this time, with frequent, high winds which often drift too much of the "beautiful" into my apiary and causes me to have to clear the snow away from the hive-entrances of all colonies oftener than I have had to do in other winters.

Bees keep quieter, remain clustered longer, consume less stores, and come into spring in much better condition when the snow is kept away from the hive-entrance of every colony in winter.

I tipped up the front of every hive on Feb. 6, and brushed off the few dead bees that were on the bottom-boards, and never found so few dead bees under the hive at this date. With division-boards I crowded the bees of every colony on from 5 to 6 combs of capped stores of the best quality, and then packed 4 inches of forest leaves at the sides, front, back and top, the same as I have done for many years.

Wm. McEvoy.

Ontario, Canada, Feb. 10.

Bees Can Hear—Illustration.

In the Bee Journal of Jan. 16, page 42, I see the question, "Can bees hear?" Now, I think they can. About 36 years ago I started in the bee-business in Thisted, Denmark. I had the German and Scandinavian bee-papers,

50 Egg Size \$5. Please mention Bee Journal when writing.

and one day I saw an item in the paper, of a man having his bees follow him at his wish, by whistling. He covered his hands with honey and went to the bee-hives and whistled the song "So leben wir, so leben wir, so leben wir alle tage, bei der allesehonsten sauf compagni," etc.; a German tune, always the tune. The bees, smelling the honey, came and cleaned his hands off. The next day he went a little further away and tried the same experiment and the result was the same—the bees ate all the honey but did not harm the man, and in time he could call them far away.

Then I tried the same experiment. I had a garden-house, or summer-house, and in a few days I could call the bees into the house by the thousand at a distance of a block. One fine afternoon I invited a party of friends (consisting mostly of ladies) to afternoon coffee in the summer-house, and, when my table was complete, I told them I expected some more friends, and, stepping to the door I whistled, and in less than a minute the room was full of bees. The ladies were so frightened that they all jumped up, and the result was that I had all the coffee for myself. So, surely, I think bees can hear.

Cook Co., Ill. JOHN P. TONNER.

Our Advertisers.—We do not make a practice of devoting much space in our reading columns to our advertisers. We take pains, before allowing them to buy space of us, to find out that they are considered reliable, and after they have used our space for some time we get to know, through our readers, something of their product and of the manufacturer, breeder or advertiser himself.

Many a person or company has advertised with us for two or three months, then dropped out and was never heard of again; while others commenced modestly—have an article of merit to start with, find a general demand for it, it fills the bill, year after year the article is improved by their experience, it is sold reasonably—and continue with us without interruption.

It is always safe to patronize this class of advertisers. You are pretty sure of a fair deal, because they cannot afford to do otherwise.

An instance: The Page Woven Wire Fence Co., of Adrian, Mich., have used our columns continuously for years; they have established themselves in the confidence of our readers, and they could never have done so if there had not been real merit in their fences. Their business has doubled up year after year, until (we are credibly informed) they use the entire output of wire of their extensive steel mill, at Monessen, Pa., in their own fences.

They do not claim to sell fences the cheapest but they do claim that since they make their own steel and wire they have a wire especially adapted for fencing purposes, and one that will sustain the special features in Page Fences.

WANTED Partner, with capital, to keep bees on large scale in honey locality never known to fail; close to good market, thus insuring good returns on the investment. To associate with party of 20 years' experience. Reference, Editor American Bee Journal, for character, ability, etc. Address, BEE-KEEPER, 622 Colorado Ave., Chicago, Ill.

Send for circulars regarding the oldest and most improved and original Bingham Bee-Smoker FOR 23 YEARS THE BEST ON EARTH. 25Atf T. F. BINGHAM, Farwell, Mich.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well if they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 98.

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you."—Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30) I never found these bees to show the least indication of anrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

Out of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chilly winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, Ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italian and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

1902—Bee-Keepers' Supplies!

We can furnish you with The A. I. Root Co's goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for beeswax. Send for our 1902 catalog. M. H. HUNT & SON, Bell Branch, Wayne Co., Mich

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey-jars.

Pumps and Spraying Machines.

We have received from the Deming Co., of Salem, O., one of their new catalogs of pumps and spraying machinery, which ought to be in the hands of every farmer, fruit-grower, and market gardener. The Deming people are among the oldest manufacturers of these goods in the country, and their line is most complete, embracing all approved patterns of bucket, knap-sack and barrel sprayers; also field and power sprayers. The adaptation of these devices in recent years to painting and whitewashing has materially enlarged their scope and usefulness. The book contains a very convenient spraying calendar; also directions for preparing and using various mixtures, all of which add to its practical value. The Deming people publish a special edition of "Spraying for Profit," which they sell at 10 cents, and give a copy free with every pump they sell. Those who are in the market for spraying machinery for the coming season will do well to correspond with the Deming Company, whose factory and main office is at Salem, Ohio. In corresponding, mention the American Bee Journal.

Do You Produce Comb Honey?

Here is something that will interest you.

"The Danzenbaker Hive I think will take precedence over all others. I am delighted with it, as it is simple, and easily manipulated."

R. H. PEPWORTH,

Pietermaritzburg, Natal, South Africa.

Nov. 30, 1901.

If you buy the Danz. hive you will find a ready market for your honey. Comb honey in Danz. sections has never yet been held because of "little demand."

EXTRACTED HONEY!

You will need good hives, smokers, knives, and most of all, a good honey-extractor. Root's Cowan Rapid Reversible Extractors are used everywhere, and always acknowledged to be the best. Be sure to get one of our make.

BEESWAX?

You should have the best wax-extractors, else large quantities of wax will be left in the refuse. See what one extensive and practical bee-keeper says of the ROOT-GERMAN STEAM WAX-PRESS:

For over 20 years past I have had to render up old combs or cappings in larger or smaller quantities, and my experience has been extensive, for I have tried faithfully almost every known method to get all the wax out, but have never succeeded to my satisfaction until recently. I got of you a German wax-press, that comes nearer accomplishing that object than any thing I have ever tried. I am more than satisfied with it, for, if used according to directions, there is little if any wax left in the refuse. Any one used to the old methods will be astonished at the results obtained. In this press you have given those in need of it the best thing, to my mind, you have ever brought out, and I really believe all who try it will pronounce it a real treasure. There are other points of advantage that I could mention, one of which is its perfect safety—no boiling over and setting fire to every thing, and it can be left alone without care for quite a time, and every thing can be kept neat and clean, and it occupies very little room. E. T. FLANAGAN. Belleville, Ill., Dec. 12.

Root's goods are for sale everywhere. See list of jobbers and agents in the January bee-journals. A full list of local agents sent you on request. We will also send you a little book, "Facts About Bees," describing the Danz. hive, and our catalog, on request.

WANTED.—Beeswax. Price, 28c cash or 30c in trade for pure average beeswax, delivered here. We want also a car of white sage extracted honey, also large lots of WHITE COMB HONEY in DANZ. sections.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

A BEE-KEEPING HOG is the title Editor Root gives the man who will locate himself upon territory already fully occupied by others. Ugh! Ugh!

EDITOR E. R. ROOT does not compare with his father as a hobby-rider. Still, he is something of an equestrian in that line. Just now the hobby he has mounted is that of pure air and plenty of it for bees in winter. Not a very unsafe hobby.

C. P. Dadant has had put upon him the honor of being made one of the regular collaborators of *Revue Internationale*. "Our Camille" knows a lot of things about bees, and knows how to tell what he knows—probably better even in French than in English.

"THE COW PEA" is the title of the latest publication issued by the Experiment Farm of North Carolina State Horticultural Society at Southern Pines, N. C. This book, neatly bound, and illustrated in plain and concise manner, discusses the value and uses of this important crop—the cow pea. Every reader can get a copy free by writing to the Superintendent of Experiment Farm, Southern Pines, N. C.

FRANK BENTON, formerly Assistant Entomologist at Washington, has been advanced to the post of Apicultural Investigator in the Department of Agriculture. The creation of this special commission is one of great interest to bee-keepers, and it is a matter of no little pleasure to know that they are thus recognized by the United States Government. And Mr. Benton is well qualified for the position.

A \$100 OFFER.—Judge E. Y. Terrall, in the Lone Star Apiarist, made the following offer:

After a research and study for a lifetime, I have failed to master the little honey-bee. I will give 12 months' time and \$100 to any one who knows all about bees to answer two questions that are of great importance to the apiarist, viz:

1. How "successfully" to fertilize queens in confinement.
2. How to distinguish laying workers from other bees.

Cunning Judge Terrall has a string to that \$100. When the claimant comes with his answer to his two questions, the judge will say to him: "Do you know all about bees?" and the man who knows enough to answer those two questions will know and confess that he has some things to learn. Then the judge will say, "My dear sir, do you not notice that my offer is only 'to any one who knows all about bees?'"

A BEE-HOUSE OF F. R. WEBSTER is presented on the first page. When sending the picture he wrote as follows:

I send a picture of one of my bee-houses, which is 50 feet in length and 7 feet wide, double deck, with a walk back of the hives $3\frac{1}{2}$ feet wide. It will be observed by looking

closely that only half the hives show plainly, as part are painted red and part of them white; the red ones show very dimly, however.

The house contains 29 colonies, mostly in hives of my own make, with half-lock corners, glued and nailed both ways, and I have yet to find one that has even started at the corners.

I make these hives the same size as the dove-tailed hive, and use the Hoffman frame, preferring it to any other, by experience. The cover to the hives I made is smaller than the cover of the *Simplicity* hive, only I rabbet the bottom edges $\frac{3}{4} \times \frac{3}{4}$, which fits over the body of the hive, preventing the entrance of bees or storm. I also use the super made after the style of shipping-case with glass in the side. The cover is easily raised at any time, allowing one to see at a glance how nearly completed the sections are. After trying several kinds I have concluded that my own make of hive is superior to any other.

F. R. WEBSTER.

NOMINATIONS FOR DIRECTORS.—Mr. P. H. Elwood says in *Gleanings in Bee-Culture*:

"In regard to making nominations for Directors before election, why not let well enough alone? Our Association is doing well; but as soon as nominations are made there will arise the suspicion that some one or some clique is trying to run it. Better put up with some minor evils or inconveniences than to have the camp divided."

That's one way of looking at it. But may not some one take the opposite view and say that some clique is running the National Association just because no nominations are allowed. No one being named beforehand, a large number will not think of any new name, but will always vote for those already holding the position, while the scattering votes are so scattering that no one candidate among them can ever expect election. At present there is practically no chance for any except the old incumbents, except some one resigns, declines a re-election, or leaves this world. But we are not complaining.

CONVENTION NOTICES.

Utah.—The Utah State Bee-Keepers' Association will hold its annual convention in the City and County Building, Salt Lake City, April 5, 1902, at 10 a. m. This promises to be an interesting convention. All are invited. It is desired to form an exchange for the protection and benefit of our bee-keepers. Come and aid a good cause. It is expected that every county will be represented. J. B. FAGG, Sec.
E. S. LOVESY, Pres.

Chicago.—Some amendments to the constitution of the Chicago Bee-Keepers' Association have been proposed, and the Executive Committee has ordered them to be brought before the next regular meeting for decision. It is proposed to change the name to "Chicago-Northwestern Bee-Keepers' Association;" and to change the time of meeting to "the first Wednesday and Thursday of December, or such other days as may be selected by the Executive Committee." The object of this is to make Chicago the rallying point for the whole Northwest, or so much of it as is likely to run to Chicago to trade or attend expositions. I believe our association is now the largest local association in America. We remitted to the National Association for 62 members. Our mailing list is about 300, or about $\frac{1}{4}$ of those in our territory. HERMAN F. MOORE, Sec.

The Emerson Binder.

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

No. 10.

Editorial.

Comb Honey Not Manufactured is the heading of an item sent to the farm papers of the country by the Frank B. White Co., of Chicago, who wrote us as follows:

AMERICAN BEE JOURNAL—

Gentlemen:—You have doubtless noticed in a number of daily and weekly papers a recent statement going around, to the effect that much of the comb honey offered for sale is artificial, cleverly manufactured by special machinery, and filled with syrup, of which the principal ingredient is glucose. This has been given such publicity that it worked undoubted and deplorable injury to the honey market, so that in some localities the demand for comb honey has fallen off almost altogether. A statement of this kind might be excused if it was founded upon fact, but the truth is that there is not a particle of artificial comb honey on the market, and any comb honey offered for sale may be purchased with entire confidence that it is genuine.

So many farmers are interested in honey, commercially, that we thought a brief notice, similar to the enclosed, would be a great favor to your readers, in that it will start a counter-agitation, and so restore the confidence of honey-users. Will you kindly run this notice in an early issue of your paper, of course making no charges for it, as we are simply doing this for the benefit of the honey-producers, feeling that a great injustice has been done them?

Thanking you in advance for the favor, we are,
Yours truly,
FRANK B. WHITE COMPANY.

The item referred to in the foregoing, reads thus:

COMB HONEY NOT MANUFACTURED.

A statement has been going the rounds of the press to the effect that nearly all the comb honey on the market is manufactured by a "cute machine," that the combs are filled with glucose and capped over by a mechanical process. The facts are, there is no such thing as manufactured comb honey anywhere in the United States, and in proof of this the publishers of leading bee-journals of undoubted responsibility offer one thousand dollars for evidence to show that comb honey is manufactured, or that such an article is for sale in the open market. Although this offer has been out for fifteen years and has been duplicated by other responsible persons connected with the industry of bee-keeping, no one has ever seen fit to take it up.

The United States Department of Agriculture has put out several published statements denying the existence of manufactured comb honey, and the American Grocer, the leading trade organ of its class, assures its patrons that all the comb honey on the market is absolutely the product of the bee.

The Frank B. White Co. have placed bee-keepers everywhere under everlasting obligation to them for this commendable effort on their part. Undoubtedly every agricultural

paper will be pleased to publish the item, which places the truth about comb honey before its readers in a very clear and concise way.

The Frank B. White Company are agricultural advertising agents, and are as clean and "White" as their name indicates. Surely, they have interested themselves in a worthy cause—one in which we trust every farm paper will co-operate, and thus aid in seeing that justice is done the honorable industry of honey-production.

A Spraying Bulletin has been issued by the Agricultural Experiment Station of the University of Illinois, giving important details of spraying that are excellent, but it seems a pity mention was not made of the fact that for the good of the fruit-crop, if not for the good of the bees, no fruit-trees should ever be sprayed while in bloom.

And this reminds us that a certain Wm. Stahl, a maker of spraying outfits, gives, in private letters, some spraying instructions "in connection with the instruction on spraying in catalog." He says:

"Allow me to advise that you give your trees one additional spraying this year [1901] while in full bloom, using for this spraying Bordeaux Mixture and adding thereto Paris-green in the proportion of 1 pound to 160 gallons of Bordeaux Mixture. Trees that have been sprayed the past year while in full bloom the results have been simply wonderful. In most cases trees have been overloaded, with scarcely a wormy or scabby apple, pear or plum to be found."

And this in face of the fact that practically all the agricultural experiment stations and experts protest against spraying fruit-trees when in full bloom. Bee-keepers will know how to condemn such advisers as Stahl.

Not only is there danger of poisoning the bees when spraying in full bloom, but there is danger of killing the pollen of the delicate blossoms, and thus preventing the full fertilization and consequent production of a crop.

Is Swarming Desirable?—During the winter months, and before the time for active work with the bees arrives, the man or woman whose veins are filled with the blood of a true bee-keeper will spend many an hour planning for what he is going to do when old Dame Nature thaws out. Among the interesting problems over which many will puzzle is that of swarming. Years ago it seemed to be the somewhat settled opinion that for best results each colony should give one swarm. Nowadays we hear less said in that direction, and some of those who advocated it are among the most earnest seekers after some plan by which the bees may be thwarted in all their efforts to swarm.

If Mr. A. is in a locality where there is a single flow, that flow coming comparatively early, as from white clover, he will have about all he can do to get his colonies in condition for the harvest, and when the forces of any colony are divided by swarming, that means a diminution of his crop.

If Mr. B. lives where there is a long-continued flow, and especially if there be a good late flow, a swarm coming early will be in condition to do fine work on the late harvest, and together with the mother colony the two will store more for the season than the mother colony alone would have done if there had been no swarming.

So the general conclusion is that in Mr. A.'s locality swarming should be discouraged as much as possible, while Mr. B. should do all he can to encourage at least one swarm from each colony.

But is there not a general fallacy in that general conclusion? Suppose each has an apiary of 50 colonies, and he has pasturage for 100. If Mr. A. keeps down all swarming he will have more honey this year, but if he allows his colonies to double by swarming this year, will he not have a larger harvest next year, and the years following? So for Mr. A. is it not the true policy to increase till he has his field fully stocked?

If Mr. B. doubles by swarming, he will have more honey this year than if he had only the 50 colonies to store. But suppose that instead of the swarms having only part of the season in which to store, they would have the whole of it, would not the yield be greater? In other words, instead of having the 50 colonies and their swarms he could have 100 colonies without swarms at work throughout the season, would he not have a greater harvest than with the 50 colonies and their increase? So is not his true policy exactly the same as that of Mr. A., to increase till the field is fully stocked, and then, if he can, to suppress swarming?

It will not do to be too dogmatic in such matters, and the reader will notice that questions are rather asked than statements made. The subject is one upon which it is desirable to have light, and the views of any who are in position to shed light upon it will be gladly received.

Basswood and Wax-Worms.—S. A. Niver, in *Gleanings in Bee-Culture*, says that while wax-worms bore or eat holes in pine top-bars they never trouble those made of basswood. Have others observed this? Serious objection has been made to basswood in any part of a hive on account of its undesirable habit of warping and twisting.

Convention Proceedings.

Report of the Ontario Co., N. Y., Bee-Keepers' Convention, held at Canandaigua, Dec. 12 and 13, 1901.

BY F. GREINER, SEC.

It was the 12th annual meeting of the Ontario Co., N. Y., Bee-Keepers' Association and a bee-keepers' institute was held in connection with the meeting, under the auspices of the Department of Agriculture and Bureau of Farmers' Institutes.

The President, W. F. Marks, in his message, dwelt upon the importance of organization at the present time, pointing out some of the benefits of the local organization and what had been accomplished through it. He compared the prevailing low price of honey with that of an early date and suggested that it was about time for the producers to name the price of that product. He censured the *teachings* that honey is a luxury, and called the attention of his hearers to the fact that most of the food upon their tables was luxuries and yet much of it had come to be looked upon as a necessity, and why not honey? He thought the bee-keepers, through their periodicals, were much to blame for spreading and maintaining the luxury idea, and it should be discouraged. The producers of other foods did not try to make the consumer believe that their foods are luxuries. The bee-keepers should not only fix the price, but it is the duty of each to work up a local trade, and thus increase consumption. He spoke of the display of honey at the county fair and urged bee-keepers to take advantage of this opportunity to advertise their honey, and at the same time to secure the liberal premiums offered. In conclusion he told his hearers not to get discouraged, but to have some desired object in view, and to work for that object.

HONEY STATISTICS OF THE UNITED STATES.

In the discussion following, it was suggested to appeal to the Government for aid in collecting monthly statistics as to amount of honey produced, and other matters pertaining to apiculture; but it seemed to be the sense of the meeting that the Government would not be able to collect reliable data as the present staff of regular correspondents would not be in any position to know or find out what the honey crop was. It was believed that the National Bee-Keepers' Association could do this work much more effectively, and a resolution was adopted later on asking the officers of said body to devise a plan and put it in operation.

THE GOVERNMENT AND MATING OF QUEENS.

Further, it was proposed that the Government establish an apicultural experiment station on some small island where no honey-bees were found present, and assist the bee-keepers to improve the honey-bee. In such an isolated place the mating of the queens could practically be controlled, and such a course would be more effective than mating queens in tents, for, when unconfined nature would usually select the strongest drones as the successful ones; in the tent no such selection could take place. It was believed that we had just as good bees in America now as anywhere on the globe, and what money our Government expends in importing queen-bees from other lands might better be made use of in the line proposed.

While the Association did not take action on this proposition, still the matter was brought up again by another member, showing that it had gotten a hold. Undoubtedly it will be pushed on at some future time.

APIARIAN EXHIBITS AT FAIRS.

As to the securing of liberal premiums at agricultural fairs it was shown that even a single person could sometimes accomplish a great deal. The agricultural society in a small town of Ontario County, had thus been influenced, and had also increased the premiums on apicultural products and implements from 50 cents to about \$30, in consequence of which the bee and honey exhibit had been

a most attractive feature of the fair. It was the general opinion that, while bee-keepers take great pride in making creditable displays, they cannot afford to spend time and money without fair pay.

"BEE-KEEPING—ITS CHARACTER AND REQUIREMENTS."

Hon. R. L. Taylor, of Michigan, delivered an address on the above subject. He said bee-keeping differed from ordinary farming in-so-far as the bee-business was subject to greater variation; there were too many exceptions to the rules, and the bee-keeper had to be on the alert all the time. The farmer may grind away each day without much thought, but each day in the apiary brought new work and needed thought; new problems had to be worked out constantly. To keep bees successfully, he said, one would have to observe the following: Abundant and timely breeding of worker-bees, requiring an abundance of stores, for bees used scantily from scanty stores. All shortage should be remedied at an early time. Sufficient supply was not enough. Attending things in season was essential, procrastination is the thief of the honey crop.

In addition to giving plenty of honey some of the sealed stores should be uncapped at short intervals, as bees would not use sealed stores as fast as was desirable for best results. The more they eat, the faster they would breed.

Spreading of the brood, he said, should be practiced very cautiously, giving empty combs or uncapped frames of honey in the center of the brood-nest, as was thought best. He recommended the Heddon method for treating the young swarms, using Heddon hives of 5 Langstroth frames capacity, with queen excluding honey-board between brood-chamber and supers. One empty comb given in the center of the brood-nest, he said, would prevent pollen being stored in the sections. He is getting all the surplus from the young swarms, drawing on the old colonies for bees to re-inforce the swarms. In the fall the young and the parent may be united, killing the old queen, thus practically re-queening all his colonies that cast swarms. How many bee-keepers, he said, have I seen, that would leave the supers on the mother colonies, giving no surplus room to the swarm, thus losing the greater part of the crop. In view of the fact that section honey built by swarms is always of higher quality than honey stored by old colonies over old combs, it is advisable to get all surplus from the swarm, for the market demanded unstained section honey. If it was desirable to produce well-filled sections, sealed all around, then not too much room should be given. In other words, the bees should be crowded; but if quantity is the object regardless of fancy filling, then more room should be allowed.

All comb honey, as soon as finished, should be taken from the hives and stored in a warm, dry room; unfinished boxes, when found, to be returned to hives where room was needed.

The improvement of our stock should be looked after during swarming-time. All queens from colonies not doing well should be removed and queen-cells from good stock should be inserted, utilizing as far as possible all the cells from the best colonies.

However, it was Mr. Taylor's opinion that Nature had already done all it could do in the line of producing a hardy bee, as well as one of greatest honey-gathering qualities; she had weeded out all the weak and the indolent, while she had preserved the strongest and the diligent; a process that had been in operation a great many thousands of years, we could therefore not hope to make any more gain in these directions.

In the line of perfect capping of honey, the honey-bee might be improved. The color of bees could be changed, or in other lines, wherein Nature had not busied herself, had not cared seemingly to bring about greatest perfection, there we might expect to accomplish something. As a comparison he said: Hardiness and fleetness had been developed in cattle, and long horns had been given them, so they might protect themselves against enemies and endure the hard winters. It was not possible to make any improvement there, but evidently Nature had not cared to develop the beef and milk-producing qualities of cattle, and man had brought about wonderful changes. The difference between bees and cattle was, that Nature had developed as far as possible those qualities in the bee that are desirable for man; but she had not done this much for

cattle. The high qualities that our present cattle possess are of most value to man, but of no value to the cattle. The high qualities bees possess are valuable both for the bees and for man. The bee had already a long pedigree.

As to breeding out the swarming habit he said when swallows and rabbits forget to rear young then bees will stop swarming.

Retrogradation, he thinks, is due to the bee-keeper nursing up weak colonies. There was virtue in the sulphuring match. Nature would destroy them all.

GENERAL DISCUSSION.

In the following discussion many points were brought out. One member said he had more call for such honey as was not filled and sealed next to the wood of the sections. Mr. Riker, of Iowa, asserted that he could take the poorest queen of a whole yard and rear as good queens from her as from the very best one. It depended wholly upon the manner she was reared. He did not give a special method of rearing queens, except that they should have an abundance of food. Others of the convention, however, took exception. Mr. Olmstead said that would eliminate all chances of improvement. Mr. Riker had observed that there was a great difference in the longevity of bees from different colonies.

Mr. Olmstead, of New York, brought out this point more clearly in his address later on. He said he had found that some colonies would feed their young more plentifully than others. The young larvae in some colonies would be surrounded with an abundance of food, not so in others, and he theorized that the more abundantly fed larvae would develop into stronger bees, in particular as to their wing-power, than those scantily fed. The wings, he said, are the most important indispensable tools for the field-bee, and when they are gone, or worn out, the bee's utility is gone and she dies. The wings of the bee develop at the very last end of the imago's life, and if the growing insect runs short of material, the wings will of necessity suffer most, and a short-lived bee is the result. To ascertain the truth of the matter he had made an experiment, selecting two colonies of equal strength; one, which seemed to provide their young always with an abundance of food, the other, which exercised great economy in this direction. Into each of these colonies, both of the German race, he placed a comb full of newly-laid eggs at the same time, said eggs originating from a very yellow Italian queen. When the time came for these yellow bees to become field-workers he kept close watch of the two colonies. The colony that fed their young abundantly, retained yellow Italian bees about two weeks longer than the one which provided scantily.

Mr. Olmstead did not agree with Mr. Taylor on the point that Nature always weeded out the poor colonies. He said the bees that stored the most honey in the brood-nest would come through the winter best, but they were not the ones the honey-producer wanted. He would prefer such bees as would store the least in the brood-chamber; but Nature would weed them out without he interfered.

A year ago Mr. Terry said, in a paper read at the convention, that bees would adapt themselves to different conditions according to the environments. If bees were employed for a term of years building comb honey, they would eventually become a fixed comb-honey strain. Mr. Olmstead said he could not see how an influence could be exerted upon the progeny of the queen-bee by the workers, since they were not directly concerned in propagating the race except as it might occur through nursing the young. To see what this influence might be, he conducted another experiment, selecting two colonies, one an Italian and extremely vicious, the other a brown German and very gentle. The queens were exchanged and results noted. After a few days, and after the queens had begun laying in their new homes, the yellow vicious bees were nursing the gentle brown young, and the gentle brown bees were nursing the vicious yellow. As soon as the yellow ones had hatched in sufficient numbers in the German colony, they showed unmistakable signs of fight just as their sisters in the other hive. But the black ones seemed to show the bad bringing up they had had, and were found on the warpath, which he could only account for on the theory of "bad company corrupting good manners," the Italians giving the word and set the example, the innocent blacks followed suit; and not because the

vicious nurse-bees had instilled viciousness into their blood. Mr. Olmstead thinks he has some proof that qualification worker-bees have acquired, cannot be transmitted to the future offspring of their mother.

Developing the Home Honey Market.

Very few producers are good salesman; this is perhaps quite true. Nevertheless, every producer of honey can, by a little effort on his part, do something towards creating a demand for his product in his town, among his neighbors. The easiest way to dispose of a honey crop is, of course, to send the whole crop to a commission man in some large business center, and take what the commission man sees fit to give for it. That is the easiest way. But is it the best way? Do you get as much money out of your product as you might or ought to? A great many people follow this plan, I know. They are too easy to make an effort. I know of but few times that sales made by commission men for me were satisfactory, and a great many that were most unsatisfactory. Unwisely I sent a small lot of honey to Pittsburg this year. The firm I shipped to quoted new honey at from 17 to 20 cents before I shipped, and I supposed my honey would sell quickly somewhere near their figures. But what were the facts—what was the result? Well, after waiting over two months, returns were made disclosing the fact that my honey had been sold at 12 cents per pound! I considered that I had been swindled out of \$15. The market report enclosed in the letter showed a wonderful decline in price of honey in that market, although another firm from the same place, and having their place of business on the same street, quoted me prices at 16 to 17 cents. Pittsburg business men are very apt to quote high and sell low, all of them. I don't think in other cities they are quite as bad. But, after all, this one fact is true: The large centers are generally well supplied, often overstocked, and this brings down the price. The remedy seems quite simple: *Do not send your honey to the city.*

I know from experience that a great deal of honey can be sold near where it is produced. I am myself naturally disinclined to do any peddling, but for the sake of the experiment I decided to make a trial this year. It seemed pretty hard work for me, and I encountered some very unpleasant things. When you have to make a dozen calls, have the door slammed in your face repeatedly, being treated as though you were a dog, and then perhaps not sell anything, or only a ten-cent box or so, is discouraging, and makes you wish you had stayed at home. On the other hand, you will meet pleasures unexpectedly; you will find some friendly good people with whom it is a pleasure to deal; and though you may not always sell to them, you go away from such a house with a good feeling. Sometimes these people are very kind, accommodating and painstaking; they help you make sales with their neighbors and friends; they insist on giving you your dinner, etc. You feel encouraged, and you begin to think the people are not so bad after all.

Occasionally you will enter the home of a storekeeper who sells honey from his store. He may tell you how you hurt his trade; he may ask you if you think it fair for you to supply his customers with the very article he is trying to sell, he having to pay big rent, and you perhaps not even a resident of the same town! You, of course, must meet his argument somehow or other. If you sell extracted honey, you can ask him how much of such honey he sells in a year, or whether he sells any at all. If he does not, how can you hurt his trade? It is right the opposite—you may benefit his trade by developing the market, getting the people to use extracted honey by showing them a good, pure article, and letting them sample it—giving the children a taste, too, telling the people how extracted honey is produced, perhaps showing them a photograph of your extractor and how it is manipulated, etc. Then after you have made converts, the merchant can sell your honey in quantities, ten times as great as he ever was able to.

The extracted honey the average merchant keeps is usually put in jelly tumblers, is of light color and of good body, but, whew! what a taste, compared with a genuine article that comes from the hive.

Tell the merchant you will supply him with honey free from such glucose mixture as he is selling, at a living price. If he objects, then tell him you have no other way but to go around from house to house and make sales to his customers.

Extracted honey is really a much better and safer article to handle, either for the bee-keeper or groceryman, than is comb honey. Very few people outside of the honey-producer know how to handle comb honey properly, and without getting it to leaking. I sometimes do wonder that storekeepers will handle the article when I see in what shape they keep it—leaking, daubing everything, shelves all sticky, cases dirty with the dust that settled on them, broken combs, etc. Now all this seems unnecessary, and yet it is not an uncommon thing to be seen.

In case of extracted honey how different it is! Unless a package breaks there is scarcely a leak. The honey is put up in original packages by the producer, some perhaps in tin, some in glass. They can be handled roughly, turned upside down if sealed; on the whole, such should give satisfaction all around, and do. The only drawback is the *granulating part*. On this the consumer needs enlightenment. After he once understands this matter thoroughly he will object to it very little. In fact, a great many people think the extracted honey just delicious when it is semi-granulated. I found many people that were just taken up with it when it was so partly granulated, sort of semi-transparent and almost too thick to run at all. When our honey gets solid and hard in small-mouthed and deep glass packages, it is then not in good shape to be sold and it must be liquefied. By keeping them in a very warm place for a time the honey will come back to its liquid state without opening the packages. I would not use small-mouthed deep glass bottles anyhow, and, if I did, I would not put up any more of the honey than I could dispose of soon. As long as we have our honey stored in tin we can liquefy it very easily.

I do not store honey in wooden receptacles and let it become hard. It requires a great deal of work to remove solid honey from wooden packages, as I have found by experience. This can and should be avoided.

I do not object to selling to retail dealers, in fact I am anxious to do so. I tell the groceryman so; but I do object to his making an unduly large profit. I also tell the groceryman that he does not understand handling comb-honey properly; that the honey he keeps for sale in the way he does rather disgusts the purchasing public, and that the honey I sell, or show to the people as I go from house to house, looks neat and clean; it has not been punched full of holes by careless handling, therefore does not leak, etc. If I can sell him a number of cases of honey I caution him to exercise more care in handling the sections, clean up all leaks immediately, and keep things looking perfectly tidy.

I cannot say that I was entirely satisfied with my peddling trip, although I sold some \$28 worth of my product. I thought I ought to have sold more. The beauty and the surprise, however, was, that orders came in for more honey in consequence of my trip right along after that and I expect in the future I will have very little trouble in selling a large share of my crop in my vicinity.

If the bee-keepers as a whole would follow a similar course in disposing of their crop, there is no doubt that the price of honey would very soon rise, for it is the large business centers that fix the price of it, and these centers are over-supplied now. Let these people get anxious for our honey, and then you can ask a fair price, and get it. We do not produce too much good honey at the present time; the trouble is the uneven distribution. F. GREINER.

A brief history of the Ontario County Bee-Keepers' Association was given by Mr. Olmstead, mentioning the names of the founders, etc., and was responded to.

HUNTING BEES.

In his talk on this subject, Mr. H. L. Case gave some valuable hints to those who like this sport. He said he had given up the "bee-box" with its bait, to start a line, long ago, but lined the bees from watering-places; he had found that bees do not travel far carrying water, but take it from the next puddle, or spring, watering-trough or the like. If bees are found working in such a place near a piece of woods, one may be sure to find the bees near by. To locate the bees is an easy matter—just keep the eyes open. He had found in a few afternoons 24 trees within a few miles of the village, and said there were 75 more in the woods. Six bee-trees he found one afternoon, lining all from one and the same little spring.

HOW MR. RIKER MANAGES.

Mr. Riker, of Iowa, produces only extracted honey; he told the bee-keepers how he managed his bees. He winters them in single-walled three-story hives; says they give better results than chaff hives in Iowa. The lower story is empty, the bees with the combs containing 40 pounds of honey are in the second story, and the upper story is filled with absorbing packing material. A temporary wind-break of cornfodder is set up around on three sides of the apiary. This shelter he thinks is most essential. Protected in this manner his bees come out of the winter with 12 pounds of bees per colony, which fill the hives with brood so that he soon has from 18 to 21 pounds of bees in each hive. The lower and empty stories are filled with combs, the packing is removed from the upper story and eight combs are given here, the eight given occupying the same room that the 10 would occupy.

When colonies become too strong, he removes combs of brood and adhering bees and forms increase. He does not take off any honey till the season is over. The upper stories are taken to a basement room and kept warm for some time, when he extracts the honey. The lower stories are emptied of their combs and the hives gotten ready again for winter.

The highest yield he has ever had in one day from one colony was 18 pounds from clover.

When queens are discovered that are not up to the mark, they are removed at once and young fertile queens are given. He introduces queens without further ceremony; as soon as the dequeened colony becomes uneasy the new queen is allowed to run in at the entrance and is accepted. Incidentally he made the remark that one of his queens, which had been clipped, did good service for seven years.

FOUL BROOD.

Mr. R. L. Taylor then spoke on foul brood, describing symptoms and appearance, and said he had cured many diseased colonies by shaking the bees off from their combs, and giving them a new hive and foundation-filled frames. However, when the disease is in the advanced stage, and could be told by the odor when entering the apiary, he thought burning was the safest and best. When he first had foul brood in his yard he said one of the affected colonies cast a swarm which he hived on foundation and it remained healthy. This showed him the way. He had found that foul brood did not spread as rapidly as we are led to believe, but advised to exercise great care to prevent the spreading of the disease by bees robbing. The work of shaking off the bees should be done rapidly; it would not do to treat diseased colonies when bees were flying. Diseased bees should also be prevented from entering adjoining hives. Early in the morning, he thought, was a good time, before the bees got to flying. He cautioned not to leave any honey lying around anywhere. With care, the disease could be cured; one need not get into a frenzy because his bees have the disease.

The question-box was conducted by Mr. Taylor, and proved to be interesting, but lack of space forbids going into the details. O. L. CO., N. Y.

No. 2.—Bee-Keeping for Women.

How to Begin the Business of Keeping Bees.

BY EMMA M. WILSON.

If you are going into bee-keeping as a business you should begin at the very beginning, and know something about bees.

When I first commenced driving I did not drive a horse until I knew how to harness and unharness it. I wanted to learn enough about the harness so that if anything went wrong about it I would know what it was that was wrong, and how to remedy it; and more than once I have

been glad I knew something about the harness, as I should have been in a bad plight if I had not.

A beginner of to-day has such an advantage over a beginner of say 40 years ago. Almost everything then had to be learned by actual experience, and some of the experience was costly. I venture to say that some of the veterans would have paid a good price to have had some of their questions answered 40 years ago. Now, all the beginner has to do is to send the question to the American Bee Journal and back comes the answer. And just think of working with bees without a smoker and all the modern conveniences we have to-day! So, beginner, whoever you are, count your many blessings, and do not forget under what bright prospects you are starting your venture, and don't you dare to get discouraged. If you are tempted in that direction, just think back what it would have been 40 years ago, and all your discouragements will vanish like smoke.

Who knows what bright prospects the bee-keeper of 40 years from now may expect? With bees with long tongues, and a non-swarming strain (I certainly hope they will reach that point during my lifetime), bee-keeping 40 years from now may be a perfect dream of bliss, even if at present it is not.

There are so many and such good books and bee-papers that a thorough study of them will give you a pretty good foundation to start on. But there are some things that you must get directly from the bees themselves.

Suppose you start with a very few colonies. That will give you a chance to experiment with the bees, and gain experience. Then, if you do have some loss in learning your lesson, it will not be as heavy as if you had a larger number.

I don't see why a woman is not in every way qualified to keep bees as well as a man, if she has the brains and knows how to use them. To be sure, in the matter of strength man has the advantage, but it is usually more than balanced by a woman's power of endurance, patience and perseverance.

Let us hope that if you are going to keep bees you are in a good locality. That has so much to do with your success or failure. It seems to me that in bee-keeping more than any other business there are so many elements entering into it over which you have no control. You may have your colonies ever so strong, all ready for the harvest, and yet not get any crop—because there is no nectar in the flowers. Or, the weather may be too cold. Or, it may be too wet, or too dry, or there may not be any clover, etc. Well, I always feel better reconciled to a failure of that kind than I would to have an abundant flow of nectar, and not have the bees ready for it.

Unless you have some capital to fall back on, it is well to make the bees pay their own way. I am not sure but it is a good plan to make them do it any way, capital or no capital. You may not increase your colonies quite so fast, but you are on pretty safe ground. If you keep a strict account of what your bees cost you, and what they bring in, you are a good deal more likely to make money on them than if you run on the haphazard plan, because you will be more careful of your expenditures, and buy only what you really need.

Another very important item is that you have good stock. It costs just as much to keep a poor colony of bees as a good one. They may be equally strong and one colony give you 50 pounds of surplus honey, and the other only 15 pounds. You will readily see that the 15-pound colony is not a profitable investment. What will you do about it? The first thing to do is to kill the queen of the poor colony, then give them a queen reared from your best colony. You may not get as good a queen as its mother, but you are not likely to get as poor a one as the one you killed; and by breeding from your best queens, and killing your poor ones, in time your stock must be improved; and good queens mean more dollars and cents every time.

What do we mean by good queens? We mean the ones that produce workers that are hardy, and are good honey-gatherers. When we have queens that will produce that kind of bees, we call them "good queens." We don't care whether they are yellow, leather-colored or black; whether their bees are three-banded or not, only so they get the honey.

To be sure, if we could have their good qualities, and the golden yellow bands combined, we would like it, but we are not going to give up the good workers for the sake of having yellow bees, no matter how pretty they are. It is honey we want. I would pay three times as

much for a tested queen that had been tested as to the quality of her bees as honey-gatherers, as I would for a tested queen that had been tested merely as to the number of bands her bees had.

Moldy Brood-Combs—Bees Fed in Winter Cluster.

BY G. M. DOOLITTLE.

"As I have read your answers to questions in the American Bee Journal for others with great interest, I have been wondering if you would answer one for me in the same paper. What I wish to know is something regarding moldy combs. I fear, by the appearances of things, that I shall have moldy combs in the spring, as my cellar is very damp and I can smell the moldy combs already. What will be best to do with them in the spring, should any be very moldy?"

I do not think that you need wonder about your questions being answered through the columns of the American Bee Journal so long as you will ask questions which will interest the readers of that paper, for even the most advanced apiarist often runs on little kinks when reading replies to queries which he has not thought of before—kinks which often prove of great value to the one who wishes to do the most possible that he may succeed in his undertakings with the bees.

Regarding the moldy combs; we will hope for the best, thinking that your fears may prove unfounded. But should the combs come out moldy, probably not more than one out of five or six will be very bad. Those which have but little mold on them can be left in the hives, where they will soon dry out enough so the bees will make them sweet and clean. If any are from one-third to covered all over with mold, it is well to take them from the hives and hang them in some dry, airy room till they are thoroughly dried out and needed by the bees. Do not attempt giving them to the bees while they are all wet and slimy, for nothing seems to discourage a colony of bees so, as nasty, wet, moldy combs.

When they get all dry, and the colonies from which they are taken are needing more combs, take the now dried combs down, and, with a rather stiff brush-broom, made from broom-corn, brush them off thoroughly (but not hard enough to break the cells, when you can put them into the colonies, one at a time, and the bees will clean them up so nice that, should you look for them two days after, you could not tell which they were, unless you marked the frames or the place in the hive where you put them. It is best not to give any colony more than one at a time, unless the colony is a very strong one. In three or four days you can give another, and so on till you have them all in the hive.

I never yet saw a comb so badly molded but what the bees would make it apparently as good as ever, if the above plan was followed.

Some say, melt up such combs; but so far as I have tried, the mold will absorb the most of the wax so that very little is obtained when melted by any process, and scarcely none at all when melted in the solar wax-extractor, as the fibre of the mold absorbs what little wax remains. If I were to melt up such combs I would calculate it would pay me to have them cleaned up by strong colonies before melting, through the extra amount of wax which could be obtained.

HOW ARE THE LOWEST BEES IN THE CLUSTER FED DURING WINTER?

"I have kept bees but a little while, so I do not claim to know much about them, but I am anxious to learn. One of my colonies in the cellar has bees hanging below the frames and I have been wondering how these lower bees are fed during the winter. A neighbor tells me that these lower bees go up into the cluster, and on the combs, every little while, so that they may have access to the honey. Is this right? An answer through the columns of the American Bee Journal will be appreciated."

The story of your neighbor is one that has been told a great many times, and is based on the very reasonable supposition that each individual bee must help itself to honey directly from the cells containing the same. But, reasonable as it may appear, I am led to believe that the story has no foundation in fact. I have just been into my beecellar to see if I could not discover something of the

kind going on, and have to report that I cannot discover any such movements. Some of the colonies have bees hanging below the frames to the amount of one-fourth of a good-sized swarm, at least; and if such moving up after honey was going on as has been supposed, it would seem that now and then a bee would be crawling in after honey, especially as the lowest bees would have to travel some six or eight inches up through or over the cluster to get where the honey is. But I saw nothing save a big cluster of nearly or quite motionless bees hanging and overlapping each other—each one, or nearly so, having its head under the body of some other bee.

Of course, it is impossible to see or know just exactly what is going on inside of the cluster of bees during winter; but I had always supposed, and so believe now, that bees give honey to each other; that is, the bees which are near the honey in the combs give to those under them, and these, in turn, to those next further away, and so on till the last bee is reached at the very bottom, outside of the cluster. Bees are continually passing honey around during the summer, and why should they not do the same thing in winter, when it is more to their interest to do so than in the summer time, when all can go about as much as they please? All know that the honey carried with a swarm is passed around, when bad weather comes immediately after the swarm issues, and all are kept alive, or the whole perish together.

I am well aware that these things are of minor importance; but I have always believed that it is better to be informed on all of the minutia of bee-keeping than to pass anything by as non-essential, as such a course allows us to drop easily some important point which would otherwise be brought to light.

Onondaga Co., N. Y.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

"THE HOME CIRCLE" DEPARTMENT.

Exit "The Home Circle!" A surprise for us that was not agreeable. Gone, but not altogether forgotten, Prof. Cook may be assured. In the real home circle it oft happens that the one who is gone is, in a kind of a way, more emphatically permanent and present than those who remain. We can hope that some of the tender sentences of our "Home Circle" may enjoy a portion of the same sort of immortality. Page 89.

A "HORSE" THAT NEVER WAS A COLT.

So Mr. Willcutt never saw a horse except he was once a colt. Most wish I could say so, too. I have a horse that was never a colt. And this long, trying cold-spell I have to go out and stand over him for a long while every day. It isn't because I love him so; (Never saw a man that loved that kind of horses) it's merely that "a cruel fate has fixed me there." Page 51.

AIKIN HITS THE "BULL'S-EYE."

You often hit the "bull's-eye," Mr. Aikin; and one of the times you did it was when you said that a man may be an expert with insects, and yet a failure in dealing with his own kind. Jars their hive and wonders at the results. Can never get over expecting them to look at everything from his own point of view—and swallow all he tells them.—and frequent his feeder when he has put no feed in it—and give up swarming, and everything else, when he sings out, "Whoa!" Page 69.

EXTRACTING WITH COMBS THE OTHER WAY.

Undoubtedly, thin honey can be thrown from combs placed "t'other way;" but part of the centrifugal force is wasted against the side of the cell in so doing, and we need it all. Cases in which the honey will not come out at all will be more frequent, and the percentage left in the combs will be larger when you get the "improvement" running. At best the amount left sticking to the comb is a sadly large part of

the whole—say a quarter-pound to $4\frac{3}{4}$ pounds, thrown out—5 per cent—and I should expect twice as much, or 10 per cent with the suggested position. Of course, the top-bar should be out, to take advantage of the slant of the cells, as Mr. Doolittle suggests, and also to support the comb lest it may break. Page 70.

BEES DYING IN THE HIVE.

I don't believe moribund bees will be satisfied unless they can get further away from the combs than $1\frac{1}{2}$ inches. Although their efforts to get further away to die may not be any great disturbance to the colony, yet it is as far as it goes a disturbance, and a disturbance introduced where we want to do all that we can in favor of quiet. Sad to do so much "carpenting" and stop short of satisfaction. Why not go a little further and have the death-chamber outside altogether? Page 70.

EAR BETTER THAN THERMOMETER.

That was a wise saying of Mr. Pettit (page 71) that an acute ear is a better guide than the thermometer as to just how warm to have the cellar. That is, I suppose, if you detect a wrong note try warming or cooling—or both.

AMOUNT OF WATER IN HONEY.

That a Professor (with a big and governmental P) should be unable to tell the exact amount of water in honey, after making a careful series of experiments—well, it rather jars us. How, then, shall poor we'uns believe they can tell the more abstruse percentages? Differences reported largely a difference of method, not a difference in the amount of water. We see. Our savants potter away for awhile by some method or other—and then guess the problem. Naturally, we practical folk think we can do our own guessing. When we go to the professors we go for a different article. All the same, we love Prof. Shutt. Honor to the man who says he failed to find out, when that was the case. Far better the doctor who says he don't know what's the matter with us than the one who looks enormously wise and says he knows all about our case, when he doesn't know a thing. But as they have been encroaching on my prerogative of guessing, I'll encroach on theirs and suggest a method. Try how many cubic inches of acetylene gas an ounce of honey will liberate, using honey instead of water, or say half honey and half water. When the amount of water in green wood is to be dealt with by practical folks it falls naturally into two parts: First, the water which can be got out by prolonged drying; and, second, the water which cannot be got out without disorganizing the wood. This second portion is, I understand, a quite large percentage of the whole weight of the wood. I begin to suspect that a similar non-get-outable increment of water in honey is large. Remember how alum, when it seems to be perfectly dry, will, nevertheless, when you heat it a little, dissolve in its own water and become a fluid. When we get around to complete statistics let's have the water in honey reported in two columns, "removable" and "non-removable" water. Page 72.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Transferring—Repetition of Questions.

We've took it—the bee-fever. Besides buying 3 colonies of bees, we got a barrel of bees; have ordered some hives, and when the proper time arrives we want to get the barrel-bees into a hive.

We're absolutely green as to the ins and outs of handling bees; have subscribed for the American Bee Journal, and read the whole of it—ads. and all—but as yet we have seen nothing regarding how we are going to get those bees transferred to a hive, or the proper time for tackling the job;

further, we expect to get the information from you, unless you'll come and do the trick for us. Come, now, give down, and get us out of this scrape. Will watch for reply.

Iowa.

ANSWER—If I was to tell you in full in this department how to transfer bees, I'm afraid the Editor would tell me there wasn't room for it. You see, there are certain things so generally needed to be known by all bee-keepers that they are put together in a text-book, and if there were no such book, and each newcomer had to depend on finding in the journal the things that are contained in the text-book, it would take up a very large part of the journal. You might like that very well for this year, but next year and every year after, the same things would have to be told over and over again, and you'd get mad at the repetition, and want something fresh. In the same way, those who have been taking the Journal before you, would get mad, if space was taken up now with things easily found in a text-book. A good text-book will more than pay for itself by telling you what to do with those three colonies, to say nothing of the barrel. You'll have plenty of time to study it pretty thoroughly long before it's time to do any transferring, and after studying it if you find anything that needs further elucidation, send on a whole lot of questions and I'll take delight in answering them. That's what I'm here for.

Sections Crosswise in the Super.

1. Can we produce as nice, and as much, honey in sections crosswise in the super as lengthwise? OHIO.

ANSWER.—Yes, if the hive is properly leveled.

Feeding at Transferring Time—Keeping Queens.

I expect to transfer a colony from a box-hive to a Danz. hive, fixed with full sheets of foundation.

1. How much may I feed that will not overcrowd them while building comb to receive it?

2. In case a queen is sent me too soon can I keep her? If so, how, and for what length of time? PENNA.

ANSWERS.—1. That depends upon the bees gathering from the outside while they are drawing out the foundation. Don't think of setting them at it before it is late enough for bees to gather from the fields. If they are getting a fair yield of nectar there will be no need of feeding. If it is warm weather in the fall and they are getting nothing from the fields, you can feed 25 or 30 pounds of syrup without danger of overcrowding.

2. You can keep her in the cage a week, two weeks, or more, if the weather is warm, by merely seeing that there is always plenty of food and drink, and that the temperature shall not go below perhaps 80 degrees. Or, you can put the cage between the frames of a colony of bees, and there will generally be some good-natured bees that will feed her. I'm afraid, however, that you are thinking of getting a queen before the weather is warm. Don't.

Hive to Start With—Bottom Starters in Sections—Wiring Frames—Stimulative Feeding.

1. I intend to start in bee-culture and run for comb honey. Which do you consider the best hive for that purpose? And what size?

2. Will it aid, in order to get nice, full sections of honey, to put a starter in the bottom of the section as well as the top? If so, how wide should the starters be?

3. Is it all right to wire brood-frames when only a 2-inch starter is used? Or does it pay to use full sheets of foundation?

4. Which is the best way to feed bees in the spring, to stimulate brood-rearing, in the open air or in feeders?

WISCONSIN.

ANSWERS.—1. I don't know. Bees will do well in almost any hive with proper management. It makes a difference to the bee-keeper, however, whether he has a hive that is easily handled. Perhaps the easiest way to tell you what I think in that regard is to say that in my own practice I am using dove-tailed hives with Miller frames. My hives are 8-frame, but unless you give the bees very close attention I feel pretty sure 10-frame hives are better, and I have used both kinds by the hundred. (But don't understand that to mean more than three or four hundred.)

2. Yes, they are more certain to be filled down to the bottom. A good width for a bottom starter is 3/8 inch.

3. It is not worth while to wire frames with such a narrow starter. I believe it pays to use full sheets of foundation in brood frames, by which means you are sure of worker-comb, and your combs will be straight and just where you want them.

4. Probably one can be made to do as well as the other, but with open-air feeding you are not sure which colonies get the benefit, and you are not sure that your bees will not divide with those of your neighbors. Remember, however, that stimulative feeding in spring is a two-edged sword, and it is a safe thing for beginners not to meddle with it at all.

The Queen's "Feelers."

Several times during my work among the bees and queens, I have noticed queens go through maneuvers that inclines me to believe that in a perfect queen the so-called stinger is a feeler that helps her to deposit her eggs so systematically. I would like to know your opinion as to whether this would be possible. I have had no queens sting me, and I have thought that those persons stung by queens happen to have imperfectly developed queens, more on the worker-bee order.

I could as honestly believe that the queen, in perfect development, has a feeler as to believe she has a stinger.

CALIFORNIA.

ANSWER—There hardly seems to be any need of a feeler at both ends; for before a queen lays an egg in a cell she always explores it by thrusting her head into the cell, and unless she can see in the cell—and she can hardly see when she lays at night—it must be that she examines the cell by means of her "feelers" or antennae.

Solar Wax-Extractor—Foundation-Fastener and Section-Folder.

1. How can I make a solar wax-extractor for melting combs?

2. How can I fasten full sheets of foundation in sections?

3. Send me a simple plan of a section-folder, that I can make myself. NEW YORK.

ANSWERS.—1. The essential thing is a box covered with glass, and it may be of any size, from a small box covered with an 8x10 pane of glass to a house large enough for your family to live in. Then there must be a surface on which to put the combs. This may be of perforated metal to allow the wax to pass through the perforations, or it may be without perforations, the surface slanting so the melted wax will run off. Under this a vessel to catch the wax.

2. If you have only a dozen to put in, you can use a putty-knife. Have the foundation warm enough to be tolerably soft, work in a warm room, and press the foundation hard into the wood. If you have them by the hundred, it may pay you to get a Parker foundation-fastener.

3. O, bless you! I couldn't do that. Don't know of any so simple but what you can buy them for a good deal less than you could make them. But if you think you can't afford to buy one, you can fold sections pretty well without any machine. But if you have a considerable number of sections to fold, I advise you to buy a machine.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

GENERAL ITEMS

Bees Wintering Well.

Bees are wintering well so far, and I hope for a good season this year, although we had a good one last year. D. E. LANE. Washtenaw Co., Mich., Feb. 13.

Spring Developing of Bees, Etc.

I have been much pleased of late, with many of the suggestions of bee-keepers in the American Bee Journal. Spring developing of bees I believe can be helped much by protecting the single-walled hives by some kind of cover from the cold, blowing winds, and sleety, rainy days of spring. Last spring I covered mine with blankets, oil-cloths, or anything I could get, and tied them on with twine, and I know it helped them very much. This spring I mean to get as much factory-cloth and boiled linseed oil and make a full cover for all hives, and cover all but the entrance.

Another little article I find very useful is a little scraper made of the section of a field-mower; pierce a hole in the center and rivet a 1/4 or 3/8 inch rod 10 inches long for a handle; it dresses up mussy frames and hives nicely.

Another thing I use for brushing bees off combs is a turkey-wing; it far excels all the brushes I have tried. R. McCRAID. North Dakota.

Think Honey Made by Man.

This is not a good locality for bees, only about one year in 4 or 5 that they pay for the work done; about enough honey produced to create an appetite for that kind of sweet.

I have been very much interested in "The Truth About Honey."

Several times I have been in town when men would call my attention to the grocers' nice display of comb honey, and declare they knew some man made it. When I would tell them it could not be done they would look at me pretty sharp, and walk off, as much as to say, "You belong to the ring." I have advised the grocers to order second grade, and if they were too white and clean, to rub them with wax and dirt until they looked like the ones I sold them. JAMES COE. Van Baren Co., Iowa, Feb. 14.

Shade for Hives.

To the bee-keepers that are looking for a pretty, cheap and green (in season) shade, that can be planted in any desirable place around your house or lawn if there is soil, I wish to offer the following:

In looking over the old and latest American Bee Journal, some of the bee-keepers complain about the combs melting in the hot sun, etc. Others want some good, cheap shade. I've had this cheap, pretty shade for the last two years and I challenge any one to show a better adapted and cheaper (hive) shade, (that can be sent through the mail or express, Mr. Hasty) for less money, and less work. After being planted it will come for years and stand upright, and make the finest shade just at the right season; after frost it will cease to shade the hives until the next summer, then it will grow up in the same place.

Going for the Doctor

through the storm and darkness while the suffering one at home is in danger, perhaps of death, is a terrible trip. Why not have a good, sure family remedy in the house? One that has proven a life saver in thousands of cases during the last forty years.

Watkins' Vegetable Anodyne Liniment.

Think what a world of terror and anxiety was saved this man. DISPENSES WITH DOCTORS.

Middle Grove, Illinois, June 4, 1901.
 We have used Watkins' Vegetable Anodyne Liniment in severe cases of flatulent colic; have employed veterinary surgeons before, but rely entirely on Watkins' Liniment now, for family use as well as for stock. WALTER DREMAN.

Watkins' Liniment is not only a great thing in cases of serious injury through accident, but is always helpful in cases of Cold, Colic, Diarrhoea, Dysentery, Indigestion, Cuts, Burns, etc. It is equally good for man or beast. If by any chance we have no agent in your vicinity, write to us, and we will see that you are supplied.

A TREAT FOR ALL.

Alfalfa Honey-- 7 cents a pound in lots of 4 cans or more.

BEST
Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-taden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

place every year, or whose hives must be moved in winter or early spring will have the same good shade, if the tubers are transplanted.

I am not a seed-merchant, nor have I colonies by the hundred, but I am a stock-raiser and farmer, and have bees. My hives are all the Simplicity, 16-frame (double hive) run for extracted. They rest on 8 pieces one foot apart, in straight rows facing east, and between each two hives in the center I plant artichokes, (the white French kind), and leave a path wide enough behind the hives to walk and work in; plant a solid row of artichokes (plant eyes about 10 inches apart). About extracting-time the artichokes between the hives and behind the hives will form nearly two green walls, shading the hives from the south and west, and bees from other hives, and those hives in rows behind will not bother very much. Most of my bees are hybrids and blacks.

Those of you that have no shade for the bees, think of yourselves, if your house would get too hot in summer time and also too hot outside and no shade to go to. Try a few artichokes this summer; it will cost you only a few cents for each hive, and see how contented the bees will hunt up the shade; and the hive itself will be in pretty, green—and, last but not least, cheap—shade.

I would like to hear Mr. Hasty's opinion on this. **ALBERT WILTZ.**

Atchison Co., Kans., Feb. 15.

Fears Spring Losses of Bees.

I have an interest in 5 bee-yards of 100 colonies each, but I could not keep bees without the American Bee Journal.

I am afraid we shall have heavy losses this spring, as the bees have not had a flight since Dec. 13.

We did not get any fall honey last season, and had to feed quite heavily, consequently they did not breed as late as they should have done. **ELMER E. TURNER.**

Tioga Co., Pa., Feb. 13.

Bee-Keeping in the Yakima Valley.

Perhaps a few remarks in regard to bee-keeping in Washington would be of interest to some of the readers of the American Bee Journal, especially to those who may be thinking of coming to this State with the view of engaging in bee-culture.

To one unacquainted with the conditions here in the Yakima Valley it would appear to be a bee-keepers' paradise, but, after two seasons' experience (as in the case of the writer), one may think differently.

In my experience I find the weather conditions to be one of the most, if not the most, serious drawbacks.

Bees winter in fine condition (as a rule) on the summer stands in single-wall hives, the only trouble being in the large consumption of stores on account of much mild weather.

In the spring there are some wild blossoms from which the bees gather pollen and some honey, then comes the fruit-bloom, and if the weather is favorable quite a large quantity of honey is gathered. Enough perhaps would be gathered to build up the colonies strong and have sufficient to last them through the long honey-drouth that lasts about two months or until the first bloom of alfalfa. But I find that even though there be an abundance of fruit and other bloom the bees are unable to do much on account of the weather conditions. There may be plenty of nectar in the flowers but our little workers would need the wings of a buzzard and a fur coat to enable them to carry on their work in the high, chilling winds.

Usually in the morning it is nice and warm; the bees rush out and begin rolling in the honey; everything looks favorable for a big day for the bees, but after an hour or two a heavy wind begins to blow from the west from off the snow-clad mountains of the Cascades, and there is no more honey-gathering that day. Last season that was the condition all through fruit-bloom; the bees consumed what stores were in the hives and barely gathered enough honey to keep them alive. After fruit-bloom for nearly two months they were actually in a starving condition. Many

29 YEARS SELLING DIRECT.

colonies had to be fed to keep up their strength until the blooming of alfalfa.

During the first crop of alfalfa the weather conditions were but little better than during the first part of the season, but the bees gathered enough honey to build up strong and put them in good condition for the second crop, from which we get our main honey-flow. The cold winds ceased to blow and the weather was hot. The flow began July 4, and was so gradual and ended in the same way so that one hardly knows when it begins or where it ends. But it generally ends when the alfalfa is cut, but it is not all out at once.

I secured from 75 colonies an average of 70 pounds of comb and extracted honey. If the weather conditions were favorable I have no doubt that twice or three times that amount could have been secured.

So far I have told only about the Yakima Valley as a bee-country, and there is much more to tell, but space will not permit. This article may put rather a discouraging aspect on bee-keeping in this Valley, but take it all in all bee-keeping has a bright future for the practical bee-keeper in the Yakima Valley.

No careless methods will do here. Only those who make a careful study of the conditions and seek for practical methods to overcome the difficulties can ever hope for success.

An effort is being made to organize, or re-organize, the Washington State Bee-Keepers' Association. I understand there was such an organization several years ago, but because of things not being harmonious it became a thing of the past. VIRGIL SIREs.
Yakima Co., Wash., Feb. 10.

Wintering in an "Ideal Cellar."

I have just put my bees in what Mr. Root calls an "ideal cellar," and find the temperature 25 degrees, while in the open air it is 30 degrees. A fall of 10 degrees does not change the temperature much. Every hive is clean, and the dull, low hum, always heard when bees hibernate perfectly, seems about the same in all parts of the cellar. Very few bees flew out while I was sweeping up the dead, which has been about the same every month for the 3 months.

The air is sweet, and the prospect now is that they will go through the next 2 months successfully. T. F. BINGUAM.

Clare Co., Mich., Feb. 17.

How the Bees are Wintering.

Bees in this locality have been confined to their hives for nearly 3 months, and being altogether wintered on their summer stands we are beginning to feel uneasy about their coming out in good condition in the spring. It being a nice day and the sun shining bright, but the bees not flying, and the thermometer registering only 28 degrees above zero, I thought I would take off the covers and give the sun a chance to dry off the cushion filled with cut rye-straw. I found the cushion frozen some to the cover, and very damp on top, but over the brood-chamber not the least sign of moisture, but warm and dry. After having removed two of the covers I came to the conclusion they would better be left alone until the bees take flight on a suitable day, and then give the cushion exposure to the sun.

With over 200 colonies in 4 yards my winter losses have never been over 5 percent. I find that meddling with the bees or their hive, when they are not flying, is very risky and detrimental to the colony.

I have just been reading in the February number of the Leipziger Biene Zeitung, that the temperature in Germany has been mostly

too moderate for the bees. Liedloff, one of the editors of that paper, does not approve of confining bees in the hive during the winter (practiced by some noted bee-keepers in Germany). Mr. Liedloff claims that the construction of the honey-bees is such that they can do without a cleansing flight for months, but must have a chance to leave the hive when the weather is favorable in winter.

I would like to add that I use the double-wall hive, dead-air space around the sides and bottom, with a cushion on the top only.

HERMAN COOK.

Wyoming Co., Pa., Feb. 17.

King-Birds—Long-Tongue Bees.

My bees did fairly well last summer, averaging 98 pounds to the colony, mostly red clover honey. I think they would have done better only for losing quite a number of queens, which I found out happened by their being caught by the king-birds. I read an item in last week's Journal, that the few bees caught by king-birds did not amount to much, but I think it amounts to a great deal. I positively know that king-birds catch queens, for I was out one day with a shotgun watching for Mr. Bird, and just when the bird caught a bee, I let go, and when I picked it up I found in its bill a drone and queen hanging to it yet alive, only one wing being torn off by the shot. I took it back to the colony that swarmed, and put it at the entrance; there came about 20 bees going for her like they meant to pull her to pieces, but that was not their idea, for they pulled something away from her, and then everything was all right and the queen marched right in and the bees were as happy as could be. Since then I have no mercy for king-birds. I may be wrong, but I think they are not a bee-keeper's friend.

In regard to long-tongued queens, I can say a word. I think we should try to rear nothing but long-tongued bees. I have watched the bees on red clover. An Italian bee will alight and go from one nectar-tube to another on one blossom, and a black or hybrid bee will alight and fly from one blossom to another until they find the one with the short tube, then they will stick. That shows that the Italian bees can out-reach them.

P. H. HARBECK.

LaSalle Co., Ill., Feb. 12.

Don't Spit in Your Hives.

Dr. A. W. Smyth says in the Irish Bee Journal:

"Woodhead states on the authority of Vignal that the bacillus alvei is an inhabitant of the human mouth—that great home of the bacteria where Leuwenhoek first discovered them. It is well, therefore, in working among bees to remember that human saliva can infect, and can start foul brood, and if the conditions are favorable to the bacteria, can destroy all the colonies in the apiary. A spark, if it can ignite the fire, is just as effectual as a torchlight.

That Bogus Honey.

In your issue of December 12th, "Watson" in his Chicago Business Letter says that "law stops bogus honey." He tells us that "geuine honey has a brown coloring around the cells, while glucose honey is perfectly white." I have been keeping bees almost 20 years, and my bees have produced tons of perfectly white honey in that time, and I never saw a pound of glucose to my knowledge. Sometimes I neglect to take off my comb-honey as soon as I ought, and it becomes travel-stained or has a "brown coloring around the cells" and then I have to sell it for a less price.

While the item does not say so it gives the impression that a carload of comb honey was

A Fortune in a Name—Under the keen and exacting conditions of modern business much more depends than formerly upon the name adopted for the business or the article offered for sale. We feel like congratulating the Clay Phelps Incubator Co. of Cincinnati, Ohio, who are advertising with us on the name "All Right," under which they are making and selling their incubators.

One or two points we wish to call attention to. One is the plan on which they sell their machines, namely, 10 days' trial. This is done to create the fullest possible confidence on the part of the public. If the manufacturer shows his own confidence in his goods, it's bound to find its answer in greater confidence on the part of the buyer. We do not remember to have seen in any catalog a clearer statement of the construction and advantages of an incubator than in the "All Right" catalog. A careful reading of these pages impresses one most favorably. In fact, it is hard to imagine how it would be possible to build a machine more conscientiously than the "All Right." The catalog is handsomely illustrated and is sure to interest and aid any one who is about to buy an incubator. Write the manufacturers to-day and get one of these books free. Address, Clay Phelps Incubator Co., Cincinnati, Ohio, and mention this paper.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

condemned in Chicago, because it was white, and contained from 50 to 60 percent of glucose. Without doubt extracted honey has been adulterated by unprincipled dealers, but I think there is some mistake about this item from Chicago and it will work an injury to beekeepers, who, as far as I know, are all in favor of the pure-food laws.—E. TARR, in the National Stockman and Farmer.

"The Jouncer" for Freeing Extracting Supers of Bees.

One of the chief up-to-date appliances in my apiary is known as a jouncer. Some four or five years ago I described, with pen and pencil, my first jouncer, and it was a very crude affair compared with the one in use at present. The photos show the device and how to use it. It will be observed that it is made very strong, made mostly of tough fir, and put together with bolts, and a cloth tray is adjusted under the hive to be jounced.

When it is desired to jounce the bees from a super it is adjusted as in photo No. 1, and the whole jounced against the ground. The sudden jar, or a few of them, send the bees all into the tray. The latter can be removed as shown in Fig. No. 2, and the bees dumped on the top of the frames of the colony.

In order to cushion the lower ends of the corner posts of the jouncer they are chambered off to a point. As there are no stones in the apiary, when the jouncer strikes the ground the jounce is broken just enough to prevent the combs from breaking.

The benefits derived from this method of getting bees off the combs are all in the line of rapid manipulation. In the American Bee Journal not many months ago, Mr. Davenport caught on to this idea and applied it to the common Langstroth hive. The best success, however, is attained with a shallow brood-chamber; and the only objection I have to it is, when there is much thin honey it slops out

FIG. 1.—RAMBLER'S JOUNCER FOR CLEANING SUPERS.

FIG. 2.—RAMBLER'S JOUNCER AND HOW IT GETS THE BEES.

upon the bees; but, of course, it is best to wait until the honey is thick. It is hard to make people believe that any new way is better than their way; but as my former good seed sown brought forth some good results, I sow again, and again watch the results. Whether bee-keepers use the Rambler's jouncer or not, I hope the bee-keepers will discard the old, obsolete use of a brush. Bees can be shaken off the combs clean enough. In Central California but few brushes are used.

I have great hopes for the shallow extracting-super. Mr. Davenport says the jouncing principle is worth \$50 a year to him, even with the standard frames. Now, I would give \$50 for a method that will enable me to extract a whole shallow super without removing the frames. Can it ever be done?—RAMBLER, in Gleanings in Bee-Culture.

Keeping a Record.

Considerable has been written in the past on the subject of keeping records of each colony of bees. Dr. Miller and Roots have had several arguments in which the Doctor was in favor of a book record and the Roots preferred the little slates, but years of experience have taught me that they do not completely answer the purpose for which they are intended. By

BETTER THAN SPRAYING.
Don't lug barrels of water around when spraying. Use the poison direct. Our

Common Sense Dust Sprayer
and Insect Extirminator is a most ingenious device that is rapidly supplanting the old methods. It blows the finely powdered dust into every nook and crevice. Reaches the bottoms as well as the tops of leaves. Destroys insect life on plants, vines, shrubs and trees. Just as effective for vermin on poultry and pigs. More rapid than spraying. Descriptive circulars and testimonials free.

using abbreviations we can keep a record on these extending through a few months or even one season, but of what use is this as a record? Of course, they are convenient in keeping a temporary record, but a record of a colony in order to be of value should extend through a number of years, for how are we to know what colonies (or the strain of bees from which queen) have averaged the best through a number of years? We can not trust this to memory. If we could, records would be useless.

I now keep a book record, and said records run from year to year so that I can trace the ancestry of any queen in the apiary back to the time when this record commenced.—S. E. MILLER, in the Progressive Bee-Keeper.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Feb. 18.—There has been a decline in the market on comb honey of one cent per pound since the month came in. Best grades of white now slow at 14c; sales chiefly at 13½c with some Western choice at 13c; no buckwheat comb offered, and other dark grades are meeting with little attention, prices ranging from 12c. Extracted is steady, white, 5¼@7c, according to quality and what it is gathered from; amber, 5¼@5½c; off grades at 5c. Beeswax wanted at 30c.
R. A. BARNETT & Co.

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c.
H. R. WRIGHT.

CINCINNATI, Feb. 7.—The honey market has been rather dull this year. Comb honey is selling fairly, and brings as follows: White clover, 15c; lower grades from 12¼@14c. Extracted honey sells very slow, the lower grades bringing 5@6c, and fancy, 6¼@7½c. Beeswax, 28@30c.
C. H. W. WEBER.

BOSTON, Jan. 20.—Strictly fancy comb honey in cartons, 15½c; A No. 1, 15c; No. 1, 14½c; very little No. 2 to offer; stock nominally running No. 1 and A No. 1. Extracted, light amber, 7½c; amber, 7c; Florida honey, 6¼@7c.

Our market continues somewhat dull in the demand for honey, while stocks are ample for the balance of the season, unless there should be a much larger demand than we at this moment anticipate.
BLAKE, SCOTT & LEE.

NEW YORK, Feb. 8.—There has been very little movement of late in comb honey, and while there is no buckwheat on the market to amount to anything, there is sufficient quantity of the different grades of white honey. The demand having been slow of late, prices have had a downward tendency and are likely to remain so during the spring.

We quote: Fancy white, 14c, and exceptionally fine stock at perhaps 15c; No. 1 white at 13c; amber at 11@12c. Extracted remains dull at unchanged prices. Arrivals of late are quite plentiful of all the different grades. Beeswax firm at 28@28½c. **HILDRETH & SROELKEN.**

SAN FRANCISCO, Feb. 12.—White comb, 11@12½ cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5¼@6c; light amber, 4¼@5c; amber, 4@— Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Considering the limited quantities offering there is a fair trade in progress, both for shipment and local account. Quotable values are without change, but market is moderately firm at the prevailing figures.

WANTED. EXTRACTED HONEY—either large or small lots; parties having same to offer, send samples, and best prices delivered at Cincinnati, Ohio. We pay cash on delivery. **THE FRED W. MUTH CO.,** 10Atf Front and Walnut Sts., CINCINNATI, O.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.77 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

Do You Produce Comb Honey?

Here is something that will interest you.

"The Danzenbaker Hive I think will take precedence over all others. I am delighted with it, as it is simple, and easily manipulated."

R. H. PEPPORTH, Pietermaritzburg, Natal, South Africa.

Nov. 30, 1901.

If you buy the Danz. hive you will find a ready market for your honey. Comb honey in Danz. sections has never yet been held because of "little demand."

EXTRACTED HONEY!

You will need good hives, smokers, knives, and most of all, a good honey-extractor. Root's Cowan Rapid Reversible Extractors are used everywhere, and always acknowledged to be the best. Be sure to get one of our make.

BEESWAX?

You should have the best wax-extractors, else large quantities of wax will be left in the refuse. See what one extensive and practical bee-keeper says of the ROOT-GERMAN STEAM WAX-PRESS:

For over 20 years past I have had to render up old combs or cappings in larger or smaller quantities, and my experience has been extensive, for I have tried faithfully almost every known method to get all the wax out, but have never succeeded to my satisfaction until recently. I got of you a German wax-press, that comes nearer accomplishing that object than any thing I have ever tried. I am more than satisfied with it, for, if used according to directions, there is little if any wax left in the refuse. Any one used to the old methods will be astonished at the results obtained. In this press you have given those in need of it the best thing, to my mind, you have ever brought out, and I really believe all who try it will pronounce it a real treasure. There are other points of advantage that I could mention, one of which is its perfect safety—no boiling over and setting fire to every thing, and it can be left alone without care for quite a time, and every thing can be kept neat and clean, and it occupies very little room. E. T. FLANAGAN. Belleville, Ill., Dec. 12.

Root's goods are for sale everywhere. See list of jobbers and agents in the January bee-journals. A full list of local agents sent you on request. We will also send you a little book, "Facts About Bees," describing the Danz. hive, and our catalog, on request.

WANTED.—Beeswax. Price, 28c cash or 30c in trade for pure average beeswax, delivered here. We want also a car of white sage extracted honey, also large lots of WHITE COMB HONEY in DANZ. sections.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

MR. JAS. A. GREEN of LaSalle Co., Ill., is moving to Mesa Co., Colo., mainly on account of his wife's health. He will keep bees there. Illinois can't afford to lose many such bee-keepers as Mr. Green. But our loss will be Colorado's gain. Mr. Green has an excellent article on page 166.

ABUNDANT RAINS are being reported from Southern California. These will help to insure a honey crop. Some day all of California's best crops of honey, and all the honey produced elsewhere in this country, will not be enough to supply the demand. You see, we have faith in the future honey-business of our country. But be sure to produce only the best honey possible, both in quality and flavor.

MR. THOMAS G. NEWMAN, for many years editor of the American Bee Journal previous to about ten years ago, and now living in San Francisco, writing us Feb. 27 had this to say concerning the condition of his eye-sight:

"I am glad to say that after having suffered terrible inconveniences during the past three years by paralyzed optic nerves, I am beginning to see some little improvement, and have much confidence that my vision will soon return. For you know how much it is needed in such work as I have to do. To depend upon the eyes of others for all that I can learn about the outside world has been a great affliction on account of its long continuation."

Mr. Newman's hosts of friends will be rejoiced to learn of the improved condition of his sight, and hope for speedy as well as entire recovery.

Mr. Newman is still connected with the bee-fraternity through being a member of the Board of Directors of the National Bee-Keepers' Association.

THE APIARY OF MR. F. W. HALL we present on the first page of this number. Here is what he has to say about it.

As promised some time ago, I send you a picture of my home and bee-yard. The general appearance of the latter gives one the impression of a veritable weed-patch, or African jungle, which former will not be much amiss. "Too many irons in the fire" made it impossible to keep some from burning, so I let that burn which did the least harm. Thus the blue-grass, timothy, clover and several kinds of weeds, had their own way save what I tramped down passing two and fro in the various manipulations of the bee-hives and fixtures, which, up to the time of photographing (July 4th), and some time afterward, was a good deal.

As you look at the picture you are looking toward the east, the sun at the 4:30 o'clock mark, and the mercury registering 109 degrees in the shade. The large-leaved plant in the foreground is rhubarb, the trees on the right are apple, cherry and three peach trees, south of which row is sweet corn (some 8 or 10 rows) and south of which is the garden; then the house and lawn (not in sight). The north row are apples, north of which are six other rows and all heavily loaded with apples, but not discernible. At the further end is a plum thicket, which extends clear across the east end of the orchard. A heavy row of willows some 25 feet in height border the north side of the orchard, and extend clear across the north

side and east end of the seven-acre lot, which give affective wind-break.

The old building in the background is a hen-house, which I expect to move to another location and build a bee-house with wintering cellar underneath. You will notice two (one on either side) milk-stool looking arrangements hanging in the trees; these are simply sticks of stovewood with a board nailed on one and a long wire hook to hang and handle it with. I smear them occasionally with the slum-gum from the wax-extractor. To use them, if they (the bees) do not voluntarily alight on them, (when I see they have begun to cluster), I hang the swarming-block as near as possible in the midst of them, and four out of five swarms in 1889 and 1900, used the blocks, but this year (1901) only four or five out of 25 used them; but I took no pains to induce them, as I found they were inclined to go to the evergreens and a small cherry-tree in the garden, and it was easy to live them from the trees.

The bees are not all in sight, some of them being back out of range of the camera.

I have the 8, 9 and 10 frame Langstroth hives, and three or four box-hives, which I have neglected to transfer. I like the 10-frame best for my locality, but may change my mind in time.

That pile of honey, 60 sections, (not all in sight but equally well filled), was just taken from one colony, there being thirty-two 4x5 no-bee-way Danz sections, and twenty-eight 4 $\frac{1}{4}$ x4 $\frac{1}{4}$ bee-way sections. The bee-way sections had separators between, except one separator which is left out, and two of the sections on the left show the result. The colony which produced the above, produced 250 such, and a super of extracting frames of honey and went into winter quarters in a 10-frame hive, bees and honey weighing 69 pounds. A daily record of the loss and gain was kept of this colony from spring until fall, but I cannot give the record, as a part of it was kept on the hive-cover and was packed away on a hive in the cellar before taking a copy. I do not know anything about the length of tongue of the bees of this colony, only that they worked red clover; but so did all the 58 colonies, so far as I could tell.

Aside from the above gains this colony cast a swarm June 5, which united with another swarm from another colony. The old queen being clipped did not go with the swarm, but went back in the old home and tore down the queen-cells and did not swarm any more. They were making a gain of five to seven pounds per day, but on this day they were 4 $\frac{1}{2}$ pounds lighter.

My bees fairly tumble over each other working on sweet-corn blossoms (tassels), and I am satisfied they were after something else than pollen.

F. W. HALL.
Sioux Co., Iowa.

CONVENTION NOTICES.

Utah.—The Utah State Bee-Keepers' Association will hold its annual convention in the City and County Building, Salt Lake City, April 5, 1902, at 10 a.m. This promises to be an interesting convention. All are invited. It is desired to form an exchange for the protection and benefit of our bee-keepers. Come and aid a good cause. It is expected that every county will be represented.

J. B. FAGG, Sec.
E. S. LOVESY, Pres.

Chicago.—Some amendments to the constitution of the Chicago Bee-Keepers' Association have been proposed, and the Executive Committee has ordered them to be brought before the next regular meeting for decision. It is proposed to change the name to "Chicago-Northwestern Bee-Keepers' Association;" and to change the time of meeting to "the first Wednesday and Thursday of December, or such other days as may be selected by the Executive Committee." The object of this is to make Chicago the rallying point for the whole Northwest, or so much of it as is likely to run to Chicago to trade or attend expositions. I believe our association is now the largest local association in America. We remitted to the National Association for 62 members. Our mailing list is about 300, or about $\frac{1}{4}$ of those in our territory.

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER
IN AMERICA

42d YEAR.

CHICAGO, ILL., MARCH 13, 1902.

No. 11.

* Editorial. *

Too Much Theory is the complaint Editor Hutchinson has had from some of his readers. Children don't always know what's good for them, Mr. Hutchinson. Americans are nothing if not practical. A man may be a good engineer without knowing just how a locomotive is built; but he will be a better one if he knows just how the different parts of his machine are put together.

Comb Honey in Barrels.—G. A. Deadman, in the Canadian Bee Journal, gives as one argument in favor of shipping comb honey in barrels the saving of freight. Honey in barrels goes as second-class freight, and as the classification does not specify extracted honey, he ships comb honey at second-class rates, the only way in which he can get so low rates, as will be seen by the following table:

Honey in glass, packed in cases.....	1st class
Honey in cans, not boxed.....	1st "
Honey in cans, boxed or crated.....	2d "
Honey in kegs or barrels.....	2d "
Honey in comb, boxed, owner's risk.....	1st "

Consumption of Stores, says M. Bellot in Revue Int., in well-protected colonies, is sometimes not more than one kilogram (2.2 pounds) for the months of November, December and January; but as soon as the bees are in activity, or even simply in movement, the consumption increases in an incredible degree. The effect of activity upon the amount of stores consumed is strikingly shown in the many swarms that he ships. For a swarm of nearly 4 pounds he calculates a consumption of 17 to 20 ounces the first day, and a little less upon succeeding days. A swarm of 4½ pounds during a journey of 11 days consumed somewhat more than 2½ pounds of honey. During the latter part of the journey the bees became accustomed to the disturbance, and quieted down so as to consume less.

Waste of Time at Conventions receives some vigorous handling from F. L. Thompson, in the Progressive Bee-Keeper. He says:

When I get up to talk I feel like a dull and rusty augur boring into tough wood. So when I listen to the false starts, the twice or thrice told phrases and the indecisive expressions that themselves make repetition necessary. I feel that we are all about in the same box anyway—if I think about it at all. But what does make me feel as if little ants were

crawling all over me, is for and easy talker—one who *can* say just what he wants to—to get up and deliberately ramble all over creation, just as if he were in a corner grocery.

Also that when bee-keepers "drive many miles to a convention, or pay railroad fare and hotel bills, they have a right to expect that the limited time of the convention itself (not speaking of the intermissions which can be spent socially if desired,) shall be devoted to that which conventions alone can give; and that anything else, no matter how valuable, which can as well be procured in other ways, shall be rigorously excluded. The presiding officer should consider it one of his chief duties to keep the discussion business-like to the point."

Large Ventilation for Bee-Cellars is advocated in Gleanings in Bee-Culture by T. F. Bingham. Instead of a 3-inch ventilator-flue, 16 inches is better. He says:

My first winter's experience with a three-inch ventilator-flue in my cellar demonstrated conclusively its insufficiency. My hives, like Mr. Doolittle's, became charged with water; and, while not painted, they do not fail to show that they have been five months in a warm, damp atmosphere. A hundred colonies of bees consuming 400 pounds of honey per month would liberate not less than 35 to 40 pounds of water per week. Just suppose two pails of water to be thrown into an airtight cellar once every Sunday for five months, said cellar to be at a temperature of 40 to 50 degrees.

Size of Hives for Idaho.—From the report of the Idaho convention given in the Rocky Mountain Bee Journal, the following is taken:

Pennington Bros. found that the average good queen could occupy 13 frames before the honey-flow. On these large hives comb-honey supers holding 40 4x5 sections are used, with shallow extracting combs when running for extracted honey. They found that such a colony would fill 40 sections as quickly as an 8-frame colony would fill 24 sections.

Mrs. Paul preferred the 8-frame hive for comb honey.

E. F. Atwater gave the bees 10, 16 or 20 frames before the flow and then contracted to 8 or 10 frames when the flow began, with a preference for 8 frames.

Wax-Presses and Solar Extractors.

—Wax-presses have come prominently to the front lately, but R. C. Aikin thinks there is still use for the solar wax-extractor. It seems to be a great waste to depend on the solar for old combs, and when it has done its best on any combs there is still paying work for the press, but Mr. Aikin, in Gleanings in Bee-Culture, expresses his view as to the further need of the solar in these words:

A press is a necessity and a money-saver. You will now say, if we must have a press, why build a solar? I will tell you. There is scarcely a bit of comb, burr-comb, cappings, or whatever you want to melt, but has in it more or less honey. If you put these through

the water process in either bag or press, you lose this honey. The saving in honey that can be used in feeding or in vinegar-making, and even for table use, will soon pay for several solars. It also saves time and loss in other ways, and the first run of wax that is gotten by the solar is brighter and nicer than can be had by the wet process. One who has never used a solar will have little idea how much honey can be accumulated by means of the solar—just that much saved. The slumgum taken from the solar can be worked by the press later at your convenience.

To this Editor Root replies:

I myself believe, and have so stated, that the solar wax-extractor has its place. I believe that nearly all refuse, so far as possible, should be put through it first, because the wax that the sun renders out is of a superior quality. But the slumgum from the solar and old combs should be put through the wax-press. A bee-keeper who thinks he can get along without a press of some kind is probably throwing away gold dollars by the handful. All refuse from the sun machines should be by all means saved.

Importance of Even Temperature in bee-cellars is urged by R. F. Holtermann in Gleanings in Bee-Culture. Even the variation of one degree causes a change in the position of the bees, and this activity is detrimental to the best wintering. One particular colony has been closely observed, and of this he says:

At 40 degrees the cluster contracts sufficiently to draw all the bees above the bottom-boards, and out of sight when you cast your eye through the opening made between the bottom-board and body by blocking up the brood-chamber three-eighths of an inch. At 41 a few bees appear below the bottom-bar; at 42, still more. This condition has prevailed all winter. That cellar, I believe, has not varied 4 degrees all winter, and it affords a beautiful object-lesson. Variations in temperature cause, as per above (contraction and expansion of the cluster), activity; and to husband vitality and stores, this is not desirable.

Acid in Wax-Refining.—An important correction is made in Gleanings in Bee-Culture, saying that instead of 5 to 25 percent, there should be only about 1 percent as much acid as water. Editor Root says:

It is our daily practice in refining the commercial product as we buy it, to use half a gallon of raw acid to two barrels (60 gallons) of water. This would be less than 1 percent of acid to water. If the wax is very dark we make a slight increase. Very light wax would require less than half a gallon. In refining commercial wax anywhere from ½ to 1½ percent of acid may be used; but in the handling of old, dark combs, especially slumgum, it will be necessary to increase the amount to perhaps 2 percent; but in that case it would be better to render the wax again in clean water so as to get out the slight traces of acid or acid smell. The ¼ or one percent solution of acid never leaves any trace, so far as we can discover, in the wax.

Convention Proceedings.

Report of the Michigan Bee-Keepers' Convention.

BY JAS. A. DART, SEC.

The annual meeting of the Michigan State Bee-Keepers' Association was called to order by Pres. Geo. E. Hilton, at 1:30 p. m., Jan. 1, in Petoskey.

Mr. Hilton congratulated the Association on the successful results of the last meeting in procuring the enactment of a foul-brood law.

The following communication, received from Mr. T. F. Bingham, of Clare Co., Mich., was read:

Safe Wintering of Bees in Northern Michigan.

Regretting that I cannot be with you I have decided to bring before our Association a feature in the management of bees which, while perhaps not strictly new, will afford at least a sense of novelty. I will, with your permission, request that you take up the subject of safe wintering in this Northern country. I define the location, as our wintering must ever be our great danger.

Young queens found laying in October are a danger, and as they are so determined to lay there seems to be no other way of disposing of them but to kill or remove them—the bee-keeper must make the decision, even though the time seems inopportune.

One colony with a laying queen in a winter repository will jeopardize the whole apiary, especially those colonies nearest to it. In looking over my bees preparatory for winter, about October 1, I killed all queens found laying, united their bees with other colonies having plenty of bees and in all respects No. 1.

It has been argued that late-hatched bees were the bees to pass the winter; all of which may be true. But those bees must all be eight days old long before going into winter quarters.

All this will lead up to the consideration of what queens will be best adapted to winter. There is but one answer, if the premises are sound, viz.: Queens that have stopped laying when the honey season stopped. Any queen that has not settled down to matronly ways, and does not go into hibernating ways as other bees do, cannot be trusted. Any queen that does not do this will surely keep the colony in commotion long after every bee should have gone into hibernating conditions and deepest repose.

You may call to mind the winter losses of years ago, when we had late-fall honey, and concluded it was late honey that caused the losses. A late honey-flow caused late brood and late supersedure of queens, and these young queens kept the colony breeding, and dying, and worrying others, and the whole dwindled, and dwindled, and dwindled away.

Again, you may call to mind that all spring-dwindled colonies have more brood than the bees can care for. Many reasons have been advanced for these conditions. I, of course, cannot explain as clearly as if with you, but I trust I have said enough to give a plain, clear understanding of the idea that our winter losses are not entirely due to cold or poor honey.

My bees are all wintering on buckwheat and other late honey, and dying much less than last winter, when, at this time (January 1), they had used nothing but granulated-sugar syrup.

One thing above honey is the hibernating rest. If that is broken by brood-rearing, the great essential of long-continued existence is absent, and premature death takes place. Temperature has much less to do with hibernation than has been supposed. The air does not require to be cold to cause bees to hibernate. When the honey-flow stops the queen is three months' old, hibernates, and the whole colony goes into winter quarters, just as do the "ground hog," snakes, etc. It is not a matter of atmospheric temperature, but of food conditions and the unerring instincts of the bees.

I don't think I ought to have written "unerring"—so many have had so much faith that the swarming instinct could be evolved out of bees, etc. Any poor season will wipe out the swarming instinct for that year.

I believe you will have a delightful meeting and a profitable reunion.

T. F. BINGHAM.

Mr. Bingham's subject was then discussed as follows:

E. E. Coveyou says he does have serious winter losses, and advocated ventilating by opening the doors and windows at night, thus keeping the cellar cool. He says 8 per cent is his heaviest loss; usually much less.

D. S. Kitson wants young bees for winter, and ventilating the same as Mr. Coveyou.

Mr. Bacon put 36 colonies in for winter one year ago; lost one colony; no late swarms, old bees; put in building. One winter he covered six colonies with straw and lost two from lack of stores. He thinks it is not a hard problem to solve in this region. He wants plenty of old bees, and thinks that wintering in a building is best for early building up.

Geo. H. Kirkpatrick thinks the important part is to re-queen in July. He put his bees into the cellar with 25 to 30 pounds of sealed honey per colony; hives with no bottom-board, and had very light losses from wintering.

Ira D. Bartlett kept bees seven years, and wintered them out-doors. He never lost a colony until last winter; that one starved. He gives about 30 pounds of honey put up in the latter part of September; makes winter hives containing about four colonies each, with three-inch space in the bottom; takes off covers and then puts on a piece of carpet, kiln-dried planer-shavings, two inches kiln-dried sawdust, then eight inches planer-shavings; gives dead-air space in front, sort of portico and board, and packs over with snow.

Mr. Kirkpatrick one winter put 63 colonies into a pit on a side hill—8 inches of straw over scantling, no bottom-boards, ducking over brood-frames, straw, then dirt—then straw and dirt again; he took out 60. The only ventilation was at the lower end of the pit, of a 4-inch wooden frame and wire netting over the opening. Straw was under, between and over the hives; boards over to shed rain.

Mr. Hilton says such pits are successful only on sandy soil, not in clay soil.

C. F. Smith had 22 years' experience both in and out of cellars, and in pits, and says cellars are noisy and bees hear the noise. He thinks, however, a cellar is the place. Beginners often have success out-doors, but will have a year come that will change their ideas. He doesn't see much difference between using absorbent or a cover over the frames. Last winter he accidentally knocked a cover off of one, and this colony wintered the best of all, but it was a very strong colony. He thinks after this he will take both bottom and top boards off, but have some heat-retainer, as burlaps and chaff.

Mr. Hilton thought best to leave the bottom off and have a top covered with a pillow of chaff.

Mr. Kitson asked to have discussed in this connection double and single-walled hives.

Frank Erdt thought chaff hives best, but does not like cellars; he thinks we ought to keep snow crust opened.

M. M. Hungerford says when he first came North he made double-walled hives by digging a hole in the snow; in spring he found one-foot space around the hives. He has had 20 years' experience in keeping bees, and never lost a colony in winter. Mr. Hungerford gave his amusing experience when coming North. He brought bees from Mount Pleasant on sleighs about 175 miles; it was hot over the bees; started with 12 colonies, and lost some by drowning over night, having left the sleighs standing in water, but the rest wintered fine.

J. A. Dart thinks there is no better place for safe wintering than Northern Michigan; he never lost any except once by starvation. He does not think it safe for amateurs to try Mr. Bingham's method of killing queens. He handles his bees in winter, any time he feels like it. He thinks noise or disturbance has no bad effect, and doesn't believe that bees hibernate.

Mr. Hilton thought that noises had no bad effect, and said that he wintered where railroad trains jarred the bee-building. He does not think the word hibernate, used by Mr. Bingham, is a proper term. He thought Mr. Bingham misleading, especially to young bee-keepers, but Mr. Bingham being absent he did not desire to take advantage, and preferred not to speak strongly on the subject introduced by the article. He thinks one of the causes of bad wintering is to have the bees too old; old bees are not so likely to live through the winter. He doesn't believe bees

ever hibernate. He can examine them any day and never find them hibernating.

Mrs. Mary Morrow has usually kept 75 colonies, reducing to 35 or 40 by doubling for winter. She always looks for brood—likes those especially; lost 7 colonies last winter, but usually has practically no losses. She uses chaff hives, and digs only sleet and where freezing after thaws. When she finds brood in a colony she unites one lacking it with this one.

Mr. Smith says sleet never smothers.

Mr. Kirkpatrick thinks sugar all right for winter stores, feeds quickly, and has combs $\frac{3}{4}$ capped over before wintering.

Mr. Hungerford says not to let sugar boil, but just warm, for feeding.

Mr. Hilton says scorching sugar kills bees:

Mr. Coveyou prefers, in feeding for winter, a large box full of holes, bottom on top of the frames; bees have to take the syrup or down. It is the principle of the pepper-box feeder.

Mr. Hilton was asked if there is not danger of selling sugar as honey, from thus feeding. He said there is no danger, but only likely to prejudice neighbors who sell it. The sugar fed is consumed in winter and spring.

Mr. Dodo said that in the fall of 1900, he put bee-hives in three rows next to a high board fence, and the losses were, in 1st row, 3 per cent; 2d, 20 per cent; and 3rd, 50 per cent; the loss being greater towards the fence. He covered with chaff and straw.

Mr. Coveyou thinks the bees might have flown and stopped in the 1st row.

Mr. Kitson said a late laying queen may be infertile. The general opinion of those present was that late laying is beneficial, there being no danger of bees being too young; the queen always stops her laying soon enough.

PUTTING UP HONEY FOR RETAILING.

Ira D. Bartlett asked as to the best method of putting up honey for retailing. He said he has trouble with tumblers not being sealed properly, and leak. He thinks the Mason jar, pint or quart, is the best can.

It was suggested by Mr. Hilton that the trouble is that inexpensive glass cans do not fit the covers, and that cans cost too much; that there is no successful and satisfactory can. The Mason jar is known to be of value. This is an unsolved problem. He says he is not satisfied, but finds it necessary to use glass. People tire of tin pails.

Mr. Kirkpatrick favors the Muth jar, or one similar.

L. C. Woodman says he sells honey at \$1.00 a gallon, and likes that method best, retaining the packages.

Mr. Smith and Mrs. Morrow say if customers buy in large quantities they will always buy so; if started with small amounts, they always buy small quantities. Except to groceries, Mr. Smith sells 1-3-pint cups in cases of one dozen each.

The general opinion of this convention is that it is difficult to improve present standard glasses; but glass jars are not all the same size, and it seems impossible to remedy it so as to sell at a low cost.

THE SALE OF COMB HONEY.

Plain sections are taking place of those with insets.

Mrs. Morrow says her customers like square sections, and the tall sections are not so well filled, and the bees are apt to fill the top part with dark honey.

Mr. Kitson says in his locality he can get two-thirds more honey with plain sections than with bee-way sections.

Mr. Coveyou says plain sections sell best, either or Danzenbaker. The thicker sections are uneven. He showed a 3d super of Ideal sections filled from a June swarm, all finely filled. He uses a unique arrangement of his own, that makes the removing of the sections from the super an easy matter.

The general opinion: Plain sections are always best, but there is little difference in the shape, that being a matter of convenience or preference.

W. Z. Hutchinson says merchants seem to prefer short-weight sections, buying by weight and selling by the piece; that in the West they sell by the case, guaranteeing a certain weight and quality. The dealers get light-weight sections, but this gives the dealers an advantage.

Mr. Hilton says the only honest way for bee-keepers is to sell by weight.

AMOUNT OF COMB FOUNDATION TO USE.

Mr. Kitson prefers full sheets of foundation for sections.

Mr. Hutchinson said if a slow honey-flow the bees can make combs, but if rapid they need foundation. He never used anything except $\frac{1}{4}$ sections, but he used different widths, preferring $\frac{1}{2}$ -inch in order to get them well-filled, but he gets better filled sections with full foundation, sheets, and better for market. Separators are needed to produce comb honey in the best shape for market.

Mr. Coveyou uses full sheets of foundation in the brood-frames and in sections; that one colony without foundation just draws out the brood-combs; another with full foundation sheets in frames and sections will fill both.

Messrs. Kirkpatrick, Bartlett, and others all use full sheets in sections, and even bottom starters, with a space of $\frac{1}{8}$ to $\frac{1}{4}$ inch between the lower and upper foundation in sections; $\frac{1}{4}$ inch is safer.

H. E. Brown says it doesn't pay to use more than starters—bees will produce just as much honey.

Mr. Coveyou says he thinks it best to put a new swarm on starters to get more surplus honey, and to prevent making drone comb put in old drone-frames.

Mr. Hutchinson says he has had considerable experience in living swarms on starters to get honey. He hives on 5 Langstroth frames, and agrees with Mr. Coveyou, who uses a queen-excluder. Set the old hive by the side of the new one to get the old bees into the new hive. Bees must then go into the supers. Place in some unfinished sections, and in 20 minutes after swarming they commence to fill the sections, and if the queen keeps up with brood-comb it makes them in fine shape, and all honey goes in the supers. Mr. Hutchinson feeds sugar for winter stores, using one-fifth honey with sugar, and has no granulation. It is done in September. He feeds 15 pounds of hot syrup at one time, and has fed late successfully, but recommends feeding early.

WINTER FEEDING OF BEES.

Mr. Coveyou advises making dough of honey and sugar. He never had to feed at any time except to small and weak colonies.

Mr. Chapman hasn't fed since 1885 to any extent, and then feeds sealed honey in combs saved for that emergency. He doesn't believe feeding often is necessary. If he didn't know enough to feed in the fall he wouldn't feed now.

Mr. Hutchinson recommends making a candy of honey and sugar.

Mr. Hutchinson says he doesn't know as he would extract in order to feed, but if he could manipulate so that bees left the brood-frames empty and stored white honey in the supers, he would feed for winter. There is no danger of carrying sugar into the supers.

HOW SHALL WE DISPOSE OF OUR HONEY CROP?

Mr. Kitson says small producers sell at any price and demoralize the market.

S. D. Chapman says he sells his surplus over local consumption, direct to outside customers, not through commission men.

C. F. Pinnell says small bee-keepers hurt his prices, and he thinks some kind of trust should be formed. He sells to store-keepers in the vicinity.

Mr. Hutchinson spoke of one bee-keeper who paid more cash to his neighboring bee-keepers than the store-keeper would pay in trade, and this kept the price up in his locality.

Mr. Hilton advises selling direct.

(Concluded next week.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Contributed Articles.

No. 1.—Desirability of Long-Tongued Bees.

BY PROF. A. J. COOK.

I have read with no small interest the late articles in the several bee-papers on the advantages of bees with long tongues, and the practicality of working in the breeding of bees to develop those with the ligula longer than the same in ordinary bees. I was specially interested in Prof. Gillette's article. The Colorado Agricultural College is to be congratulated in having so able, painstaking and thorough a scientist among her corps of instructors; and the apiarists of the country are to be felicitated, in that he gives a part of his valuable time and research to matters which so deeply interest them. His work in 1900, in connection with comb-foundation, no less than these researches to determine the real facts regarding the bee's tongue, are of great value.

I was the more interested as Prof. Gillette's results were so nearly a duplicate of my own, as determined and published years ago. Put Syrian in place of Cyprian, and we have a very close duplicature of my own conclusions. I proceeded a little differently from Prof. Gillette in making the measurements, though. I gave the length of the entire tongue, including the mentum, as I think this should be done. The bee stretches its tongue, undoubtedly, to the very utmost when probing the long flower-tubes for the coveted nectar. A longer mentum will permit a farther reach. Thus I think in all our microscopic work we should measure the entire length of the labium or tongue, from the base of the sub-mentum to the tip of the ligula. For obvious reasons, I would also include the sub-mentum. It is so connected with the braces at the base of this important organ, that it also serves to elongate the tongue proper though its measurement would not affect to materially change results.

As we know, the tongue, or ligula, rather, is a double tube. The inner smaller tube—which, by the way, is slit-
ted on the under side nearly the whole length, though it is so rigid as to be practically a tube—is open at both ends of the ligula, and is the channel through which the nectar from deep flower-tubes must all pass. At the base of the ligula on the upper side is an opening through which the nectar passes to the mouth, and thence on through the œsophagus to the honey-stomach. The outer tube is closed at the outer end, but opens at the base of the ligula into the mentum, and so into the blood-chamber of the body. The bee extends its ligula by forcing the blood into this outer tube. We can copy this action by laying the ligula on a glass or board, and then pressing on the mentum, with a scalpel or our knife-blade. Immediately the ligula will shoot out just as it does when the bee extrudes it.

In my measurements, I took the bees off the frames by the wings, cut the heads off by use of scissors, carefully removed the tongues, laid them bottom up on the microscopic slide which had been previously covered with a little thin transparent glue, and then by pressing on the mentum the ligula was extended to its full length. I think no other way so good to insure correct results.

I also used a glossometer, or tongue-measurer, which I placed in the hive. This was exhibited at the Paris Exposition and received favorable mention and a medal. It consisted of a piece of glass one inch by three, and a similar piece of wire-gauze, each held by wooden side-pieces. At one end the gauze touched the glass, at the other it was one-half inch from it. The glass slid in grooves so it could be pulled out, and returned. Wood also closed the thicker end of this wedge-shaped implement. To use it we simply have to draw out the glass slide, coat it thinly on the inside with honey, replace it, and suspend all in the hive. As the distance from the gauze to the glass increases as we recede from the sharp edge of the wedge, the distance which marks the removal of the honey marks most accurately the maximum tongue-length of the bees of that hive. I found, as of course I must, that the glossometer and microscope told the same story.

The black bees had the shortest tongues, the Italian next, and the Syrian bees the longest of all. The micro-

scope showed that there was very little variation in the length of the tongues of the bees of the same colony, and not much, though more, in bees of the same race.

I was not surprised to find that the Italians varied a little more than did either the blacks or Syrians. We have worked more in breeding our Italians. Selection has been made from our best colonies, in securing brood for our queens. Thus, as we should expect, these bees would vary more than blacks and Syrians, which have been left almost entirely to nature.

The fact of this variation undoubtedly explains in considerable part, the varying amounts of honey secured by different colonies. Mr. Hawley, of San Diego county, Calif., secured queens from a noted breeder in the East, and the product from these bees was surprisingly in advance of that from his other bees. Thus there is a practical side to this question, rich with promise, which I will reserve until my next.

Los Angeles Co., Calif.

Selling Comb Honey by the Piece vs. Pound.

BY J. A. GREEN.

In the recent discussion of the matter of selling comb honey by the case, the Editor has shown one side of the question, the Colorado bee-keepers another, while still others have endeavored to show that we can not all be bound by the same rules. It is an important subject, and we need all the light we can get on it.

Those bee-keepers who market honey by the case with as much variation in the net weight of the cases as has been reported in some instances, are certainly guilty of a carelessness that will react severely on the interests of bee-keepers in general. If a case of honey is figured as 21 pounds, and the average weight of a lot of cases is 21 pounds, it is quite true that there has been no dishonesty practiced as between the producer and the wholesale buyer, even if there is considerable variation in individual weights; but where this variation exists, unless the wholesale buyer re-grades the honey, or sells by weight, there is bound to be more or less injustice and dissatisfaction before it reaches the consumer.

This results in inevitable injury to honey-producing interests. Bee-keepers as a class are too apt to lose sight of the fact that the sale of the crop is quite as important as its production. They are too apt to think that once they have got their honey off their hands their interest in the matter ends. Compare their attitude with the scrupulous care taken by the producers of most other articles, that their product gets into the hands of the consumer so that it is satisfactory and pleasing to him.

If the consumer is not pleased with the honey he buys, he can, and frequently does, do without any more honey. If the retailer gets honey that he can not handle conveniently, satisfactorily and profitably, he may drop the sale of honey altogether in the future. I have frequently found such men who have become disgusted with a poor lot or two of honey they have become "stuck" on, and have quit the sale of honey entirely on that account. Honey is not the necessity or the staple article that we would like to see it, so he loses little or no trade thereby in other lines, as his customers, if they do not see honey, will not usually ask for it or go elsewhere to hunt it up.

It is a short-sighted policy that does not consider the fact that the interests of the retailer and consumer must be taken into account, and that to practice any injustice on either of them must inevitably injure our trade. This is true of all branches of trade, but particularly so in ours, where the consumer may readily dispense with our product if he wishes.

There are great and undeniable advantages in buying and selling honey by the case, or by the section, which amounts to the same thing. Grocers almost invariably sell honey by the section if its condition will at all admit of it, and after they have once experienced the advantages of the plan, they generally prefer to buy as well as sell by the piece.

To enable them to do this advantageously, there must be a certain uniformity, not only between sections in each case, but between different cases.

It is quite possible to have this uniformity. For years I have been selling my honey in our local markets by the section instead of by the pound. It has been most satisfactory to me, and that it has been so to the grocers is evidenced

by the fact that the exception of two or three whose business habits lead them to demand cheap honey, regardless of its condition, there is no longer any objection to this way of selling, but they prefer it as a more practical, business-like and time-saving method. Not only has this been the case in the local markets and surrounding towns, but I have had very little trouble to sell this way in new markets. Recently I took a quantity of honey to a city some distance away, where they were accustomed to buy their honey by the pound. In selling to eighteen grocers I heard no objection to my plan of selling, but some commended it, saying they had been making a mistake in selling by weight.

It is true that to make this method satisfactory requires very careful grading, together with such management as will secure practical uniformity in weight and appearance. To show how readily this is possible, I may say that for a number of years I have put up a large share of my honey in cases that were exact and uniform in weight as well as in appearance.

This year I put up 50 cases for this trade; 40 of them weighed exactly 22 pounds net each, and the remainder 20 pounds net. For another purpose I put up a number of 12-section cases, each of which weighed exactly 9 pounds net. Notice I say these were exact weights, as exact as your grocer uses when he weighs out sugar or coffee. Also, in all of them the sections in each case were practically uniform in appearance, with no extra light or heavy sections. Case after case of this was filled with honey just as it came from my storage-crates that without any selection tipped the beam at the exact weight. Most cases of course, required a little selection to make the weight come out right, but a moment's work was all that was required to even them up.

Several factors helped to produce this uniformity. This article is not on the production of honey, so I cannot discuss these now, except that I will say that in my opinion the principal of them is the use of a narrower section than is common. I use 7-to-the-foot, which, by making a comb more nearly the thickness which the bees build naturally, tends to much greater uniformity.

But even though your $1\frac{7}{8}$ sections will not run as uniform in weight, it is an easy matter to make each case of a standard weight. Set your empty case on a double-beam scale and balance it on one beam. Put the weight at the required point on the other beam, and, with the case still on the platform, put in the honey. As you set it in, set aside all extra-light and extra-heavy sections. Of the remainder, put the lightest at one end of the case and the heaviest at the other. If the weight does not come out right, it is an easy matter by a little selection to vary it either way. When you can guarantee weights—not average weights or estimated weights, but exact weights—you will have your business on a sound commercial basis, and not until then. It will take a little time and trouble, it is true, but you will be more than paid for these.

But, you say, what shall we do with the light and heavy sections that were set aside? You can case them separately, making cases of lighter or heavier weight than the standard, or you can combine them, making cases of standard weight, even though the sections are not uniform.

It is better to have nine-tenths of your cases uniform and one-tenth very uneven, than to have all more or less uneven. Those which are over or under weight, or in which the sections are not uniform in weight, should be sold, if possible, to those who prefer to buy by weight. Incidentally, let me say that the surest way to cure a grocer of the desire to buy honey by weight instead of by the section is always to sell him your heaviest sections.

No doubt some will say that it does not pay to be so particular. It has paid me well. It has enabled me to compete successfully with the careless and ignorant bee-keepers who sell their honey for whatever they can get. Competition has been particularly strong during the past season, as I have had to compete not only with the farmers and others who keep only a few bees, who are very numerous in this locality, but with some making a business of bee-keeping, who ought to know better, but who have been selling honey all the season for from two to three cents a pound less than I have been getting. In spite of this unfair competition, I have supplied the majority of the grocers of the neighborhood and have been able to maintain my price, which is always based on the top price in the Chicago market, and which I never change throughout the season if possible to avoid it. I fix my price in the fall, after a careful consideration of the market, and only once in fifteen years has it

been necessary to change this price during the selling season.

My light-weight, but carefully graded, section, averaging a little less than thirteen ounces, has brought as much money as the average bee-keeper has received for sixteen ounces.

Adopt methods that will give you sections of uniform weight and appearance, grade your honey carefully and honestly, sell it by the piece, and you will have some strong and effective weapons in your commercial struggle against the careless and incompetent. La Salle Co., Ill.

No. 6.—Apiculture as a Business.

Producing Not All; Marketing a Large Problem —Difference Between Selling at Home and the Foreign Trade—Effect of Competition.

BY R. C. AIKIN.

To produce is one thing, and to market is another. To produce well, and fail in marketing, means unprofitable business; and to produce poorly and market well is but little better. Both problems must be well considered in undertaking the business. Marketing at home—that is, where one has a home demand for all his product—is not so complicated or hard a problem as the outside marketing; the home selling does not require the goods to pass through so many hands or agencies. For these reasons it is evident that there must be more co-operation in the outside work. Should some other producer come into my field where there is now a local production equal to from two to four times the local consumption, he should leave out of his calculations the home trade, counting only the foreign.

There is a great and wide field in which to sell honey, in which to develop trade. When we consider the great hosts of our population who do not use honey, the thousands of communities who scarcely know what honey tastes like, there need be no question about there being an undeveloped foreign trade. By "foreign" I mean any field away from the producing point.

These foreign markets must be reached almost exclusively by the co-operation of apiarist with apiarist, and apiarists with transportation companies and middlemen—there is no other feasible way of reaching distant points. Near-by markets can be reached with only the transportation companies between, or possibly by wagon, and there is room in that field, but the biggest field is the one to be reached by the general co-operation of all concerned. This co-operation question I hope to consider later on; at least it should be considered, it is of very grave moment to all classes of producers, and more so to honey-producers than to some other branches.

Having decided to go into honey-production, or, being already in, we want to know how we are to get the best results in honey, both quality and quantity. In each locality one must adapt himself and management to conditions. Whether you have light, amber, dark, or all shades of honey; this or that flavor; slow, medium, rapid, intermittent, or all kinds of flows; all these things are factors that will influence results, and must be understood and observed in management if a good product is obtained. Just so sure as we neglect these things we will drop behind. It is a fact that the price of nearly every product is set largely by the cost of producing by the best and up-to-date methods; and he who is behind in his management is usually also behind in his accounts.

To my way of thinking, there is something radically wrong in the present competitive methods; they drive out of business the common or mediocre in knowledge, vigor, capital, and natural or acquired advantages. All cannot be at or near markets, post-office, depot, and other facilities; cannot have the same capital, the same machinery, the same materials. It is out of the province of this journal to discuss the cure for general social evils; but they exist and must be faced, hence I touch upon them to prepare the reader better for success in the line of business he has chosen. The short-cuts, kinks, better appliances and what-not pertaining to the science and detail, are things to know in any case. So much for the imperative need of much practical knowledge and understanding.

If one has a home demand that takes his product right from his honey-house, almost any kind of product can be sold—crooked and bulged sections, broken comb, extracted in bulk, and drawn right from a tank. If the trade passes

out to the village and small-town grocers, broken comb gets to be out of the question, and uneven and crooked sections also do not meet with favor. I find many customers coming to my honey-house for 15, 25 and 50 or more cents' worth of comb honey, and the customer cares not whether one section weighs a pound and a half and its neighbor only a half or three-fourths of a pound—just so long as I can give them the money's worth in good and fairly nice honey to eat.

In my practice I use separators, planning to have my section honey straight, smooth and even, such as can be retailed by the piece at 10, 12½, 15 or 20 cents each. In a large crop, however, there is now and then a cull section caused by a defective foundation or starter, or one with a brace against the separator that causes a break in the capping—some that meet with accidents in one way or another, and some that I buy from the farmers and from careless apiarists. I sell my nice, smooth honey to go to city and fancy markets, but retail the off-grades from the honey-house, weighing out by the pound.

Selling by weight from the average grocery is not practical in these days. There is a growing custom to sell almost every thing put up in regular packages, each package alike and the same weight. We find coffee, tea, baking-powders, flavors, meats, flour of every kind, in fact, almost every thing, sold in regular packages packed by the producer or manufacturer. I have heard that there are some places where butter is cut off in big chunks and weighed out, but in this part of the country and all up-to-date places, selling by the piece or package is very largely practiced, and the bee-man must come up to demand or custom else he is out-of-date, and cannot satisfactorily sell his product. Even potatoes in this country sell often "by the sack."

Honey must surely come to be sold as other things are put up in packages of even weight, and sold by the package at retail. It follows, then, that whether we prefer it or not, we must use separators in our supers, or some other device or method used that will obtain uniformity in weight of sections. I almost see some one or more writers hustling into print with arguments to prove my position wrong, saying it is possible to produce a fancy, even-weight section without separators. It is possible, but not PROBABLE. Possible when you have full sheets of foundation, thin sections (say 1½ inches), strong colonies, warm weather, rapid flows and skilled apiarists who know how to get the greatest number of these factors working harmoniously together. I say it is possible, but not probable—not probable with even the fair-to-good practical apiarist, and not always possible with the expert. Whenever the apiarist can make or supply all the deficiencies or defects caused by natural causes, then, and only then, can he produce a fair average finished product year by year.

A practical farmer knows that first and foremost he must have a good soil, and that it must be put in order, moist, mellow, and in fine condition to receive the seed. No matter how good naturally the soil may be, it must be prepared. After the soil is ready to receive the seed, then comes the choice of good seed to put into the soil. It is a familiar thing to most farmers to have observed or experienced the loss of a crop from a fine, well-prepared field, only because the seed was defective. So may the apiarist have the finest stock obtainable, but a miserable failure of hives and supers. Farmer bee-keepers and careless and impractical apiarists will buy the best hives on the market, then proceed to use them like a farmer putting poor seed into good ground, or good seed into hard, untilled ground. A good hive wrongly handled makes the possessor worse off than a poor hive well handled.

The value of a hive is in proportion as it enables the apiarist to apply methods, to produce results in short cuts, saving labor, obtaining control of bees, and thereby turning their habits and instincts to further our ends, and facilitating the best finished product. Do not be deceived into thinking that a "patent hive" of itself will get you more and better honey. It is method—an intelligent management and application of principles—that gets results. The hive is but the medium by which we bring about results—it is the vehicle. I do not believe we have yet the perfect hive, the one that best enables us to practice to the best advantage the knowledge we have attained to in scientific apiculture. I will confess (parenthetically) that I am striving to perfect a hive that will best enable me to apply my present knowledge of the scientific principles of apiculture, but, if I have not that scientific knowledge, or having

it will not apply it, my fine, improved hive is worse than useless. Bees, of themselves, and following instinct and nature, will be just as healthy, gather just as much honey, and be better off (they and their owner), dwelling in plain box-hives without a frame in them. Remember that the hive is but the vehicle by which the apiarist is able to apply HIS KNOWLEDGE.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

BEES AND SOUND FRUIT.

The Canadian experiments to prove that bees do not injure sound fruit seem pretty satisfactory. By starting very hungry bees to work on sound fruit dipped in honey, and also on similar fruit with little holes punched in it, right alongside, the conditions seem to be made sufficiently alluring and natural. And when they wreck the perforated fruit, and polish off the dipped fruit without making any holes in it, it's pretty plain that they at least don't know how to do anything more. It matters comparatively little to the fruit-man whether they don't know how or are physically incapable. Still, this does not entirely obliterate previous testimony that they do sometimes learn the trick of forming a hot, seething, miniature swarm on a bunch of grapes until they either burst the berries or pry them loose at the stem. I have grapes of many varieties, and only once in twenty-odd years do I remember to have seen something that looked a little like this. By rubbing long enough in one place a single bee could wear a hole and there is some testimony on record to the effect that they sometimes learn the trick of doing this. Page 73.

ELECTING OFFICERS OF THE NATIONAL.

Say, combine the two methods of electing officers. Begin the ballot at the annual meeting, where the desirability or non-desirability of changes can be talked over. Report the vote as far as it has gone. Then (after it is seen just how the cat is jumping) allow a sufficient time for the votes of absent members to be sent in. Or, would that lead to spite-work, to defeat just the ones that ought to be elected? I premise that the Scylla and the Charybdis of the thing are, that one method elects by a disgracefully lean minority, and the other method gives the voters no chance to concentrate on anybody else than the man already in the office. Page 83.

THE WHIMSICAL HONEY-EATER.

Yes, the man who cultivates a whim that he can't eat genuine honey, but can eat imitation honey all right—he's a tough proposition. What Edison, what Whitney, will invent a method that can reach and evangelize him? Page 88.

SUGAR-MAPLE AFTER FRUIT-BLOOM—RATTLE-HEAD BEES.

Why is this thus? North Carolina reports sugar-maple blooming after fruit-bloom. Here it is the other way. Page 92.

Rattle-heads indeed were those bees that took up their quarters in a five-gallon oil-can. Page 93.

CARBON BISULPHID.

Carbon bisulphid is a live topic on account of the present probability that it will displace sulphur in the important work of killing off our vermin and things. We greatly need the best, whatever it is. Very heavy, both as a fluid and as a vapor. Four cups of it weigh as much as five of water; but it only takes two—say bushels—of the vapor to balance five of air. One result is that with care it can be poured from one bushel to another. This is a practical matter, for we need to remember the difficulty of getting it equally distributed in the top of a closet or the top of a stack of hives. Water don't run up hill. Fortunately, heavy vapor, although it doesn't love to run up hill, will eventually mix with the air and then go up to some extent. Page 99.

Questions and Answers.

CONDUCTED BY

DR. O. C. MILLER, Marongo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Honey from Box-Hives.

On page 10 instruction is given to melt combs of honey taken from box-hives, with the hint that the melting will not improve the quality of the honey. A much better way is to get out the major part of the honey before there is any melting. Sort over the combs, and crush them, then give the honey time to drain out in a warm place.

I would not have made this correction if it had not been for the "after-thinking" my good brother Hasty gave it, page 122. It is a comfort for me to know that such sharp eyes are upon my work, and that an occasional slip will thus do less mischief. Never mind the "know-it-all style," Bro. Hasty; give us the truth.
C. C. MILLER.

Questions Answered Before.

What is the new style section D. H. Metcalf calls attention to on page 61?

Please describe "Golden's combination comb-honey hive," with plan or system, as mentioned on page 57.

CALIFORNIA.

ANSWER.—You will find these questions answered a week or two ago as fully as I could answer them.

Moving Bees 60 Rods.

I have about 100 colonies of bees, and I want to move them 60 rods. They are within the corporation, and the people are getting stung and bothered around the wells and watering-places. I have plenty of water for them, but they go elsewhere. I would like to know when would be the best time to move them. They are packed with chaff, with a shed over them. Do you think they will come back home again?

ILLINOIS.

Moving the bees 60 rods may and may not make a difference about their troubling wells and watering-places. If a good watering-place is afforded them near by, they may not care to go a great distance, otherwise they will not mind a distance of 60 rods. There will be less trouble about their going back to the old place if moved right away than if moved after they have begun to fly freely. But the unpacking and disturbance will not benefit the bees. Better wait till the weather gets a little warmer, say the middle of April; then when you are expecting a warm day, shut them up the evening before, move them in the forenoon without trying to handle them carefully, pound on the hives till they roar, then open the hives and set boards in front of the entrances.

Driving Staples in T Supers.

I am in trouble. Can you help me out?

How can I drive in staples like the enclosed without bending them all crooked? I've got to use such staples for T-tin rests, and I can't succeed in driving in a single one properly.

As they are to be used with supers having a bee-space at the top, they must be bent at right angles after being driven in. How can I bend them without losing them in the wood?

I thought that you could help me because you used the T-supers yourself. If you do not use bent staples for T-tin rests, will you please tell me what you use?

Please, please do not answer through the American Bee Journal. I can't wait so long. No doubt the answers appear by turns there, and I'd have to wait weeks. WISCONSIN.

Use a big, heavy hammer—no toy affair—so that you will not drive alternately one side then the other, and if the face of your hammer is not broad enough you might use the side of the hammer. Drive the staple in to the proper depth, then by one or more blows of the hammer bend it over while you hold

firmly against the staple the back edge of a saw or something of that kind; then draw out the saw and finish driving in the staple.

If I should do as you say, and not make answer in the American Bee Journal, that would practically bar me out from making any answer at all, and you wouldn't want that, would you? For you see, the same reason that would make it desirable for you to have your answer by mail would make others want theirs by mail, and it would hardly do for me to make fish of one and fowl of another. And if I should answer all by mail I'm afraid you'd have to wait longer than you do now, for such letters would have to take second place, and with so many I'm afraid I would get several weeks behind, whereas at present the Editor pays me for answering them and they take first place. All such letters are answered as promptly as possible, and I try to manage so there shall be no delay in getting them to Chicago, and I suppose effort is made to get them in print in the first number possible after they are received. So there is not the long delay you suppose. In some cases, however, it may happen that if the question is sent direct to me the answer will get into print a week sooner than if it is sent to Chicago.

Requeening—Dividing Colonies—Rearing Queens—Galvanized Iron and Honey.

1. I have the crossiest bees that ever were—there is no end to the fight there is in them. Last summer they kept sentries at the doors and windows all the time, and woe be to the stranger or neighbor who might visit. I tried to be as gentle with smoke and handling as possible, but sting they would. Now I know the Doctor will say, "Kill the queen." Is that so, Doctor?

2. Well, then, I am after you for the shortest way to fill up her place again.

3. One more question: How and when to divide for increase, and how to give queenless part a queen or queen-cell. I think it is best for me to divide for increase; it gives less trouble in watching swarms to double the colonies, as less is all I want; I am after the honey.

4. Do you think it the best way to put an extra hive on top of a strong colony with excluder between, near the time of honey-flow, or would you put extra below?

5. Is it best to rear queens in a full colony? Would a strong half-colony not do as well?

6. How many sheets of foundation or starters would you give a swarm at first?

7. How would this plan do for securing a few fertile queens, and to have them on hand when needed? I divide a 10-frame empty into 4 sections, by division-boards, each apartment to have an entrance of its own, then place in each section a frame with bees, brood and queen-cell, and another with honey; then let the queen get fertilized before using.

8. Will galvanized-iron tanks injure the quality of honey if standing in them for a time? NORTH DAKOTA.

ANSWERS.—1. No, I'm not so sure I would say to kill the queens. I'm a little afraid I can't trust you to do them justice. Sometimes it seems that all the bees in the apiary are cross when it's only the bees of one colony, and it would hardly do to start with a gun after queens till very sure just which are the guilty ones, or which is the guilty one. Watch closely the behavior of different colonies, and you may find there is just one colony which has bees that follow you all over the apiary. So long as you are nowhere near their hive they may not molest you, but if you go at all near the front of their hive they promptly make an attack and keep it up until you leave the apiary entirely. Neither will it always do to issue a verdict of guilty upon one single count. There may be some special reason why a colony is very cross today without it being irretrievably bad. But if it has established a permanent reputation for viciousness then off with the head of the queen.

2. Rear queens in nuclei, and use them as needed.

3. As a leading object with you is to prevent swarming, do your dividing a little before there is danger of swarming, but not necessarily before any preparations for swarming are made. How best to divide is a very hard question. What is best for one may not be best for another. You will do well to try different ways and then decide what is best for you. One way is to take from a colony all its brood but one frame, and to take that away two or three days later. Take the bees with half the combs, and brush them off the other half, of course being sure that the queen is left in the old hive. Start a new colony with these combs, and give them a laying queen after a day or two. The queen may be given in the usual manner in an introducing-cage, or if she is given from a

nucleus she may be given without caging; merely take a frame of brood from the nucleus, queen, bees and all, and put in a hive. Another good way is the nucleus plan. Commencing with the colonies most in danger of swarming, take from them brood enough to discourage them, and distribute it among the nuclei you are building up. Better have the queen laying in the nucleus before beginning to build up much.

4. I'm not sure that I know exactly what you are after. In any case, I would have the queen below, and if the extra story were filled with extracting-frames I would put it above, although I have known bees to make good work storing in extracting-frames below. If the extra story is to help prevent swarming, then put *all* frames of brood in the upper story, leaving the queen with empty combs or foundation below. That will work well for extracted honey, and will be better to prevent swarming than the plan you tried of putting up the brood piecemeal.

5. Yes and no. Up to the time the cells are sealed no colony is any too strong, in my opinion, to care for them. There are some, I know, who think a weaker colony will do as well, but my view would do no harm, even if they are right. When a cell is about ready to have the queen emerge, it may as well be given to a nucleus, for it will be wasting something like two weeks' time of a strong colony to take care of it.

6. I don't know. The easiest way is to fill the hive at the start, and for extracted honey it may be as well. For results in comb honey it may work better to give only half the number at the start, and give the rest in ten days or two weeks.

7. First-rate. Reared many a queen that way. Of course, have entrances on all four sides.

8. Testimony varies. Reports from abroad say harm has been done by it. In this country it is generally believed to be all right. Possibly it would be best, not to have a large surface of the metal in proportion to the amount of honey.

Feeding Bees in the Cellar, Etc.

1. My bees are sometimes a little restless, buzzing and coming to the hive-entrances (I winter them in the cellar). As I have not had any experience with bees I don't know whether they are short on stores. In that case, what is the best thing to do?

2. Is it harmful to open and examine the hive at this time of the year (Feb. 17)? I have been thinking about doing it, but if I should open the hive and disturb the bees, I believe I would get them all around the cellar.

3. One hive seems to be slightly damp, which I suppose it should not be. What can be done about that?

MINNESOTA.

ANSWERS.—1. The best thing to do depends upon circumstances. If you are fortunate enough to have a deep space under the bottom-bars, sections of honey, or a comb of honey, can be shoved under, taking care to see that it touches the bottom-bars, or at least that the bees get started on it. It may be necessary to stir the bees up a little to make sure of this. It may be that the top of the hive is the only part you can get at, in which case you may put in honey in frames or lay a cake of candy on top, covering up well.

2. Of course, it is not the most desirable thing to disturb the bees at all, but if carefully and gently done, the hives may be opened and frames even taken out without disturbing them very much. There is not much danger of getting them all over the cellar.

3. It is possible that the hives need a little more ventilation. If there is no ventilation above, and if the entrance is too small, the moisture from the bees will condense on the walls of the hive. It matters little how the air gets to the bees so there is plenty of it. It may be sealed air-tight above if it is all open below; and it may be sealed air-tight below if there is no covering on top; or it may have the usual summer entrance and a little chance for air to escape at the top, such a chance as would be given by laying a nail under one corner of the cover.

Swarming Management—Clipped Queens.

1. My bees usually swarm during April and May. What is the best plan to get the most honey? Is it best to let them swarm and give the prime swarm the most of the brood-frames with the brood, and give the new swarm empty supers? or is some other plan better? If you advise giving the new swarms combs from the mother colony, how many would be best? I find it to be the best plan with me to push the new swarms at the expense of the mother colony, to get the most honey. But if you will give me a better plan, I will certainly be glad.

2. If a queen is not hurt while being clipped, does the

clipping ever injure her in any way afterwards? A thing I do not like is a prime swarm to leave me and go to the woods.

SOUTH CAROLINA.

ANSWERS.—1. You're right, "to push the swarms at the expense of the mother colony to get the most honey." But instead of giving the brood to the swarm and leaving the partly-filled sections with the old colony, do just the other way. Give the swarm frames filled with foundation or with starters, and after a day or two, when the queen has begun laying in the brood-chamber, take the supers from the old colony and give to the swarm. In order to make the swarm stronger, do this: When the prime swarm issues, hive it on the old stand, and set the old hive close beside it. A week later move the old hive to a new stand. That will throw all the field force into the swarm, making the mother colony so weak that it will not send out a second swarm. All this is on the supposition that your earlier flow is the more important one. If you have a heavy flow continuing late in the season, and there is no danger of overstocking your field, then it may be better not to concentrate all your effort upon the swarm.

2. Of the great number of clipped queens I have had, I never could see that one was worse for the clipping afterward.

American and European Linden—Wintering Bees—End of Honey-Flow.

Well, here I am again asking questions, but if you get weary of me, why just turn me down.

1. What is the difference between the American and German linden? or, in other words, which of them is what beekeepers call "basswood?"

2. Which is the better, a dead-air space about the bees, or to have that air-space filled with mineral wool or some other packing-material?

3. Is it a good plan to raise the hives say about four inches from the bottom-board for wintering bees on the summer stands—I mean to have a frame made four inches high and the same dimensions as the bottom-board, so they may be removed in the spring?

4. Have you any way to tell when the honey-flow is over in summer?

PENN.

ANSWERS.—1. I don't know enough to tell just what the difference between the American and European linden is; but it is not very great. The American is called basswood.

2. It is considered better with the packing.

3. It is a very excellent plan. I get something like the same result by having a bottom-board 2 inches deep, filling up the extra space in summer.

4. Yes; when the bees have been doing good work at storing, and some day when you go into the apiary and feel inclined to say, "What under the sun makes the bees so cross to-day?" the probability is that the flow is letting up. So long as the flow lasts you will have little or no trouble with robber-bees; but when the flow stops you will find them inclined to pounce upon a frame of brood or honey if left exposed.

Don't you worry about being turned down for asking questions, so long as you do not easily find answers to them in your text-book. Come on with your questions; I've a whole lot of answers left, quite a large percent of them being, "I don't know."

Why Did the Bees Die?

I have lost 27 colonies during the winter. They had plenty of stores but it was very nearly as thick as taffy. Is this the reason they died? If not, what do you think killed them? They had good winter quarters.

ILLINOIS.

ANSWER.—I don't know. It is possible that along with the thickness of the honey there may have been something wrong about the quality. You do not say anything about the condition of the bees except their death. If they suffered with diarrhea, the quality of the honey was probably at fault. It is just possible that they died for want of moisture, in which case I should expect to find them in much the same condition as if they had starved; but I'm not entirely sure about this.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

GENERAL ITEMS

Winter Is Over Here.

My 28 colonies have come through in fine shape. They are gathering pollen every day. Winter is over in this locality.

H. D. MURRAY.

Rankin Co., Miss., Feb. 27.

Wants More Particulars.

We are often induced to read a seemingly interesting article and at the conclusion exclaim, "O pshaw!" Just so with the buckwheat item on page 108. We have no way of judging the value of the plant by that item, as we do not know whether he had one colony or a thousand working on the buckwheat.

Bee-keepers, please give us complete reports, not half-finished, unintelligible ones. Our time is too valuable to be thus wasted.

JOHN M. DAVIS.

Maury Co., Tenn., Feb. 25.

Wintering in Chaff Hives.

Bees did fairly well last season. I started with 25 colonies last spring, and increased to 45, from which I harvested 125 cases of 24 sections each of comb honey, and 1,000 pounds of extracted.

I have 40 colonies in winter quarters, which are all right at the present time. I wintered them on the summer stands, in chaff hives of my own construction, made of lap-siding 26x20x24 inches for the 8-frame dovetailed hive, giving room for 3 inches of chaff all around, and about 13 inches over the brood-nest. The cover is made like a roof of shingles. I find that the more chaff there is over the brood-nest the better it is, because it takes up more moisture during severe, cold weather.

C. J. OLDENBURG.

Scott Co., Minn., March 3.

A Florida Report.

If my health were good I would consider myself in good pasturage; but I am afflicted with sciatic rheumatism and a good part of the time I am not able to be with my bees. I have produced some large crops of honey here on the river. Three years ago my bees gave me 22 gallons of honey to the colony. Last year was a bad one, and they stopped at 14 gallons. I keep from 60 to 70 colonies.

We winter bees on the summer stands, of course. I have 76 colonies now, nearly all apparently in good shape. One of my neighbors had a good swarm yesterday. I study bees, read bees, work with bees, and with the help of the "Old Reliable." When asked if I am a bee-keeper my answer is, "I bee."

H. F. BAKER.

Liberty Co., Fla., Feb. 27.

A North Dakota Report for 1901.

Last season I was very successful with 8 colonies, spring count, and got over 600 pounds of honey, 70 was in sections and balance extracted; besides, I increased to 20 colonies, which were put into winter quarters the first week in November in fairly good condition.

I took a Michigan man's plan that I saw in the Bee Journal, to run more for honey than increase of bees, but I got fooled some. The plan was, when the colonies became strong in brood, to put an-extra hive on top with excluder between, and keep lifting up frames of brood from below to the upper part. This was to give no swarming and lots of honey, but instead there was galore of swarming, and I fairly lost track of how they were, and where they were.

I was fortunate in having a visit at the time

To make cows pay, use Sharples Cream Separators. Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

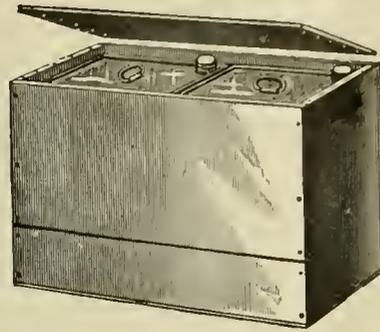

Alfalfa Honey-- 7 cents a pound in lots of 4 cans or more.

—BEST— Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Up a Stump 10 MILES TO A DOCTOR Watkins' Liniment all Gone

Enough to discourage anyone. Ill health, big doctor bills, no pleasure in life; blue and discouraged. What's the matter? Simply this. You can't work well, play well or sleep well until your body is in good healthy condition, and you can't keep the body in good healthy condition if you allow disease to once get a foot-hold. It is for this reason that a bottle of

Watkins' Vegetable Anodyne Liniment is so valuable in the house. It is ready when the first sign of cold or chill is felt. A few drops then does what a doctor would charge many dollars to do later. We receive numberless letters like the following:

MANAWA, Wis., July 5, 1901.
 I have used Watkins' Vegetable Anodyne Liniment for colds and cramps with very best results."
 H. F. ORA.

The Best Remedy made for

Colds, Coughs, Colic, Diarrhoea, Cholera Morbus, Dysentery, Indigestion, Cuts, Burns, Bruises, etc.

An especially strong point about Watkins' Liniment from the farmers' view-point, is that it is equally good for

MAN AND BEAST.

Our agent will furnish you with any of Watkins' Remedies, or if we have no agent in your neighborhood, write to us, and we will see that you are supplied.

GIFT FOR 1902.

low, upon its receipt, or 30 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

Please Mention the Bee Journal when writing Advertisers *****

This is a good time to send in your Beeswax. We are paying 28 cents a pound—CASH—for best yellow.

of an old bee-keeper who examined all the colonies, and found out their whereabouts, and how they were for queens, brood, etc. One trouble was, the queens would hatch out in the upper part, and there was no "go out" for them.

There was one very good plan he told me of, and that was to keep a record of how each colony was, on a piece of board, day and date; so after that every hive was looked over so many days after date, and all went splendidly for honey and increase.

The basswood yielded finely, and I cannot speak too much in favor of the sweet clover. One thing I would notice about a patch of yellow sweet clover—that I raised from the seed of one plant 3 years ago—it bloomed 3 or 4 weeks before the white kind, and just at the right time, and the bees seemed fairly to go for it. Then they took to the white bloom and worked on it until the frost came in September. It grew from 7 to 8 feet tall. Our cattle will eat it whenever they get a chance.

I have had a very good time this winter looking over the copies of the American Bee Journal, and am sure to be benefitted by its useful hints.

Thanks to Dr. Miller for his clear, honest talk and answers to questions; likewise Dadant, Doolittle, and others. R. McCRAIDIE.

North Dakota, Jan. 29.

Few Dead Bees in Wintering.

Bees have wintered well so far. I never saw so few bees die during the winter in the colonies left on the winter stands. Up to within the past three weeks there were scarcely more than a dozen dead bees to the hive. It warmed up yesterday, and those on the summer stands lost a few bees by their dropping into the snow-water; in fact, there were more lost from this cause within a few hours than died all winter. H. G. QUITMAN.

Erie Co., Ohio, Feb. 24.

Fine Weather—Selling Candied Honey.

The weather is very fine in this part of the country, and if it stays mild we will be able to report fine wintering of bees.

I have sold all my last year's crop of extracted honey—about 24,000 pounds—over 20,000 pounds being put into lard-pails. This was sold candied. You see, the people don't want it that way. As soon as they get it they will melt it and eat it. But some prefer it candied. R. C. AIRIN.

Larimer Co., Colo., Feb. 25.

No Honey Last Season.

There was no honey here last season. I probably will have to feed my bees when spring comes. But a bee-keeper is always hopeful. FRED BIESEMEIER.

Johnson Co., Nebr., Feb. 19.

Heavy Loss in Wintering.

As I have seen no letters from this part of Illinois, I thought I would give the condition of things. We have had a cold winter here. Bees went into winter quarters in fine condition, colonies strong, with plenty of supplies, such as it was, to last them, but, alas, it was honey-dew, and the result is that nine-tenths of them are dead, and those that are living are in bad condition.

We had no clover last summer, consequently they gathered honey-dew in September and October. It looks as if we will have to go out of business, or stock up from some other locality. C. ZOLL.

Fulton Co., Ill., Feb. 25.

A Severe Winter.

We are having one of the most severe winters here in years. Snow came very early, there being good sleighing for Thanksgiving, and staying right along, with the exception of a sudden but short thaw in December, which washed terribly, tearing out bridges and doing immense damage.

We are now undergoing our third blizzard

this month, and the snow-banks were ten feet deep before this began, there being many instances where the sleigh tracks were higher than the fence on either side of the roadway and other places where the banks have been shoveled through, where it was impossible for a person standing in the field adjacent to the highway to see any portion of either team or driver as they passed through these deep, shoveled places.

Winter came so early, so we are looking for an early spring, but we have fears for the safety of our bees, on account of their long confinement and the severity of the winter.

CLARENCE WILKINS.

Cortland Co., N. Y., Feb. 19.

May Have a Fair Season.

The unexpected good rains have come, and it is raining now. It is late but we may have a fair season after all. M. H. MENDESSEN.

Ventura Co., Calif., Feb. 25.

Thinks Bees Will Winter.

My bees have not had a chance to fly since last December, but I think they will come through all right as they had plenty of good honey to winter on. J. I. CLARK.

Addison Co., Vt., Feb. 25.

Honey Sold Well.

We had between 600 and 700 pounds of first-class honey last season, which I sold mostly in the home market at 25 cents per pound for both comb and extracted, and could have sold double that if I had had it.

L. E. AMMIDOWN.

Worcester Co., Mass., Feb. 24.

A Good Suggestion.

Talk is of no value without action. If everybody waits for the crowd there will not be any crowd. Mr. Ferguson (page 140) starts out with a dollar for 1902. Here is my dollar for 1903, toward the type-setting machine.

Now, come on boys; make a crowd; pay up all arrearages, and a year in advance if possible; and here we are. A. F. FOOTE.

Mitchell Co., Iowa., March 3.

[Wouldn't it be a fine thing if every subscriber who is in arrears on his Bee Journal subscription would pay everything to the end of 1902? Why not?—EDITOR.]

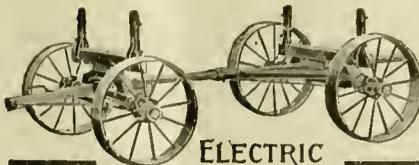

Gill's Weather-Proof Hive-Cover.

Easterners can not easily understand the effects of a Colorado sun in warping, twisting, and checking hive-covers. One man says a Colorado sun "will pull out nails and hide them." That may be exaggerated. M. A. Gill has devised a cover that he thinks will defy the worst that a Colorado sun can do. He says in the Bee-Keepers' Review:

I use the standard, 8-frame hive, and in getting out the material for the cover, I first get out a rim, the sides of which are 1x2 3/4 x 22 inches long. Along one side of the side-pieces I cut a rabbet 3/4 x 3/4 inches. Across the ends of the strips I dado in 3/4 x 3/4 of an inch, to allow the end-pieces of the rim, which are 1x2 3/4 x 14 inches long, to set in, and I nail both ways, as you will notice by referring to the cut of the cover.

On top of the rim I nail two boards that are simply ship-lapped together (very common lumber can be used). In nailing the cover together I use thirty 7-penny, cement-dipped,

ELECTRIC Handy Farm Wagons

make the work easier for both the man and team. The tires being wide they do not cut into the ground; the labor of loading is reduced many times, because of the short lift. They are equipped with our famous Electric Steel Wheels, either straight or stagger spokes. Wheels any height from 24 to 60 inches. White hickory axles, steel founes. Guaranteed to carry 4000 lbs. Why not get started right by putting in one of these wagons. We make our steel wheels to fit any wagon. Write for the catalog. It is free. ELECTRIC WHEEL CO., BOX 16, QUINCY, ILL.

flat-head nails. I then give the cover a heavy coat of paint, using outside white made from oxide of zinc and lead, and then right on to this green paint I lay a piece of thin, unbleached muslin, cut two inches larger all around than the top of the cover. Standing at the end of the cover, I cut a two-inch gash into the cloth, two inches from the corner. This allows the side strips to lap around under the ends. I now give the whole cover another heavy coat of the same paint right on top of the cloth, and make the laps at the corners in green paint, both underneath, in the middle, and outside; and I would advise to give it another coat of paint after it is dry. Such a cover will not warp, twist nor check, and it can be exposed to all of the elements of this or any climate; and, in my opinion, if given a coat of paint, such as I have named, once in three to five years, its owner will have a good water-proof cover as long as he cares to keep bees.

When this cover is placed on the hive, it rests upon the sides only; the ends shutting down over. There is about 1/4-inch play all around, and it is at the ends where is secured the circulation through the air-chamber, which I consider one of its most important features.

As an inside covering I use two or three thicknesses of burlap, both summer and winter; and when I crowd the cover on, the burlap, being cut 1/2 inch larger than the hive, is drawn taut so that the bees have a space above the frames; and the cover is held securely without any stooping over 700 times each week to pick up a ten-pound stone.

Old Bees More Poisonous Than Young Ones.

When I have forced a very young bee to sting me, I have been surprised at the mildness of the sting. So I am not surprised that Dr. Langer reports the amount of poison carried by a nurse-bee to be .00015 of a gram, while that of a field-bee was twice as much, ranging from .00025 to .00035—[Sometimes the sting of a worker right from the fields is so painful that I feel like groaning—yes, and I do groan—with pain. I am quite prepared to believe that the fielders have twice the amount of poison in their poison-sacs that the home-bees have.—Ed.]—Stray Straw in Gleanings in Bee-Culture.

Shipping Comb and Extracted Honey in Barrels.

Henceforth I want all honey in packages of 10 pounds and under in barrels. There is no packing case that can compare to it, anyway you take it. A barrel will hold about 250 pounds when in 5-lb. or 10-lb. pails, which is more than 4 crates of six 10-pound pails each. I prefer empty sugar-barrels, which if purchased when not much in demand (I suppose any time except during apple harvest) they can be had for about 10 cents each. They are preferable to either the regular apple-barrel or salt-barrels.

We can readily see that when compared as to cost the barrel is away ahead of crates; besides, it takes less time to pack and close one barrel than it does our four crates, but the difference here is not so marked, but apart from the cheapness it is much easier to handle a barrel than any other large package that has, or even can be, devised. I would rather handle one barrel of 200 pounds or 250 pounds than half that amount in crates, especially when in one crate.

Then, again, it is handled much more carefully in barrels. It is for this reason I frequently ship comb honey in them. I referred to the contents getting soiled when in crates; there is no trouble of this sort with the barrels, so that I know of no reason why they should not be used in preference, unless the quantity is not large enough. Even then, if you fill the barrel half full it will compare favorably with crates, unless it may be slightly heavier, but they are a gain in this respect when compared to four crates.

As to honey in the comb I prefer shipping in barrels when the quantity is not large and the distance very far. Some four years ago I shipped to 18 different places in the West, one lot going to Edmouton, 200 miles north

Every day during March and April we shall sell

Cheap Tickets To The Northwest

Montana, Utah, Idaho, Oregon, Washington and N.W. Wyoming

of Calgary, or over 2,000 miles with all the changes incidental to shipping "lake and rail," but in neither this nor any of the rest was a section broken. I have reason to know, as I was on hand to see. The heads were closed in the usual way so that rolling it was probably in order.

Comb honey in barrels has this advantage, there is more spring or "give" to it than when in a box. It stands a good chance of never being so placed that the sections will be exactly the opposite way to what they should be so that the jar and shunting is not so fatal. Honey in crates will be loaded one of two ways—the right or the wrong way, no half-way between. Apart from the "give" or spring this is a strong point in favor of barrels.

As I have already said, it is when shipping comb in small lots or long distances, and not when shipped in quantities, that I favor this method. Just how large a quantity, that I am not prepared to say.—G. A. DEADMAN, in The Canadian Bee Journal.

A Common Course in Bee-Keeping.

Theoretical bee-keeping around the winter's fireside is one thing, and practical bee-keeping in the field quite another. A mere amateur may operate the former, while it not infrequently requires a whole crew of experts, aided by all members of the family, regardless of sex, color or former occupation, together with invited guests thrown in for good measure, to control the latter.

How few of us but have seen men standing around all day in the cold and perchance storm, at "the sale," only for the blessed privilege of paying three or four prices for old, dilapidated hives inhabited by weak or otherwise inferior colonies of bees, and then taking extra precautions about moving their precious treasure, only to find them dead in the spring, or, should a portion survive, keeping them year after year, ever hoping for returns, (presumably on the "open sesame" principle) until all succumb to want and neglect, when the wrecks are converted into kindling wood. This, too, when the amount of the investment would have secured not only the kindling wood, but many a pound of sweetness with which to regale friends and family.—SOMNAMBULIST, in the Progressive Bee-Keeper.

Melting Honey.

Without special conveniences for it the melting of candied honey in 5-gallon cans is not always the most satisfactory. It takes a long time to do it with a slow heat, and with considerable heat there is danger that the outer portion will be injured by the heat while the mass is still solid. J. F. Munday helps matters by stirring the granulated part into the liquid just as fast as it liquefies, thus doing the work in one-third the time, and leaving the honey possibly in a better condition. He says in the Australasian Bee-Keeper:

It is necessary to make or procure a suitable tool for the purpose of breaking up and stirring the candied honey in the tin while it is being melted; this tool I made (and I found it just the thing) from the steel back of an old scythe-blade.

I removed the back from the blade with a cold chisel and hammer, cut off about twenty inches from the point, knocked out or beat down flat the old rivets, and then flattened out the point to the shape of a screw-driver (this screw-driver point I wanted for the purpose of prising up the lids of the cans). I then straightened the rod, as we may call it, with the hammer, scraped off the rust, and polished it with a piece of sandstone and it was done.

The tool requires to be strong and stiff, as great force is necessary to cut up the candied honey in the can. Now for the operation:

When the honey in the tin has melted say 3/4 inch around the insides of the tin, put in the stirring-rod, and scrape with it the two sides of the block of candied honey near the mouth of the can, just a little the first time. Then take out the rod say with your right

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you."—Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30) I never found these bees to show the least indication of unrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

Out of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chilly winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, Ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italians and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

hand, and as you do so, let it pass between the first finger and thumb of your left hand to remove the honey from it. Put on the lid, and let the honey remain in the now boiling water for ten minutes. During the interval, serve other tins the same way; if you have more than one tin melting you can keep a dozen tins going. At the expiration of the ten minutes, you will be able to cut some slices of candied honey off the block in the tin. Stir them about in the honey that is melted till no more will dissolve. Keep on doing so about every eight or ten minutes till all the candied honey is quite dissolved, but not for much longer. The water may boil all the while so long as you cut off and stir about every ten minutes. If you have to leave, you must take the water off the boil by adding cold water to it, as you know.

You will find that your tin of honey will be quite melted in less than 1 1/2 hours, when the honey was candied as hard as possible, and that the color and flavor of it has not been injured.

New South Wales Bee-Farmers' Association.

This organization has among its twelve "Rules and Objects" the following, which are somewhat peculiar:

- 3. To advise members as to suitable localities for establishing apiaries.
- 5. That every member with more than 50 hives shall be allowed an extra vote for every additional 50 effective hives.
- 6. No member be eligible for office who has less than 50 effective hives, or his subscription is in arrear.
- 8. The principal officers be such as will undertake to meet each other in committee at least once in twelve months.
- 11. Supply dealers or commission agents cannot become members.
- 12. Members unable to attend meetings or conventions can authorize or nominate any member they know will be present to vote for them on any subject brought forward. Such vote or votes to be in addition to the member's present own vote.

Positions of Eggs in Cells.

On page 10 of Mr. Cowan's book on "The Honey-Bee" is the following paragraph:—"It will be noticed that the egg (fig. 1, A) stands in a position parallel to the sides of the cells, and this position it retains the first day. On the second day it is inclined at an angle of 45 degrees (fig. 1, B), and on a third day it assumes a horizontal position (fig. 1, C), resting perfectly flat on the base of the cell."

Also H. W. Brice says in the British Journal:

"On examining a cells just after an egg is laid we find a small white speck standing on end, attached to the base of the cell, and slightly on one side of the apex thereof; it is fixed in position by a watery, semi-sticky substance, which at this period envelops the whole of the egg. Within a few moments, however, one of the nurse-bees enters the cell—head first, of course—and after a few seconds of activity, withdraws and hurries away to the next cell to 'go on' as before. Now, let us examine the cell again, and we find that the nurse-bee has carefully placed the new-laid egg down on its side and in its orthodox and proper position at the bottom of the cell. The egg from this time forward is a matter of constant care and attention on the part of the nurses, which are persistently examining it, probably to see how it is 'getting on.' On the second day we find the bees have shifted its position to an angle of about 35 degrees; on the third it is again moved to an horizontal position; and on the fourth day it hatches out."

The correctness of this teaching has been called in question, but it is doubtful that any one has actually disproved it. Some careful observations upon the matter might be of interest.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 7.—The decline noted in last quotations are still more pronounced at this time, large offerings of Western comb are pressing for consumption which are difficult to place. Prices are nominally 13@14c for the best white, with travel-stained and light amber, 10@12c, that which is candied selling as low as 7c, with the partially candied at 9@10c. No great amount of dark honey is offered. Extracted is steady in price but slow of sale, white, 5 1/2@7c; amber, 5 1/4@5 1/2c; dark, 5c, according to what it is gathered from and quality. Beeswax in urgent demand at 30c.
J. R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, bring from 5 1/4@6 1/4c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax sold at 27@30c.
THE FRED W. MUTH CO.

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c.
H. R. WRIGHT.

BOSTON, Jan. 20.—Strictly fancy comb honey in cartons, 15 1/2c; A No. 1, 15c; No. 1, 14c; very little No. 2 to offer; stock nominally running No. 1 and A No. 1. Extracted, light amber, 7 1/2c; amber, 7c; Florida honey, 6 1/2@7c.

Our market continues somewhat dull in the demand for honey, while stocks are ample for the balance of the season, unless there should be a much larger demand than we at this moment anticipate.
BLAKE, SCOTT & LEE.

NEW YORK, Feb. 8.—There has been very little movement of late in comb honey, and while there is no buckwheat on the market to amount to anything, there is sufficient quantity of the different grades of white honey. The demand having been slow of late, prices have had a downward tendency and are likely to remain so during the spring.

We quote: Fancy white, 14c, and exceptionally fine stock at perhaps 15c; No. 1 white at 13c; amber at 11@12c. Extracted remains dull at unchanged prices. Arrivals of late are quite plentiful of all the different grades. Beeswax firm at 28@28 1/2c. **HILDRETH & SEGELKEN.**

SAN FRANCISCO, Feb. 12.—White comb, 11@12 1/2 cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5 1/2@6c; light amber, 4 1/2@5c; amber, 4@—, Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Considering the limited quantities offering there is a fair trade in progress, both for shipment and local account. Quotable values are without change, but market is moderately firm at the prevailing figures.

CINCINNATI, Feb. 7.—The honey market has been rather dull this year. Comb honey is selling fairly, and brings as follows: White clover, 15c; lower grades from 12@14c. Extracted honey sells very slow, the lower grades bringing 5@6c, and fancy, 6 1/2@7 1/2c. Beeswax, 28@30c.
C. H. W. WEBER.

WANTED. EXTRACTED HONEY—either large or small lots; parties having same to offer, send samples, and best prices delivered at Cincinnati, Ohio. We pay cash on delivery. **THE FRED W. MUTH CO.,** 10Atf Front and Walnut Sts., CINCINNATI, O.

WANTED A Competent and Reliable APIARIST

to handle two out-apiaries on shares. Must have experience, and be well posted in the business. Address,

P. W. DUNNE,

River Forest, Oak Park Post-Office, Cook Co., Ill.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well if they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 171.

Do You Produce Comb Honey?

Here is something that will interest you.

"The Danzenbaker Hive I think will take precedence over all others. I am delighted with it, as it is simple, and easily manipulated."

R. H. PEPPORTH,

Pietermaritzburg, Natal, South Africa.

Nov. 30, 1901.

If you buy the Danz. hive you will find a ready market for your honey. Comb honey in Danz. sections has never yet been held because of "little demand."

EXTRACTED HONEY!

You will need good hives, smokers, knives, and most of all, a good honey-extractor. Root's Cowan Rapid Reversible Extractors are used everywhere, and always acknowledged to be the best. Be sure to get one of our make.

BEESWAX?

You should have the best wax-extractors, else large quantities of wax will be left in the refuse. See what one extensive and practical bee-keeper says of the ROOT-GERMAN STEAM WAX-PRESS:

For over 20 years past I have had to render up old combs or cappings in larger or smaller quantities, and my experience has been extensive, for I have tried faithfully almost every known method to get all the wax out, but have never succeeded to my satisfaction until recently. I got of you a German wax-press, that comes nearer accomplishing that object than any thing I have ever tried. I am more than satisfied with it, for, if used according to directions, there is little if any wax left in the refuse. Any one used to the old methods will be astonished at the results obtained. In this press you have given those in need of it the best thing, to my mind, you have ever brought out, and I really believe all who try it will pronounce it a real treasure. There are other points of advantage that I could mention, one of which is its perfect safety—no boiling over and setting fire to every thing, and it can be left alone without care for quite a time, and every thing can be kept neat and clean, and it occupies very little room.

Belleville, Ill., Dec. 12.

E. T. FLANAGAN.

Root's goods are for sale everywhere. See list of jobbers and agents in the January bee-journals. A full list of local agents sent you on request. We will also send you a little book, "Facts About Bees," describing the Danz. hive, and our catalog, on request.

WANTED.—Beeswax. Price, 28c cash or 30c in trade for pure average beeswax, delivered here. We want also a car of white sage extracted honey, also large lots of WHITE COMB HONEY in DANZ. sections.

THE A. I. ROOT CO., MEDINA, OHIO, U. S. A.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

MR. A. I. ROOT is taking a ride—on a hobby. This time it is starting plants from cuttings in a greenhouse.

THE TWO ROOTS and Dr. Miller have much to say* in Gleanings in Bee-Culture about a "personal devil." Do they speak from a "personal" acquaintance?

THE APIARY OF H. W. CONGDON.—Accompanying the picture shown on the first page this week was the following:

As I am always interested in reading the reports of other bee-keepers, I have thought perhaps a report from me would be of some interest to others.

I bought 2 colonies in the spring of 1900, in old-fashioned hives, increased to 4 by natural swarming, and 21 days after I drummed out of the old into new hives. I took off about 120 pounds of honey in the fall, and bought 6 more colonies, 5 in S-frame standard hives, one in an old shoe-box, and came out last spring with 8 colonies, having lost 2, and bought 22 more in April with 10 extra hives, 2 supers on each hive, and a lot of supplies and old truck for \$75. Six colonies were in box-hives. I have sold about \$70 worth of honey, and have about 100 pounds on hand for our own use.

All the time I can get to work with my bees is in the morning and evening, and sometimes a few minutes at noon.

I clip my queens, and during swarming-time I hired a small boy to stay in the yard from 8:30 to 3:30, and paid him extra for every queen he would catch, and he very soon got to be an expert at it.

Through the kindness of the owner, I keep my bees in the private park of one of our wealthiest citizens. I have a 4-foot poultry fence around four or five rods, and keep the gate locked, and the bees molest no one. I keep them supplied with fresh and salt water all the season. The yard is right across the street from my house. My son and I have a camera, and have taken up amateur photography. I enclose a picture of the bee-yard. I think I have a very cosy place for the bees, and enjoy working with them.

I get many good points and hints from the "old reliable" American Bee Journal; I could hardly keep house (or bees) without it.
H. W. CONGDON.

THE ONTARIO ASSOCIATION.—In the Canadian Bee Journal we find this interesting historical sketch of the Ontario Bee-Keepers' Association, by Mr. R. McKnight, one of its organizers and an apiarian writer of no mean ability:

It was, I think, in 1879 the Association was organized. The year previous, D. A. Jones rolled ten tons of honey into the exhibition at Toronto, for which he was awarded the gold medal. This created a furore in the country. The next year he called a bee-keepers' convention to meet in the City Hall, Toronto, while the exhibition was being held. In response to that call bee-keepers and prospective bee-keepers gathered in, to sit at the feet of the Gamaliel of apiculture and learn the mysteries of bee-keeping. That was the most numerously attended bee-keepers' meeting that ever was held in the Province. The hall was crowded with people during the three days of its session. The writer had the honor of occupying the chair. That meeting resulted in the formation of the Ontario Bee-Keepers' Association. D. A. Jones became president; I was elected secretary and treasurer. The president, secretary, and the Rev. W. F. Clarke, were appointed to formulate a constitution and by-laws for its government. (When

the Association was incorporated and became the recipient of an annual money grant, it was my privilege to modify its constitution and by-laws to meet the new condition of things. I am pleased to know that it has not been found necessary materially to change these since.)

We had no organ at this time. One of our members edited a weekly paper published in the town of Welland; with him we arranged for the use of one of its pages to be devoted to bee-literature. The conditions were—we were to supply the "copy" and I was assigned the duty of editor of the bee-department of the Canada Farmer (long defunct). By and by, D. A. Jones started the Beeton World, to which we transferred our patronage. Shortly after he started the Canadian Bee Journal—then the only weekly bee-journal in America—with the exception of the British Bee Journal the only one in the world. The Journal once became, and still is, the organ of the Association.

I remained secretary-treasurer till I became president, when I resigned the secretaryship, but continued treasurer up till 1892, when, on my resignation of that office, the Association very generously presented me with a gold watch.

Mr. McKnight's memory hardly served him well when referring to the starting of the weekly Canadian Bee Journal. Vol. I, No. 1, of that paper is dated April 1, 1885—4½ years after the American Bee Journal had begun to be published weekly, and 9 months before the British Bee Journal began to be a weekly. Previous to January, 1881, the American Bee Journal was a monthly, and up to January, 1886 (and we know not for how long before), the British Bee Journal was a "fortnightly." The Canadian Bee Journal was published weekly for about five years, then was issued for a time as a semi-monthly, and finally as a monthly, which it is now, and has been for many years.

MR. W. A. PRYAL, of Alameda Co., Calif., writing us March 5, said:

"We are having glorious rains here. The year bids fair to be as prosperous for the tiller of the soil and the delver for gold as any we have ever had. I am speaking for the central and the northern portions of the State. The south has had rain, I am pleased to say, but not in as liberal quantities as the agriculturist, etc., could wish. Still, they may have more in that portion of the State. Here all vegetation is looking up grandly; some sorts of fruit-trees are in bloom."

BUCKWHEAT CAKES seem to be in season at Stenog's home. He says in Gleanings in Bee-Culture:

That song for bee-keepers, music by George W. York, words by Eugene Secor, "Buckwheat Cakes and Honey," was received just as the familiar thump, thump, thump of the family batter-paddle was doing its work in making such cakes, rendering the song very appropriate. It is good all through, and all who have music in the house should have a copy.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 186.

42d YEAR.

CHICAGO, ILL., MARCH 20, 1902.

No. 12.

Editorial.

The Home Honey Market.—On page 182, Mr. C. P. Dadant has an article that will bear reading over several times, or until it is thoroughly learned. We have never been quite able to understand just why it is, that so many honey-producers have not yet been able to see that almost invariably the most profitable market for honey is the home market—right among the people living not further perhaps than five or ten miles from their apiaries.

As Mr. Dadant well says, honey is different from wheat, corn, potatoes, pork and beef. There is always a settled city market for such products, these having become staples, and thus in constant demand. What is needed now is for every bee-keeper to push the sale of honey everywhere until it, too, shall be in demand, equal, if possible, to that of soap and bread.

Small bee-keepers need never fear that the city market will become bare of honey, especially of extracted; for there are the large producers of honey, or specialists, who produce by the car-load—they will keep the large centers of population well supplied with honey. But there is often little sense in any bee-keeper who produces a ton or less, ever shipping it to a city market. There is scarcely a town or village but what, if properly solicited, would use several tons of honey on their tables in the course of a year.

Most people are fond of honey. Only convince them that it is the product of the bee, and they will not be long in purchasing, and also in consuming it.

Bee-keepers need to get close up to the editors of their local newspapers, and induce them to give to their readers information on the use of honey, which information the bee-keeper would need to furnish. It would pay to invite the editor to visit the apiary about the time of taking honey off the hives, and show him how that part of the work is done. Of course, no true bee-keeper would be so forgetful as not to present the visitor with a liberal sample of the sweet product of the hive.

Mr. Dadant has given much good advice in his article on another page, which, if followed, will make this particular number of the American Bee Journal of immense value. There is often almost as much in selling a crop well as there is in getting the crop in the first place—whether that crop is honey or cattle.

An "Infallible" Method of introducing queens was given on page 670 (1901) by A. D. D. Wood, who says there: "This may not be my own invention, yet I have never seen it mentioned." This plan will be found in "A Modern Bee-Farm," by S. Simmins. On page 160 of the 1893 edition, after emphasizing the point that where food is given to a queen confined in a cage, "honey from the same hive should alone be supplied," he goes on to say, "and on no account may any of the bees which accompanied her be placed in the cage; but it is advisable to give her an escort of some half-dozen young workers picked from the comb just after hatching, and taken from the hive in which the queen is to be caged."

This gives occasion to say that this book, written by so practical a man as Mr. Simmins, is well worth possessing. Among the many good things it contains may be found the "Simmins fasting method" of queen-introduction; and the bleaching of sections, which has had prominent mention in this country within the past few years was probably first given in this book nine years ago.

Discrepancies Among Bee-Writers

is the underlying text of a discourse from G. M. Doolittle in *Gleanings in Bee-Culture*. He says a rule in arithmetic and a rule in bee-keeping are different things. Two and two make four always and everywhere; what is true about bees in one locality or season may not be true in another locality or season. So two men may both be right from their own standpoints while appearing to hold widely different views.

The feeding of meal in spring is useless if not mischievous, says A. It is a good thing to give the bees in spring some substitute for pollen, says B. Both are right, although apparently in direct contradiction. In A's locality there is plenty of pollen in spring, either from early flowers, or else left over from the previous year. In B's locality the bees are short of pollen in spring, with no early flowers to yield it. One says put on sections early; another says not till swarming. Both right: one wants to discourage and the other to encourage swarming. So with other things. But the wise reader will get the views of all, and use what best fits his own case.

Instead of ceasing to read the bee-papers because in the nature of the case there will be real or apparent discrepancies, Mr. Doolittle says:

"One hundred dollars per year would not hire me to cease from reading on this subject, for it is to this reading that I owe nearly all the knowledge I possess relative to bee-keeping."

Dangers of Inbreeding.—Since interest has been generally awakened to the importance of striving for improvements in bees, considerable as been said about inbreeding. Some have cited examples from Nature to show how she abhorred inbreeding in the vegetable kingdom, etc. Others have cited examples of important results obtained from inbreeding, and from their writings one would judge that not only should no pains be taken to avoid inbreeding, but that it is the proper thing in the hands of every one. Still others have held that only as necessity compelled should inbreeding be resorted to, and that good results were obtained in spite of, rather than on account of, the mating of two beings closely related.

In the *Bee-Keepers' Review*, F. B. Simpson discusses the matter at considerable length, and he certainly can not be considered as encouraging inbreeding in the hands of the every-day bee-keeper. While admitting that "inbreeding has done us remarkable service in improving our domestic animals," he thinks the chances of success are so much against it that only one man in a thousand will be successful, and that man in only one of a thousand cases. He says:

So far as I have been able to learn, no man of unprejudiced mind has yet claimed that inbreeding will produce anything that can not in time be produced without it, provided we can supply a sufficient quantity of unrelated individuals. In breeding the domestic animals, the great element of *time* enters into the matter to such an extent that inbreeding has proved a practical necessity; yet there is no reason to believe it will be likewise with the bee, for the generations are too frequent. Also, as inbreeding can not be individual, but only collateral, in bees, it is doubtful whether it will have anything like the same effect for good and likewise for evil as in the higher animals. Furthermore, we have as yet no proof that insects can be made to vary (hereditarily) in as great a degree as the higher animals. It is true that the same laws of development run through the entire system of animated nature, but in her communal relations as against the individual, besides the fact of parthenogenesis, places the bee on a basis decidedly her own.

On the whole, he thinks it would be a good thing in actual practice for bee-keepers to let inbreeding alone until something has been ascertained experimentally as to its results among bees.

The Large White Clover (Colossal Lading) which has been highly spoken of in foreign journals stands a chance of being tested in this country, as the *Gleanings in Bee-Culture* people have secured some of the seed. It may be a great improvement, but too much should not be expected from it. It is not likely that it is large enough to be harvested as hay, and without this it may not be more valuable than the common kind.

Convention Proceedings.

Report of the Michigan Bee-Keepers' Convention.

BY JAS. A. DART, SEC.

(Continued from page 165.)

"BUILDING UP COLONIES IN SPRING FOR THE HONEY CROP."

Mr. Chapman says he puts away more bees than he expects to winter. He unites in the spring, taking two light colonies, puts on one queen-excluder, then puts the other colony on top, removing the queen from the top one. He says there is not much use in uniting three or more weak colonies; it is no better than each one separate.

Mr. Hutchinson agrees in this. He spreads brood later, but only as they can furnish proper heat.

Mr. Kitson says those colonies that have the most honey over winter work best in the spring.

Mr. Hutchinson in earlier days practiced stimulative feeding, but if left with sealed brood they will do better.

Mr. Coveyou advises in a cold snap in spring to sprinkle sweetened water in the front of the hive to save the bees going out and getting chilled. He uses an atomizer in the evening.

Mr. Kirkpatrick sees that the covers are tight, and that no heat escapes.

It was suggested that some one use an empty comb filled with water, or use a sponge for water in spring.

Mr. Hilton and Mr. Hutchinson suggested that in feeding one can put the syrup outside near the apiary, and after the first day it is safe from robbing.

COMB HONEY OR EXTRACTED?

"Which is the more profitable, working for comb honey or for extracted?"

Mr. Kitson says extracted is the most profitable, as the nights are too cold so far north to build comb.

Mr. Pinnell says there is more money in extracted at 8 cents than comb at 14 cents so far north; and counting extra work it is much more profitable. He says this year he run 20 colonies for extracted and 30 for comb, and got more money out of the 20 at 8 cents than the 30 at 14 cents.

Mr. Chapman says he got almost as much comb honey as extracted, but the weather was warm. He says in three-fourths of the years there is more money in producing extracted honey; the expense is no more for comb, as packages cost less; but he suggested that with a local trade the cans can be returned.

Mrs. Morrow says this past was the best year she has ever seen for selling honey.

Mr. Smith thinks the locality determines. He is in the coldest place in northern Michigan, and can't do well working for comb honey.

TOO MUCH POLLEN IN THE BROOD-NEST.

"Are we ever troubled with too much pollen in the brood-nest?"

Mr. Smith says it may bother the bees, but it does not bother him.

Mr. Chapman advises putting comb containing too much pollen in the center of a good brood-nest, the pollen will disappear.

SECOND DAY—JAN. 2.

Pres. Hilton, having contracted a hard cold, left for home, and the meeting was called to order by W. Z. Hutchinson.

CLIPPING THE QUEEN'S WINGS.

"Does the clipping the queen's wings shorten her life?"

Mr. Chapman shortens her life himself, and does not try to see how long she will live; also Mr. Kirkpatrick. Mr. Coveyou says he sees no difference, and others agreed.

E. E. Brown says he had a clipped queen live six years.

"How do you clip the wings?" was asked.

Mr. Kitson holds the queen by the wings on one side, and clips both wings on the other side.

Mr. Chapman, Mr. Kirkpatrick, and Mr. Pinnell, pick the queen up by the thorax.

Mr. Coveyou clips just at the time of fruit-bloom, when laying freely, and when workers are out gathering. He takes hold of the legs and wings on one side.

Mr. Smith advises clipping earlier in the spring; and holds the queen by the thorax.

Mr. Hutchinson picks her up by the wings on both sides, and then clips one wing.

Mr. Bartlett uses a queen-clipping device.

SHALLOW FRAMES VS. STANDARD IN EXTRACTING.

"In the production of extracted honey what preference has shallow frame over standard Langstroth?"

Mr. Coveyou says if any advantage it is that one can uncap with one stroke, and might get more uniform color of honey.

Mr. Chapman sees no advantage.

Mr. Smith prefers the Heddon frame (shallow), for the same reason given by Mr. Coveyou.

Mr. Kirkpatrick likes the Langstroth frame as there are less frames to handle.

Mr. Brown says he can handle two shallow frames quicker than one Langstroth, and bees go up quicker in the spring. He thinks deep frames make the honey darker. He uses one frame less than the super's size, as 9 in a 10-frame super.

Mr. Chapman starts the bees up in 15 minutes after putting on the super. He puts a frame of brood in the super and waits until the bees are ready to go up. He extracts when two-thirds capped, and thinks 7 frames in an 8-frame super is too wide. He likes 9 in a 10-frame super, and wants 14 to 20 frames of brood, thus making the queen do all she can in one year; then he kills her.

Mr. Kirkpatrick thinks there is a disadvantage in the shallow frames. He can't bait bees up. He uses 7 frames in an 8-frame super.

Mr. Coveyou doesn't like to put the brood up, as it makes darker honey above.

Mr. Chapman thinks it is a waste to force the queen to fill the top and corners of frames with brood. He gets better results with 50 strong colonies than 100 less populous.

Mr. Pinnell thinks all frames in the yard should be of the same size.

BEST DEPTH FOR BROOD-FRAMES—QUEENS.

"What depth frames are best for the brood-chamber in this region?"

Mr. Coveyou has two sizes—the Langstroth for old hives and the shallow for swarms.

"Is the queen most valuable before one year old, or afterward?"

Mr. Coveyou says she is best the second year.

Mr. Dart says he finds queens as good the second as the first year.

"How is it best to find a queen in a populous colony?"

Mr. Chapman looks till he finds her, in the middle of day, in July.

Mr. Hicks asked why he hunts in July.

Mr. Chapman said because he hunts them up to kill them except in the very best colonies. He thinks drones are as important as queens, and uses the best queens for rearing drones.

BEST BEES FOR THE NORTH.

"What is the best bee for the North—Italians, Blacks, or Carniolans?"

Mr. Kitson says the Carniolans are more gentle.

Mr. Chapman gave the Carniolans good trial, but gave them up. He says they are the hardest bees, but they rear drones anyway; will tear out comb and make drone-cells; also swarm too much.

Mr. Kitson says Carniolans build up quickly in spring.

Mr. Coveyou says Carniolans are good to get up an apiary quickly; then change to Italians.

General experience: Carniolans swarm too much.

Mr. Hutchinson says Carniolans build up quickly but swarm too much; he doesn't think them more gentle.

INBREEDING OF BEES.

Mr. Smith has inbred for 20 years, and takes no stock in the talk against it.

Mr. Hutchinson says there is not much danger, as there are so many bees in the country.

Mr. Coveyou says beginners have a good deal to do in getting hardy bees, by their losing the weaker in winter and breeding from the remaining strong ones.

Mr. Pinnell thinks it best to keep good strain.

Mr. Chapman thinks it is better to cross. He says a hybrid queen did good work, but he tried rearing from one and could not duplicate her. He thinks it safer to buy a few good queens.

PLACE OF MEETING—ELECTION OF OFFICERS.

It was moved by Mr. Chapman that the next annual meeting be held at Lansing, at a time to be set by executive committee. The motion was seconded, and carried.

The election of officers resulted as follows: W. Z. Hutchinson, president; Geo. H. Kirkpatrick, vice-president; James A. Dart, of Petoskey, secretary; and Samuel D. Chapman, treasurer.

Former treasurer, W. Z. Hutchinson, reported a balance on hand of 65 cents.

LOCATING OUT-APIARIES.

"What are the essential points to be considered in locating out-apiaries?"

Mr. Chapman advises locating so that bees will take advantage of all of the pasturage; not too close to a small patch, as the bees will work that to death. Pick the location so that there is good pasturage in equal distances surrounding. He prefers three miles between good-sized apiaries, the distance depending on the pasturage and the number of colonies. He says he gets little basswood now, mostly raspberry to take its place; uses a tent in the out yard, and pays farmers \$10 a year for a location in an orchard, and gives the farmers all the honey they want.

Mr. Kirkpatrick says 3½ to 4 miles bees worked successfully on basswood.

Mr. Smith never saw a bee over two miles from home.

Mr. Coveyou has had bees work successfully 2½ miles, and a neighbor 4 miles away had bees come four miles to his place.

INCREASE BY SWARMING OR DIVIDING.

"Should we increase by natural or artificial swarming? Which is the better practice to get white honey? and what method?"

Mr. Chapman takes the queens away after the spring flow after queen-cells are capped. He takes a comb having capped queen-cells, making increase in that way. He has no swarming.

FRUIT-GROWERS AND BEES.

"Can a fruit-grower afford to be without bees, provided there is no bee-keeper within two miles of his orchard?"

Mr. Woodman says some fruit-growers in his region say the yellows are spread by bees, but he had one neighbor raising pickles who had a double crop while the apiary remained there; that it would be better for a fruit-grower to keep bees.

Others said they would keep bees, and that honey-bees are earlier at the work and more to be depended upon than other insects.

The afternoon meeting was enlivened by music. A quartet of Petoskey singers beautifully sang, "The Hum of the Bees in the Apple-tree Bloom," and "Buckwheat Cakes and Honey." Emmet Co., Mich.

Report of the Vermont Bee-Keepers' Convention.

BY M. F. CRAM, SEC.

The meeting of the Vermont Bee-Keepers' Association was held at Vergennes, Dec. 18, 1901. It was a joint meeting with the Horticultural Society, they holding their meeting the day before, with a joint session in the evening.

The meeting was opened with prayer by H. L. Leonard; the secretary's and treasurer's reports were read and adopted; and the following committees were appointed by the chair: On nomination, H. L. Leonard, W. G. Larrabee, and R. H. Holmes.

R. H. Holmes and M. F. Cram were appointed to confer with a like committee of the Horticultural Society, to see if the two societies would best unite and report at the next convention.

CAUSE OF RECENT WINTER LOSSES.

W. Blackmer—The loss was caused by dysentery. The disease was caused by young queens laying in winter, and

by being confined for too long a time without a flight.

W. G. Larrabee asked why bees die with honey close to the cluster. The cause is not known.

A. M. Hill inquired whether to winter his bees in a cellar with the temperature 32 to 38 degrees, or in his fruit house. He was advised to do neither. Mr. Leonard said he would not risk his bees in a cellar where there was frost or that lacked ventilation.

Mr. Lowrey said that at the Vermont Experimental Station, two years ago, they lost 22 out of 25 colonies packed with sawdust on top and all around. Last season they lost one out of 16 packed with planer-shavings.

BLEACHING HONEY.

J. E. Crane said he had more or less stained honey. Last year he had bleached some of his darkest honey so it passed for No. 1. He had built on a room 10x13 feet, with glass on three sides of the room. He can bleach 1000 pounds at one time. He used sulphur, but not too much, as it gave the comb a green color. In a room containing 850 cubic feet, burn 6 ounces of sulphur, then let it stand 20 minutes. He had to do it several times to make the comb white. This season the color was caused by propolis. He showed several samples which had been bleached by the side of that which had not been bleached. Out of 6500 pounds, 500 pounds could not be brought out to No. 1. One sulphur bath would not do as much as a week of sunlight. When the combs are slightly stained, they can be brought to a pure white; but when badly stained it can not be removed at all. If he were to build another room he would have it light overhead.

G. C. Spencer—Would it turn the comb yellow?

Mr. Crane—It would not.

Mr. Holmes—What makes some honey so yellow?

O. J. Lowrey—It is caused by the bees working on corn, but the yellow largely goes off in time. The temperature has not much to do about bleaching, but it helps ripen the honey.

Mr. Crane had not been able to discover that the honey was injured by bleaching. He thought it had paid him financially for building the room.

How can this stain be prevented? was asked. The only way is to take off the honey as soon as completed. Black bees make the comb look whiter than the Italians.

CONTROLLING SWARMING IN OUT-APIARIES.

Mr. Holmes—He had some help in each yard, but that was not what he wanted. It was when he left the bees without an attendant. They must have plenty of room to keep down the swarming-fever.

Messrs. Blackmer and Lowrey remove the brood and let the bees go back on starters or full sheets of foundation.

Mr. Lowrey uses queen-excluders 14 by 2 inches.

Mr. Larrabee thought the swarming instinct could be bred out. He had brought home from an out-apiary 15 colonies which had been run 10 years for extracted honey, and not one offered to swarm in 1900, or until late in 1901, although run for comb honey.

A vote of thanks was extended to the people of Vergennes for the use of hall and lights.

AFTERNOON SESSION.

The committee on nominations nominated the old board of officers, and they were re-elected.

WAX-PRESS—LONG-TONGUED BEES.

Mr. Crane talked on the use of the wax-press, which was very instructive. We have been losing a large amount of wax by not having proper facilities for extracting the same.

Mr. Leonard spoke of long-tongued bees, saying he had not measured their tongues, but had measured the other end of the bee a good many times, and it reached clear through his pants, and some besides.

Mr. Crane thought there was something in long-tongued bees, but it was more in the hardness of the bee. He had known that some of his queens had transmitted desirable qualities for two or three generations. He spoke of one queen he purchased whose bees had produced more honey than any other colony in the yard, and had capped their honey in a very peculiar manner, so much so that he could distinguish it after it was all mixed up with other honey.

Mr. Lowrey read a paper on the loss of virgin queens.

Mr. Holmes—There is more loss some seasons than in others.

RESOLUTIONS.

WHEREAS, An All-Wise Providence has seen fit to re-

move from our midst the wife of our friend and brother, V. N. Forbes: therefore, be it

Resolved. That the members of the Vermont Bee-Keepers' Association, in convention assembled, do hereby extend our heartfelt sympathy to our brother in his deep loss and bereavement.

The above was unanimously adopted, and voted to send a copy to Mr. Forbes, and also to record it on the journal of the Association.

A vote of thanks was extended to the Central Vermont & Rutland Railroad Co., for reduced rates of fare.

The time and place of the next meeting was left with the secretary to confer with the secretary of the Horticultural Society, and they to decide. — M. F. CRAM, Sec.

Contributed Articles.

The Sale of Honey—Increasing Its Consumption.

BY C. P. DADANT.

In the article on page 88, I showed that there has been a perceptible change in the conditions of the honey market, due to the better knowledge that the people in general, or at least the better-informed classes, have of the manners of production now in vogue. On page 46, I see a quotation showing how the people can be educated to the use of pure granulated honey. This is exactly in the line of my experience, and I wish to insist a little more on the necessity for the large honey-producer, and, in fact, for the readers of our bee-papers in general, to extend their efforts in the direction of vulgarizing, or spreading, among the masses the information concerning the latest methods of bee-keeping, and the manner of recognizing good, wholesome honey.

The need of the present generation of honey-producers is not only to make their pursuit truly known, but to increase the consumption of an article the production of which has been probably increased one hundred-fold in the past 50 years.

The most potent cause of the low prices in honey has been the custom prevalent among bee-keepers to ship their crop to the large centers without previously investigating the possible chances of sale in their vicinity. Allow me to make an example of this in an altogether different line, which will probably serve well as an instance of what may be achieved by seeking a home market.

There is quite an extensive production of grapes in this vicinity. The city of Nauvoo, some 11 or 12 miles from here, is renowned for its grapes of all varieties. The bulk of the crop is shipped to Northern points—St. Paul, Duluth, Minneapolis, Chicago. We grow grapes ourselves on a comparatively large scale, having some 12 acres of vineyards, and we have often been tempted to ship our crop as the Nauvoo fruit-growers do. But after investigation we have found that in ordinary seasons, especially when there are no apples, the peddling of grapes among the farmers and in the neighboring towns would bring more per pound for the grapes than could be realized in the North, in countries where a grape is never grown, owing to the cost of shipping and distributing. We have made sure that a basket of grapes could be sold to a farmer, besides paying for the peddler's time, for more than the same basket would bring, net, on the St. Paul market. There have even been times when the grapes shipped to those common points brought so little money that it would have paid the shippers to have crushed them into wine, even if they had only been able to sell this as vinegar.

On the other hand, some seasons, when the crops in the large producing districts were small, the prices in those Northern cities was away beyond what could be secured here, so that the success of sales has resolved itself in watching the markets, but especially in first trying the home sales on as large and extensive a scale as possible.

The producer of corn, oats, wheat, the hog-raiser, the horse-breeder, do not need to hunt about for a market, because they have daily reports of the least fluctuation, and they find dealers in the commodities they produce right at home, in every town. But the growers of grapes, as well as the producers of honey, are in no such circumstances.

So they must take more pains if they would be sure of securing the best prices that their goods will command.

To find a home market it is necessary to push it, but when it is properly canvassed one will be surprised at the amount that can be disposed of. It is, however, useless to expect the same success every season. Many things go toward making or injuring the sale of an article, and one can not expect that the demand will be the same each year. If the fruit crop is large, both honey and grapes would be of slow sale. But there is always a very fair market for a properly-packed article, offered in a particular manner, with a good guarantee of purity.

The fact is, that no matter how careful you are, how diligently you canvass the retail stores, and the homes of your neighbors, you will find that some articles in your line will still be brought from the large centers for sale in competition with your own product. But what a loss to the producer when his goods have to go to the large market and work their way back again, through the commission man, the wholesale house, via the railroad both ways! If it is not your own honey, it is perhaps that of another producer just as far away as you are, and if this product comes in competition with yours at a low price, you may be sure that he has not realized much on his shipment. How many of my readers have shipped honey to a large city and have been sorry for it. And perhaps they have laid the blame of the low price on the commission man. But let them remember that the fault is mainly theirs, because they have not taken sufficient pains to seek customers. Perhaps their very next-door neighbor would have purchased honey if they had only offered it at a reasonable price and in neat shape.

In seeking a home market, however, there is one stumbling-block, that is, the possible competition of two or more producers in the same goods. This competition will not assume an unpleasant shape, if the producers understand their interests enough to join hands and agree on prices. This is where the local bee-keepers' association becomes useful. A judicious discussion of conditions will readily point the prices at which goods may be sold in any locality to satisfy both producers and consumers.

There is nothing impracticable in the points I have shown. The only thing needed is to take hold of this matter in the right way. There are plenty of associations at work, and many bee-keepers are doing that which I would like to see the great mass do—seek an extensive home market for their product.

Hancock Co., Ill.

Forerunners of the Movable Comb.

Gleaned principally from Bienenwater, Imkerschule, and other German and Austrian bee-papers,

BY F. GREINER.

As we have it in use to-day, the movable comb is not the product of one man's brain. We Americans give Father Langstroth all the credit; the Germans feel equally grateful to Rev. Dzierzon and Baron Berlepsch for the same discovery. However, there were other men before Dzierzon, Berlepsch and Langstroth who conceived the idea of making combs movable, and succeeded more or less in accomplishing this object.

During the earlier part of the 18th century a hive was in use in Greece which might demand the name of a movable-comb hive. It was made willow-basket fashion, wider at the top than at the bottom, coated with clay inside and out. Bars were fastened across the top at proper distances to answer as comb-carriers. If it was desirable to divide a colony, half of the combs and bees were taken out and transferred to another hive. Honey-combs could be removed if wanted. It is not improbable the knowledge of these hives may have come from the Egyptians, for the Egyptians were well advanced in bee-culture long before other nations had any knowledge of bees. It will be remembered that Solon made a trip to Egypt about 600 B. C., in the interest of apiculture. The same kind of a hive is also found on many islands of the Mediterranean Sea. Della Rocha, residing on one of them, describes this hive in 1790. He also constructed and describes a two-story hive with bars.

The hive used on the island of Sicily may not have been the outcome of the desire to make the combs movable, or the brood-chamber divisible, as much as to make use of the material at hand. The hive consisted of little frames about 9 inches square, made of bamboo sticks 1½ inches thick. These frames were fastened together by fine wooden

ins, sometimes as many as 25 or 30, and were coated on the outside with clay.

Hives consisting of several separate chambers were used in Sweden and England during the 17th and 18th centuries. J. L. Christ, of Nassau, describes such hives in 1783. He also made use of the bar in connection with the separate honey-chamber (super).

Reaumur made many valuable discoveries regarding the natural history of the bee in his one-comb glass hive during the forepart of the 18th century. The blind Huber united a number of such combs—regular frames—by hinging them together. Thus he constructed a hive which could be opened like the leaves of a book.

Felix Pina introduced a simplified Huber hive into Austria, and wrote a work on bee-keeping soon afterward.

Propokowitz, a Russian, is said to have used a hive with a separate honey-chamber filled with regular Langstroth frames as early as 1812.

We observe, then, that Genius has been at work a long time on the problem of how to make the combs of the beehive movable, and get the most out of bees, even before Langstroth and Dzierzon were born. And, after all, had it not been for Langstroth and Dzierzon—although we may not make use of the exact appliances as they gave them to the world—we might be to-day using the old box-hive, and know but little more about bees than was known a hundred years ago.

Ontario Co., N. Y.

No. 2.—Desirability of Long-Tongued Bees.

BY PROF. A. J. COOK.

It is patent from my last article, that the length of the tongue varies in different bees, and very markedly in those of different races. It is also important to remember that the bees of the same race, and notably those of the same colony, vary but very little, as compared with those of different races and in different colonies. The yellow races possess the longest tongues, and the Cyprian and Syrian bees stand in the lead in this peculiarity.

ARE LONG TONGUES OF VALUE?

This would seem to go without saying. Is the long neck of the giraffe of importance in the desert, where the very uppermost leaves of the shrubs may stand between it and starvation? Not only the red clover, but many other flowers have long tubular corollas. In many cases whole families of plants have these long, slender flower-tubes. We all know that seasons vary greatly in favoring nectar-secretion. A cold wind, or spell of weather with low temperature, may shut up the nectar-secretion of the flowers as absolutely as winter itself. Some flowers are much more susceptible to such influences than are others. Suppose, then, that in the season of clover or linden bloom the season is unpropitious, and that later come some flowers with these long corollas, and also the genial warmth and sunshine that favors nectar-production, then plainly the bees with long tongues will come to the front, and a few hundredths of an inch in length of tongue may stand between life and starvation. The cold may chill to inaction the nectar-glands of clover, linden, and sage, while possibly some wild plants with deep flower-tubes will prove more hardy, and will yield an abundance of honey to such bees as are able to reach to it.

I have frequently seen, as have many others, the red clover swarming with yellow bees—Italians or Syrians—while not a black bee could be seen on the bloom, though the black bees were quite as numerous in the neighborhood. I have seen the same thing in observing wild flowers, in both Michigan and California. There is no doubt whatever that the bees with longer tongues are a decided advantage in any apiary. Bees with shorter tongues may still, in certain cases, gather more honey, for reasons of superiority in other directions, but not because of their shorter tongues, which are certainly never a disadvantage, but in spite of these.

The very best bee will be better in every way, and certainly will be appreciated in value if among other anatomical, physiological and temperamental peculiarities it has the longer tongue.

To breed bees, then, with longer tongues, and clover with shorter corollas, would both be of advantage, but the former would be of most service to the apiarist, for then the bees would glean from all deep-tubed flowers, and not simply from the clover.

CAN WE BREED LONGER TONGUES?

There can be no more doubt that this can be done than that the sun will rise to-morrow morning. All organisms—plants as well as animals, and all animals, from the lowest protozoan to man himself—are alike embraced under the laws of breeding. Those interested in this subject should read Miles' "Stock Breeding," or, still better, the classical work of the great Darwin, "Animals and Plants Under Domestication." All animals tend to vary. This tendency may be inherent, or, more likely, is the result of environment. Selection, either by Nature or man, will continue and fix these variations.

Through the three laws—variation, inheritance, and selection—the world is indebted for its wonderful varied life. Through the wiser, sharper selection of man, our cultivated plants and domestic animals have developed races with astonishing rapidity. The American trotting-horse has been created within the memory of those living, while the Poland-China hog—another valuable gift to the world from American breeders—is the product of but a few years.

IS THE BEE AN EXCEPTION?

I believe the bee would show exceptional susceptibility to such modification. Nature, unaided by man's keen observation and painstaking selection, has made or developed several races of bees. The Italian, the Cyprian, the Syrian, the Egyptian, the German, etc., are not species, but races of the one species—*Apis mellifera*. Where else in all the realm of life do we see so many Nature-made races as in the species of our honey-bee? I know no other example at all comparable to this. Surely, if our bee is so plastic in the duller, more plethoric hands of Nature, what may we expect when man applies the well-known laws of breeding towards its modification, along any desirable line? We have seen what man can do with the bee in color. He can add rings at will, or cover all with gold. If color were as valuable as a long tongue, we should have a still more valuable bee to-day than are our best strains of Italians.

Again, I know of no animal with such wonderfully varied organs as has the bee, and such a multiplicity of them. Glands, mouth-organs, legs, stomach, even the hairs, are marvels of varied modification. Man is only wonderful in his brain and hand, while the honey-bee has a half-score of marvels to exhibit. This has all been done in the slow, plodding machinery of Nature. Let man, eagle-eyed, take the honey-bee in hand, and with some worthy ideal—not color, which has only the virtue of pleasing the eye—in mind, and he may mold any product he may desire. This is as sure as that love will always conquer.

I know that the difficulty of controlling mating stands in the way, but the plucky breeder will easily find ways to conquer this difficulty. As I have urged for years, there is certainly a brilliant success awaiting the man of pluck and genius who will attack this problem, guided by the best that is known regarding the laws of breeding. Bates, Booth, and Blakewell had not such a field of promise, nor such preparation as he may easily gain, and yet what an enviable record they made for themselves, and what a legacy they bequeathed to the world.

Los Angeles Co., Calif.

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

BREATHING AIR FROM A PAPER-BAG FULL.

We find it nearly or quite impossible to keep from breathing for any length of time, even in poisonous gas, or with head under water. We know an attempt to breathe can only draw water into the lungs—or choking gas—yet we breathe in spite of ourselves. An excellent device to get on disobedient Nature's blind side is given on page 100. Big paper-bag full of air, and tied around a short length of rubber-tubing, the other end to be held in the mouth. This is really better than no breath, and if it could get as bad as none it would still help us keep from doing worse. If we find it necessary to stay in sulphur fumes, or fumes of

bisulphid of carbon, it's well to have this simple device in mind. I think its most valuable use would be in saving life or property at a fire. Personally, I am so intolerant of smoke that I would often be thankful for such a device at outdoor fires.

HOW TO TIE UP COMB HONEY.

I don't believe, Mr. Davenport, I should like driving nails into sections of honey, to hold them together on the road to the customer's pantry—but then I might—perhaps it's the sound of the thing that repels me. Like yourself, I also used lath crates awhile for the purpose, and quite a bit different from your style of thing. Presume I also experimented with heavy strings, although my memory on that point is not very vivid. As I never could tie a string anyhow, quite likely my string packages never won my confidence enough to be trusted to start out. But at last came the great Marconi discovery, that paper around the outside held by ordinary wrapping-twine was the right way. Don't you think, brethren, that I'm generous to give it to you "mitoud a cent?" Use newspaper sheets just big enough and lots of them, *big* lots of them. There is really a little art in rolling the sections into the paper tightly, and quite a bit of art in folding the ends without marring the outside honey. Properly done, the package will stand quite a blow on the ends, which are projecting and puffy. Page 103.

NOTE THE LONGEVITY OF BEES.

F. Brown, of Florida, wants some one to say why his champion honey-gatherers live longer than other bees. I waive the question, and hail as a valuable item the *fact* of extra longevity being attested. That is a fact we greatly need to establish before we go much further. I'm glad a competent man shifted the queen three times and observed the age of the left-behind bees. Don't be entirely dashed if daughters fail to transmit. Try granddaughters, and perhaps they will. But I'll grant that holding mainly to stock that produces uniform queens is a good plan. Page 105.

CARBOLINEUM TOO STRONG A FUMIGATOR.

Don't believe we have much use for a chemical so strong that the fumes take the skin off the painter's face. This is anent carbolineum as mentioned on page 108.

ANTS AND WET LOCATIONS.

I freely yield to Mr. Lovesay as to knowledge about ants. All we have here in Ohio are mere insect "uncles" compared with those he tells of in Utah. The suggestion to put the apiary on very wet ground seems to be a good one. A wet location is not to be chosen on its own account, however. Dry locations much the best, other things being equal. Page 108.

ROBBER-BEES AND THE ROBBED.

Yes, that's a matter on page 115 that I have sometimes longed to know; yet I have never thought of it when there were convenient means of finding out. Is the pile of dead bees in front of a hive from which robbers have been repulsed all robbers? or do robbers in the last extremity do their best to kill? If they try to kill of course they part of the time succeed. 'Spects now we shall hear.

THE BOTTOMLESS CELLS OF STINGLESS BEES.

You didn't say whether the comb you got with the little stingless bees was paper or wax. If of paper perhaps the seemingly bottomless cells were not exactly so in fact. Capped brood of our own paper wasps is in one tier only, but only one end is ever opened. No good, the door-keepers among our bees would vote the Mexican tactics of stopping the door all up with one's own body. Business-end pointed away from the enemy. But stingless bees stand off enemies by biting them; so their tactics just fits their structure. Some of them have jaws that will snip a hair off quick as a flash—and bite so terribly, and "go in" so boldly that the man who gets among them votes their stinglessness to be in the nature of a humbug. As belligerents they seem from reports to be about as fierce as ants; and if ants could fly we would keep at a pretty respectful distance. Very interesting (and all in our line) to see bees carried to southern Mexico to pollenize coffee-trees and fruit-trees. Page 115.—[It was a wax-comb, of course, else we would have mentioned it, Mr. Hasty.—EDITOR.]

The Premiums offered this week are well worth working for. Look at them.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Closed-End Brood-Frames.

If the closed ends of brood-frames warm the hive in comb-building, are they not warm for winter also?

Granting that closed ends are desirable, why not have them in the Langstroth hive?

I have long had an idea that a dovetailed hive with the side-boards built two or more inches longer than usual, and thin end-boards mortised or let in at the right distance from the true end-piece or outside end, so as to take the Hoffman frames, but a super that takes an extra row of sections, would be a good hive for outside wintering. My plan is to get a hive that is 10-frame in size, has chaff-packed ends, and in the fall all the preparation necessary is to take out two end frames and insert in their places chaff division-boards, and place a chaff cushion over frames.

Would not this arrangement give a combination of the closed-end frame and the chaff-hive? Has such a hive ever been tested? If so, what were the results? ILLINOIS.

ANSWER.—Closed-end frames have been used in various ways, and there is nothing to hinder using them with Langstroth frames. Of course, the greater trouble with bee-glue, and the danger of killing bees, is to be considered. I think such an arrangement as you propose, or something very similar to it, has been in use more or less, beginning years ago, but the number of such hives does not seem to be on the increase.

Was It Buckwheat Honey?

I think I did well last year, considering the dry season. I started in with 18 colonies in the spring, mostly black, and increased to 54, and took off about 1000 pounds of comb honey, mostly from buckwheat. How is it that my surplus came from buckwheat, and the color is so white, and the flavor so fine, that I can sell it all for white honey? A few boxes were filled, and the body of the hives were filled, after the buckwheat flow was over; it, too, was of the same color. I think that came from what is called here "wild sunflower."

I have been able to sell all my honey here for 14 and 15 cents per section—14 cents by the case, and 15 cents per single pound. A great many merchants here want to weigh the cases of honey. I tell them they may weigh it if they want to, but if they buy it will be by the section instead of by the pound. I think that is the stand all bee-keepers ought to take. MINNESOTA.

ANSWER.—I don't know the answer to your conundrum, but if you will let me shut my eyes and guess, I will guess that your buckwheat honey came from some other flowers than buckwheat. One year a piece of buckwheat was close to my house, and I could see the bees working on it a little sometimes, but they never stored enough from it to give a smell of buckwheat to the surplus, and that's about equivalent to saying that they didn't store anything from it. Buckwheat is by no means reliable as a yielder in all places, even when it blooms abundantly. Possibly the wild sunflower was in bloom at the same time as the buckwheat, but I'm not sure about the color of sunflower honey.

Foundation Starters—Queenless Colony, Etc.

1. If I use comb-foundation starters and put them in the frames some time before I use them, will the worms be likely to bother them? If so, can I prevent it?

2. Last fall I had a queenless colony; it had several queens hatch out, I think, but the drones were all gone. Afterward, every drone-cell in the hive seemed to have six or more eggs in them. Was it a no-account queen, or laying worker, or what?

3. I bought a full-blooded untested Italian queen, and she laid all right for some time, and then disappeared. Do

you suppose she died, or they killed her? There were several young ones sealed up when I looked in the hive, and they hatched out about the same time as the one previously mentioned. I united both with one, and I thought it had a good hybrid queen. I looked in the hive yesterday (Feb. 24) and found what drone-comb they had was full of young drones, and some able to crawl about. They looked like full-blooded Italian drones. Do you suppose they have one of those young Italian queens? If so, do you think she can ever be of any account? If not, what would I best do? There are a good many bees now.

4. I have a colony of rather short bees, and they don't look like Italians, hybrids, or blacks. They almost try to sting a shadow, and store more honey than most of my other bees do. I don't know where they came from. Can you guess what race they belong to?

5. Sometimes I see blacks, and 2 or 3 banded bees in the same hive. Have they the same mother? ALABAMA.

ANSWERS.—1. No, there will be no trouble whatever.

2. Laying workers.

3. I don't know the cause of the queen's death. You can hardly expect any good from the colony, and the best thing is to unite it with another.

4. No, I don't know.

5. Yes, the same mother may produce bees that look very unlike. When an Italian queen mates with a black drone, the worker progeny may vary all the way from pure Italians in color to pure blacks.

Bee-Houses and House-Apiaries.

I live in the city, and can not keep bees unless I keep them in a bee-house; nor can I devote much of any time to them during working hours; so I wish to keep them as nearly non-swarming as possible. I have a fine little grove of young trees in my yard—a nice place to keep bees. There is plenty of white clover here, and but very few bees around. I have the "A B C of Bee-Culture" and "Bee-Keepers' Guide." I can not make a cellar that will be suitable to winter bees in, on account of it being somewhat low and springy. I see in the books that a good bee-house will be all right if made right, and I have decided to make one next summer, so as to have it ready for the bees when I put them into winter quarters. I have also decided to use the deep or Jumbo hive, and to run for extracted honey.

1. Will the Jumbo in the bee-house make them practically non-swarming?

2. I have thought of keeping the house warm with hot water when it got too cold. Will that do any harm to the bees if the temperature is kept between 40 and 46 degrees with hot water?

3. Will it need to be so warm if I put a casing around the hive, and a good cushion on top?

4. If I divide each colony into two colonies, will there

be any danger of swarming the same season, providing I divide just before they get ready to swarm?

5. Would you advise using the shallow extracting super on the Jumbo hive, or a division-board in the brood-chamber, and extracting often enough to keep the bees working?

6. Will it be advisable to feed in spring with a division-board feeder so as to stimulate brood-rearing?

7. Will a bee-house 10x12 feet, inside measure, by 8 feet to the rafter-plate, be large enough for 24 colonies?

8. How much more extracted honey will a colony produce than comb honey?

9. Where can I get insurance on the bees and supplies I have on hand?

10. Have the plans for a good bee-house changed since the "A B C of Bee-Culture" gave its plan for building? If so, please give plans.

11. Would you advise Italianizing my bees?

I hope you will excuse me for asking so many questions, and taking up so much of your time. MINNESOTA.

ANSWERS.—1. It is hard to tell just what will be the case with you. Some report almost entire freedom from swarming with the Jumbo; but with me it seems but little better as to swarming than smaller hives. Yet your working for extracted honey makes an important difference.

2. It depends on how you use the water. If you carry vessels of hot water into the house, letting them stand open, it will not do at all. It will be all right if you use hot water pipes, or if you use jugs of hot water tightly corked, or if you use the hot water closed in any way so there is no chance for any vapor to escape in the house.

3. It will make some difference, but not such a great deal.

4. It will help, but will not be a sure preventive.

5. Use shallow extracting frames, and leave the brood-chamber undisturbed.

6. Until you are an experienced bee-keeper you will do well to let stimulative feeding alone.

7. Yes.

8. I don't know. The estimates of different persons run all the way from saying there is no difference, up to more than twice as much.

9. In other countries there are special insurance companies connected with bee-keepers' societies, but I know of no such companies in this country. The best way for you to do is to inquire of insurance agents in your neighborhood.

10. I think there is no material change.

11. Yes; by all means.

I am almost sorry you did not make out the even dozen by asking me another question, that is, whether I would advise you to build a bee-house. If you had asked that question I should have told you that while some have been successful with house-Apiaries others have not, and that the last I knew about it the one in "A B C of Bee-Culture" shown with eight sides, had no bees in it. The only reason I don't tell you this now is because you have not asked the question.

Bee and Honey Statistics.

In reply to inquiries, Editor Root gives the following interesting figures in Cleanings in Bee-Culture:

There are no data as to the number of pounds of honey and beeswax exported from the United States, and I can, therefore, give you no information. In a good year California might produce 200 cars of honey, Colorado somewhere about 40 cars, and Arizona 20 or 30. New York is another good State, but probably does not produce, all told, to exceed 100 cars. But the honey is not exported from New York, it being consumed largely in the country where it is raised.

There are something like a thousand members of the National Bee-Keepers' Association.

The estimate of the number of pounds of honey produced in the United States is somewhere about as follows: For comb honey, 50 million pounds; for extracted, about 125

BETTER THAN SPRAYING.
Don't lug barrels of water around when spraying. Use the poison direct. Our

Common Sense Dust Sprayer

and Insect Extirminator is a most ingenious device that is rapidly supplanting the old methods. It blows the finely powdered dust into every nook and crevice. Reaches the bottoms as well as the tops of leaves. Destroys insect life on plants, vines, shrubs and trees. Just as effective for vermin on poultry and pigs. More rapid than spraying. Descriptive circulars and testimonials free.

million, or a total money value of from eight to ten millions of dollars.

Capt. J. E. Detherington of New York, and W. L. Coggsall, are the two most extensive bee-keepers in the United States. The former is credited with owning 3,000 colonies, and the latter about 2,500.

Shaking Bees from the Combs.

There is a good deal in doing it just right. Probably no way is better than that given a number of times by G. M. Doolittle, with whom it is probably original. He gives very minute instructions in the Progressive Bee-Keeper as follows:

With me it is very easy to rid the combs of bees by shaking, especially if each frame is filled with comb as that the same is attached to the bottom-bar the whole length. Where combs are not so attached, there will always be a few bees between the bottom-bar and the comb which will stay there no matter how the frame is shaken, and these will have to be brushed off. Desiring to take a comb away from the bees, I place the projecting ends to the frame on the ends to the middle fingers of each hand and then, with a quick upward stroke, throw the ends of the frame against

the ball, or thick part of the hand at the base of the thumb. As the frame strikes the hand let the hands give a sudden downward motion, which makes the shock still greater. As the frame strikes the fingers it is again thrown back against the hand, and so on until all, or nearly all, the bees are off.

The principle is that the bee is on guard all the while to keep from falling off downward, thus holding on tenaciously so as not to be shaken off by any downward motion. By a sudden stopping of the upward and quick downward motion, the bees are thrown off their guard and dislodged in an upward direction. In this way I have no trouble of shaking every black or hybrid bee off; and if the Italians are disturbed enough to cause them to fill themselves with honey, they can be shaken off the combs about as easily as the black bees. But even if we cannot afford to wait until they are filled with honey, nineteen-twentieths of them can be shaken off, when a bee-brush will easily take off the rest. To any one not used to this way of shaking, it may appear to be a little awkward at first; it will soon become easy, and after once becoming used to this method none will be willing to use any other.

Hand-Picking Drones.

Mr. Doolittle hand-picks his drones. In my opinion it is extremely doubtful that any (other) man will be successful in picking out the drones which are superior. Is there any bee-keeper anywhere who can with any degree of certainty pick out a superior queen from a batch of them, just by her looks? She may be yellow; she may be without fault and blemish as to outward appearance; but who can tell what her workers will be? Is it any different with the drone? "By their work ye shall know them." But in case of the drone, he is gone when you see his work. It seems improbable that we will gain anything by hand-picking. In all probability nature will attend to that part better than man can hope to do. The very best we can do is to select the mother of our drones.—F. GREINER, in the American Bee-Keeper.

Apis Dorsata.

Interest in the introduction of this big bee is not what it was a few years ago, and the present indications are that for utilitarian purposes it will never have any direct interest for American bee-keepers. B. Hamlyn-Harris, the well-informed correspondent of the British Bee Journal, has contributed an article to The Entomologist's Record and Journal of Variation, from which the following is clipped:

About three years ago a special inquiry was set on foot to ascertain whether or not the Giant Bee of India was a suitable subject for domestication. At that time I was permitted to look over various reports at the India office, and all these agree that *Apis dorsata*, mentioned generally under native names, could not be domesticated on account of its intractable character. The chief points noted are:

1. It is said to be exceedingly vicious, often attacking man or beast on the smallest provocation.
2. It preserves the same habits and appearance wherever its habitat.
3. It has never been known to build its nest under shelter, but mostly on isolated lofty trees or overhanging rocks.
4. After the honey season they will desert their nests, and often travel for long periods and great distances, even crossing such mountain chains as the Nilgherries in their course.
5. They build single combs.
6. And are used to approach from north, south, east or west.
7. They rarely remain in one locality for more than three weeks.
8. Emigrating as flowers become scarcer.

It is well known that one of the greatest obstacles to the domestication of this bee is its natural wildness and its inability to settle permanently in one spot. When we consider that *Apis dorsata* usually makes its nest in

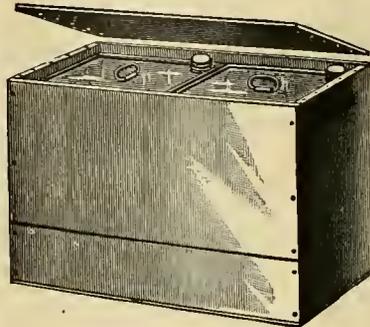

Alfalfa Honey--7 cents a pound in lots of 4 cans or more.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa
Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood
Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

wild and rocky country, only remaining in one locality so long as flowers abound, we shall better realize why it moves from place to place, and the importance of so doing to its general welfare. Therefore, we see that only in completely altering its natural habits could we hope to domesticate this bee, or bring it into use under other circumstances to those in which it has always lived. Also, on account of its size and the power of its flight the Giant Bee will travel as much as 100 miles before again settling down to home life.

It is not so much the honey gathered by these bees which is valuable to the natives, but the large quantities of comb they produce, which is melted down into wax, which forms a valuable article of industry in India. The hillmen do not trouble much about the honey, but are said to eat the young bees and larvae with great gusto. Another hindrance to domestication is the way they build their nests, quite in the open, entirely unprotected, and always single combs from about 5 ft. to 6 ft. in length and about 2 ft. to 3 ft. in depth. Some fine specimens of these combs are to be seen in the South Kensington Natural History Museum.

When a species of insect has been used to certain habits for generation after generation—in fact, has never known any others—it will be readily understood how difficult would be the problem presented to us did we attempt to keep such a refractory creature in confinement. The only attempt made seems to have been a failure. A queen-bee was tied by a thread to a stick and placed in the hollow of a tree, and after two or three months a very small piece of comb was found, and the experiment, proving useless, was abandoned. Since this a writer to the last Government reports says that "he had seen seven hives all well and fed for the winter," but in the spring the "little brutes" decamped by twenty or thirty a day, until each queen in turn left the hive in disgust. Clipping the queen's wings, as done in modern bee-keeping, would prove fatal to *Apis dorsata*. On account of her uncontrollable character she would probably be lost.

The question arises, if we cannot domesticate *Apis dorsata* itself, could we by judicious crossing attain the desired end? The best answer to this question will, I think, be found in the fact that European bees exist which are closely allied to a species found in Northern India, which never crossed with *Apis Indica*, very similar to our European bee, with which domestication might be a success, but if any real advantage would arise therefrom or not is doubtful, and no doubt can remain that the facts relating to *Apis dorsata* must forever bar the way to domestication.

Germ that is Killing the Market for Extracted Honey.

W. W. McNeal, in the American Bee-Keeper, says it is not one outside of bee-keepers themselves. He strikes pretty close to the truth when he says:

Now, bad as glucose may be, the germ that is sapping the life of trade in honey finds its abiding place in unscrupulous methods of production! To people of taste and refinement the quality and general appearance of extracted honey in so many instances reflects on the producer such slovenly habits as to be in reality reprehensible.

The man who produces thin, unripe, unstrained or dirty honey, and palms it off on another is just as deserving of censure as one who puts in glucose and calls it honey. The effects are the same in both cases, for both rob honey of its rightful constituents.

Apiculture in Chile, S. A.

I am situated near 38 degrees, while the whole territory extends from 18 deg. 40 min. to 55 deg. 50 min. In the extreme north rain never falls, and consequently no place for bee-keeper nor bees; whereas, in the region south of this—about latitude 40 deg.—rain is constant all the year round, not the most desirable location for the bee-keeper, either.

It may interest some readers to know that the mean rainfall varies from 12 millimetres

in latitude 27 deg. to 2,860 millimetres in latitude 40 deg.; further south, to latitude 53 deg. 10 min. (Punta Arenas) the rainfall decreases 550, of which one-fifth is snow. My own experiences extend to regions from latitude 33 deg. to 39 deg., and I flatter myself in thinking my own situation about the happy medium as to extremes of temperature, moisture, etc. After twelve years' experience here I am prepared to say that the swarming fever referred to in the "Revue" is by this time so much eliminated with me, that I can work under quite as high pressure as at home. When I first commenced the bees would swarm in spite of extractor or unlimited working room, and, of course, to work for sections was out of the question. Now I get 2-lb. sections worked with greater certainty than the 1-lb. are at home. Of course, I use the "B.B.K.A." standard frame. All the bees I meet with in apiaries here are the Italian race.

With me, swarming begins about the latter part of November. Honey begins to come in as surplus in December, the heaviest months being January and February.

The statement that the produce of 500 colonies amounted to 36,400 pound of honey goes to confirm what I have been trying to drive into the heads of some of the bee-keepers here—to wit, the mistake made in laying down apiaries of over 100 colonies; the vogue here is 500 or 1,000 and upwards. Notice what follows in the article referred to, "ninety-five colonies gathered 18,000 pounds." I have taken 250 pounds to 300 pounds in my own apiary from one hive when no swarm has issued, and over 150 pounds from a swarm hived in December. The statement that the native Chilian does not eat honey is not my experience.—J. R. W. HOLE, in the British Bee Journal.

Young Larvæ for Queen-Cells.

In Gleanings for July 1, 1900, in a footnote on an article of mine, you say, Mr. Editor, "We have heretofore assumed that larvæ just hatched, or larvæ not more than three days old, was the preferred age; but there is a case where the bees evidently had a preference for the five-day limit." The fact that this continues to be quoted in foreign journals, and that it is likely to be misunderstood, makes me now refer to it. While you may have meant all right, there is danger that you may be understood as meaning: "In this case the bees preferred larvæ five days old to anything younger." This is not true. The only possible preference at all in that line would be expressed thus: "The bees preferred to wait till some of the larvæ were to old for good queens, rather than to start all cells earlier." Now let me give the truth deduced from my investigations—the truth that I think any one will deduce from any fair investigations—it is this: Bees will not start queen-cells with larvæ as old as three days when younger larvæ are present; but they will continue to start queen-cells after all the larvæ present have become too old for that purpose. Will my good friend of the Review say whether he believes this to be the truth?—[I accept your amended correction.—Ed.]—Stray Straw in Gleanings in Bee-Culture.

GENERAL ITEMS

A Beginner's Report.

I am a young bee-keeper and appreciate the American Bee Journal very much.

There is only one bee-keeper in this neighborhood besides myself. I started with one colony, which swarmed 4 times, and now I have 5. I did not get any surplus honey but I think my bees are wintering well.

As I did not know much about bees I thought I would give them a good letting alone.

JOHN A. DUNN.

Reno Co., Kans., Feb. 20.

Early Spring.

Spring is opening up very early here for this country, and the bees, as a rule, except perhaps Salt Lake County, have wintered fairly well, and a fair, average season is looked for by our bee-keepers. While there is no drawback in sight, the only fear is drouth or grasshoppers.

E. S. LOVESY.

Salt Lake Co., Utah, Feb. 21.

Nailing Up Shipping-Cases.

Mr. C. Davenport says he can now put 2 non-drip shipping-cases together in less time than he could one before. Now my way to put slats in the bottom, nail on the 2 ends, then I take a board that just goes inside of a case, 3 inches wide, cut slots in it the space of the sections, then slip the strips into these slots and nail each end, then take out the board and nail the center, and then nail up the case.

S. D. BUELL.

Branch Co., Mich., Feb. 20.

Bee-Keeping in Oklahoma.

We had a very poor season in northwestern Texas the past season, although my loss is only 10 percent, while that of others has been 50 percent.

I am now moving my apiary near the Wichita Mountains, in Oklahoma Territory, I being one of the lucky ones to draw a fine place through the opening up of the Comanche Reservation. I think I have a fine location for bees, and, as before, will give my attention to bees and fruit-raising.

I am the first man to establish an apiary in the New Eldorado; it will be watched with interest by other bee-keepers who want to bring bees to Oklahoma Territory.

J. W. ADAMS.

Montague Co., Tex., Feb. 20.

Heavy Winter Losses.

After a month of very severe wintry weather I find I have snuffered the greatest winter-losses in my experience. I have lost at least 60 colonies, or $\frac{3}{8}$ of my bees, and most of the rest very weak, and if the weather does not moderate I fear the loss will be much greater.

My loss was caused by being confined so long without a flight on stores containing honey-dew.

The prospects for 1902 are gloomy. It has been nearly a year since we have had a good rain.

We have not had any honey since 1899; we had some honey-dew in 1900, also a little last year.

I will continue reading the "Old Reliable," anyway. I have been a cash reader since I have been a bee-keeper, nearly 7 years now. I commenced with 2 box-hive colonies, and increased to 202 colonies in 5 years, all in Langstroth dovetailed hives. I have decreased considerable in the last two bad years.

I am the only member of the National Bee-keepers' Association in the Indian Territory. I am sorry to say.

I let merchants handle honey on commis-

It Means Something to the world that there is one old family remedy that is believed in by endless thousands of humanity after 40 years' trial.

WATKINS' Vegetable Anodyne LINIMENT

It means that here is a remedy that makes you feel certain of the lives of your dear ones in cases of accident or sudden sickness. It means many dollars saved to you that would otherwise go to the doctor or veterinary. In all cases of children mumps, diarrhoea, flux, rheumatism, cuts, cramps, strains, burns, mumps, sore throat, diphtheria, etc., it is a God send.

Worth Its Weight in Gold.

Red Lake, Minn., June 5, 1901.
One time last summer I got very sick with cholera and thought sure we would have to send for the doctor, but after taking 3 doses of Watkins' Vegetable Anodyne Liniment I felt as well as ever. Since then I use it every day and find it the best family medicine in the market to-day; it is worth its weight in gold. JOSEPH DUCHARMÉ.

Thousands of good people have written in the same vein. Don't wait until you are down sick, or injured by some bad accident, but be sure to get a bottle from our agent when he calls. If no agent in your county, write us at once and we will see that you are supplied. Price \$1.

FREE! FREE! FREE!

We send our instructive 100-page finely illustrated Home Doctor and Cook Book to every inquirer free. It is a very valuable and interesting work for farm and home, containing weather forecasts, fine cooking recipes, etc. We send it free whether you are ready to buy now or not.

sion for me and two of them refused to settle. I reported them to Hon. Eugene Secor, and the money came forthwith, so I saved enough there to pay my membership several years. "A word to the wise is sufficient."

Let every one that reads this not only pay up his subscription (if in arrears), and a full year in advance, but inclose \$1.00 membership fee to the "National," and make Editor York and yourself happy.
J. T. HAIRSTON.
Indian Territory, Feb. 20.

Deep Snows—Wintering Well.

We have had the deepest fall of snow for several years, about 8 inches on the level. It did not drift very badly here, but delayed trains about a day.

Bees went into winter quarters in the best condition since I have been in the bee-business (1896).

They have not had many flights, but I think they are all right.
W. H. MEANS.
Greenwood Co., Kan., Feb. 21.

Evidently an Error.

Mr. Editor:—Did the printer take liberties with Mr. Bingham's copy, page 156, or are we to understand that 25 degrees is an "ideal" temperature for bees in a cellar? IDEALIST.

[Yes, it is an error. It should have been 35 degrees instead of 25.—EDITOR.]

Entrance Feeding of Bees.

It is near feeding-time for the colonies out of stores and for stimulative brood-rearing. I have been feeding some old sorghum honey I bought cheap. I make an entrance-feeder on the plan of the Boardman. I take a round tin can 8 inches across, run a gauge-mark around it about 1 3/4 or 2 inches from the bottom, and cut it off. This makes a dish nearly 2 inches deep and 8 inches across; almost any old dish will do. Then make a box with two points to run into the entrance with a loose cover; the box must be tight, and great care taken not to let robber-bees get a taste. Liquefy the feed by mixing water with it. The dish must be full of old comb to keep the bees from drowning.

C. H. AUSTIN.

Eddy Co., New Mex., Feb. 21.

Poor Prospects for Honey.

It is now the time of year when a tolerably safe report can generally be made concerning honey prospects in this part of the State.

We have had, to date, a trifle over 4 inches of rain, and the most of it came early, and was succeeded by dry weather lasting until the latter part of January. We have had more cold weather than common this winter; little damage, however, has resulted, but it aided very much in retarding early bee-feed.

I have been to my apiary several times lately, and in traveling a section of country 30 miles in length, and observing closely on every hand, I must say that I have never seen the prospects for the apiarist much poorer than at the present. Unless rain comes soon in plentiful quantity, we will have to feed back to the bees some of last year's crop. Eastern markets, I think, will get but little California honey in 1902.

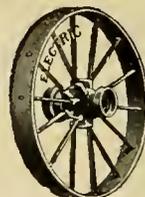

ALBERT ROZELL.

Los Angeles Co., Calif., Feb. 21.

Do Robber-Bees Sting?

Answering the question (page 115), "Do robber-bees sting?" Rarely; though very rarely indeed they do. The robbing question has always been very interesting to me. I have watched and studied it for days and weeks with pain, pleasure and profit.

The conditions in which a robber-bee is most likely to sting is when a defending bee grabs the robber by the leg and then hangs on, and hangs on, until the robber drags it clear down the alighting-board into the grass. The robber then seems to say, "Come, now, old fellow, you are as mean as I am; we are now on common ground; let go or I'll sting;" and in

short order it grapples the other bee and stings. But generally when the robber makes a sharp turn both take wing.

I have seen a bee in cases of robbing sting, dead or dying, and still clinging to a robber's leg. Robbers always respect the colony that makes short, decisive work of it, and summarily stings every robber that they can catch. In such cases I never could see that robbers sting back, but of course I can not say that they never do. S. T. PETTIT.

Ontario, Canada, Feb. 21.

Fears Another Dry Year—Foul Brood.

I am afraid we are in for another dry year. Everything is shaping that way now. We have had only about 3 inches of rain so far this winter. It has looked very much like rain for two days, but the rain does not come.

I am having a sad experience with foul brood, not in my own apiary, but as deputy foul-brood inspector. The first apiary I examined of 25 colonies was a rotten mass—old hives in which bees had died out lying around in a promiscuous way. I said to the man in charge (the owner being in the East), "The only thing we can do is to burn everything." He finally gave his consent, so just at dark we piled the 25 colonies as close together as possible, piled the 50 or more old hives around them, and set fire to it. Radical cure, but a safe and permanent one.

Other apiaries which are not so bad we will give the McEvoy treatment.

B. S. TAYLOR.

Riverside Co., Calif., Feb. 23.

Worst Dry Year Since 1864.

This will be the worst dry year since 1864 in Southern California. Even in the northern part the rainfall is short. I would not advise any bee-men to come here and go into the bee-business; the seasons are too uncertain, and they would only meet with discouragements.

M. H. MENDLESON.

Ventura Co., Calif., Feb. 18.

CONVENTION NOTICES.

Chicago.—The next meeting of the Chicago Bee-Keepers' Association will be held in the Briggs House, Chicago, April 3, 1902, afternoon and evening. A full attendance is desired, as important business comes before the Association. Let all come and enjoy a good social time, and banquet in the evening; 50 cents a plate. The ladies are especially invited to be present, and bring their fathers, husbands and brothers. Dr. C. C. Miller has promised to be present. HERMAN F. MOORE, Sec.

Utah.—The Utah State Bee-Keepers' Association will hold its annual convention in the City and County Building, Salt Lake City, April 5, 1902, at 10 a. m. This promises to be an interesting convention. All are invited. It is desired to form an exchange for the protection and benefit of our bee-keepers. Come and aid a good cause. It is expected that every county will be represented. J. B. FAGG, Sec.

E. S. LOVESY, Pres.

Deserves Its Success:—It is always a pleasure to us to notice the growth of any concern which builds up its business by honorable methods and first-class goods. In this day it is hardly possible for any concern to succeed for any length of time unless the above is their policy. When any concern starts as did our advertiser, the Reliable Incubator Co., of Quincy, Ill., almost 20 years ago, in a modest way, and their business grows constantly from year to year until it becomes one of the very largest concerns in the country manufacturing incubators and brooders exclusively, one cannot but believe that they make the right kind of goods and treat their customers in accordance with the Golden Rule. Probably no incubator in the world has a higher reputation than the Reliable. It has taken many highest awards at various Expositions, as for example, the Columbian at Chicago, Cotton States at Atlanta, Trans-Mississippi at Omaha, International at Brussels, Universal at Paris, where they not only took highest award but the grand prize. They

have the first premiums at State Fairs and Poultry Shows almost without number, and the Reliable is always a favorite wherever exhibited. The Company is already planning great things for the Louisiana Purchase Exposition to be held in St. Louis in 1903.

One reason why the Reliable has always been a successful machine is that its makers are practical poultry people, having owned and operated extensive poultry-yards for many years, even before engaging in the incubator business. Every improvement which has been put out on the Reliable has first been tested many times in the Company's own establishment. The present poultry-yards are an immense plant covering 13,500 square feet of floor space. They raise about 5,000 chickens annually and every bird shipped from the Reliable Poultry Farm is guaranteed in every way. Send for the Reliable catalog. Address, Reliable Incubator Co., Quincy, Ill., and mention the American Bee Journal.

BEEES FOR SALE!

50 good, heavy colonies in 8-frame, dove-tailed hives, well painted; most of the bees show Italian markings. Prices: Single colony, \$6.00; 5 or more, \$5.50 each. They are located within 12 miles of Kankakee, Ill. Can be shipped April 1. Address,

Northrup, King & Co.—We have just received from these advertisers a copy of their new seed catalog for the current year. This is a very interesting book, and every one, even those who buy seeds in a small way, would be well repaid by writing for a copy. Some of the many interesting features are as follows: On page 1 the letter from a leading railroad, offering half-freight-rates on certain seeds. This will be a direct benefit to buyers in certain sections. The statement regarding Corn Insurance, on page 15, is also novel, and their illustrations of corn, made from actual photographs, speak for themselves. On page 15, the Grading of Grass Seeds, illustrated by microscopic pictures, is a revelation. Many seed-buyers evidently need education along this line. Very many of the illustrations all through the book are made from photographs, and the general arrangement of the book is commendable. Mr. Northrup is recognized as a high authority in the seed-trade, and is president of the American Seed-Trade Association. Write to Northrup, King & Co., Minneapolis, Minn., for one of the catalogs, and mention this paper.

\$1.00

Please mention Bee Journal when writing advertisers.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, March 7.—The decline noted in last quotations are still more pronounced at this time, large offerings of Western comb are pressing for consumption which are difficult to place. Prices are nominally 13@14c for the best white, with travel-stained and light amber, 10@12c, that which is candied selling as low as 7c, with the partially candied at 9@10c. No great amount of dark honey is offered. Extracted is steady in price but slow of sale, white, 5½@7c; amber, 5½@5½c; dark, 5c, according to what it is gathered from and quality. Beeswax in urgent demand at 30c. R. A. BURNETT & Co.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½@6½c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c. THE FRED W. MUTH Co.

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c. H. R. WRIGHT.

BOSTON, March 8.—We beg to report a fairly good spring demand for comb honey, and from present indications stocks will clean up in good shape. Prices range as follows: Fancy, 16c; No. 1, 13@13½c; No. 2, none. Extracted is in good supply and moves slowly; California, 7½c. BLAKE, SCOTT & LEE.

CINCINNATI, March 7.—The general tone of the honey market is lower. Water-white comb honey sells from 14@14½c; it is hard to obtain 15c for extra fancy. Extracted has weakened a little, and sells at 5@5½c; fancy, from 6@6½c. C. H. W. WEBER.

NEW YORK, March 8.—Comb honey is now pretty well cleaned up, and what remains on the market is nearly all fancy and No. 1 white honey. The demand is fairly good at following quotations: Fancy white, 14c; No. 1, 13c; No. 2, 12c. Extracted remains dull at unchanged prices with plenty of supply. Beeswax firm, 29c.

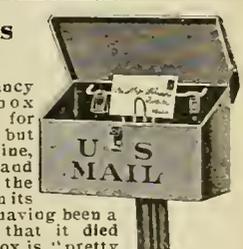

We have just received the first large shipment of comb honey from Cuba; some in tall sections, packed 20 combs to the crate and some in square sections packed 32 combs to the crate, glass front on one side, plain, no-bee-way section. The honey was packed in shipping-carriers, containing 8 of the large and 9 of the small crates respectively, and arrived in first-class condition. The flavor of this honey is very fine, and as to the quality—some of it is fancy white, while others is of a yellowish tint. HILDRETH & SEGELKEN.

SAN FRANCISCO, Feb. 12.—White comb, 11@12½ cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5½@6c; light amber, 4½@5c; amber, 4@—. Beeswax, good to choice, light, 26@28c; dark, 24@25c.

Considering the limited quantities offering there is a fair trade in progress, both for shipment and local account. Quotable values are without change, but market is moderately firm at the prevailing figures.

WANTED. EXTRACTED HONEY—either large or small lots; parties having same to offer, send samples, and best prices delivered at Cincinnati, Ohio. We pay cash on delivery. **THE FRED W. MUTH Co.** 10A1f Froot and Walnut Sts., CINCINNATI, O.

In a Glass Case.

The light fancy rural mail box would last for a long time, but rain and shine, with frost and snow soon tell the story, and then its only claim to having been a good box, is that it died young. Our box is "pretty tough," hence long lived. As for beauty, why "handsome is what handsome does." Write for the why and wherefore.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

Do You Produce Comb Honey?

Here is something that will interest you.

"The Danzenbaker Hive I think will take precedence over all others. I am delighted with it, as it is simple, and easily manipulated."

R. H. PEPPORTH,

Pietermaritzburg, Natal, South Africa.

Nov. 30, 1901.

If you buy the Danz. hive you will find a ready market for your honey. Comb honey in Danz. sections has never yet been held because of "little demand."

EXTRACTED HONEY!

You will need good hives, smokers, knives, and most of all, a good honey-extractor. Root's Cowan Rapid Reversible Extractors are used everywhere, and always acknowledged to be the best. Be sure to get one of our make.

BEEWAX?

You should have the best wax-extractors, else large quantities of wax will be left in the refuse. See what one extensive and practical bee-keeper says of the ROOT-GERMAN STEAM WAX-PRESS:

For over 20 years past I have had to render up old combs or cappings in larger or smaller quantities, and my experience has been extensive, for I have tried faithfully almost every known method to get all the wax out, but have never succeeded to my satisfaction until recently. I got of you a German wax-press, that comes nearer accomplishing that object than any thing I have ever tried. I am more than satisfied with it, for, if used according to directions, there is little if any wax left in the refuse. Any one used to the old methods will be astonished at the results obtained. In this press you have given those in need of it the best thing, to my mind, you have ever brought out, and I really believe all who try it will pronounce it a real treasure. There are other points of advantage that I could mention, one of which is its perfect safety—no boiling over and setting fire to every thing, and it can be left alone without care for quite a time, and every thing can be kept neat and clean, and it occupies very little room.
E. T. FLANAGAN.
Belleville, Ill., Dec. 12.

Root's goods are for sale everywhere. See list of jobbers and agents in the January bee-journals. A full list of local agents sent you on request. We will also send you a little book, "Facts About Bees," describing the Danz. hive, and our catalog, on request.

WANTED.—Beeswax. Price, 28c cash or 30c in trade for pure average beeswax, delivered here. We want also a car of white sage extracted honey, also large lots of WHITE COMB HONEY in DANZ. sections.

THE A. I. ROOT CO., MEDINA, OHIO, U. S. A.

EXECUTIVE COMMITTEE.

- W. Z. HUTCHINSON, President.
OREL L. HERSHISER, Vice-President.
DR. A. B. MASON, Secretary. Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

"ANNEETI—THE GYPSY ARTIST" is the title of a delightful book written by Rev. W. S. Sly, of Lansing, Mich. We have read it, and know that it is exceedingly interesting. Briefly, the story may be outlined thus:

A little orphan girl was kidnapped by a band of gypsies from an asylum near Cincinnati, reared as a gypsy, and some years later was rescued near Chicago by a friend of the author. Through her talent and love for art she was trained into a splendid womanhood and an artist of ability.

Around these facts a web of fiction and other facts has been woven to illustrate the sadness of orphanhood and separation from loved ones.

Price, \$1.00, postpaid. It may be ordered from the author, as above.

A CLEAN AND SWEET CROWD.—Mr. G. A. Deadman—one of Canada's good bee-keepers—wrote as follows to the Canadian Bee Journal concerning the last convention of the Ontario Bee-Keepers' Association:

"I regret very much not being present at the Woodstock convention. Glad to hear that it was such a success, and that 'one of the boys who was there' reports that there was a notable absence of tobacco-spitting, etc., so common at large gatherings. I have had the impression for some time that bee-keepers, as a rule, are not tobacco-users nor good customers at 'the bar,' and am pleased to have this belief confirmed."

Recently there was held in Chicago a convention of the school superintendents' department of the National Educational Association, and we verily believe that there were more smokers present among the superintendents than there would be among an equal number of bee-keepers at a National convention. And to think that those superintendents stand before the rising generation five days in a week as models! But there is cause for thanksgiving that the tobacco-using school superintendent is the exception rather than the rule.

But one would be justified in thinking that a teacher or professor, who, in these days of required instruction on the injurious effects of nicotine on man's delicate physical organism, would know better than willingly to inflict injury on himself, to say nothing of imposing an offensive odor upon those around him who detest tobacco, whether smoked or "chewed."

Think of being a slave to such a habit! But when the tobacco-heart comes—well, the tobacco or the man has to go.

Brimstoning Bees seems to be still considerably in vogue in Ireland, according to Dr. Smith, in the Irish Bee Journal. He says:

As to the brimstone robber, he should be induced, in some way, to stop his cruel work, but I fear it is not likely to take place very soon. An old veteran near me declares that there was far more honey in the country before the new honey-robbing hives were invented, and he, for one, is ready to join in a crusade to burn them all up, as he had to do with his own. For, unless it is done, he says there will soon not be enough honey in the country to cure a sick man's sore throat. He is in earnest, and believes every word of it.

A Foster Stylographic PEN....

This pen consists of a **hard rubber holder**, tapering to a **round point**, and writes as smoothly as a lead-pencil. The **point and needle** of the pen are made of **platina**, alloyed with **iridium**—substances of great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and **do not leak or blot.**

As they make a line of **uniform width** at all times they are **unequaled for ruling purposes.**

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

BEST MANFOLDING PEN ON THE MARKET.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

How to Get a "Foster" FREE.

Send **TWO NEW SUBSCRIBERS** to the American Bee Journal for one year, with \$2.00; or send \$1.90 for the Pen and your own subscription to the American Bee Journal for one year; or, for \$1.00 we will mail the pen alone. Address,

GEORGE W. YORK & CO.
144 & 146 Erie St., Chicago, Ill.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 186.

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

Queen-Clipping Device Free....

The **MONETTE Queen-Clipping Device** is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it **FREE** as a premium for sending us **ONE NEW** subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., MARCH 27, 1902.

No. 13.

Editorial.

"Bee-Culture, Bulletin No. 77, of the Department of Agriculture of the Commonwealth of Pennsylvania," is the heading of a handsome 100-page pamphlet written by Dr. C. C. Miller, bearing the date, 1901. As he plainly said in his letter of transmittal, "No attempt has been made to write a complete treatise on bee-culture." It is beautifully illustrated. It is simply a handy booklet containing those things in relation to the honey-bee and its care that any well-informed person would like to know. And the beauty of it is that it is all clear and correct in its every statement. Dr. Miller was employed by the Pennsylvania Department of Agriculture to write the booklet, so it is for distribution in that State alone.

We take quite a little pride in the fact that Dr. Miller was called upon to prepare the pamphlet referred to. To be thus selected was an honor to be coveted, and he acquitted himself magnificently—as is his usual custom.

Quoting the Honey Market.—We have received the following communication from a bee-keeper residing near Chicago:

I have been interested in the honey market of Chicago, as I have been a Chicago bee-keeper for two summers past, and the article on page 121, by B. A. Hadsell, is timely and largely to the point, as tending to explain the low price of honey to-day as compared with the prices of 20 years ago. The commission man has the honey-producers in his grip in this market, more especially when he is a buyer as well as a commission man. A buyer is always a "bear" in the market, and when he also gives quotations of prices for the supposed guidance of honey-producers, it is beyond human nature, however honest he may be in general, not to try to buy low, when it is almost absolutely certain that his quotations will go to nearly all possible shippers.

I am certain there is this tendency here in Chicago, for I have time and time again investigated prices on South Water street, inquiring of dealers in honey, as a possible buyer, and invariably had prices quoted me one cent higher per pound on comb honey than the regular "quotations" in the American Bee Journal.

Again, the prices quoted for Milwaukee, Wis., are almost invariably one cent per pound higher for comb honey of like grades than for Chicago. There seems no good reason why Milwaukee, located very much nearer the great basswood forests of the great honey-producing State of Wisconsin, should pay more than Chicago for the same grade of honey, unless the market reports are "fixed" to suit some one who is interested in buying honey low.

The bee-keepers of Cook County, Ill., at least ought to have an organization and investigate just such things, and let the shippers of honey know it, as I am trying to do.
Cook Co., Ill. RIP VAN WINKLE.

Rip Van Winkle should go into the honey-dealing business a while, for by so doing he would soon learn some things that he will scarcely be able to see in any other way. Suppose the commission man did publish quotations a cent or two per pound higher (at the price he gets for a few single cases), how soon would it be before he would have his store flooded with honey which would be sent to him because of his high quotations? Then, of course, the market would drop, and the honey would have to be sold several cents below the quoted prices. How the shippers would howl then, when receiving their returns. That commission man would be called a fraud, a swindler, etc.

It is better to quote a cent lower rather than a cent above the market. If comb honey is quoted at 15 cents, and then sells at 16 cents, and a report is made at the latter price, no bee-keeper is going to kick. But quote the price at 16 cents, and then make returns at 15 cents (the best that could be obtained), and how high would the shipper kick? Well, he'd likely say, "That commission man quoted high so as to get the honey into his hands, then sold it so as to get his commission."

Any "Rip Van Winkle" who goes along the street enquiring the price of honey is easily "sized up" by the commission man, who is up to his business. He (the commission man) can tell very quickly that "Rip" is only "nosing around," and doesn't mean to buy, in nine cases out of ten. We have often been such a "Rip" ourselves, and we felt the commission men of whom we enquired knew that we were simply out "enquiring."

But we would like to have those who quote the honey market in our columns also help answer Rip Van Winkle. If all of us try, we think he ought to get what he is after—or something else equally satisfactory.

A Sun-Proof and Rain-Proof Cover was described in the Bee-Keepers' Review by M. A. Gill, of Colorado; a heavy coat of oxide of zinc and lead paint having bedded upon it thin, unbleached muslin while the paint is still wet, another heavy coat of the same paint immediately laid on the muslin, and after drying a third coat. Referring to this, the editor of *Gleanings in Bee-Culture* says:

I asked Mr. Calvert to figure on the cost of Neponset paper and unbleached muslin for hive-covers. After figuring a little he surprised me by saying the muslin cost only about half as much. My impression is that I should prefer it, even if it were twice as ex-

pensive as paper, because, treated as Mr. Gill recommends, it would certainly be very durable. If the paint be first applied to the cover, and then cloth be laid upon it while the paint is green, it forms a bond of union with the wood. Now, then, if he covers it with another coat on the outside, it is rendered impervious to water, and stiff and hard. I suggest that the readers test paper and muslin side by side. Let us see which will stand the most "grief" in different localities.

A New General Manager.—As we anticipated when Mr. Secor sent out his annual report as General Manager of the National Bee-Keepers' Association, he almost immediately resigned after re-election. His successor has just been elected by the Board of Managers. The new General Manager is Emerson T. Abbott, of St. Joseph, Mo., to whom dues and other matters relating to the Association may now be sent.

Mr. Abbott has a good opportunity to show his ability as a manager of the important interests of bee-keepers. He should succeed in the work. The American Bee Journal is ready to co-operate with him in continuing to make things hum—the things for which the Association exists.

Errors About Laying Workers, like other errors, seem hard to kill. It was formerly held by many, if not by all, that a single worker was engaged in the unprofitable task of laying eggs. Actual dissection has shown that in a bad case of laying workers a large proportion of the population contain eggs. Yet there are still instructions given occasionally to shake the bees on the ground at some distance from the hive, so that the laying worker may not find its way back to the hive. With regard to another error, Arthur C. Miller says in the *American Bee-Keeper*:

Let any bee-keeper who wishes to satisfy himself that laying workers arise from mature, normal workers, and not from larvae having a bit of "royal food," try the following experiment:

Move to a new stand any fair colony having a young queen which has been with them for at least two months. Provide for the old bees returning to the old location as may be most convenient; they concern the experiment only in that they are not wanted in the moved colony. In ten days or more take the queen and all the brood and eggs away from the moved colony, leaving only the bees, to which give combs of honey and pollen. To be absolutely sure no eggs are given these, combs should have been away from the bees for several days—weeks would be better. Now watch for results. Ordinarily in four or five days a few eggs will appear, and the number will increase daily until the colony begins to decline. The reason for selecting a colony having a young queen, and for getting rid of the old bees, is to be certain that all bees subjected to the experiment are reared under such conditions that there can be no likelihood of any of them receiving "royal food" while in the larval stage.

Convention Proceedings.

Report of the Wisconsin Bee-Keepers' Convention.

BY ADA L. PICKARD, SEC.

The 18th annual convention of the Wisconsin State Bee-Keepers' Association was held in the State Capitol at Madison, Feb. 5 and 6, 1902.

The convention was called to order by Pres. N. E. France, a man of sterling worth, nobility of character, and great experience in all branches of apiculture.

Copies of the song, "Buckwheat Cakes and Honey," presented to the convention by our congenial friend, Editor York, were distributed to each person present, and all joined in singing the jolly song under the leadership of Mr. York.

PRESIDENT'S ANNUAL ADDRESS.

Our genial vice-president, Mr. Huffman, took the chair while Pres. France delivered his annual address. He spoke of the last honey crop of Wisconsin as not being an average crop. The outlook for the southern part of the State last year was good, but the drouth cut the crop short. He also mentioned the fact that the reason why many did not obtain good prices for their honey was because they did not put their honey up in salable packages.

He recommended that the National Association adopt and furnish to each member of the Association, a badge that will be suitable for a State Bee-Keepers' Association, as well as the National Association, as we are a part of that Association.

Mr. France also spoke of the advisability of holding our conventions in different parts of the State, on years except Legislative years. He said we could not afford to meet elsewhere than in Madison on those years, as there were frequently bills introduced into the Legislature very detrimental to the bee-keeper, as there was in 1901, and only through the ardent work of the committee of bee-keepers going before the Legislative Committee was the bill defeated.

BEE-CELLAR IN THE SOLID ROCK.

Mr. C. H. Pierce, of Columbia County, said, in beginning his paper: "Being a beginner in the bee-business, as well as being somewhat timid in coming before a gathering of mostly veteran bee-keepers, I was on the point of declining to write a paper, but thinking I had something in the way of a winter repository for bees which perhaps none of you have ever tried, I answered the secretary that I might give a description of my bee-cellar blasted from solid rock."

As most of the Wisconsin bee-keepers are not so favorably blessed as Mr. Pierce, to live in a community as noted as the Wisconsin Dells, and have access to those old sandstone bluffs, it was very interesting to all to listen to his description of his bee-cellar. If Mr. Pierce is a beginner in the bee-business he is a wide-awake, practical man, and is willing to break the bread of his experience to others, and at the same time sit and drink at the fountain of others' experience.

An interesting discussion followed this paper, and the question was asked, "Does noise disturb bees while in winter quarters?" Mr. Kluck said he winters his bees in the house-cellar, and that the boys and girls made as much noise in their play as they pleased, and it did not disturb the bees.

Mr. Lathrop's bee-cellar is near a railroad track, where the passing of the trains jars the ground terribly, and it did not seem to disturb the bees. The general consensus of opinion of the convention was that noise did not disturb bees while in winter quarters.

A CENTRAL HONEY-PRODUCERS' EXCHANGE.

It has been the good fortune of the Wisconsin Bee-Keepers' Association, for the past three or four years, to have Mr. York meet with us. He gave an address on "The Need of a Central Honey-Producers' Exchange." He advised that in some inland city (preferably Chicago) there be organized and conducted a stupendous honey-producers' exchange. The central organization should ascertain the probable amount of honey in the country at the close of the honey harvest; should have a large, suitable place for

the storage of honey, and be in position to advance a quarter of the actual value of the honey handled. He proposed this should be managed by one efficient man (with his own special assistants) capable of managing great affairs, and that he should be responsible only to a board of five directors, elected annually by the stockholders. Stock should be taken at so much per colony of bees owned. An exchange of this sort ought to be a handsome dividend-paying investment.

Those who heard the address and discussion were convinced that *that* was the only way the bee-keepers could realize good prices for their product. I believe such an exchange ought to be organized, and that all of the Wisconsin bee-keepers should be interested in this subject, and fall into line and help make it an effective co-operative organization.

A resolution was passed recommending the National Association to bring up the subject of a honey-producers' exchange at their next meeting.

QUESTION-BOX—SELLING BEES.

The question-box is a prominent and helpful feature in our conventions, and the rest of the afternoon was spent in questions and answers, or, perhaps I should better say, discussions. This is where some can be made to talk. Some of the most backward about talking in conventions have the best and most practical methods, but are too bashful to let their still, small voices be heard in an assemblage of that kind, but if called upon, and urged, they will disclose their secrets.

Which would be the more profitable, to keep bees for their honey product, or for sale?" was asked. Some thought it the most profitable to keep bees for sale. Mr. York suggested that it would pay to rear bees for sale, and said he thought he could dispose of 500 colonies annually at \$4.50 to \$5.00 per colony. But the question came up, if there would not be a greater danger of overdoing that than any other branch of bee-keeping.

Mr. Lathrop said that from personal experience it was not profitable to sell bees for less than \$5.00 per colony. One member said he would not sell bees to his neighbors as he wanted their honey-trade. But if Mr. Neighbor really wants bees, and so many people are in the business of selling bees, he will buy of some one else, and then you have lost the sale of the bees and also the honey.

SWEET CLOVER.

The sweet clover question was discussed. It was thought that it was peculiarly adapted to some kinds of soil, and thus was more valuable as a honey-plant in some localities than in others. One having experience in sowing sweet clover seed suggested that the seed should be sown about the time the seed ripens, as it was best to follow up Nature. Mrs. Lucky said that the bee-keepers' sweet-clover enemies will turn out friends if we will persist in sowing sweet clover seed. Almost all farmers object to sweet clover until they become acquainted with its value, and then they like it.

The bee-keepers did not hold an evening session, as we usually do, but went in a body into the Assembly Room where the Wisconsin agriculturists, horticulturists and bee-keepers, held a joint meeting. The evening program consisted of addresses by Prof. Henry and Ex-Gov. Hoard, interspersed with vocal and instrumental music and readings. It was a very profitable evening. Prof. Henry made us better acquainted with our Holland neighbors than we ever were before.

SECOND DAY—MORNING SESSION.

Thursday morning's session opened at 9:30 with Vice-Pres. Huffman in the chair.

EXTRACTED HONEY.

The first on the program was a paper on the "Production and Care of Extracted Honey," by Elias Fox, of Vernon County, read by Mr. York. We were sorry Mr. Fox could not be present to give his paper, as he is a good convention man. But we were glad to hear his paper, as it was a good, practical one, full of note-worthy pointers. A lively discussion followed it and the subject of sour honey came up. The man who extracts unripe honey, whether at the convention or not, was scored on all sides. Mr. Wilcox thought people who produce sour honey ought to try to earn a more honorable living than to sell unripe honey. The question was asked, "What should be done with sour

honey?" and was answered that if the honey was heated the flavor would be greatly improved.

Our honest Mr. Gross was asked what he did with his sour honey, and he answered, "I eat it." The secret is, Mr. Gross never has any sour honey to eat.

Mr. Wilcox said if thin honey was put into barrels or cans, and corked up tight, it would not sour; but if the barrels or cans were left open to the air, fermentation would be the result.

MOVING BEES—LAYING WORKERS.

It would indeed seem strange not to see the familiar face of Mr. Gross at our annual conventions, and indeed we would miss him for he is the life of the meeting. He kindly consented to give some of his experiences in moving bees. And I suppose not any one man in Wisconsin has had more experience in moving bees than he. I wish I were a shorthand reporter, so we could have his full talk here, so all could enjoy it as we did. Mr. Gross spoke of losing all of the brood after moving bees long distances, and also experiencing heavy losses in queens.

Mr. Pierce spoke of a friend moving bees a long distance, and said he watered the bees while *en route*, and that the brood was all right.

Mr. Lathrop said he had quite a good deal of experience in shipping bees, and that he filled an empty comb with water, thus furnishing the bees plenty of water while *en route*.

Some one suggested that Mr. Gross' loss in queens when moving was due to having old queens, as they were not as likely to stand the trip as well as young queens.

At this time the subject of laying workers came up, and Mr. France spoke of a method he used in disposing of them. He said he took the colony containing the laying worker, bees, combs and all, to an outer edge of the apiary, just before sundown, and brushed all of the bees off the combs, returning the hive and combs to the old stand. The bees will return but the laying workers will not; then a queen may be introduced with perfect safety.

BENEFITS OF CONVENTIONS.

Mr. Huffman read an excellent paper on the benefits derived from attending conventions. It seemed the subject was particularly adapted to Mr. Huffman, because he is one that can get the most out of a convention. He is always able to turn the searchlight on the dark places in almost every subject in practical and successful bee-keeping. He said, "The conventions have proven to be a school of no small importance; it is at these gatherings we get the very extract of success in a nutshell. They are important, not only in regard to dollars and cents, but important in regard to social acquaintances." The thought he wished to indelibly stamp upon the minds was that much can be done through organization, and in exchanging of thoughts which no individual could otherwise hope to do.

OTHER SUBJECTS.

The next number on the program was a paper by Mr. C. A. Hatch, on wax-production. Owing to Mr. Hatch's inability to be present many were disappointed. He was president of the organization a number of years when it was in its infancy, and being a man of progress he always has something new in vogue. He had something entirely new and improved in the way of a wax-press, which he was going to bring to the convention. Indeed, we regretted his absence very much.

The next on the program was a paper on the value of good queens, and methods of introduction, by the secretary.

The program was concluded by an address by Pres. France, on co-operation of State and National associations.

The rest of the forenoon was spent in a business session. One very interesting item of business was the paying over of \$7.00 to the State Association from a disbanded Association of nearly a quarter of a century ago. As early as 1878 there was a Wisconsin Bee-Keepers' Association, and it seems they were quite prosperous in a financial way, for they had in the treasury \$7.00 when they disbanded, and at this last convention Mr. James McLain turned the money over to our present organization. Mr. McLain was made a paid-up life member of our present Association for his honesty and integrity.

The reports of the secretary and treasurer were read and approved. The election of officers, or perhaps I would better say, the re-election of officers, resulted as follows:

N. E. France, president; Jacob Huffman, vice-president;

Ada L. Pickard, of Richland Center, secretary; and H. Lathrop, treasurer.

F. Wilcox was chosen as Judge of the apianian department at the State Fair for 1902.

The Wisconsin Bee-Keepers' Association is certainly in a flourishing condition, and every member ought to be proud of it and hold it up as an exemplary association. We have more members and more money than ever before, and nothing but friendliness and brotherly love prevails. Those who fail to attend the conventions miss an intellectual and social feast. Resolve now to be present at the next meeting in 1903, and make everything else secondary. Convention week is the first week in February.

Contributed Articles.

No. 3.—Bee-Keeping for Women.

Getting a Start in Bees—What and Where to Buy

BY EMMA M. WILSON.

If in starting out in bee-keeping you intend starting with one or two colonies you will probably want to buy them about the middle of May.

The first thing you are interested in is what to buy, and where to buy. If you can get good Italian bees near home, you would better take them, even if you have to pay quite a little more for them than you would for black bees. To be sure you can Italianize the black bees, but it will take time and considerable trouble, and if you are only a beginner, and have not had any experience, it may cost you more than you would have had to pay extra for the Italians to begin with.

If you can not get the Italians near home, and can get the blacks, then you will have to take your choice between the blacks and Italianizing them, and sending away for Italians. I hardly know which to advise. A good deal will depend upon circumstances, at what price you can buy the blacks at home, and how far you would have to send for your Italians. Expressage on bees is very high, and unless you can get Italians somewhere near home I believe I would take the blacks at home. If you are buying of a good, reliable bee-keeper, better tell him what you want, and leave it to him to decide what colonies to give you. If, on the other hand, you are buying of a farmer who knows nothing whatever about bees, you better do your own selecting. Select colonies with a strong force of bees, and heavy with honey. If you can get a colony that has cast a swarm the past season, you will be sure of getting a young queen.

Having got your bees, the next thing is what to do with them. You are anxious that those bees should do the very best they can, and you want to give them every advantage.

Place the hives in a somewhat sheltered spot, not so much sheltered but what they will have plenty of air, letting them face east if convenient, although a southeastern or southern exposure is also good. Then I should certainly want them in the shade of some tree, if possible, for the sake of my own comfort while working with them.

I can readily imagine how carefully those two colonies of bees will be watched. Not much danger of any swarms getting away from them, if careful watching will prevent. Still, I think I would want the queen's wings clipped. It will save you lots of trouble climbing after swarms. To be sure, you might manage those two colonies, but you know you are going to have a whole lot more after awhile, and you might as well begin right.

I think I hear you say, "I never could clip a queen." Let me tell you it is just the easiest thing in the world when you know how. Of course, you will have to be able to find your queen for the first step, but with a little practice you can soon do that. Now you are to catch the queen. Don't get nervous, but gently pick her off the comb by the wings. Take her head and shoulders between the thumb and finger (be careful not to catch her by the abdomen, or hinder part) of the left hand, and then with

a pair of embroidery scissors clip off both the wings on one side. Don't pinch her so tight as to hurt her, and be careful that you do not cut off a leg while you are clipping the wing.

I remember how my heart beat, the first queen I clipped. I felt sure I was killing her, and I assure you it was a big relief to see her scamper over the comb when I let her go. I have clipped a good many queens since, and have never hurt one yet that I know of. So you see it is not such a dreadful thing to do, after all.

You want your bees to swarm—of course you do. Let me tell you, you will see the time when you will wish most heartily that they never would swarm; but just now you are anxious for more bees, and every swarm means another colony. But be careful that they do not swarm too much. For that will result in weak colonies, and what you need is strong colonies. A good, strong colony in a good season will give you one good swarm. It might give you two, but the chances are that the second swarm would not be good, and it would probably weaken the old colony too much.

When the swarm issues, move the old colony a few feet away and put in its place a hive filled with frames containing comb foundation. Put the caged queen at the entrance and when the bees return as soon as they get to running in nicely liberate the queen and let her run in with the other bees. Then place the old colony close to the swarm. In about a week take it away, and place it on a new stand. The flying force of the old colony will then return to the swarm, making it a good, strong colony. The old colony will be reduced enough to prevent any desire for swarming. It will rear a young queen, and the hatching brood will make it a good, strong colony for winter.

It is advisable to have hives, combs, etc. all ready for the swarms when they issue, so they can be placed right where they are wanted without the delay of getting them ready after the swarm is out. The first swarm is quite an event to a beginner, and you are likely to be somewhat frustrated. It helps much to steady your nerves to know that everything is ready waiting for use.

McHenry Co., Ill.

Bees in Spring—Extracting-Combs—Foul Brood.

BY C. P. DADANT.

1. Would you remove the covers from the outer casings and super, so as to allow the packing to dry, the sun shining warm, but not warm enough for the bees to fly out? Or would you not disturb the bees, but wait till it is warm enough for them to fly?

2. How do you have your extracting-combs built? In the surplus case, or in the brood-chamber?—C. D., Michigan.

1. We never remove the covers from the hives in chilly weather on account of moisture. If the weather is so cold that the moisture in the super is frozen, it can do but little harm, and if the bees are powerful enough to keep it thawed, they run no risk from its dampness unless the dampness is so great that water may run down into the body of the brood-chamber. Such can never be the case unless the hive top or roof leaks badly, and a good bee-keeper should not allow this. But it is an error to disturb the bees in cold weather. Every bee that leaves the cluster is a lost bee, unless the colony is strong enough to keep every part of the hive warm, and we must not expect this, especially at the end of a cold winter. It is best to leave the bees alone till a warm day comes.

The present winter has not been a hard one on the bees, but nevertheless we have heard of quite a number of losses owing to the bad quality of the food. This was the first time in our experience that bees were seen to gather honey-dew in September, and this honey-dew—the worst bee-food after fruit-juice—is now showing the results of its consumption, by the amount of diarrhea that it has caused wherever the bees have been confined a month or so without interruption.

2. We have our extracting-combs built in the super where they are to remain. We use a frame that is only 6 inches deep in the super, and we could not have the combs of this frame built in the brood-chamber because they would not fill the full space of a brood-frame. Besides, we can see no advantage whatever in having the extracting-combs built in the brood-chamber. We usually use sheets of foundation of the same grade as those that are used for brood-combs. Some of our friends who produce honey in extracting-frames, with the intention of consuming a portion of this honey in the comb use a light grade of surplus foundation so that the honey may be consumed without the objection of the fish-bone,

which is caused by a heavy grade of foundation. But it would be a mistake to produce honey in this shape for sale. The large combs—say 6 inches deep and of the full length of the brood-chamber—are very advantageous to produce surplus honey if it is for home consumption, because the bees much prefer putting their honey in such places rather than dividing it up into small sections, and for this reason I am sure there is a greater production in large frames; but the sale of this honey would be very slow, for the customer wants small packages, and it is quite probable that not more than two-thirds of the actual market value of comb honey could be realized when sold in these large frames; but the bee-keeper who produces honey only for his family does not consider that, and can certainly make a better season by using the larger frame. Such combs when fully built and sealed, are very fine. I remember that, years ago, before the invention of the section honey-box, we took the first premium at the Iowa State Fair on a pyramid of full-sized combs of white honey, and I do not see at the present day any display of honey that can please the eye as much as these large white sheets did.

ROSEMARY FOR FOUL BROOD.

The question of foul brood seems to be interesting a great many people now, and from the reports that I have seen, it would seem that there is a great deal more of this disease in the country than was thought. I have never seen a case of foul brood anywhere, and I wonder whether in many instances they do not mistake accidentally dead brood for foul brood. The easily cured cases are very probably of this category, like the case quoted to me by the manager of the Luxembourg Garden Apiary at Paris, which he said had cured itself without any doctoring.

I see a new suggestion in the January number of the International Review of Apiculture concerning foul-brood. If this is not a case of false foul-brood, the suggestion may be of some value. I quote:

"Having noticed, last winter, in Tunis, where I was taking care of a large apiary of over 500 colonies, that during the blooming of rosemary (*Rosmarinus officinalis*) which is very abundant and melliferous, the condition of several foul-broody colonies had been improved, I concluded to treat the hives with essence of rosemary, which has well-known and strong antiseptic qualities. The results obtained by this new process have been excellent, and in order to make sure of its efficacy, upon my return in Valias, I applied it to 3 diseased colonies. After three weeks, although the disease was deeply rooted, I could no longer find a single diseased larva in those hives."

"The low price of essence of rosemary, which is to be found in every drug-store, and the ease with which this remedy can be used, some 15 or 20 drops being poured into the hive from time to time, give each apiarist a very good chance to try its efficacy. It would be advisable for bee-keepers all over the land to try this method and report to the publishers, if successful."

This may be worth trying.

By E. E. HASTY, Sta. B Rural, Toledo, O.

NATURE AND HONEY-STORING QUALITIES.

As to the discouraging thought that Nature has already bred honey-storing qualities to the extreme limit, there are important arguments on page 118. How about milk-secreting qualities? Nature has bred at them—after a fashion—and her fashion is to have just enough milk to rear a calf, and no more. When man takes a hand he doubles and triples the milk—does it with comparative ease, and in a limited time. Nature does not want three times as much honey stored as is needed to winter a colony; but man does want it. My present feeling is that this argument is a little too strong. Calves rarely die for lack of milk; but colonies often die for lack of honey. But I guess there is some validity in the argument; at least I hope so.

CONDITIONS OF BEE-EXISTENCE.

There's an idea on page 120 that will pay for some more reflection, perhaps. The conditions of existence which surround the bee cannot be very greatly changed. Animals are plastic in man's hand *because* in domestication the conditions of their existence have been changed immensely. The struggle and anxiety about food is entirely removed. No more trembling fear, and running away from rapacious beasts. Shelter in place of exposure to the elements. Leisure time in abundance in the place of preoccupation. Provocation to think. Opportunity to form friendships both with man and with each other. No wonder metamorphosis sets in and gets lively. Will not the lack of similar things make the bee unresponsive? Sounds forcible. But why then should these two crowds of people disagree so? One crowd says: Don't cross varieties, and beware of the daughters of your best honey-colony—else your stock will get to varying *too much*. T'other crowd says: Don't expect much result in one million years because *bees will not vary enough*. Let's mix these two crowds and take the average.

TESTING TONGUE-LENGTH OF BEES.

Mr. Simpson's way of testing tongues with honey in small glass tubes is obviously the right way. I used actual clover-tubes when I was in the biz; but I wished for glass tubes pretty strongly. The going-to-be difficulty of filling them worried me a little; and I never thought out the correct solution. To see Mr. Simpson's solution made me mentally swing my hat. Put the shorter leg of a J-shaped wire in the tube, and withdraw it while the mouth of the tube is plunged in honey. Also his way of testing the capacity of the honey-sac seems about as good as weighing, and very much less fuss. 'Spects any of our bees have sacs big enough; so let's not worry about that at present. If we could make their sacs bigger more bees would fall and perish on the road. Page 120.

BEWITCHED WITH BEES.

Bewitched by a ruta-baga turnip—some men would as soon be, as to be bewitched by a bunch of torpid bees underneath a down-cellar hive. As related on page 121, Mr. Doolittle finds it difficult to get out of his cellar, he's so bewitched. No possible doubt about the fact that Mr. D's bee-fever struck in and became chronic. We really hope he won't be killed (Biddle-brother style) eloping with any apicultural turnip.

ARE THERE TWO VARIETIES OF YELLOW SWEET CLOVER?

Anent Dr. Miller's answer on yellow sweet clover, page 123. If I remember the reports aright, there are two quite different yellows—one the same thing as the white, the other a totally different species. Just now I half remember that we have been told somewhere of the distinct species having at least two varieties that varied considerably.

HAULING BEES IN OPEN HIVES.

About hauling bees with wide-open hive entrances, if there are two persons along, and a smoker, and only a few hives, it is very much the best way. To keep in an infuriated condition for hours is quite damaging to the bees; and being unable to get out does not help the damage any. Even if the two persons are greenhorns they can be told how to keep bees in subjection with a smoker. On the other hand, having captive bees break loose on the road (as they mostly do) will "try the bottom" of non-bee-keepers very severely. Page 126.

PROPER VENTILATION FOR A BEE-CELLAR.

"Here she goes, there she goes"—first complete victory for ventilation through the soil only—then fresh air and lots of it every night. Both ways certainly succeed in the beecellar. Which is the one that will *always* succeed? Page 127.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Biographical.

REV. OSCAR CLUTE.

The death of this good man, so well and so favorably known to apiarists the world over, which occurred at the Soldiers' Home, Santa Monica, Calif., about Feb. 1, will come to bee-keepers generally, as it did to the writer, with a shock, and will bring sorrow no less than surprise.

Mr. Clute was born in New York, near Binghamton, about 63 years ago. Early life on the farm formed attachments which never let go their hold. His preparatory course was passed with high grade at the Binghamton Academy. He entered the Michigan Agricultural College with the class of 1862, in 1859, where he was a highly-respected classmate of the writer. His character and scholarship while at the College were excellent. He won not only the regard of students and teachers, but, likewise, the admiration of all connected with the College. By hard study he gained time to teach one year during his course, when he was at the head of the Ionia city schools. His success there was pronounced. This bright record, both as a teacher and as a student, led to his engagement as instructor at his Alma Mater, immediately upon graduation.

He was specially good in mathematics, literature, and science, which he dearly loved, and his professorship, which he received later, was in mathematics, though he taught with marked success the biology, especially entomology, which always attracted him greatly.

In 1866 he resigned his position, and was succeeded by the writer. He then took a theological course at Meadville, Pa., and upon its conclusion entered the Unitarian ministry, his first charge being at Vineland, N. J.; while there he was one of the founders, and the first president of a very successful horticultural club. He also took great interest in agriculture, and wrote extensively and ably for the agricultural press.

In a few years he resigned at Vineland to take a more responsible position at Keokuk, Iowa, and later he was advanced to the First Unitarian Church at Iowa City. While at Keokuk he visited the writer at the Michigan Agricultural College, and of course looked over the bees. He was enthusiastically won to the bee-keeping ranks. His culture and ability stood him in good stead, and he marched rapidly to the front. He came intimately to know the Dadants, and, as Garfield said, to sit on one end of a log with Mark Hopkins on the other was the equivalent of a college course. So to be in close touch with the elder Dadant was sure to push one naturally fitted rapidly to the front as a bee-keeper.

Mr. Clute often told me that his income from his bees was for several years in excess of that received from his church, though the latter was an influential one. While at Iowa City he wrote "Blessed Bees." This charming romance was at the same time so fascinating and so realistic that it had a wide reading, and many supposed it was the record of actual experience.

About 1888 he came to the First Unitarian Church of Pomona, Calif., from which he was soon called to the presidency of his Alma Mater. He remained at the Michigan Agricultural College for three years, when he resigned to take a like position at the Florida Agricultural College, where he staid for some years. He was always known as a hard worker, a close student, and at the Michigan Agricultural College he always did what he could to aid the bee-keeper's art. He was always an eloquent advocate of any and all efforts to further every department of agriculture.

Prejudice, because of his Northern birth, was bitter against him in his Florida home. His home was burned while there, and with it went valuable manuscripts, which was not only a loss to him, but to agriculture.

President Clute, after a short, well-earned rest, came again to his old Pomona church. He remained there less than two years, when disease—a kidney trouble—necessitated his rest from all mental work. For a year he was very successful as a breeder of Belgian hares, but he was unable to continue, and for the past year or more he had been unable to do any work.

The past months he spent at the Soldiers' Home, near

Santa Monica, where pneumonia, coupled with his chronic stricture, removed him from us.

Dr. Clute married a most estimable lady—Miss Merrilees—in 1869. He leaves her and five children, none of whom were with him at the last trying hour.

As an earnest student, a devoted friend of agricultural education, a writer of vivid, exact English, a warm, earnest friend, and a man of sterling character, Dr. Clute was an exceptional man, and one who will be sorely missed.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Cleaning Up Combs Where Bees Died.

I have a lot of combs taken out of hives where the bees died. I am straining out the honey, and would like to have the bees clean up the refuse; also the hives which are smeared with honey.

1. When should I put the hives and refuse out for cleaning up.

2. Would it tend to prevent robbing if they were placed say 20 or 30 rods off from the apiary? ILLINOIS.

ANSWERS.—1. It matters little when; but perhaps it will be well to wait till bees are flying freely.

2. It will be well to set them some distance away, although there is little danger from having the work done near the hives, *providing* you do not take away the combs till after the honey has been cleaned out, and not only till then but till the bees have ceased trying to work over it. If you want to make a sure case of robbing, set a hive with honey near the apiary for the bees to rob, and then take it away while the bees are working at it in full blast.

Taking Bees Out of the Cellar.

I have 100 colonies of bees to take out of the cellar this spring. They are all in good shape. Last year they were all right when I put them out, and it was very warm, and putting them out all together they would all go out of the hive, and they do not all go to their home again; some hives would be crowded with bees and the other colonies would be very weak—just little bunches of bees with their queens.

Would it be better to take them out at night, or when it is colder, so they would not rush out of their hive and get mixed up? The weather is very nice now, and I may take them out soon. MINNESOTA.

ANSWER.—I am not sure I know enough to advise what is best to do. For many years I have taken out my bees without any such trouble as you mention, yet I know that others have had just that trouble, many colonies being ruined by the wholesale desertion of hives. Having had no experience in the matter myself, I can only give you the advice that others give to avoid the trouble. I think the common advice is to avoid bringing out a large number at once. They say that a large number coming out at one time makes so much excitement that the bees rush out of their hives pell-mell, as if swarming, and then they don't know enough to get back into their own hives. In a late number of *Gleanings*, a writer advises to bring out about one out of twelve each good day till all are out, setting a board in front of each entrance as soon as the bees of that colony have had a good cleansing flight. The idea in this is to avoid the excitement that occurs when so many are taken out.

Without advising you to take the course I pursue, I'll tell you what I do that may *possibly* account for the fact that I have no trouble when I take out two or three hundred at a time.

The evening before I think I will take out the bees, I open wide all cellar doors and windows as soon as it gets late enough in the day so that the bees will not fly out of the cellar. Very likely the cellar has been opened up in this

way every night for several days, and not closed up in the morning till there was a show of bees beginning to fly out. Put that down, then, as the first essential, that the cellar must have been well aired all night previous to taking out. The next is that the weather must be right. The sun must shine, and there must be nothing in the way of clouds or mist. Neither must there be a strong wind. If the day is not of the right kind, then the only thing is to wait till a day comes that is of the right kind. In that way I have safely taken my bees out in large numbers for more than a quarter of a century; but you must use your own judgment as to whether the thing will be the best for you.

I may add that as a rule my bees are very quiet when taken out, sometimes four or five colonies being carried out one after another before the first one of the four or five begins to fly.

Feeding Bees—Increasing an Apiary.

1. Will it be a good plan to feed my bees after I put them out-of-doors?

2. By feeding them will it make stronger and better colonies of them when the honey-flow comes on?

3. Should bees be fed in the cellar? Am I doing it properly by placing unfinished sections over the cluster, and leaving the top cover off?

4. I wish to increase my apiary to about 100 colonies. Would it be advisable to buy bees in box-hives in April, for \$2.00 to \$3.00 per colony, and then transfer them into other hives? There are no Italian bees in this section.

5. Would I get pure Italian bees by purchasing 2 or 3 Italian queens and introducing them into my hives? Would the bees in the colonies in which they were placed be pure Italian bees? Would it be advisable to do this, as my best colony last year produced 80 one-pound sections of honey in the super while some of the others stored scarcely enough to winter on? NEW YORK.

ANSWERS.—1. Yes, if they have not enough feed to last them till they can gather. If they have plenty it will probably be better to let them alone.

2. If they have plenty of honey to last them through, extra feeding, unless in the hands of a person of much experience, may weaken instead of strengthen them.

3. Your plan of feeding is all right; but it may be well to give no more than you think necessary to bring the bees through.

4. Yes, only it is possible you may do as well to let the bees swarm, and keep the box-hives for swarms another year.

5. If you give a colony a pure Italian queen, all the workers coming from her eggs will be pure Italian, but, of course, there will be workers there till the progeny of the former queen have time to die off. It will pay to replace any very poor queen.

How to Get Increase of Colonies.

I wish to ask a few questions through the American Bee Journal about how to get increase of colonies. I now have 20 colonies. I have taken the American Bee Journal for the past 5 years; I also have Cook's "Bee-Keeper's Guide," and 4 volumes of the American Bee Journal in Wood binders, but cannot find just what I want to fit my case.

I use the 10-frame Langstroth hives, and run for comb honey, extracting only unfilled sections.

There is lots of sweet clover close by, but no other bee-pasture after maple-bloom until sweet clover. I think that is why I don't get increase during maple-bloom, fruit-bloom, etc.

The colonies build up fast, get strong, and act like swarming, then all of a sudden there is a change; some of the colonies kill off their drones and show in other ways that there is no honey to be had. Then for 3 or 4 weeks they get barely enough to keep them from starving until the sweet clover comes, about July 1, then they begin to rush, and then it is too late. I don't want them to swarm, but want to get them in the supers and keep them so busy that they will forget all about the swarming, except 2 or 3 strongest colonies which will throw off a great swarm, but no more for the past 4 years. I have had only 2 to 3 prime swarms a year. From 15 colonies 4 years ago I have 20 colonies now; the losses each year and increase keeps me about even; for the past three years I had an average of 100 pounds of surplus honey from each colony, spring count,

and there is sweet clover around here enough to supply 75 to 100 colonies.

Now, how many colonies can I increase to and still get my average, 100 pounds, spring count, the coming season?

I will give you my plan and see what you think of it, and then tell me a better way. I have read up a good deal on the nucleus plan, but do not think I would like that; it would take too much time and work. I have some extracted honey and I propose to buy granulated sugar, make a syrup and mix $\frac{1}{4}$ honey and $\frac{3}{4}$ syrup, and take 10 colonies and feed them right after maple and fruit bloom all they will take to stimulate and keep up brood-rearing, and get them to swarm naturally before June 1, if possible; then right after the first swarm, divide the old colony equally, giving the most brood and one or two of the best queen-cells to one, and buy a laying queen for the other half, filling both hives with full foundation frames. But if they don't swarm before June 10 I will divide nearly equally, giving the queenless half the most brood and best queen-cells, if any, or buy a queen for them. I have made some feeders that will hold about a quart of syrup (the bees are packed with supers on the top), and I intend to turn back one corner of the cloth covering the frames, put the feeder on and pack around it so that the bees cannot get in the super (only in the feeder), which is covered with glass so I can see the condition of the super by lifting the super-cover. The bee-house is made tight and plastered so that they are not affected with sudden changes in temperature. The hot sun will not bring them out until it is warm enough not to chill them.

I have never fed my bees anything yet except to set out combs or waste honey for the bees to clear up.

1. About how much syrup will a good, strong colony use up in 24 hours.

2. Would I better fill the feeder, or just give what they will use every day?

3. If I divide the old colony after the first swarm, how long must I leave the queenless half before giving them a new queen? or will there be queen-cells enough to give each part cells?

4. If I divide before June 10, in case of no swarms before then, which would be the most profitable, to let them rear their own queen, or give them a queen—say the queen costs 75 cents and the honey harvest begins July 1?

5. Would it be more profitable to feed the whole 20 colonies, and divide equally June 1, in case of no swarms before then, and feed all that need it until the honey-harvest begins?

6. How many queen-cells must I leave in the queenless half?

ILLINOIS.

ANSWERS.—Answering first the questions that are not numbered, I should say that you can not expect to keep up the same yield per colony if you increase any at all beyond the same rate you have had in the past. You may as well count that when part of your force is devoted to increase it must take that from your crop. But that does not make it inadvisable to increase, for the loss by increase this year will be more than made up in the crops of succeeding years.

You say you will feed all the bees will take. You will probably find that brood-rearing will keep up as well if you feed a pound or so to a colony each day.

Whether your plan of increase would be best under all circumstances is a question, but one's own plans are generally liked a little better than the plans of some one else, and are better understood, so you may succeed well with the plans you mention.

I am just a little afraid about your feeding business. I don't understand what kind of a feeder you will have that will allow the bees to come up at one corner of the quilt, and it is quite possible that it will work quite differently from what you expect. The sun will not bring the bees out when it is too cool for them to fly, as you say, but if they work on the feed you may count on that bringing them out. If it is so cool that the bees will not fly, then it is likely that it will be too cool for them to work on the feed. Better not feed at all when it is not warm enough for bees to fly. Now for your numbered questions:

1. All the way from nothing up to 20 pounds, depending on circumstances.

2. It will be generally better to give them what will be used each day, but that also depends somewhat upon conditions and circumstances. Speaking in general terms, during May and June the weather ought to be warm enough usually to make no trouble if feed is left on all the time, except the trouble that comes from feeding too much.

3. If the queen is in a provisioned queen-cage, she may be given at once. It will be a remarkable case if there are not more queen-cells than are needed for both parts.

4. It would probably be economy to buy the queen.

5. I don't know. It may be a good plan to operate upon half, and then you can decide as to what is best for the future.

6. One is as good as 20 if it is the best one in the 20, and in a place where it will not be chilled. But you can hardly tell as well as the bees which is best, so it is better to have more than one. You will probably have enough so as to use several.

Having answered your questions, and understanding that you favor natural swarming, let me suggest a plan that you might try, at least in one case, to see how you like it:

Have five colonies built up strong, and about June 1, or sooner if they are strong enough, take from No. 1 a frame of brood with adhering bees, and the queen in an introducing-cage; put these in an empty hive, filling out the hive with frames of foundation, and put in place of No. 2, setting No. 2 on a new stand. Keep the feeder going and No. 1 will start a number of queen-cells, and when the first young queen is ready a swarm will issue with her. Have the swarm on the old stand, set No. 1 in place of No. 3, setting No. 3 on a new stand. A day or two later, No. 1, having been strengthened by the returning bees of No. 3, will swarm again. Set the swarm in place of No. 1, set No. 1 in place of No. 4, and set No. 4 in a new place. In a day or so No. 1 will swarm again, when you will set the swarm in place of No. 1, putting No. 1 in place of No. 5, and No. 5 in a new place. Of course, the feeder must be kept going all the while if there is no pasturage.

Transferring Bees from a Log.

Last fall I cut down a white-oak that had in it a colony of bees; they are in a log about 2 or more feet long. As there were only a few days after I got them that it was fit for them to be out, I was afraid they lacked honey for the winter, so I put honey in the comb on top of the log and they took in about 4 pounds, or all I gave them. I put them into the cellar and they seem to be alive at present. The question is, When and how shall I get them into a hive? I cannot see into them, and know nothing of their condition, only of late when the day would be warm a few of them would find their way up the cellar-stairs to the light, and they at times make considerable noise. This is all I know about them.

The piece of log has in it a regular exit-place; also, since cutting off, it has a hole in the top and bottom, but I have nailed a board over the bottom. WISCONSIN.

ANSWER.—You will do well to leave them in the log till they swarm. Before that, however, see what part of the cavity is not occupied by combs, and saw off the log so there shall be no unoccupied space. Otherwise it is possible they may go on building more comb and not swarm at all. When they swarm, if you are anxious for honey, set the swarm on the old stand with the log close beside it. A week later set the log in a new place. Two weeks later still, or three weeks after swarming, drum all the bees out of the log, and unite them with the swarm, smoking both well. Or, you may drum the bees out of the log and treat them as a second swarm. If you are anxious for increase, when the bees swarm out of the log, hive the swarm and set it in a new place, leaving the log undisturbed. In eight or ten days a second swarm may issue, and you can put that on a new stand, still leaving the log undisturbed. Then you can leave the log to furnish you more swarms next year, or you can drum the bees out three weeks after the issuing of the first swarm. When all the bees are drummed out of the log, you can set it some distance away and let the bees rob out the honey. Then you can split the log open and melt the combs.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it

Cutting Foundation for Starters.

This is done for sections after the following style by M. A. Gill, as given in the Bee-Keepers' Review:

In the cutting up the foundation, I put 50 sheets into a box that just fits the sheets of foundation, but with one end and the top open. The box has saw-kerfs sawed down through the sides, at equal distances apart, as guides for cutting the sheets into five equal parts. In cutting I use a scalloped bread-knife dipped in warm soap-suds; and by a quick, sawing motion, I can, in less than one minute, have five piles (250) of starters that are true, and as loose as a pack of cards.

My wife is champion at the filling of supers, as she will average to fill 100 supers in eight hours.

Small Pieces of Glass in Shipping-Cases.

These have been recommended in Gleanings, a small piece of wood being fitted between the pieces of glass so as to cover up the edges of the sections, and the glass of old negatives discarded by photographers come into play for this purpose. F. A. Salisbury tells in Gleanings how to clean them.

"He uses a common wash-boiler, and places in it two pails of water and a pound package of Babbitt's potash. After the water comes to a slow boil, he is ready to place the glass in. But instead of immersing it in bulk in every shape imaginable, it must be placed on wooden racks so that the water can get at *both* surfaces of each light of glass. For that purpose he uses a pine board 3 inches wide, and just long enough to go inside of the wash-boiler. Into this he drives 8-penny casing nails about $\frac{1}{4}$ of an inch apart, zigzag, the entire length, and deep enough so they will stand up $1\frac{1}{2}$ inches. Wooden handles are nailed on to each end. The lights of glass are now stood up on edge between the nails, and the whole is immersed in the solution of potash. It is then left there for about ten minutes, when it is lifted out and soured down into a tub of water to rinse off the glass, for the photographic film will all have dissolved off in the solution.

"To expedite the work, three wooden racks for holding glass are made; and if one works right he can take 50 every 5 minutes, and have 2 minutes' rest out of each 5. When the rack is taken out with the glass it is set on the inverted boiler-cover and carried over to the tub. This catches the drip.

Comb Foundation for Swarms.

G. M. Doolittle makes a plea for utilizing the wax that is already secreted by a swarm when it issues. He says in The American Bee-keeper:

When the prime swarm issues, they go forth, as a rule, with wax already secreted in their wax-pockets, so that they may at once commence to build combs in their new home, and if the new home is already supplied with all the needs ary combs this wax is wasted, or, what is often the case, worse than wasted, it being added to the foundation already in the sections, so that instead of drawing out the side-walls of the foundation they build with their own wax the cells of the combs, thus leaving the foundation in the sections the same as it left the mill. This causes the grumbling we have heard so much about, regarding the "fishbone" in section honey. Now, where I hive swarms on full combs, or frames filled with foundation, I use only starters in the sections, and find that the bees will

build the combs in the sections while they are drawing out the foundation below, and thus a saving is made. But, as a rule, unless we are very short in the family, I prefer to fill the sections with foundation, that I may have handsome, salable sections of honey, and use only starters of foundation in the frames below, having the starters in the frames, say from one to one and one-half inches wide. By contracting the brood-chamber to so few frames that a part of the swarm is forced at once into the sections, the bees go to work there storing honey and drawing out the foundation, while during the same time they build all straight worker-comb in the frames, so that by the time the frames below are filled with comb and brood the sections will be nearly completed also. In this way there is no deduction from the amount of section honey, so far as I can see; and we have worker-combs built that are nearly or quite as perfect as those from foundation.

Influence of Nurse-Bees.

C. A. Olmstead says in the Bee-keepers' Review that he thinks the longevity and usefulness of a bee is greatly influenced by the nurse-bees, but not its color, temper and other general characteristics. He gives the following interesting experiment:

Colony No. 2 consisted of yellow Italians, and were the meanest, ugliest bees I ever saw.

No. 14 was one of my old black stock, some I have had for 15 years, and is hard to equal for industry and gentleness; I never used a veil nor hat, and only a little smoke.

I changed places with these queens, putting the one from No. 2 in No. 14, and that from No. 14 in No. 2. From that time the brood from the cross queen was nursed by the gentle bees of No. 14; and as soon as there were enough of those yellow ones to set up shop they were ready to defend it against man or beast; and, as time rolled on, the once gentle blacks were found following their example, and often stung me.

Colony No. 2 was the cross Italian to which had been given the gentle black queen. As her bees began to hatch and mingle with the yellow ones, they were inclined to fly up, and often stung when handled; and some might think it due to being nursed by the cross bees, as they were stirred up nearly every day while caring for the brood, but, hold on now, I took out a frame of this brood just before it hatched, and put it in a colony of Albinos, the gentlest bees I ever saw, and when that brood hatched, the bees were very gentle and showed all the old-time traits of their strain. Being nursed by those cross bees did not affect them in the least.

Liquefying Canded Honey.

S. E. Miller gives his plan in the Progressive Bee-Keeper as follows:

I have purchased two lard-cans, such as are usually kept for sale in a general store; the smaller one holds about six gallons and the larger one about ten gallons. By placing the smaller one inside of the larger one, it leaves a space of about 4 1/4 inches all around. I took these to the blacksmith, who can also handle a soldering-iron, and had him join the cans together by means of braces in such a way that the bottom of the smaller can was about 1 1/2 inches above the bottom of the larger one, and a space between the two as mentioned above. I was unable to find a honey or molasses gate in the town, so I had the blacksmith use a steam valve with two sections of pipe attached, thus forming an elbow. One section of the pipe was passed through the outer can into the inner one, very close to the bottom, and securely soldered to both. In short, it is a can within a can, with a space all around the inner one to contain water and a valve for drawing the honey from the inner can. Fill the inside can with honey and the space between with water, set it on top the stove and let boil until ready to draw off.

According to those who have had experience in bottling honey, we should not heat it to above 160 to 180 degrees F., therefore we

should have a thermometer for testing the temperature. Mine is an ordinary thermometer graded up to 220 degrees. I took the scale, with glass attached, out of the frame and case, punched a hole in the upper of the metal; attach a string long enough so the bulb of the thermometer will reach nearly to the bottom of can, tie the other end of the string to a stick that will reach across the top of the cans and drop the thermometer in the honey. Honey will be perfectly liquid and flow freely at 120 degrees, but if to be bottled and kept liquid it is no doubt best to heat it to 160 degrees. Here is the cost of my apparatus: 1 can 60c; 1 can 40c; paid blacksmith for valve and work 60c; thermometer 30c; total \$1.90.

A Correction of an Old Matter.

EDITOR YORK—I desire to direct your attention to an error under which you are laboring, in regard to the weight of the honey sent by the Ontario Bee-keepers' Association to the C. E. I. Exhibition held in South Kensington, London, England, in 1886.

On page 224 of the American Bee Journal for 1901, you give the amount as 40 tons; when in fact the whole amount was less than 19 Canadian tons; or a little less than 17 English tons, (the English ton is 2240 pounds, as we all know).

It will be remembered by some that a few years ago it was stated in Gleanings that the amount was 40 tons. Feeling that that error should be corrected I took the liberty to do so in that paper. Then at the Buffalo convention, held in August, 1897, again the amount was given out as 40 tons. These erroneous statements may be responsible for your heavy figures. It may be that the correction I made in Gleanings escaped the notice of some.

Before the honey was staged, all the invoices but one or two were in the hands of our secretary, and I gave him the missing figures. Then each exhibitor's exhibit was placed by itself, and the packages were compared with and checked off from the invoices. And as I had sent in to the Government officials the amount before I left home, as I had to do, we knew that not one pound more was to follow.

Now, Mr. York, to settle this matter of amount of honey beyond all doubt, I refer you to the British Bee Journal, page 604, Dec. 30, 1886. I also enclose a statement from Mr. Wm. Couse, secretary Ontario Bee-keepers' Association—proof enough, I hope, to convince you that you are in error in quoting 40 tons.

There was a difference of opinion as to the amount of honey we should take; some said 50 tons, and some 100 tons, but principally through the poor crop taken that season the amount settled down to about 19 tons; but, after all, it was a very creditable exhibit indeed, of which every Canadian bee-keeper ought to have felt proud.

Ontario, Canada, March 1. S. T. PETTIT.

[I wish to thank Mr. Pettit for calling our attention to this matter, and only regret that he did not do so long ago. We simply were misled, else the 40-ton statement would not have appeared in our columns. We can see no reason for the wrong statement going out in the first place; and then for us to aid in repeating it—we, we would not have been guilty of helping on the misrepresentation had we remembered ever hearing the correct or 19-ton amount. But we are always glad to aid in setting matters in their true light, and always desire to publish the exact truth concerning everything we undertake to say anything about, if it is possible to get at the real facts.—EDITOR.]

A Virginia Report.

I began the season of 1901 with 42 colonies, spring count, and increased to 65. We had a very poor season, generally speaking, the weather being too wet the fore part of the season. The bees did well at the start, as we have plenty of sugar maple for them to gather pollen from, but when the locust bloomed

it was too wet, and they got no honey from that source, and the same way when white clover bloomed, and also when the linden bloomed, but later in the fall we got some nice honey from golden-rod and wild aster. The bees gathered sufficient stores for winter so that we did not have to feed any. We got about 3000 pounds of comb honey, for which we found ready sale near home.

Taking our situation as a whole I think our locality a good one for bee-keeping; we rarely ever have a complete failure. We winter our bees on the summer stands, and rarely lose any; and if we do lose any it is by some other cause, not cold weather.

We have had what we call a severe winter for our locality, but at my place the mercury has not been as low as zero, but it has been cold and wintry since Nov. 15, and today (March 5) it is snowing; it began last night, and the snow is about 10 inches deep, and still coming down, but I do not think it will stay long on the ground, as the season is too far advanced.

P. I. HUFFMAN.
 Rockbridge Co., Va.

Bees Wintering All Right.

My bees are wintering all right in the cellar; I put in 63 colonies. I have no trouble in wintering my bees. The cellar is 8x10 feet. I use the Langstroth 8-frame hive, loose top and bottom, and pack them one on top of the other 5 high. I have the swarms on the old stands. I had only 13 swarms from 50 colonies last year, and over a ton of comb honey. I have sold it at home for 15 and 16 cents a pound.

L. C. GREEN.
 Winnebago Co., Iowa, March 4.

A Report of Last Season.

It is not four years since I commenced the business, the first 2 years being nearly a failure, but I think now I can do better.

Last spring I started with 4 colonies, increased to 9, and took 300 sections of nice comb honey, and my bees had plenty of honey when I put them into the cellar. They appear to be wintering well.

I use a hive of my own make, which I think is a very good kind for comb honey.

Geo. W. Davis.
 Windsor Co., Vt., March 13.

Bees Doing Well.

My bees are doing well, I think. They seem strong, and are gathering pollen almost every day when it does not rain. There have not been more than 30 days all together, but what they have been flying; they are quite strong. I was looking at them, and they were in between all the combs, and all seemed to have plenty of honey. I did not take the frames out, but could see sealed honey where the bees were not in the way.

We have had quite a good deal of rain lately, and it is raining to-night, and the wind has been blowing very hard all day.

W. H. ROSEBROOK.
 Siskiyou Co., Cal., March 11.

Some Canadian Suggestions.

A man asked me the other day how to prevent a small queen from going through the metal honey-board. I told him to feed her on dried apples and give her plenty of water to drink. Was that right?

What I want to suggest is this: I have read so often where valuable queens have been ruined by transit through the mails. Why not send such queens by carrier-pigeon? I understand that carrier-pigeons will return home immediately when they get their liberty, several hundred miles. And by using 2 or 3 pigeons a queen could be sent 1000 miles or more. For illustration, say that I want a queen from Chicago. I get a pigeon, send it to Detroit; have a party there to get another and send it to Chicago; the second pigeon would be held by the party in Chicago long enough to give the party in Detroit notice just when the pigeon would be released, and the party in Detroit hold the queen long enough to give me notice; and so on.

Where it is convenient, cheap queens might be sent a few hundred miles in the same way. Has anyone ever tried the above way of transportation? If so, let us hear from him; if not, and no one cares to try it, I think I will try it the coming season.

I would like to suggest to some one who has a cream separator, and also keeps bees and produces extracted honey, to extract

Every day during March and April we shall sell

some the same day that the bees gather it, and run it through the separator just to see the thick honey run out of one spout while the water runs out of the other.

We have had a very dry winter—I mean a dry atmosphere. The bees seem to have wintered well so far; they had a good flight about February 25, which will satisfy them until spring opens. J. ALPAUGH.

Ontario, Canada, March 10.

A Brief Report.

About 1/4 crop surplus secured last year; 43 colonies, fall count, and all alive now. No swarming for 2 years. W. D. HURT.
Cass Co., Mo., March 8.

Wintering Well—Good Home Market

We have only 12 colonies of bees. I think they have wintered well so far, and they seem to be in good condition. There have been only a few days warm enough for them to fly, but last week Monday they were out strong and seemed all right.

We have a market right at home for all the honey we have to spare. But we never do without it ourselves for the sake of selling it. R. T. CLASON.

Midland Co., Mich., March 6.

Species of Anthophora.

I this day mail you 2 bees, dead, of course. I should judge from the description they resemble *Apis dorsata*, but haven't they a fine reach? In those bees I think I see the ideal of those long-tongued venders in the east. If you do not object, you can give me the name of these bees through American Bee Journal. EDWARD PORTER.

San Diego Co., Calif., Feb. 19.

[The bees sent by Mr. Porter are species of *Anthophora*. These are long-tongued, robust bees that look in a general way like male honey-bees or drones. They are solitary bees, and so will never be of any use in bee-keeping. They work on flowers, and like all bees feed their young on pollen. Thus they bie away to fields and orchards for both nectar and pollen.]

Like all bees, they are valuable in pollinating flowers and rendering fruit-trees and vegetables more fruitful. They will serve to spread pear-blight even if all the bees are banished from the pear-orchards. These can not be pushed away, and will prove ample to inoculate with blight, but far from enough to pollinate the blossoms.—A. J. COOK.]

Not a Bee-Subject.

"A horse that never was a colt," is what Mr. Hasty claims to have in his possession (page 152). Is it possible that he has made a mistake? or has my old dictionary "gone wrong" in the definition of a colt? It says a colt is a "young horse." Wonder if Hasty's horse was never a "young horse."

A. E. WILLCUTT.

Hampshire Co., Mass., March 8.

An Experience with Bees.

I am a merchant and have a general store in a small town in Oneida county, N. Y., and carry a general line of merchandise. I have been keeping a few bees as a side-line to my business, having had a few colonies for the past 10 years. But I never had any success with bees until I got a bee-book, and subscribed for the American Bee Journal, which I have taken for nearly a year but of the two I would prefer the Journal but would say to any one who keeps bees he should have both.

Last winter I had 2 colonies which I wintered in the cellar; and they came out in the spring rather weak, and in April I purchased 2 more colonies in old hives, for \$2.75 per colony. They took to swarming, the first swarm coming out May 22. They kept on swarming all through June until I had 18, all told. I did not know enough about the bee-business to increase my little apiary any other way, so I was very much pleased when a swarm issued.

You would have laughed if you could have seen me one hot June day last summer. Just as I was having one swarm, another one

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you."—Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30) I never found these bees to show the least indication of unrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

Out of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chilly winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, Ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italians and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

issued and started for the woods, and as I did not wish to lose any swarms I started on a chase after them, and bundled up with my bee-regalia on. I kept up with them for nearly half a mile, until I had to climb over a stone wall, when I lost sight of them. Then I returned, with the perspiration streaming down into my boots. These 2 swarms issued from the same hive about one hour apart. Why did they not all come out in one swarm, both being large swarms? I doubled some of the smaller colonies up after the honey season, so I had 14 colonies that I put into the cellar last November.

I placed all the new swarms in 8-frame Langstroth hives. I have just been in the cellar to examine them and found them all alive and with plenty of honey except 3 colonies which I think are just about out, and as I had a quantity of sections that were about 2-3 full, I took the covers off and set these sections right over the cluster, and they went to eating it at once.

I think this is a good locality for bees. As a rule they can be taken from the cellar about the middle of April and placed on their summer stands.

There are not many bees kept here within 10 miles, only 2 or 3 colonies in a place by some farmer who does not half care for them.

There is an abundance of white clover here which lines the roadsides and pastures.

F. E. CASTLE.

Oneida Co., N. Y., March 1.

How He Began With Bees.

In the bee-business "some are born great, others have greatness thrust upon them." The bees were thrust upon me, that is, a swarm came and settled on a plac-oush in my front yard, August 5, 1899. I now have 9 colonies in my cellar in Danzenbaker hives.

I see the question is asked, "Do bees near?" If they do, I should think that some one who is good with the microscope might find their ears. They seem to have good, large eyes, anyway.

D. M. HANSON.

Marathon Co., Wis., March 7.

Loss in Cellar-Bees—Tongue-Reach

While looking over the back numbers of the American Bee Journal, I found a promise above my name to report later on matters referred to therein (see March 23, 1901, page 204).

Having swept up what seemed to me an excessive amount of dead bees, I began with the middle of January to measure and record the amount, and I did by referring to the memorandum that from the 70 colonies, from Jan. 10 to April 3, 83 quarts of dead bees were swept up and 32 hives were spotted, and here I find the memorandum defective; I failed to note how many of the 70 colonies came out alive, and built up into good shape for the honey-flow. But they did better than I supposed they could. I think about 10 died, but many of the 70, as well as those outside, were rather weak in bees.

If you will refer on page 469, for July 12, 1890, you will find that for 100 colonies for 4 months in the cellar, Prof. A. J. Cook says, "from 2 gills to 4 quarts;" G. M. Doolittle, "from a peck to one bushel;" Dadant & Son, "half a bushel or more;" C. C. Miller, "perhaps a bushel," Eugene Secor, "two bushels." This estimate is on 4 months for 100 colonies, while the 83 quarts from 70 colonies is only a little over 2½ months. Had the time been 4 months and with 100 colonies instead of 70, the same death-rate would have made a total of almost 6 bushels.

Do you wonder that I felt blue? Now as to the length of tongue-reach of the bees, the measurements were in one-hundredths of an inch, and I found some as short as 17-100, placing the points of the mandible even with the base line, then stretch the tongue full length and let it contract what it would as it lay on the rule, under the glass, and then count the tooth marks. The most of my colonies showed 19 to 22½ tooth marks. I shall continue to investigate and try to have others measure bees from the same hives and compare notes.

The year 1901 was cool and extremely wet in the spring; all the early bloom was full of nectar. Clover came out fine and gave a grand flow until the drouth came on, when we had a month without any flow. Drones were all killed, and but little brood. With the later rains came a good flow from hearts-ease, etc., which continued until frost, giving the bees abundant stores for winter and leaving us nearly 2 tons for our trouble.

We have 98 colonies in the cellar and 17

30 DAYS FREE TRIAL
 You do not know what you can do with an Incubator until you try it. Here is a \$10 **HAWKEYE INCUBATOR** which we send on thirty days' free trial. outside, having lost 2 outside in chaff hives; those outside had a good flight Feb. 23, the first since Jan. 6.

I have taken up 22½ quarts from the cellar-floor so far, and I don't think there is a hive spotted now. The temperature has run from 45 degrees to 52 degrees, the latter making them restless. We keep the window open part way all the time, excepting when it is very cold, and give them a good airing occasionally.

THEODORE S. HURLEY.

Tama Co., Iowa, Feb. 24.

Wintering in a Bee-House.

My 75 colonies of bees are wintering well in a bee-house above ground at a temperature of 10 from 32 to 38 degrees, for almost the entire winter of 3 months past, in which I have wintered my bees for the past 3 years, and not losing a single colony at that temperature. My bee-keeping dates back for 10 years, and I have been experimenting on every kind of way of wintering bees, and I have settled down to the fact that good stores have more to do with it than anything else. Give me white clover and bass-wood honey and I will winter them at 30 degrees the entire winter. Let some of my American cousins in the South read this and they will call me a fool, but I do not care so much when I bring my bees out fine and strong.

When I put them out in the spring I shove them for all they are worth to brood-rearing, and by my manipulation I keep down swarming and make my increase by dividing. If there is honey in the fields I will get it all. I run all my bees for extracted honey, as I find it pays the best here.

In my next I will describe my summer work in detail, and the kind of a house I use.

MICHAEL MADDOEN.

Russell Co., Ont., Canada, Feb. 23.

Wintering Nicely.

My bees are wintering nicely so far, out-of-doors, and they were all flying nicely yesterday (March 5).

I have 8 colonies of fine, healthy bees. I think if I have 15 hives with Langstroth frames and supers I shall be supplied.

I am more anxious for comb honey than I am for increase of bees. I do not care to have them swarm much.

Stephenson Co., Ill. C. S. SPALDING.

Hiving Bees.

In the first place I will tell how I make the catcher. I get a pole with 2 prongs, and nail on the third prong, then take a small barrel-hoop, and nail it in between the prongs. Then sew around the hoop mosquito net, quinine, to hang down as far as I want it to go, then sew it up and gather the bottom and draw it tight together; that makes it comb-like.

When a swarm comes out and settles, I take the hive, bottom-board and cover to the place where they have clustered. If they have clustered low I set the hive on the ground; or if they are low enough, put the hive on a bench or anything; then I put on top of the hive an empty super and shake them right into the super. If they go in in too much of a bunch, I take a twig and stir them over the prongs; then if they settle on the sides I brush them down and put on the cover a little while, and get the canvas ready, then take off the cover and super. If they have not all gone down I lift off the super and stand it in front; they will soon march in. I spread on top of frames the canvas and put on the cover, and put a little something under one end so as not to crush any of them. I leave them until night where I have them, then carry them to the place I want them to be.

If they have settled too high to do as I have said, then I put the catcher up right under the cluster so they will fall into it, then jar them in it and then take hold of the bottom of the netting and turn the catcher over the hive and turn it inside out, right in the super, and empty them all in and shake them off. If a lot go back I repeat the operation until I get the most of them. Then I do the same as with the others.

My bee-hat is a common straw hat with netting around the brim. If they settle low I don't always put it on. I do not use gloves, or any smoke. My bees are very gentle when they swarm. I can pick out any leaves or anything that goes in when I shake them in. It is very rare I get stung when hiving

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers. We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.77 a gross; five or more gross \$4.50 per gross. If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.

ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.

J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself. M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Abbott, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens

FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order for one queen for sending us the names and addresses of two new subscribers to the American Bee Journal and \$2.00; or for sending us one new subscription and 30 cents more (or \$1.30), we will mail you a queen; or send us \$1.60 and we will credit your own subscription for one year, and mail you a warranted queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a long time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., APRIL 3, 1902.

No. 14.

* Editorial. *

A Large Edition of this number of the American Bee Journal will be mailed, some of the copies going to bee-keepers who are not now subscribers. We trust they will be so well pleased with it that they will want it regularly hereafter. Only \$1.00 will pay for it for a whole year—52 weeks—52 copies! It ought to be a good investment to any one who wants to make anything out of his bees.

The Chicago Convention Report is begun this week. While it has been some time since the meeting was held, it will read just as well as if it had been published sooner. We preferred to give place to the proceedings of all the other conventions first, and let our own local meeting come last. It will be a good report of a good convention, and will probably run in installments every week for two months or more. It was the best convention ever held by the Chicago Bee-Keepers' Association.

An Attempt to Outlaw Sweet Clover, says Gleanings in Bee-Culture, has been made in Ohio, and if Ohio bee-keepers are alive to their interests they will at once write to their Representatives and Senators urging the defeat of House Bill 598, which classes sweet clover among noxious weeds, and directs that to township trustees shall cut it down whenever complaint is made. It is refreshing to know that at the Ohio Agricultural Experiment Station the Director is such a man as Prof. Thorne. Here is a letter from him to A. I. Root:

My Dear Sir:—If you find any serious attempt to have sweet clover declared a noxious weed, please let me know. I should consider such a declaration about as wise as one to call red clover such a weed, and will fight it with all my might. I was one of the first to call attention to the peculiar habit of this plant of growing on soils where no other plant will thrive, a little article of mine on this point having been published as far back as 1877, and quoted throughout the range of the agricultural press. Yours truly,
CHAS. E. THORNE, Director.
(Dic. L.)

The Colorado Foul-Brood Plan of managing so as to kill it out and at the same time get a crop of honey by shaking off nearly all the bees upon frames filled with foundation, was copied some time ago from the Rocky Mountain Bee Journal. Editor Hutchinson says it is really the Heddon method of transferring, and his advice that the work

should not be prematurely undertaken deserves strong emphasis. He says:

I might say, in a few words, that the old hive and its combs of hatching brood should be managed almost exactly the same as would the hive of a colony that had swarmed. In short, this method is nothing more or less than forced swarming, and the work should not be done until the colonies are nearly ready to swarm—perhaps some of them have swarmed. To attempt it too early, before the colonies are populous, the weather warm, and plenty of honey in the fields, would be disastrous.

He further says that the plan is really swarming, with the advantage that the swarming is done when we want it rather than when the bees want it, and quotes H. R. Boardman—one of the most reliable practitioners—as following the plan in his out-apiaries to solve the swarming problem. "He visits his out-yards about once a week, and every colony populous enough to swarm is thus 'swarmed' by the shaking-off process."

With regard to disposal of the brood taken away, enough bees are left to care for the brood, which is put upon a new stand, and Mr. Hutchinson suggests that after all brood is sealed the queen-cells should be destroyed and a cell of choice stock be given.

Wax-Worms and Basswood.—It was given out in Gleanings in Bee-Culture that basswood was the proper lumber for top-bars, because wax-worms would not burrow in it as they do in pine. Dr. Miller replied that basswood would warp and twist too much to be used in bee-hives, and later he says he has found unmistakable proof that wax-worms bore into basswood the same as into pine.

Ventilation of Bee-Cellars is a topic that is being ventilated in Gleanings in Bee-Culture by T. F. Bingham and G. M. Doolittle. The former advocates a ventilator 16 inches square, while the latter seems to think little or no ventilation is needed. "When doctors disagree," etc.

Bee-Keeping in the United States.—The Census Bureau, on March 21, issued a complete report showing that for the country as a whole, on June 1, 1900, there were 707,261 farms keeping bees, substantially one for every eight farms. These farms reported 4,109,626 colonies, valued at \$10,186,513, averaging a little less than six colonies to each farm reporting, says the Washington Post. The twelfth census is the first to report the number and value of bees, or the number of farms reporting them.

During the year 1899, there were produced 61,196,160 pounds of honey and 1,765,315 pounds of wax, of an aggregate value for the

honey and wax of \$6,694,901, or \$9.42 for each farm reporting the same. Of this value, 35 percent is from the North Central, 12 percent from the North Atlantic, 15 percent from the South Atlantic, 23 percent from the South Central, 14 percent from the Western States, and 1 percent from Hawaii. The products of Hawaii were 96,870 pounds of honey and 1,720 pounds of wax.

Of the States reporting honey, Texas reports the largest quantity, 4,780,204 pounds. California reports the second largest quantity, 3,667,738 pounds, and New York the third largest, 3,422,427. The counties showing the heaviest production are Fresno, San Diego, and Tulare, of California, and Tompkins, Cayuga, and Seneca, of New York.

We imagine that the reported pounds of honey, and also of beeswax, are far below the actual production. We think perhaps 700,000 farms where bees are kept must be somewhere nearly correct. Perhaps by the time the next census is taken more reliable apiarian statistics can be had.

The British Standard Frame is 14x-8½—not quite three-fourths the capacity of the Langstroth—and the British Bee Journal is emphatic in the opinion that an increase of size would be a backward step. Ten frames in a hive is considered about the right thing, that being about the same as 7½ Langstroth frames. There is, however, a controversy starting in the British Bee Journal as to the advisability of a change in frames. F. W. L. Sladen says:

When I was in America I was surprised to see the great diversity of sizes of frames used, and all were claimed by their advocates to be better for their purpose than any others.

Influence of Nurse-Bees.—F. B. Simpson—the man who is writing such an interesting series of articles in the Bee-Keepers' Review concerning the breeding of bees—thinks there must have been 'some very careless reading on the part of the American Bee Journal to allow it to say that Mr. Simpson inclines to the view that a changing of nurse-bees might produce a queen very different from what she would have been had her own sisters been the nurses. The carelessness, so far as there was any, was not in reading but in writing. It is true that Mr. Simpson inclines to that view, but he is far from being strongly inclined, and it would have been much better to have said that he inclines very slightly to that view. So far from taking the ultra view that some have taken, he expressed the belief that the influence of the nurse-bees "is undoubtedly extremely slight in comparison with the hereditary properties

of the combination of the germ-cell with the sperm-cell."

He quotes with astonishment the remark that "if the nurse-bees have as much influence on growing royalty as some have urged, it ought not to be difficult to prove it by a single exchange of eggs." If Mr. Simpson is familiar with European bee-literature, he must know that that statement is true, and if he will read again he will see that in making it there was no reference to him.

It may in turn be in order to ask whether it was careless reading or writing that allows Mr. Simpson to say: "Suppose that the editor of the American Bee Journal were correct in expectations, and also that there could be a marked difference in each generation, due to nurse influence." There is nothing on page 50 to show that there was any expectation whatever on the part of the editor of any change being made by a change of nurse-bees, although there is a possibility that such a thing may exist, but if it does, Mr. Simpson is no doubt correct that such a change must be very slight.

It seems that none of us have yet reached perfection, either in the art of expressing ourselves or deciphering the meaning of others, but with the practice of a little patience we may easily come to an understanding.

California Reports of late date seem to show that prospects for a honey crop are not so gloomy as formerly supposed.

Salt the Ants if you want to drive them away, says Frank Gilmore, of Connecticut. He says he has proven by experience that if salt is sprinkled wherever they are they will leave. If little red ants annoy the good housewife, put a tablespoonful of salt in a teacupful of water, dissolve well, and then pour it around where the ants enter.

This is such an easy remedy to apply, that any one who has both salt and ants can soon test the matter. If it is as effective as Mr. Gilmore says it is, a good many bee-keepers will want to extend to him a big vote of thanks.

Cane vs. Beet Sugar.—For years the British Bee Journal has strongly urged that those who feed sugar to bees should be sure that cane and not beet sugar be used. If that journal is right—and it is possible it is—we are in a bad case in this country, for there is probably not one bee-keeper in a thousand who can tell beet sugar from cane, and beet sugar, which formerly formed only a small portion of the sugar used, forms now the larger part, and is constantly on the increase.

Tongue-Length and Tongue-Reach.—In Gleanings in Bee-Culture Prof. C. P. Gillette calls attention to the mistake that has been made in deciding from his experiments that there is no direct relation between tongue-length and tongue-reach, in spite of his saying: "I believe, for practical purposes, it may always be considered true that the bee with the longest tongue has the longest possible tongue-reach." It is true that according to his table of measurements it appears that tongue-length and tongue-reach do not correspond, but he does not con-

sider the measurements of reach as reliable as he does those of length, and says: "I place no value whatever upon my measurements of tongue-reach except to show how variable and unreliable such measurements are."

Weekly Budget.

THE EPWORTH HERALD, with its nearly 120,000 circulation every week, kindly published the item on "Comb Honey Not Manufactured," in its issue of March 29, which is its annual Easter number, and a beauty. The Herald has the largest circulation of any religious young people's weekly, being the organ of the Epworth League of the Methodist Episcopal Church. Its able and popular editor, Dr. J. F. Berry, is one of our very intimate friends, and would do all he could to aid bee-keepers in getting the truth about honey before the people.

BEE-HOUSE OF L. J. CLARK.—When sending the picture shown on this page, Mr. Clark wrote as follows:

I enclose a view of my bee-house, part of my apiary, and rear view of my residence. I was born in Vermont, Aug. 21, 1840; came to Minnesota June 1, 1858, and have grown up

business—milling, farming, etc. I have never made a specialty of bee-keeping.

I have lately secured a farm on the Mississippi river bottom, that I think is a good location, especially for fall honey, so I expect to increase my apiary largely in the near future. At the home apiary, shown in the picture, our surplus hoovey nearly all comes from white clover.

L. J. CLARK.

APIARY OF JOHN H. BLESSING.—On the first page is a picture of the apiary of Mr. Blessing, concerning which he has this to say:

My apiary consists of 29 colonies in Langstroth and dovetailed hives, all 10-frame size. I began keeping bees about nine years ago, and was very successful until last year, when they didn't average over 20 pounds per colony. The hot winds killed all of the white clover, and there was no buckwheat sowed; but I am not discouraged yet, as I have hopes for better things.

My bees are all hybrids, but they are great workers when there is anything to do. They had the swarming-fever last spring, and I had quite a time with them.

January 9, 1902, I noticed the bees were flying quite freely; I had placed a bucket on a bench that had some rye and oats ground together, and the bees were very busy carrying it to their hives. I had intended this rye and oats for the pigs.

I have always wintered my bees successfully on the summer stands. The stakes which can be seen in the picture behind the hives are for holding straw. After nailing the poles to the stakes I pack straw in around the hives.

I read the "Old Reliable," and couldn't get along without it. I also have "Langstroth on the Honey-Bee." JOHN H. BLESSING.

BEE-HOUSE AND RESIDENCE OF L. J. CLARK, OF WINONA CO., MINN.

with the country. When 15 I enlisted to fill a vacancy in the 1st Minnesota Volunteers, but on account of my age, and the War coming to a close, I was not sent South. I was married when 23 to Lueie E. Balch, of Lockport, N. Y., with whom I lived happily for 17 years, when death claimed her, and since that time I have remained a widower. The two girls on the back porch are my daughters, May and Allie, aged 13 and 15 years.

Ever since I can remember I have taken much interest in bees, and when about 10 years of age had, at one time, about 7 colonies of bumble-bees, and enjoyed myself very much in watching the occasional bee that would come and go.

The year that I was 16, in June, I paid \$12 in hard cash, that I had earned by working out, for a colony of young bees in a very plain, unpainted box-hive, and I got up at 1 a. m. and went 12 miles so as to get there before the bees were out in the morning. Since that time I have had more or less bees the most of the time, although being engaged in other

HAVE THE BEST TOOLS.—Editor Hutchinson has this to say in the Bee-Keepers' Review, on the subject of tools for the apiary:

It is all right for a man with limited capital to put up with make-shifts. In fact, he is compelled to or go in debt for them. *Get improved tools and machinery just as fast as the profits of your business will justify the expense.* To squeeze along with imperfect tools, when the profits of your business will allow the purchase of good ones, is the poorest kind of economy. Don't let the habit of putting up with poor tools become so fixed that it can not be changed when conditions change. Another thing: Watch the conditions; study them closely; they may change so gradually that you do not realize the change.

Fortunately, bee-keepers require new tools, and there is little excuse for their using poor ones. The largest factor in the production of honey is labor, and anything that tends to lessen this factor should be given the most thoughtful consideration.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

The convention was called to order by Pres. George W. York, at 10:30 a. m., after which T. E. Hogge offered prayer.

Pres. York—As president of the Chicago Association, I am delighted to find so many here to begin with. We will now listen to the reading of the minutes of the last meeting, and also the financial report. We will do all the business up first, or at least most of it, before we start on the questions.

Sec. Moore then read the minutes, and also the financial statement, both of which were approved.

Pres. York—It affords me much pleasure to introduce to the audience Dr. C. C. Miller.

Dr. Miller—How do you do, audience?

Pres. York—I also want to introduce Mr. C. P. Dadant.

Mr. Dadant—Mr. President, I am a little bit ashamed.

Pres. York—You needn't be ashamed; you are good looking.

Mr. Dadant—I will be doing lots of talking anyway, so I will say nothing just now.

Pres. York—Mr. Green and Mr. Clarke will now distribute the paper slips for questions. Write one question on a slip and they will be passed at different times so we will have enough to go on with. You will have a chance to ask all the questions you wish before we get through. I would like to say a word about the membership while you are writing the questions. Our dues are \$1.00 a year, which dollar pays not only your membership for the Chicago Bee-Keepers' Association, but also the dues in the National Association. I would like to have every one become a member of the Chicago Bee-Keepers' Association. I hope you will be very prompt about writing questions, so that we will have them to go on with. Dr. Miller, I know, is just aching to talk.

Dr. Miller—I do want to say one word. I want to congratulate this Association on the plan of having the time not taken up with a lot of long speeches and papers.

Pres. York—Doctor, I think you had better sit down again.

Dr. Miller—Will you please keep still until I am done? Years ago, the pace was set in this very city by the old Northwestern, of having programs that were not programs in the ordinary sense of the term, and I believe now it is getting to be the common custom in all of the bee-keepers' meetings to have the time taken up largely in discussion. You know how it is; two bee-keepers get together, and the first thing they begin to talk about bees. They don't need any program. If I should happen to meet Mr. Dadant (that Frenchman, who got away, and came into this country in spite of all I could do)—if I should meet him, we wouldn't stop to discuss whether France or America is the best country, but we would begin to talk bees, and in this convention, by talking bees and having questions here and there, the time is put in profitably, and I don't know any reason why this Chicago Bee-Keepers' Association should not become a power; it is, I believe, and there is no reason why we should not have exactly the same meetings here as in the old Northwestern, and they were fine meetings, too, and I do know you can have a fine meeting here to-day.

Pres. York—I have just been looking over the questions, and have a lot of good ones. We will begin with an easy one. Listen to this:

"WHICH IS THE BEST HONEY?"

Dr. Miller—Bees' honey!

Sec. Moore—That question I am asked every day, and my answer uniformly is this: It is the honey that you like the best, that you are used to, and that is in California one kind, in Ohio one kind, and in Cuba another, and go on and give them the names of honey in those localities. You may think this is a very unimportant matter, but it isn't. It is clearly a case of what we are used to. There is no best honey. For the candy-maker one kind, for the cake-baker another kind, for the detective another kind, and the tailor another kind. I should say alfalfa. Take a vote.

Pres. York—How many think basswood the best? One.
Pres. York—Those who think white clover the best raise your hands? Eight.

Pres. York—How many think alfalfa is the best? Three.
Pres. York—How many think sweet clover is the best honey? Twelve.

Pres. York—How many think buckwheat is the best honey?

M. M. Baldrige—Buckwheat is the best honey for some.
Pres. York—How many think the California sage is the best honey? One.

Pres. York—How many think orange-blossom honey is the best? Two.

(Voice from audience)—Best there, but there isn't much of it.

Pres. York—How many know what alfalfa honey is, and have tasted it? Thirteen.

J. A. Green—You didn't hit my case. Sweet clover with fall flowers. I find that everybody who has tried it prefers a small amount of aster with sweet clover.

A Member—Just my experience; same crop and same experience.

Mr. Blunk—It suits this Hawkeye best, too.

Dr. Miller—I think there are two things in the case. In the first place there is, as the secretary has suggested, the prejudice of familiarity; and, then, you will see in the foreign journals, or in journals here, some one comes out and says, This is the best honey in the world. He honestly believes so. That's what he is accustomed to; that's what he likes. There are mixtures, sometimes, that are better than the pure article, and that sometimes makes confusion about it. Sweet clover was spoken of a while ago, and if there was any one honey that seemed to be spoken of enthusiastically it was sweet clover. I am not sure I know just exactly what the best sweet clover honey is, but I have had some and I have used a good deal of it, and had some I got for the pure article. If it was correct, then I don't like sweet clover. I have gotten what I supposed to be, and had good reason to believe was, a mixture of sweet clover with white clover. I think if I should say what honey I liked best of any I had ever sampled in my life, it would be the white clover flavored with sweet clover. The sweet clover alone, to me, has a disagreeable flavor and seems to me a little like this: You take the flavoring of vanilla and nearly every one likes it; but you overdose it, and put too much in your ice-cream—and it seems to me it is a little the same way with sweet clover. It has too strong a flavor, and there will be some that like it. I know people that like the taste of tobacco. The majority of people, I think, would say that the pure article of sweet clover isn't so good as if you have just enough of the flavor, and then it is a fine article. If you will allow the comparison, for two or three years I ate it without knowing what it was, and I called it vanilla flavor, and I think it was sweet clover.

Pres. York—There may be some in the room who are not bee-keepers, who misunderstand Dr. Miller when he said he believed that a mixture might be better than the pure article. He doesn't mean adulterated with glucose or syrup.

Dr. Miller—Not in the same way I would say pure Durham stock.

Chas. Clarke—As regards sweet clover honey, when it is properly ripened it loses all that taste that the Doctor speaks about. I think we will have some here this evening, possibly, in which you cannot find any of that taste, and I think it is a good deal the fault of the apiarist in taking the sweet clover honey right from the super, packing it and sending it to market. It has the taste you speak of, and it loses it when it has ripened thoroughly for six weeks. Sweet clover honey then will hold every customer it goes to, in place of white or alfalfa, or any basswood or other honey; but there are so few that seem to care about the reputation of sweet clover honey, and ship it right to market and get rid of it, the quicker the better. I never have lost a sweet clover honey customer. I never sell any comb honey until it has been thoroughly ripened, for six weeks or three months, and when you go into a room with three or four thousand pounds taken right off from the hives, I can't describe the smell, and in two or three weeks it will lose that and get the beautiful aroma of honey; but I think the alfalfa is really the cause of having so much trouble with adulterated honey on account of its very light flavor.

Dr. Miller—It is only fair to sweet clover for me to say, that in the samples I have tasted and eaten—and I have done it quite largely—that the taste seemed to me just as has been described—that it was raw, and not fully ripened, and it may be that I have not eaten any thoroughly ripened, extracted sweet clover honey, and if any one could give me a sample I would be very glad to sample some that was thoroughly ripened.

Pres. York—Send Dr. Miller a five-gallon can of it, prepaid!

Mr. Riker—I visited in Colorado this fall, in some sections where they raise sweet clover altogether, other sections alfalfa, and in others the two kinds mixed. Where they raise sweet clover people don't like it. Where it is pure sweet clover they can't eat it. It sickens them. They can eat a mess, but can eat very little of it. Of the alfalfa and the other there is no end to their eating it. The more they eat the more they want of it. That experience I found there. Since I have returned I have put extracted alfalfa honey on the market and am selling it to my neighbors. Every person that I have sold it to likes it. They can eat of that when they cannot eat of any other honey. Well, it seems to me that the alfalfa honey really is the best honey I ever had anything to do with. White clover comes next, but the pure sweet clover in the West, where I was this fall, and they told me it was pure sweet clover which smelled exactly as pollen smells, as they grew it, is pure honey there. The gentleman who has sweet clover honey must have some other honey mixed with it in order to make it good honey.

Mr. Clarke—That reminds me of the boy and the cake. You give him a very nice-flavored cake, and give him bread afterwards, and the bread doesn't go good: he likes the cake. My experience has been this: Where I have had a sweet clover customer you can't get him away with alfalfa. He is used to good-flavored honey, where sweet clover is properly ripened—(I am not talking about "green goods," taking off all the honey and selling it). You give him alfalfa and he will probably tell you that he had a lot of artificial honey. I meet with that everywhere, nine times out of ten, on account of the mild flavor of alfalfa, and the strong flavor of the clover. I don't say anything against alfalfa, because it is a beautiful honey, but it is the change from the strong to the mild which is the cause of the trouble.

Mr. Whitney—I would like to endorse what Mr. Clarke has said with reference to sweet clover. Of course, we have in our locality a sprinkling of white clover but not to any extent—largely sweet clover. I have never proved it finer honey in my life than I have this year, and it is nearly all sweet clover, but, as he says, it should be ripened. Mine was two months in a very warm room and I sold it all, most of it at 15 cents, and I haven't had a word of complaint. There was very little of that strong, sweet clover taste that we get in the smell as we go through a patch of sweet clover. I am inclined to think, however, as the secretary proposed, that the honey that is the best is that which people like best; and I like sweet clover.

(Continued next week.)

Contributed Articles.

Transferring Bees—When and How To Do It.

BY G. M. DOOLITTLE.

A correspondent writes thus: "When is the best time to transfer bees? I have quite a number of colonies in box-hives which I wish to transfer, and I should like to know when this can be done to the best advantage. Can I do it as soon as spring opens? or would I better wait till the bees are securing honey from the fields? or wait till swarming-time? I should be pleased to have your answer through the American Bee Journal."

The transferring of bees from box-hives, or "gums," or from one style of frame hive to another, can be successfully done at any time of the year when bees can fly, if the operator understands just what is needed in the case; and it is with pride that I look on the man or woman who has ability enough to accomplish anything successfully which is necessary to do at a certain time, no matter whether such time is the most propitious or the most unpropitious. The person who can successfully transfer a colony of bees in early spring, when robber-bees are prowling around, is to be admired; yet, unless there is some urgent reason why a certain thing should be done at a certain time, it is always best to wait about doing anything till the time when everything is the most conducive toward a successful outcome.

□ As I consider it, there are two seasons of the year when bees can be transferred to the best advantage, the first being fruit-bloom, and the other 21 days after a prime swarm has

issued. During the first part of fruit-bloom the scramble after new honey is such that one is not liable to be annoyed by robber-bees, and at this time there is very little honey in the combs to cut through, such honey making a sticky mess of everything used during the operation. Again, as the bees are getting their first honey, they are eager for something to do inside the hive at night, hence will repair all mutilation of the comb, fasten the same in the frames, etc., much more rapidly and readily than at any other time.

With all the above being true, fruit-bloom brings the most auspicious time for transferring bees; but it has this drawback: As a rule, the bees have got under good head-way rearing brood, and we shall find the combs half or two-thirds filled with the same, so that in cutting them to fit the frames, much brood must be sacrificed, as well as displaced in the brood-nest, owing to our not being able to secure all in the shape in the new hive which it was in the old one. All of this has a tendency toward a loss of bees, and as all of the brood that is sacrificed at this time would become bees of the right age to do the best labor in the honey-harvest, had we left the transferring till later on, we can see that a loss must be made by doing our transferring at this time of the year, with all colonies except those which have little brood in their combs. For this reason I prefer to wait till 21 days after the prime swarm went out. However, even though some brood is lost, fruit-bloom is a much better time to do our transferring than any other except 21 days after swarming, and many think that through transferring in fruit-bloom, the bees are incited to enough greater activity to make good all loss that comes through destroying so much brood by cutting through it.

At the time of 21 days after the prime swarm has issued, all of the brood will have emerged from their cells, except perhaps a few drones, and the young queen will have only just begun laying, or have laid only a few days at most—not long enough so there will be much but eggs in the combs—so that all we have in our way at this time is the honey which the combs may contain, which will not be a great amount if the colony has been at work in the sections: for as soon as the young queen begins to lay the honey is quite generally hustled out of the brood-combs, up into the sections, to give room for the eggs necessary to yield the bees for the future prosperity of the colony later on in the season. And as this comes at a time of the year when bees are generally securing all the honey they want, and the weather is always warm, so that there is no danger of brood or bees becoming chilled, no matter how slow we may work or where we are, we can now do our work right in the bee-yard, this being much more convenient and giving a better prospect of success all around.

So far, I have been looking at the matter from the standpoint of the old way of transferring, as it is styled. If we should desire to use the Heddon or modern plan of transferring, by driving out the bees and hiving them in a hive filled with comb foundation, this is just the time, and the only time in which it can be done successfully, for the combs are free from brood, so only one operation is needed. Otherwise we must first drive out a swarm and hive it in a hive whose frames are filled with foundation, taking our chances of getting out the right proportion of bees, and leaving the right proportion in, and then wait 21 days till the bees have all emerged from the cells, at which time there will very likely be a honey-death on, so we will be troubled with robber-bees, while the young queen, in this case, will have already begun to lay.

When using the Heddon plan we do not have to fit any combs into the frames, but the old combs are cut out full size from the old hive, and when we so work, at the time above advised, there will be no brood in the combs to hinder, and nothing to prevent our taking the old hive right to the solar wax-extractor and doing the work right beside it, so that in an hour or two we can have both the honey and the wax from the old hive in shape to use, thus saving time and delay which would result at any other time of the year.

Onondaga Co., N. Y.

Winter Bottom-Board for Outdoor Wintering of Bees

BY H. DUPRET.

Fig. 1 is the winter bottom-board, with the movable parts shown separately. *a* is a 3½ inches thick combination bottom-board made of three layers nailed together; the middle one *x*, being 1½ inches thick, in order to provide a 1½ inch space under *b*, the bottom-board proper (as in Fig. 2). Length and widths to suit the hive which is to rest on *R, R, R*.

b is the movable bottom-board proper. When in place, it will rest on 2½ inch blocks *l, l* nailed to the floor *V*, in the rear; and in front, on another longer movable block *k*. Two or three holes in *k* serve as entrance-holes under the frames.

I usually leave only one open at a time. In preparing this movable board *b*, provision must be made against warping, by nailing cleats to both ends; an allowance of about $\frac{1}{4}$ inch must also be made in the width of *b* (as in *R*, Fig. 2); otherwise dampness in the spring-time will so extend the width that the boards will no longer be movable. Meanwhile the gap is closed by a thin board *c*, placed under and resting in front

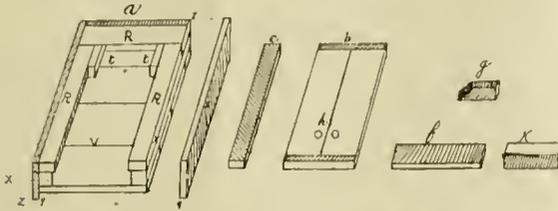

FIG. 1.—Winter Bottom-Board for Outdoor Wintering of Bees.

on a little block *d* (as in Fig. 2); a little roll of paper closes the hole which remains in front.

f is a thin board used as a sort of bridge over the front of the bottom-board *b* between the holes in the front end, to prevent sawdust or any other filling material from falling in *V*. It is not necessary to have it nailed. (See it in position Figs. 2 and 3).

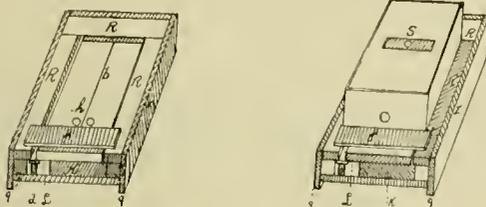

FIG. 2.—Ready for use.

FIG. 3.—With hive set upon it.

k is the oblong block to reduce the width of the front entrance to suit the taste.

Z, Z, Z, are three thin boards to cover the sides of the combination boards; they must be of such width and so nailed as to provide a space under the whole apparatus, as at *g*.

I generally slip a piece of coarse paper over the inside floor *V* for convenience. Bees, in cleaning the hive, when the temperature allows it, drop the dead bees, etc., in *h*, over this paper, and it is easy for the bee-keeper to remove these dead bees by drawing the paper out, and replacing it, if it has become soiled. But late in February or March some colonies

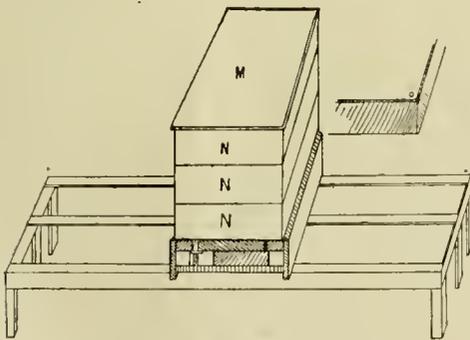

FIG. 4.—With Winter-Case.

will have accumulated dead bees over the movable bottom-board, under the cluster, to such an amount that it will be well to draw this bottom-board out: clean it and replace it inverted, which operation can be performed without arousing the bees much. This is the principal advantage of such a movable bottom-board. The others are: The entrance-holes *h* are never plugged by ice or dead bees; the severe winds never blow directly on these holes; neither do the rays of the sun strike on them.

Care must be taken not to make any of the movable parts (*b, g, k,*) too tight, for easy removing of them; for dampness causes them to smell a good deal. So these blocks (*g, k,*) should be a little less than $1\frac{1}{2}$ inches thick.

g is used partly to sustain the movable bottom-board in front (inside), and is also placed near the holes *h* to provide a sort of ladder for the bees to climb up and down.

If robbers are troublesome in April or May, a strip of perforated zinc can be used in the front entrance.

Fig. 2 shows the whole bottom-board ready for the hive to be placed upon it. Although it might be used that way all the year around, I exchange it for the ordinary bottom-board some time in May, when I also remove the winter-cases.

Fig. 3 shows the hive in position. It does not lean on the movable bottom-board, but on the three sides of the upper layer, *R, R, R*.

s is my own "Hill's device," provided with an auger-hole—very handy for spring feeding. I generally use a chimney feeder, covered with glass.

Fig. 4 shows the whole winter arrangement.

n, n, n, are the separate parts of the winter case; *m* is the

FIG. 5.—Hive-Stand (to accommodate 3 hives with winter-cases.)

This stand serves 3 purposes: 1. Convenience in handling frames 2. Keeping away rats and mice. 3. Protects against snow embankments.

zinc-board cover. The edges in each part of the case (also in *Z*, Fig. 1) are beveled so as to shed rain-water as in *o*, Fig. 4.

I use sawdust as most convenient for a filling-material; about 4 inches thick on the four sides, and as much as 7 or 8 inches on the top of the frames.

Fig. 5 is the hive-stand, all the year around.

Quebec, Canada.

An Experience in Wintering Bees in the Cellar.

BY C. DAVENPORT.

A year ago this winter I wintered about 150 colonies of bees in a basement or cellar that was only partly under ground, and besides the disadvantage of being only partly under ground it was so small that the hives had to be packed very close together and tiered up from the floor to the ceiling. There was no means of ventilation except by the door and two small windows. The temperature varied greatly during some severely cold weather; with both windows closed it would be as low as 38 degrees, and when it was mild, with both windows open at night, it would rise to 60 degrees. Toward spring, when the weather began to get warm, the temperature was even higher, and the bees became very restless and uneasy. They were clustered all over the front of the hives, and if the outside door was left open enough so there was light enough to see, the air inside would be literally thick with flying bees, and the results were about as bad as though a lantern was taken inside.

It became a serious problem how to get the bees on the summer stands. As soon as a hive was set out-of-doors all the bees clustered on the outside would take wing, and those inside would begin to pour out by the hundred as soon as the light struck the hive. I tried setting the hives on a large canvas, then wrapping this quickly around and over the whole hive before many bees could escape, but by the time the hive was carried to its stand most of the bees were out of the hive and in the folds of the canvas or cloth, and when this was removed there would be a cloud, in fact, practically all the bees that were not crushed in the fold of the cloth would be in the air without taking bearings or knowing where they belonged. Smoke only made the matter worse, that is, trying to smoke a colony after it was removed from the cellar. I came very near smoking the whole number in the cellar, but hardly dared to, for I was afraid if the whole air of the cellar was heavily charged with smoke that it might make the matter worse.

These first attempts at putting them out was during a few warm days the first part of March; the weather for a short time after turned colder, but the bees were becoming more restless and uneasy all the time, many colonies beginning to spot their hives badly. I would leave the

windows open and the temperature would go down to 40 degrees or so, but during the day the windows had to be closed to exclude the light, and the temperature would run up to 60 and 65 degrees even when it was quite cool outside.

Of course, with a larger cellar, or a less number of colonies in the same one, there would not have been such a variation in the temperature, even if it was partly above ground.

Another thing that was very unfavorable was that owing to the hives being crowded so close, I was unable to remove the great mass of dead and decaying bees that accumulated.

The colonies in the fall were very strong, and the loss of individual bees was from the first very heavy, so those of experience know what these conditions imply.

As soon as it became apparent that these bees could not be removed to their stands during the daytime, without great loss, I had been thinking about trying to take them out at night, but I had never had any experience in putting bees out at night, and could find but very little in regard to the matter in any books or journals I have, and this is the reason I am giving my experience in regard to the matter.

I have described how restless and uneasy the bees were, and I will say here, before beginning extracts from my diary, that if the temperature at night was not above 35 the bees made no effort whatever to fly when put out of doors even if it was quite light. When a hive was first put out the bees would set up a great roaring, but this gradually subsided, and what bees were clustered on the outside of the hive soon crawled in.

My plan was to put outside, near the door, as many hives as I intended to remove that night, and in one-half to an hour and a half, depending upon the temperature, the bees would be so quiet that the hives could be removed to the yard, a number of rods distant, on a wheelbarrow, without closing the hives. Here are some of the records:

March 18—Carried out 25 hives this evening; temperature 28 above zero.

March 19—It snowed all day; temperature up to 38 at noon. Many bees flew out and were lost in the soft snow.

March 20—Snowed and blowed all day. Temperature 16 above zero; many bees came out of the hives and died in the soft snow.

March 21—Temperature up to 44 to-day. The bees flew quite freely, but many were lost in the snow.

March 22—Temperature up to 46. Cold north wind; bees flew considerable, but many were chilled and lost; snow is about gone.

March 23—Temperature up to 60 in the shade. Bees had a good flight. Tried to remove some from the cellar during the day, but gave it up; carried out 50 colonies this evening.

March 24—Rainy; cold, raw wind. Temperature up to 43 at noon. Thousands of bees from each hive carried out last night flew and were chilled to death. Many, or perhaps nearly all that flew or crawled out of the hives, had bloated, distended abdomens filled with pieces that they seemed unable to void; whether this would have been the case if they had been put out on a warm day I am unable to say, but my opinion is that a large part of them that died to-day would have died just the same, only farther away from the hives, if the day had been ever so warm. One thing certain, they cannot stand such daily mortality very long, or they will all have perished.

March 25—Another rainy, cloudy day. Temperature was up to 46 for awhile. The bees from 50 hives carried out last flew freely, and I think there is no doubt but what great numbers, perhaps thousands, from each hive were chilled and lost that would not have been had the day been warmer. I fear a few more days as unfavorable as yesterday and to-day will cause the loss of the whole 50 colonies. I shall let them remain out now whatever the weather and outcome are. It would be hard to imagine two more unfavorable than yesterday and to-day were; if it had been a little colder the bees would not have left the hives so freely. On the other hand, if it had been a little warmer, or even at the same temperature, if the sun had shone they would not have been chilled.

The bees in the 35 hives carried out first have not attempted to fly since the 23d. I think they will be all right unless the spring should prove very unfavorable.

March 26—Cloudy and colder; no bees flew to-day. The ground is freezing to-night and it looks like snow.

March 27—Clouds and sunshine to-day, with cold wind

from the north. Temperature up to 42 for awhile during the middle of the day. Many more bees from the 50 hives, carried out last, flew and were chilled to death in the cold wind. The bees from the other hives did not fly.

March 28—Clear to-day; temperature up to 40 for awhile; cold wind. Thousands of bees from the hives carried out last flew, and many were chilled to death. The rest of the bees in the basement are getting very uneasy. Great numbers are leaving the hives and dying daily.

March 29—Fair most of the day; temperature 42 for a short time; cold wind from the east. Large loss of bees again from the 50 hives carried out last. It is evident that these bees are dying for want of a flight, but the condition they are in, a flight means death during such weather as there has been since they were put out. It must be there is considerable hatching brood in those hives or they would, after suffering such great losses daily, be weaker than they appear to be. This evening they all, with few exceptions, responded quite strong and brisk to "taps" on their hives. Three are about gone and another one is very weak. I think most of the rest would pull through if they could have a good flight soon.

March 30—Snowed some last night and this forenoon. Temperature 26 above zero; no bees left the hives.

March 31—Temperature up to 49 for awhile; no wind. The bees in all the hives out-of-doors flew freely. Considerable loss of bees again. Carried the rest of the bees out of the basement this evening.

April 1—Fair; still very temperature up to 55 in the shade.

I will not quote from the diary any farther just now. The spring turned out to be fairly favorable; the loss among this lot of bees was much less than I expected it would be. There was no colony that died outright. A few colonies spring-dwindled, 3 or 4 lost their queens during the winter or early in the spring, before they had commenced to lay, and a few colonies deserted their hives soon after they were put out.

As I surmised, almost all of these colonies had commenced to rear brood in the cellar; many of them had an amount nearly equal to a whole frame of hatching brood, and it was this early-started brood-rearing that saved them. The old bees died off very rapidly after they were put out. The majority of the colonies got down pretty weak, but they built up fast.

If the spring had been late and cold the loss from spring dwindling would undoubtedly have been great. There were 148 colonies put into this basement in the fall, and by referring to my record-book I find that there were 119 colonies in this yard the first of May recorded as strong to medium, and 4 weak ones. As I said in the first part of this article, the colonies were all very strong in bees in the fall. There was a late fall flow so that brood-rearing was kept up late, and they had plenty of good, sealed stores, but there was another matter that might be expected to be against favorable wintering even in a good cellar; perhaps I can best explain by quoting a brief extract from my diary again:

Dec. 16—Finished putting the bees in to-day; they have not had a flight since the fore part of November; left them all out in hopes that they would have another flight, but there was no day warm enough. There were no very bad storms or severe cold; a few nights it was down to zero or a little below.

The rule is to put bees in within a day or so after they have had a good flight, but these were out in the yard for 5 weeks or more after their last flight.

Considering the cellar they were to be wintered in, they were perhaps as well off in the yard as they would have been inside, as long as the weather was not very severe.

Before closing I will speak of a matter in regard to cellar-wintering upon which my opinion has been asked. Two years ago, I think it was, Mr. Barber, in one of our bee-papers, claimed that no fresh air should be admitted to the cellar when the bees became so warm that they were uneasy, but instead the cellar should be banked and fastened up still closer towards spring, or during a warm spell, so as to exclude all fresh air from entering. He claims fresh air does harm because it arouses and excites the bees. Dr. Miller and others advise letting in fresh, cool air at night, when the cellar becomes so warm that the bees are restless and uneasy. Both Dr. Miller and Mr. Barber are veterans whose opinions are entitled to great respect, and in this matter my experience has been such that in a way I agree with both of them. I believe the

quieter bees are kept, or remain during the time they are in the cellar, the better, and fresh air admitted by means of an open door or window certainly arouses and excites them. In some cases this fresh air causes a great roar of excitement and I believe it does harm.

There is a saying in regard to drugs, to the effect that their use is always a great evil, but that their use is sometimes necessary in order to overcome evil. Now I believe that this fresh air does harm by exciting the bees, but I know much greater harm would result in some cases if it was not admitted. In the case I have been describing I do not believe a dozen colonies would have survived if the windows had remained closed from the time the bees were put in until the weather was warm enough to put them out in the spring. I have always been an advocate of plenty of fresh air for cellar-wintered bees, but I believe it is much better to admit it through a room or ventilator, in some way gradually, so as not to excite the bees. Southern Minnesota.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

HIVE-COVERS AND ANTS.

Another way to have the double cover free from ants would be to have the two edges entirely open. Then, if it was thought worth the fuss and fragments involved, they might be closed for winter with strips of wood—to be pulled off in the spring. Page 132.

THAT ADVICE TO BEGINNERS.

Beginner's advice for those who ought not to begin, eh? That's all right, Mr. Morehouse; yet, like the famous and brief advice to those about to marry, it may not be heeded. When the passion and the fever burn at their highest, a mountain pitched right in the path would be only a pebble under the wheels. Page 133.

SWARMING.

Mrs. Barber's remark that during an epidemic of swarming more than half the young queens disappeared before beginning to lay, is an important corner of an important subject. Workers feel murderously hateful because their desires are continually thwarted—is my guess about it—and if correct, how are we going to help ourselves except by letting them have their own way? A modified guess might be that bees at such times are excitedly meddlesome, and too easily convinced that somebody needs killing.

I think abundant pollen-supply and steady honey-flow—not quite heavy enough for much surplus—to be two of the most important provocatives to swarm-fever. Bad wintering the winter before stands about third, perchance. Hot weather, frequent showers, small hives, and frequent manipulation—especially persecution to kill their drone-brood—are also provocative, I think. Mr. Hawley's remark that during a heavy honey-flow two apiaries under the same management behave differently about this matter of swarming—well, it makes one scratch his head and say: "There it is again." As Mr. Aikin rightly suggests, enthusiasm for honey-storing on the part of the bees is the grand remedy; and this must begin before the fever gets started. Unfortunately, that's what we can't possibly secure when by reason of dearth it is lacking. Page 135.

THE DEMAND FOR EXTRACTED HONEY.

Wonder if A. F. Foster is a prophet where he says the use of extracted honey is going to decline relatively. Doubtless would if certain evils are to continue forever. But let us brace up and say, "The Kingdom of Glory is coming"—and then pitch into the evils as often as we can. My customers are decidedly increasing the proportion of extracted which they take. Page 135.

MATING QUEENS IN CONFINEMENT.

Mr. Flower, you are rough on the editors, to complain of the small space devoted to mating in confinement. How can they devote space to it until competent brethren try the thing some more, and report? It seemed last spring that we should have something new in that line; but the season passed, and it now looks as if nobody actually got at it. Page 137.

LONG-TONGUED BEES AND WOMEN.

And Mr. Flower is a little rough on the long-tongued bee, also. The long-tongued woman *does*, more frequently than the ordinary woman, make a wonderful housekeeper—keeps the dirt out, keeps the flies out, keeps the boys out, keeps the traveling agents out ("Diamond cut diamond;" and "Two of a trade;") keeps the owner of the house out, when he might be wasting time in an easy chair; and keeps superfluous company out, that might be wasting the time and resources. Page 137.

WINTERING A NUCLEUS IN AN OBSERVATION HIVE.

Comrade Chrysostom certainly did a unique thing when he wintered out-of-doors (Northern Indiana) a three-frame nucleus in an observation hive. The three frames, if I understand aright, were one above the other; and the only space the bees had to cluster in were between the one comb and the outside glass. Possibly glass has a value as a winter wall which we have not exploited yet. Page 142.

CAN BEES HEAR?

If we are to take at full face value the account on page 142 and 143, it seems to be the long-looked-for, and always-provokingly-lacking, positive proof that bees can hear. If they can be taught by long feeding—and patient whistling of a particular tune always while feeding—to leave the hive and fly several rods at the sound of the whistle, what more can be asked? But there must be no "gammon"—no intentional or accidental timing of the sound with some other thumping or display or perfume which actually calls the bees. And it must not be always at exactly the same time of day. On the wind side a smell too slight to be noticed by people would probably be sufficient. Possibly the perspiration smell of their keeper standing there would be enough, especially if they had been drilled to that by licking honey off his hands. I, too, think bees hear; but when we get the positive evidence let it really be positive. That they are often non-responsive to sounds fails to prove they lack hearing. They are just as often amazingly non-responsive to the sense of sight; but that does not prove they cannot see.

Questions and Answers.

CONDUCTED BY

DR. O. O. MILLER, Marengo, Ill.

Keeping Combs of Honey for Swarms.

I lost 4 colonies of bees out of 26 this winter. The combs in the 4 hives are as bright as ever and $\frac{3}{4}$ full of nice sealed honey. How can I keep these combs and honey for swarms next season and prevent wax-moths from destroying it then, using a disinfectant which will not cause the bees to leave the hive in which I shall put a swarm on these combs? What should I use, and how? OHIO.

ANSWER.—Use bisulphide of carbon. Set a saucer or other dish *over* the frames, pour into it one or two teaspoonfuls of bisulphide of carbon, then cover up as nearly airtight as you can, having no leaks at top or bottom; pile them up in a pile and treat the whole at once, putting the drug on top of the pile, and using a fourth of a pint for the four. You may as well leave the pile covered up till the next day. Then if you keep the combs where the moths will not get at them, they will be all right till you are ready to put swarms in them. Look out! though. Bisulphide of carbon is highly explosive, and if you bring a light near it there may be trouble.

Transferring Bees from One Size Frame to Another.

I have a colony in an old hive which I desire to transfer to a dovetailed hive, but I do not want the mess of cutting out the comb from the frames and fitting them to the Hoffman frames. Would it be a good plan to put full sheets of foundation in the frames of the new hive and place the old one on top some time in May, with the queen in the lower hive

and an excluder between the two? Would the bees take care of the brood in the upper hive until hatched?

My idea is to have the old frames cleaned out by the bees without losing the brood; then if the combs are in good condition I can fit them in the Hoffman frames. The old frames are about 10x15 inches. NEW YORK.

ANSWER.—Your plan will work all right, except that it will plunge you still deeper into the mess you want to avoid; for the old combs above the excluder will become filled with honey. If you can extract that, you will be all right.

Specialist Bee-Keepers—Rearing Queens, Etc.

1. About what percent of the successful bee-keepers of the United States make bee-keeping their only occupation?

2. "Honor bright," do you think as good queens can be produced from a queen-mother that is confined in a nucleus (to prolong life) as from the same queen when kept in a full or normal colony?

3. Do young bees which hatch too late in fall to get a cleansing flight live until spring? MASSACHUSETTS.

ANSWERS.—1. That's a tough one. I haven't data on which to base an answer, and it would probably be very difficult to obtain such data. In the first place, I don't know what proportion are "successful bee-keepers," and I don't suppose every one would agree upon what should be called a successful beekeeper. Taking bee-keepers as a whole, my guess would be that in most of the States not more than one in 500 makes bee-keeping his only occupation. Take such States as Colorado, and it is possible that the number may rise to 1 in 25 or 50. Yet that guess may be very wild, and I should be very glad if some of the bee-keepers in those regions where specialists are plenty would tell us what percent have no other occupation.

3. "Honor bright," yes. The form of your question suggests that you think differently, and there is a possibility that you may be right. Will you kindly tell us your reasons?

3. I think so.

Bee-Sting Remedy—Dark Color for Hives.

1. Can you give any remedy for the swelling caused by bee-sting, or, rather, an antidote to prevent the swelling? The sting causes little or no annoyance. I hardly notice it, but the swelling is something awful. I have tried ammonia, arnica, soda bicarbonate, iodine tincture, and hot water. I have been subject to stings for the last 5 or 6 years.

2. What are the objections to hives being a dark color, except being hotter in summer? PENN.

ANSWERS.—1. It almost seems that the only thing is to keep away from bees. Possibly an application of honey or cold water might be good.

2. I do not think of any other objection, unless it be a matter of taste. Unless the sun shines on the hive a dark one would hardly be hotter than a light one.

Spring Feeding—Making Nuclei.

1. About how much sugar syrup will I have to feed my three colonies of bees, that have run short of honey this spring, to last them from now until they can gather honey. I am feeding these three colonies one pound of sugar syrup every day. Is it enough?

2. How can I form nuclei? I am after increase. How many nuclei can I get from one 8-frame colony? NEW YORK.

ANSWERS.—1. That depends. If you have plenty of pasturage from the time of fruit-bloom, it may be well to count that they need something like 10 pounds each from the middle of March. If they gather nothing till white clover they may take five pounds more. That's a liberal allowance, but it's on the safe side.

2. Something depends upon the number of frames filled with brood, for you can make a good nucleus from each two frames. You can make a nucleus for each frame of brood, but you will hardly do it a second time, and it is better not to try it the first time. Suppose there are 6 frames well supplied with brood. Of course there will be two other frames of honey and pollen. Take two frames of brood with adher-

ing bees with one of the frames of honey, and put them in an empty hive, taking the queen with them. Two days later take from the old hive two frames of brood and bees and put in a hive on a new stand. Use the other two frames of brood and bees for another hive. That leaves your old hive with only the one frame of honey. Go to the hive that has the queen, and take from it the frame of honey, and put it along with the queen in the old hive. The object of taking the queen away two days in advance is to be able to form your nuclei from queenless bees, which stay where they are put better than bees that do not feel themselves queenless. If you want to make the matter more sure, you can stop the entrances with green leaves for 24 hours after forming your nuclei. Only you need not close the entrances of the two hives that have had the queen in them.

Feeding Bees in Winter.

Last fall I got a colony of bees from a neighbor, which I have kept in the cellar up to this time (March 12). March 10 I happened to go down into the cellar, and took a look at the hive. What I found was a quart of dead bees. I thought the bees must all be dead, and took the hive up in the sunshine, where I scraped some of the bees from the bottom, when quite a swarm of live bees came out. I then opened the cover and removed one frame, and there seemed to be thousands of bees still alive, even if a quart of bees had died. The frame I removed did not contain any large amount of honey—about 2½ inches square of honey was found in the frame, all the other cells being empty. I decided they must be short of stores, and made a mixture of sugar and water (I dissolved the sugar in the water), which I ran into the cells of the frame I had removed. (I should think there was about ½ quart of sugar syrup.)

In the evening I put the hive back into the cellar again. The next day (March 11) I went down (into the cellar) and examined the hive. I heard the low hum of the bees, but I decided I would see how much of my syrup the bees had eaten, and again took the hive out of the cellar, and put it in the sun. Some of the bees came out and flew about for awhile, and returned to the hive. I removed the same frame that I had filled, and found the bees had eaten all the syrup. I again filled it with syrup. Now what is the best thing to do? What can I do to keep those remaining bees alive till it is time to put the hive out? What else could I have done instead of what I did. MINNESOTA.

ANSWER.—What you have done may work all right. The best thing would be to give them enough comb honey to make them pull through. Likely you have none. Then make candy. The Scholz or Good candy described in your bee-book will be best; but if you have no extracted honey with which to make Scholz candy, make plain sugar candy.

Transferring Bees.

How can I best transfer bees from an old-style box into a modern hive. ILLINOIS.

ANSWER.—The instruction given in your text-book on this subject is all right, only nowadays there is a tendency toward the practice of allowing bees first to swarm, then transferring three weeks after the swarming, when the worker-brood has had time to hatch out.

Transferred Bees Fighting—Having Too Much Honey in Spring—Placing Hives, Etc.

1. Will not the bees fight when you return the old bees that are left, to the new swarm, 21 days after swarming when transferring?

2. Can bees have too much honey when put out in the spring?

3. Does it make any difference how far apart the hives are placed?

4. About how many dead bees should there be on the cellar-floor from 23 colonies if they are wintering all right?

5. Is the north slope of a hill a good place for a bee-cellar? Wouldn't sand, put on the floor about 4 inches thick, and then sawdust 2 inches thick on top of the sand, help to keep the cellar dry? IOWA.

ANSWERS.—1. That will nearly always be at a time when the bees have good pasturage and will be peaceably inclined. The drumming will take all the fight out of the bees from

the old hive, and a good smoking will in nearly all cases take the fight out of the others.

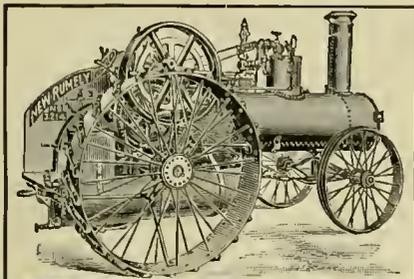

2. It would probably be an impossibility in most places. They can not go into winter quarters with more honey than to have all their combs filled. In the course of the winter they will eat out enough so as to afford the queen a place to begin laying, and the enormous draft made on their stores to keep up brood-rearing would empty out enough more to allow all the room needed up to the time of harvest. If, however, the locality is such that from the time they were taken out there would be enough honey gathered to make good the amount used each day, then the queen would become crowded for room. If you find in your part of Iowa a place where the queen becomes crowded for room to lay in a colony to which you have fed nothing after putting in winter quarters, be sure to report it.

3. Yes, indeed. If you put them too far apart it makes too much travel when working at them. If too near each other you will not have room to work at them, and there will be danger of queens and bees getting into the wrong hives. If you leave room enough so that you can be com-

fortably seated between them, it will be about as well as to put them farther apart; and you can just as well put them in pairs, putting the two hives of a pair as close as you can without touching, then have space enough to put a seat between that pair and the next pair.

4. The number varies. With equally good wintering, the number of dead bees will be much more in a colony that has a large proportion of old bees. There may also be the same number of dead bees with none on the floor in one case and many in others, for in one case they may all be on the floor of the hive and not on the cellar floor. The time they are taken out also makes a great difference. In the past winter, no more bees died for me in the first 75 days than in the last 5. If not more than a quart die for each colony, you may be pretty well satisfied.

5. Other conditions being all right, it would be a good place, but probably no better than any other slope. If the sand and sawdust were very dry when put in, it would make some difference about the dryness of the cellar. But dryness is not so important as temperature and ventilation.

RUMELY

Rear Gear to the Fore.

This Traction Engine should receive the attention of all threshers. Investigate it. Modern in every part. Has all latest devices and appliances. Perfect in traction, unsurpassed in generating and supplying power. A full line of general and special purpose engines. Separators should interest you. The New Rumely is what you want. It threshes it all, cleans it all, saves it all. Catalog sent free.

GENERAL ITEMS

No-Drip Shipping Cases.

After reading Mr. Davenport's minute detail of no-drip shipping-cases, it seems all comb-honey producers should be told a much better and more modern plan of fastening strips in no-drip cases. Mr. Davenport was told of the troubles, and cut off his hammer handle, not thinking that the nails were objectionable in any way but in the probable incident of putting them in. While the fact is that anything less thick than honey could find its way under and through the nail holes very readily. Of course everyone is supposed to have nails, etc., but such is not always the case; and, further, not many men are able to hold a small nail in their great fingers and drive it even with a short-handled hammer. We do many small things, and know how difficult they are to do.

The plan pursued by us was promptly adopted by Mr. O. J. Hetherington (a very ingenious bee-keeper who is a frequent visitor at our home), several years ago, and he has pursued it ever since.

There is no red-tape in getting comb-honey and having money left after selling it. Every reasonable reason should be brought to bear upon its care. Mr. Davenport's plan of forming the paper tray is all right, excepting that it should not project the same distance on all sides. The paper should project about 2 inches more on the ends than on the glass sides, so the board or form may be raised by taking hold of the ends of the paper above the form. This plan enables the form to be placed over the case firmly and accurately. No one will fail to see that there will be an excess of paper at the corners, and that it should be avoided or removed. We remove it by cutting off the corners before beginning to use it on the form. Those who send out the cases can do it. The paper should be cut off at the corners about 3/4 of an inch, at an angle of 45 degrees, leaving the paper longer than the case.

The form may be 1/2 inch thick and must

have a hole in it or a handle to lift it out of the case. The board or form I use has a knot-hole about 3 inches from the end which serves the purpose, the hole or handle should be near one end, or the paper will come up with it from the air-suction. Several one-inch holes through the form would facilitate its quick removal. In rapid work a little paste spread in places on the bottom of the crate would help hold the paper in place. We depend on the wide ends of the paper to hold on to the end of the case firmly; while the form at one end is lifted by the fingers, holding the paper against the case.

Referring to the nails again, you will now see that ordinary flour-paste, rather thick, put on the under side of the strips will hold them in place—no nails, no short-handled hammer, no nail-holes in the tray; in short, a no-drip case used by no one but Bingham and Hetherington that I know of. There is no patent on it, yet it is a vast improvement on any other I am acquainted with.

Clare Co., Mich. T. F. BINGHAM,

Do Bees Hear?

This seems to be a very puzzling question among the entire bee-fraternity, even among the most learned and experienced. It has always been settled in my mind even from a small boy, that bees do hear.

There was a circumstance that occurred when I was a boy 8 or 10 years old that so fixed the belief that it will take strong arguments and even "showing" to change my ideas in that line.

That circumstance was like this: My father and a neighbor went to a sale, and each of them bought a colony of bees. This was something new for the oods concerned about the bees. In those days the highest degree of success was marked by the number of swarms any one had. Of course we watched to see who would get the first swarm, as the time of swarming came on. One Sunday morning the alarm was sounded that the neighbors' bees were swarming, and we all started for the scene, and as we gathered near the place the hiving of the swarm soon began, but they were rather stubborn about being hived, or the neighbor did not understand how to handle them as he should, for all at once they rose up in the air and commenced to start for the woods, when the neighbor began whistling, and they all at once turned and came back just as suddenly as they started away, and settled on the same tree under which the neighbor stood.

Now I want to say here that most of the colony had broken the circle so common to swarming and started in a course some 4 or 5 rods away.

In the summer of 1900 I had a swarm issue and was making up in the air, as if they were lost or bewildered, but in a few minutes they started off in one direction, and I started with them for about a block until I was under them. I then commenced

would have alighted on my head had not I stepped among some small peach-trees near by, upon which they settled.

Then, again, when all the bees are in the hive save 1 or 2, and you in some way pinch one, how soon a number will come rushing to its help, in answer to its loud call for assistance.

I would also ask, Why does a queen pipe if she cannot be heard by the colony?

With these facts staring me in the face, I must have experiments in this line the coming summer.

H. W. HECHLER,
Keokuk Co., Iowa, March 4.

Experience with Bees.

The fall of 1900 found me with 4 colonies, heavy in stores and bees, and for the season 24 sections of honey, several stings, and some experience. Winter problems confronted me. My neighbors were ready to advise me as to the wherewiths, etc. I was told that bees froze stiff and remained in a dormant state until spring, and, when they thawed out, to feed them corn-bread and molasses. Another bee-keeper who had gone out of business, for lack of stock, said to kill a chicken and bake it and put it in the hive for the bees. I wanted to do the right thing for the bees, and, like many other beginners, I was inquiring of every fellow that had ever kept bees, what to do with them, and I found them ever ready to advise.

Let me say right here, before I forget it, that about that time I received a sample

copy of the American Bee Journal, and one of the first things I noticed was an editorial in which Editor York cautioned the beginner in regard to taking advice of men that had failed to make bees pay, but advised them to get a standard text-book and subscribe for some good bee-paper. That timely advice was all that saved me going out of the business. I had subscribed for a paper and concluded that I could do without the text-book; that was a big mistake, but I didn't see it then.

I was greatly pleased with the American Bee Journal, but my 24 pounds of honey would hardly stand two bee-papers. (Some people keep bees for pleasure, some for the dollars, but a combination suits me best; I find much pleasure with my bees, and a little money is a right handy thing to have around the house).

I would advise the beginner to take the American Bee Journal, and then if he gets into trouble, all that is necessary is to make his wants known and Dr. Miller will do the rest.

But, in December I bought 7 more colonies, and moved them on a sid over as rough a road as there is in southern Ohio; they bumped around over the rocks, and I expected to lose them all, 4 colonies did die, but the other 3 colonies pulled through in very good shape. The colonies that died were queenless and had laying workers, at least so I supposed, as I found drone-brood in worker-comb and no queen present. They left at least 40 pounds of honey in the hives which I fed to the bees in the 6 colonies which remained.

As evidence of my ability as an up-to-date apiarist, increase was the paramount issue with me, when spring came. There being no bees within 3 miles, except about 5 colonies, I fed my bees in the open. I contracted the entrances to 2 inches, and found that proof against robbing—only use the preventive before commencing to feed. I also succeeded by following Doolittle's plan of stimulating and spreading brood.

I produced apple-bloom honey, of which I received for my trouble some 20 pounds per colony, it being the first apple-bloom honey produced in sections in this vicinity. So I concluded it paid to read bee-papers even if I am a 2x4 apiculturist.

Ants bothered my bees badly in early spring, and I tried to "lick them" in a hand-to-hand contest but failed. I tried salt, hot water, coal-oil, and even turpentine; still they came. I then smeared the bottoms with pine tar which did the work. My new hives I fixed by driving four 8-penny nails, one in each corner, like legs, and smeared the nails with tar and let the nails rest on blocks which I also gave a good coat of tar. Shallow cans filled with water and the nails resting in the cans would produce the same effect. If you are troubled with ants just try my simple remedy and note the results.

By stimulating, my bees swarmed 3 weeks sooner than any in the country, and by natural swarming I increased to 15 colonies. Some of the after-swarms were very small, so I concluded I would double up some. I hived an after-swarm on Tuesday, and on Friday I ran another after-swarm into the same hive and again another on Sunday, using a little

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get grand bee-book for a very little money or work.

tobacco-smoke each time. Each succeeding day I would find a dead queen near the entrance, but no fighting among the bees. (Davenport is correct again).

Now I went one step further, to build the colonies up very strong. In about a week, after sundown one evening, when the bees were hanging out on the alighting boards, I picked the boards up very carefully and held at the entrance of my experimental hive; I shook a few of the bees down. The bees came out of the hive and went for them, and some of them were foolish enough to pop it at me. After they had settled down I let the cluster on the board down so the bees would just touch the entrance, and they went right in and were not molested; on the same plan that if the bees are hanging out and fanning and you jar the hive they will quit fanning and go in the hive. I put all the bees from 5 alighting-boards in the same way and then gave them a few puffs of smoke, and awaited results. They filled 10 frames with stores for winter, and I got 24 sections of honey from them.

They appear to be wintering all right. Was it locality? "Tut," I suppose some of you wise sages will say, "It's a lie." I say I can do it again, so can you if you knock some of the scales off your stout-edged glasses, and let up on Davenport long enough to try it.

Pike Co., Ohio, Feb. 21. J. M. West.

Loss in Cellar-Wintering.

While in the cellar a short time ago I noticed a bee dragging one of its dead comrades towards the edge of the floor of the hive, and when it got to the edge over went the living bee with the dead one down to the cellar floor. Now I wish to express two opinions right here: First, that was a strong, healthy, vigorous bee, that (barring an accident) would be likely to come through the winter all right and do effective work in the spring. The next is, that bee would never get back into the hive, but perish on the cellar floor. I would like to ask the cellar-wintering fraternity if they have made observations along this line, and if it is shown conclusively that we suffer serious loss in that way, the next move will be to devise a remedy.

Since making the above observations, I have enjoyed a very pleasant call from that prince of bee-keepers, S. T. Pettit, and he agrees with me that we suffer loss as above.

J. M. CRUCKSHANK.

Ontario, Canada, Feb. 24.

Queens Hurt in Mail Still Good for Stock.

The editor of the Bee-keepers' Review says:

Queens are often injured in shipment. Of this there is no doubt. One proof is that a very superior queen often turns out to be a very poor queen after a long journey; while daughters of this queen prove to be most excellent. I have often sent out a queen that I knew to be the best that could be secured only to have customers complain; and then, the next year receive a letter of apology, saying that a daughter of this queen had proved superior to anything in the apiary. A queen should be bought, not so much for the work that she may do herself, but for the blood that she brings into the apiary.

Time to Take Bees Out of Winter Quarters.

R. F. Holtermann, in Gleanings in Bee-Culture, advises to begin about March 15. To this Editor Root replies:

It may be well to bear in mind that localities vary greatly as to the proper time to set bees out. Dr. Miller once gave the good rule that applies equally to all places, to set out when the soft maples come into bloom. This

will usually be about the time when safe warm weather comes on. We shall, however, set our bees out late rather than early. We are liable to have a very warm spell in April, during which the bees will get a large amount of brood started. This will be followed by cold weather during which not only a large part of the brood is lost, but many of the bees, in their efforts to cover and preserve the brood. It therefore seems to me (except in the case of actually diseased colonies) that March 15 is about a month too early for most localities. Last year we did not set our cellar bees out till after the 1st of May, and those colonies proved to be the best we had. Of course, if one can't keep his bees quiet he will have to set them out earlier.

A Handy Tool.

"It is a long iron spoon about 15 or 18 inches long. With it we can work our cappings, also in lighting our smoker. A little charcoal from last using in bottom, the spoon can quickly take live coals from the stove to add to, then fill up with—we use dry apple-tree bark."—Australian Bee-Bulletin.

Foul Brood.

Foul brood is not always apparent at a spring examination. A colony that appears free from the disease early in the season, may turn out badly infected in August and September. Don't be lulled into a sense of security because no infected colony is found when supers are put upon the hive.—Bee-Keepers' Review.

Purity of Italian Bees.

"Nor do I consider any Italian queen as pure." When Bro. Doolittle says that, I think that what he means is true, but that what he says is not true unless he uses the word "pure" with some meaning other than that found in the dictionary. From what he has said in other places, I understand him to believe that no Italians are of an entirely fixed or permanent character, in which he is probably strictly correct. But I do not know that in the term "Italian" there is at all involved the idea of strict permanence of character. If a man should order a queen, saying, "I want a tested queen, for I want to be sure that I have nothing but pure Italian," I think Bro. Doolittle would be able to fill the order, and it would not surprise me if at some time he may have sold a queen that the purchaser supposed was "pure Italian." If there is no such a thing as a pure Italian queen, there is an immense amount of correcting that should be done in our bee-literature. In looking over a half-page in the "A B C" I found just nine such corrections needed. Moreover, if no Italian queen ever sold was pure, an immense number of frauds have been committed by men supposed to be honest.—Stray Straw in Gleanings in Bee-Culture.

Exposing Brood to Robber-Bees.

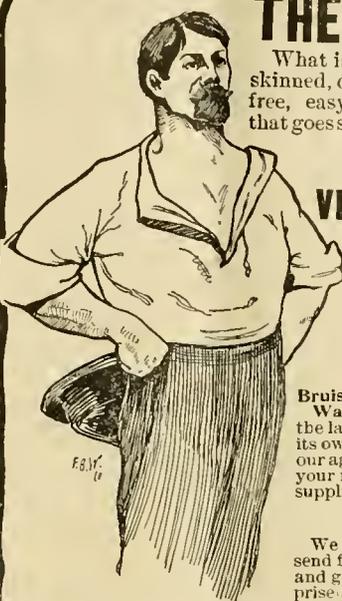

Did you ever notice that bees rob worse when brood is exposed? If you never have, the next time you have the ill luck to have bees waiting to rob, just open a brood-nest and see how quick the robbers pour into it. Bees will rob when brood is exposed when they would pay little attention to honey alone. I suppose that when they smell brood they at once conclude that some colony is in a bad fix, and that it is a good time to make a raid on it.—Lone Star Apiarist.

English Versus American Pluck.

C. H. Tomlinson, in the British Bee Journal, reports that he was driving some bees, and says:

There happened to be staying in the house a bright American girl, and a very inquisitive, excitable and stout old lady (English), both of them desirous of seeing "the fun"! As it was getting late in the day, and the bees were not in the best of tempers, I advised the ladies to don their veils (which the younger did), and then placed them in an advantageous position to view the whole proceedings. Hardly had I commenced operations, how-

THE GLORY OF HEALTH.

What is more pleasing to the eye than an athletic, clear skinned, deep chested man, ready to toil or play, with the free, easy grace of perfect health? The kind of man that goes singing about his work, because he feels that way.

WATKINS' VEGETABLE ANODYNE LINIMENT

will not make a lazy man muscular, but it will keep the body in such perfect condition that the food you eat, the work you do, will all help to build up a big, strong body. It is the cold in the chest, followed by a troublesome cough that breaks down so many strong bodies. A dose of Watkins' Liniment will stop it all before the harm has been done. No running for Doctor, no paying big doctor bills. Use internally or externally for Colds, Coughs, Colic, Diarrhoea, Dysentery, Cholera Morbus, Indigestion, Cuts, Burns, Bruises, for man or beast.

Watkins' Liniment is good for so many diseases because of the large number of valuable ingredients, each of which does its own work and does not interfere with the others. Let our agent leave a bottle at the house. If there is no agent in your neighborhood, write to us, and we will see that you are supplied.

over, when I heard a shout, and the exclamation, "Oh, I shall be stung, I know I shall!" from the dame, who at once commenced to throw her arms about in the usual style. Her hostess endeavored to calm her fears, telling her that beating off the bees in that fashion was the very way to get them to sting her; the next instant there was a perfect yell! A bee had pinned her on the face. Without waiting further risk of damage she whipped her skirts up over her head and ran screaming into the house. I would have given almost anything at that moment for a "Kodak" snap shot, the back view being exceedingly fine.

The American girl stood it without any sign of retreating, indeed, seeming both interested and highly amused.

It would be a very unfair inference to conclude that the American girl had any less fear than the other. Indeed, did she not show the greater fear by putting on the veil?

Selling Honey.

In the Progressive Bee-Keeper, S. E. Miller discusses the manner in which a full supply at commission houses brings down the price, and then says:

The question then arises, What is the remedy? My answer is: Withhold as far as possible our honey from the principal market centers, and the way to do this is to dispose of every pound that we can in the smaller cities, towns, villages, and even in the county. I know it is much less trouble to dispose of the entire crop in bulk and be done with it, but by selling in smaller quantities and supplying the demand nearer home, we can realize enough more per pound over what we would receive if shipped to a commission merchant, to pay us well for the time devoted to selling, and the extra cost of smaller packages. One who has never tried selling honey to his home trade and near-by towns does not know how much honey he is shipping off to help keep down prices in general that might just as well be used near home to make new customers and an increased demand.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 19.—There is continued depression in the trade owing to light output on the part of retailers and the desire on the part of those having stock on hand to dispose of it. The past two weeks have noted a further decline in price of comb honey, with the exception of basswood, which is scarce and wanted at 2 to 3 cents above any of the other white grades; it now brings 14@15c; alfalfa and other fair white, 10@13c; ambers, 8@10c. White extracted dull at 5 1/2@5 3/4c; ambers, 5 1/2@5 3/4c; Southern and dark, 5@5 1/2c. Beeswax scarce at 30c.
R. A. BURNETT & CO.

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, bring from 5 1/2@6 1/2c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c.
THE FRED W. MUTH CO.

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c.
H. R. WRIGHT.

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7 1/2c; Florida honey, in barrels, 6@6 1/2c.
BLAKE, SCOTT & LEE.

BUFFALO, March 23.—Buffalo is very quiet on honey, except very low grades at very low prices. We quote extra fancy, 14c; No. 1, 12@13c; other grades, 8@10c. Extracted, 5@6c. Beeswax scarce; honey, 28@30c; dark, 22@25c.
BATTERSON & CO.

CINCINNATI, March 7.—The general tone of the honey market is lower. Water-white comb honey sells from 14@14 c; it is hard to obtain 15c for extra fancy. Extracted has weakened a little, and sells at 5@5 1/2c; fancy, from 6@6 1/2c.
C. H. W. WEBER.

NEW YORK, March 8.—Comb honey is now pretty well cleaned up, and what remains on the market is nearly all fancy and No. 1 white honey. The demand is fairly good at following quotations: Fancy white, 14c; No. 1, 13c; No. 2, 12c. Extracted remains dull at unchanged prices with plenty of supply. Beeswax firm, 29c. We have just received the first large shipment of comb honey from Cuba; some in tall sections, packed 20 combs to the crate and some in square sections packed 32 combs to the crate, glass front on one side, plain, no-bee-way section. The honey was packed in shipping-carriers, containing 8 of the large and 9 of the small crates respectively, and arrived in first-class condition. The flavor of this honey is very fine, and as to the quality—some of it is fancy white, while others is of a yellowish tint.
HILDRETH & SEBELKEN.

SAN FRANCISCO, March 12.—White comb, 11@12 1/2 cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5 1/2@—; light amber, 4 1/2@5c; amber, 4@—. Beeswax, good to choice, light, 26@28c; dark, 24@25c.

While spot stocks are of rather light volume, holders show more inclination to unload than they did a month ago. Although quotable values are without marked change, concessions are granted to buyers which would not have been thought of at the beginning of the year. A large proportion of the honey now offering is comb of medium grade.

WANTED. EXTRACTED HONEY—either large or small lots; parties having same to offer, send samples, and best prices delivered at Cincinnati, Ohio. We pay cash on delivery. **THE FRED W. MUTH CO., 10A1f Front and Walnut Sts., CINCINNATI, O.**

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MEDICAN FALLS, MAINE, Feb. 29, 1902.
THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.
J. B. MASON,
Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Abbott, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

**FOR GETTING NEW SUBSCRIBERS.**

Red Clover Queens FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the untested queens he sent out were purely mated, this season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order for one queen for sending us the names and addresses of two new subscribers to the American Bee Journal and \$2.00; or for sending us one new subscription and 30 cents more (or \$1.30), we will mail you a queen; or send us \$1.60 and we will credit your own subscription for one year, and mail you a warranted queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

No. 15.

* Editorial. *

The Chicago Association held its semi-annual convention last Thursday afternoon and evening. The attendance was fair, and the meeting a good one. Two changes were made in the constitution. The name was changed from Chicago Bee-Keepers' Association to Chicago-Northwestern Bee-Keepers' Association. Also, it was voted to hold an annual meeting instead of semi-annual hereafter, and such meeting to be in the fall, in Chicago, at the call of the executive committee. This will give a chance to select a time when there are low railroad rates in force. There is to be a two-days' meeting—Wednesday and Thursday.

The above actions will, it is hoped, cause a revival of an association fully equal to what was once the old Northwestern convention, which was so popular and influential some 20 years ago. There is nothing in the way now to prevent making this Association, both in membership and influence, second only to the National. It already has over 60 paid members. Let all who are included in the great Northwest, resolve to be on hand at the meeting next fall.

The Scene in Cuba, shown on the first page, was sent us by John H. Martin (Rambler). At the same time he wrote us as follows:

EDITOR YORK:—I am in a very mild climate beside the climate you are in. It is even more equable than in California. The nights are so mild that a sheet is all that is necessary for a covering. It is not too hot in the daytime, but yet warm enough for light cotton or duck clothing. A naked urehin is not an unusual sight. Last Monday was Cuba's national holiday—their Fourth of July. There was a parade of school children—14,000 in line. It was called purely a Cuban affair, but behind it all were Uncle Sam's methods.

I hand you some snap-shots. You will note the smart appearance, as well as good looks, of the little folks. You will note that the color-line is not closely drawn here—black and white march side by side, and sit side by side in school. Yours truly,
JOHN H. MARTIN.

The picture which we reproduce, shows a Cuban stone-house with tile roof, barred windows, heavy shutters, and no glass. The balcony is of elegant iron-work.

What Causes Swarming? is a question of deep interest, for with an exact knowledge of the cause there might be strong hopes of prevention. It is well known that some-

thing may be done toward the prevention of swarming by giving plenty of room, by shade and ventilation, and by having young queens, but with the knowledge of all these there will still be cases of swarming; and just why it is that bees swarm has generally been considered as one of the things dwelling very nearly within the realm of mystery. S. D. Chapman expresses some decided views upon the subject in the Bee-Keepers' Review, and in view of the importance of the subject his views may be worth considering, even if not proven correct. He thinks the swarming-fever does not come from queen or drones, but from the workers, and "almost invariably has its origin with those bees that are under 15 days old."

He says: "It is almost impossible to create the desire to swarm in a colony where all the bees are field-bees. . . . On the other hand, take a colony of bees that are all under 12 days old, and see how easy it is for them to get the swarming-fever." Without at all attempting to dispute his theory, one can not help wondering whether Mr. Chapman speaks from actual experience in this matter, seeing that the cessation of the honey-yield is counted upon to stop further preparations for swarming, and with bees under 12 days old there would be no bees of the ordinary age for storing.

Even if Mr. Chapman should be mistaken upon this one point, it does not disprove his fuller theory as to swarming, which is, that at the time when bees swarm there is a lack of balance, and there is a surplus of young bees in proportion to the number of field-bees. He says:

"There are not field-bees enough to furnish work for these young bees. If you give to such colonies one pound of field-bees, before they get the swarming-fever, to balance up such colonies, you will have no premature swarms. When the field-force is in proportion to the young bees, the probabilities of swarming are past."

Sounds Like a Romance.—"A Reader" sends a clipping which quotes from a Nebraska newspaper, and asks, "Is this report true?" The first part of it is so rich in romance that it is hard to believe it could have been meant as truth, but the truthfulness of most that follows makes it pretty clear that no burlesque was meant. Dr. J. L. Gandy was interviewed, and the following paragraph of the interview makes interesting reading:

"I am a great admirer of the busy little bee, and have several thousand colonies in different places, and keep some 125 at my home, and give them my personal attention and care. You will doubtless be surprised at my yield this year, which was 407 pounds to the colony from the 75 colonies, spring count. I also hived 50 swarms which will pay the entire expense of the season, leaving me a net

profit of \$61 to the colony, which represents an investment of only \$5.00. I produce pound sections, extracted or strained, and chunk honey, and all of it is put on the market at 15 cents per pound. Most of it is sold right here, although I occasionally ship some to other towns. I sold 200 colonies for \$1,000, and during the latter part of May had a chance to sell 500 colonies for \$2,500 to a Colorado party, but before the deal was consummated the heavy June flow came on and I refused to sell. I have each year purchased a farm from the sales of honey and bees, and this year I branched out a little and bought some \$40,000 worth of real estate, and paid one-third of the purchase price from this year's profits on the bee-industry. Why should I not be enthusiastic in praise of bees? I sat in the shade during the forepart of June while my bees were making me \$140 per day. I am in the business solely for profit, and money obtained from the industry is much the same as so much found.

In the course of what follows the Doctor says 100 colonies, "with ordinary care, will yield over and above expenses \$1,500 annually." Pity he did not say how many times that could be obtained with extra care.

Stimulative Feeding of Bees.—The opinion has been expressed in these columns in a somewhat emphatic way that beginners should have nothing to do with stimulative feeding, and no exception was made for any cases or localities. Fuller thought upon the matter forces the conclusion that there may be conditions in which it will be wiser to risk the dangers incident to stimulative feeding than to omit all effort in that direction. Given a locality in which there comes good weather for bees to fly, and yet not enough for bees to do to start them at brood-rearing until the harvest comes, and it is better to do something to have the hives filled with bees, even if some mistakes are made in the doing. This fuller thought and "change of heart," it may as well be confessed, comes from the presentation of the case by the Rocky Mountain Bee Journal. Under the caption, "A Beginner's Lesson in Spring Feeding," the whole matter is so well presented in that journal that it is a pleasure to give it entire. It will be found on page 231.

A Large Edition of this number of the American Bee Journal will be mailed, some of the copies going to bee-keepers who are not now subscribers. We trust they will be so well pleased with it that they will want it regularly hereafter. Only \$1.00 will pay for it for a whole year—52 weeks—52 copies! It ought to be a good investment to any one who wants to make anything out of his bees.

Yellow-Box Honey, according to replies in the Australian Bee-Bulletin, is the only kind in Australia that does not readily granulate.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 214.)

SWEET CLOVER AS A FORAGE CROP.

Dr. Miller—I doubt the advisability of our spending much more time in discussing this matter, but a closely related item I think we might discuss with profit. I think we are pretty well settled, whatever may be the character of sweet clover honey, that wherever it is introduced, wherever it is known, there is no one wishes it away, and all of us would like to have a little more sweet clover grown where we are. But there seems to be somewhat of a difficulty in having its qualities as a forage crop known, and if we can do something to further that, we will do more good than talking about the honey that comes from it. I would like to learn something as to what it is worth as a forage plant. If some one here has tried it and knows whether cattle, horses or anything of that kind will eat it, they may be a help to us. There is a great deal of contradictory testimony about it. One man says that when alfalfa and sweet clover are in the field—one at one side and the other on the other side—when cattle are turned into it they invariably go to the sweet clover side. Other say that sweet clover will not be eaten by stock at all, and I think they are right. I think both sides are right; the thing is that stock of any kind must learn to eat it. They must acquire a taste for it. I have been trying for years to get a crop of sweet clover hay and have failed. When I have gotten it into my barn, and I have considerable of it, I find that in the barn it will be eaten greedily by the horses and such stock as have learned to eat it. The grown plant is not eaten. This year I had sweet clover growing and I was afraid there wouldn't be enough left for seed, it was eaten up so close, and just the stump left. When stock learns to eat it in my locality—everything goes by localities—they eat it readily. Is there any one here who has ever succeeded in having a wagon-load—one-half ton of sweet clover hay—that he has taken into his barn?

Pres. York—I think we can sum up the honey question by saying when asked which is the best honey, "The best honey is my honey." Now go on to the question of sweet clover as a forage plant. Who has had experience with growing it for that purpose?

Dr. Miller—Will you ask how many have ever sown sweet clover seed?

Eleven indicated they had.

Mr. Dadant—We tried sowing sweet clover. We have never harvested a wagon-load of it because we always thought it made too coarse feed. Sweet clover grows from the seed, blossoms, and dies. During the first year it grows about a foot high, the second year the stem becomes so large and hard that I doubt if the cattle would eat it even if harvested. We have harvested some with other hay and always had the stalks left even though the stock would eat the tops. In sowing sweet clover, at least in our locality, as the Doctor says, if we sow sweet clover and let it come up and grow, I don't care how rank and thick, and turn the cattle on it, in three years it is entirely destroyed and there is nothing left, which shows that they will eat it. It grows the first year from seed, and if stock is turned upon it they will eat every bit of it, and leave no chance for the second year; and during the second year, if you turn stock upon it before it blossoms, they will turn in and damage it to such an extent that it will grow very little. One party, a friend in Canada, we advised to try sweet clover for his bees. He came at the time of the World's Fair and told us he was making a success of sweet clover in this way. There grass grows very late. The thaw takes place the last of April or beginning of May and there is no grass. The sweet clover that has taken root the season before, in the course of two weeks grows a foot high; they then mow it, and have an increased quantity of milk. Now after a while they feed it to their stock, but they have never let it ripen and get into hay.

Dr. Miller—How fully have you tried making it into hay?

Mr. Dadant—We haven't tried at all. We grew about an acre of sweet clover for the bees, and when we found it was a very rich piece of ground—the sweet clover grew 6½ feet high—we let the bees work on it. You all know how tough it becomes if you cut it for hay, and the bees would not have any chance. When we turned the cattle into that pasture it took two or three years before it was all destroyed. There was some blue grass that took root in the same pasture, and there isn't a bit of it in that place, nothing but clover. Since that there isn't a stem of it. Of course, it will grow in corners around Chicago because there are no cattle running at large, but I do believe if there were they would destroy it. You see it along railroad tracks and waste places where cattle can't run upon it. Put in pastures you wouldn't find it would last very long, because if there very long the cattle would eat it, I think, more readily than blue-grass.

Mr. Duttall—I live here in Chicago and I keep my cows on the road, and they never touch sweet clover.

Mr. Dadant—Not even the first year's growth?

Mr. Duttall—No.

Mr. Dadant—I would like to ask Dr. Miller if the yellow sweet clover wouldn't made a better forage plant than the white?

Dr. Miller—I don't know.

Mr. Green—There is a little herd of cows herded where I live; I have had a good many sad moments watching them eat the sweet clover down to the ground; the second year's growth, too.

Dr. Miller—That proves the point that they must learn to eat it. Keep those same cattle upon it long enough and they will learn to eat it. Do you know that Texas cattle will not eat corn? They must learn to eat it. So cattle must learn to eat alfalfa; they wouldn't eat it at first sight. Now as to the matter of hay. Mr. Dadant says that they haven't used it for hay because it is too coarse. The cattle will not eat the stems of red clover, but you may cut sweet clover when it has no more stem than red clover.

Dr. Dadant—What of the bees, then?

Dr. Miller—Take the first year, and cut it, the bees will not get it, and you may take as your Canadian friend did—the first year's growth they cut.

Mr. Dadant—No, the second.

Dr. Miller—Cut that, and cut it several times. Doesn't it make up afterwards?

Mr. Dadant—They use it as green feed.

Dr. Miller—They use it as green feed for some time and it is so early in the season they cannot very well ripen it, and so could you in Hamilton County; you could cut, and ripen, and make hay of it.

Mr. Dadant—What of the blossom then?

Dr. Miller—It would blossom just a little latter, and if in the white clover season it will be worth as much again by cutting, instead of losing. To my certain knowledge you can get a good crop of hay from it the first year. I have had it grow three feet the first year.

Mr. Josephson—I watched a patch of sweet clover closely the past summer, and I saw in the early spring when the cattle had plenty of grass to feed on they wouldn't touch it. The dry season came and they ate the sweet clover just as well as other grass.

A Member—That is my experience.

Mr. Chapman—I got half a ton of hay into the barn. I have not had the experience myself, but within a few miles of the courthouse I can relate the actual experience of the Normal Park Improvement Association. They employed a team, bought a mowing machine, and cut down all the sweet clover that grew in the vacant lots around our premises, and the man who did the cutting got permission to store that hay for his team. Altogether, he must have harvested about five tons, mixed sweet clover hay. It contained other weeds and some tall grass which naturally grows on our vacant property. He is now cleaning the sidewalks of snow with a snow-plow with the same team. I asked him how they eat the hay, and he says fine. That was sweet clover that was headed to blossom the first of July. It was cut from July 1st to 10th; it lay there in the lots and he employed some small boys to hand-rake the hay, and he also raked it with the hay-rake, and he gathered it up after three or four weeks: some even rained on, but his team is eating all of it. They expected of course to destroy the sweet clover. I was one who helped. They cut it off as low as they could, but in a vacant lot they had to hold the mower bar up pretty high. The result was that the sweet clover branched out close to the ground, long limbs some places four or five feet long, and then stood up and blossomed well, and that made the late crop of honey for my bees, and I was very glad to get it. There wasn't as much

bloom on the succeeding plant, but sufficient to make fine forage for my bees. It blossomed luxuriantly after that. In November it was fine.

Mr. Baldrige—In Mississippi I have seen as high as 75 acres on one farm where they grew it for a hay crop. They cut it before it blossomed, when it was about three feet high. They then depend upon its coming up to produce seed, and secure all that grows, from 200 to 500 bushels of seed, and from the second crop they get their honey.

Dr. Miller—I would like to answer Mr. Dadant as to the character of the long but coarse stems. I had a good deal cut after it was in blossom, and, as he supposes, there are, of course, stems that are worthless, but, after all, there will be enough to make it tolerably valuable as a hay crop; but it will be very much more valuable as a hay crop if it is cut before it blossoms at all; and then the loss is nothing, because it will blossom so much later, and then it is eaten, and if I would have my way about it—and there is a good deal growing along the roads where I live—I would have the road commissioners cut it off close down before it first comes into blossom. It would be worth more to me than if they let it all grow.

Mr. Sylvester—That's the experience we have. They cut it down all through the season, and the result is blossoming later; it comes on after the others stop.

Mr. Childs—We have the same experience in our town. The citizens got up in arms about the sweet clover. It grew so high they couldn't get through the street. Father said he wished they would cut down more as it helped his honey crop nicely. I believe it would be a good thing if they would agitate that and have it cut down early in the spring.

Dr. Miller—In that same connection comes something that I don't know perhaps is so generally known. Two places within two or three miles where cattle are upon it upon the road almost constantly, and it is eaten down throughout the whole season, I don't think it grows in any case more than six inches high, and there is really a carpet of white that is beautiful on the side of the road, and in any village or town it would be an ornament instead of a detriment or disagreeable. If cut early enough in the season, and constantly cut, one pasture done in that way will be a thing of beauty instead of being something distasteful.

Mr. Hodge—I observed in watching where the cattle ran on it and ate it down in June, when it began to blossom in May and June it is higher on the sides where cattle are not tied, and no great amount of cattle kept it eaten down, and it blossomed constantly until frost. But I notice another thing, that while some say cattle won't eat it, there is good grass growing around there (I was interested in the yellow clover and was watching the process)—they seem to leave the grass and eat the clover, but it didn't stop the blooming. As Dr. Miller remarked, they kept it close down but it constantly bloomed. When the yellow clover that had not been eaten at all in the month of June closed its blossoming, the seed would mature and the stalk die; but that eaten by the cattle was brought into such a condition that it constantly shot out lower limbs and kept blooming until frost.

Mr. Green—Referring to the question of having it cut by the city officials—they sometimes will be a little slow. The ward superintendent of my ward was; he cut it down about September 20, and there wasn't another blossom.

Mr. Fairbank—My experience with sweet clover in Iowa—and sweet clover is our principal flow—the sweet clover as a forage plant, take it when the white clover and fall flow help the bees out—that in the roadsides we have no trouble about cattle and sheep keeping it down in the pasture, but where they can't get at it it grows very rank. A good many of the road-bosses are prejudiced against it. Where it is kept down, and eaten down, it blossoms till the frost kills it.

(Concluded next week.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.

Reading Bee-Keepers' Text-Books and Papers.

BY C. P. DADANT.

I HAVE always been a poor hand at paying compliments to any one, but I must compliment the Editor on his advice to beginners on page 83, where he recommends getting a text-book and let the bee-paper go—if the reader cannot afford both. This unselfish advice is certainly sound. Too many people go into a business without learning how to manage it, and thereby make a failure. A Chicago party some two years ago bought a large farm in our vicinity and settled upon it, with the intention, as he said to me, to "play at farming" a while. This playing has proven an expensive venture. Two bad seasons in succession, joined to absolute lack of knowledge of the management of a large farm, have so thoroughly disgusted him with the "play" that he is seeking a purchaser at a much less price than the original cost, and will probably have to make a sacrifice.

It would be about the same with a man who would start in bee-culture without some knowledge of the habits of the bee. He must know how to distinguish workers from the queens and from the drones, how to rear queens, how to ascertain how much feed the colony must have to winter or to reach the crop if winter is over. If feeding is necessary, he must know how to do it properly, how to prevent robbing, and stop it if it begins. He must be informed that the appearance of the first blossoms is not indicative of a constant supply of honey for his bees.

In this connection, I will cite the instance of a man who had purchased half a dozen colonies of bees in spring, and had brought them home during fruit-bloom. He had seen our success with bees and had concluded that all he had to do was to buy a few "for a start," and that they would go on increasing without his having to attend to them, in any other way than taking away their surplus honey. As a matter of course he expected to ask us for a little advice once in a while.

He brought his bees home, as I said, while the apple-trees were in bloom, and came to me to tell me how strong the colonies were, and wanted to know whether he would not best put on the supers. I went over to his yard and we examined the colonies together. The weather was rainy and rather chilly, and they were getting nothing out of the fruit-bloom, and were rather short of stores. So I told him that he would best keep the supers off for a while yet, as the bees would probably need feeding before clover bloomed. This thoroughly disgusted him with my advice. "What! Feed them when there are blossoms all around?" It probably looked very suspicious to him, for he asked no more questions and did not feed, the result being that he lost a portion of them and the remainder reached the clover crop in poor condition. But there is no end of things needed to be known, in bee-culture, that cannot be learned unless it be through a protracted experience, or through a book.

But the book is not alone needed; and here, Mr. Editor, I think you might have said something a little more pointed, as to the necessity and usefulness of a good bee-paper. The text-books give the digested knowledge acquired by the leading bee-keepers and scientists of the world; they give it in a form that is at once exhaustive and elementary, because they not only explain details, but give reasons for all advice. But a text-book cannot follow progress, except through repeated revisions, and these revisions are only made from time to time, while the weekly or monthly publication keeps us posted on the present improvements. These improvements are of all kinds, both in the domain of scientific discoveries and mechanical appliances. Without the magazine, that reports these improvements, we are bound to get belated in the race for progress, and it is not only local improvement that we want but a general information of what is going on the world over. Those who do not read find themselves distanced within a few years.

I never was so much struck with the idea of steady progress as when Father Langstroth visited us after having retired from the bee-business for some 15 years. It seemed to me as if we had been following his teachings almost to the letter, and that we could hardly show him anything in the bee-line that he had not already seen; yet, after witness-

ing our extracting crew at work for a few hours, he said: "It is of no use for one to think that he can, after 15 years of absence, find an industry just as he left it, for he is sure to be *away behind*."

And so, if we read a text-book, we will get knowledge acquired at the date when the text-book was printed; but if we do not take a bee-paper, we are sure, after a few years, to find ourselves "away behind."

Yet practical bee-keepers are very careful not to accept new theories, or new implements, or new methods, until they have been thoroughly tested, and it is well to warn the beginner against taking hold of any new thing which he has not seen recommended in the text-books, unless it has been previously tested on a sufficient scale to make it reasonably sure of success. Many and many an implement or a new method has been lauded to the skies, to be found afterwards only an imposition, usually introduced in good faith by some self-deluded individual.

No. 4.—Bee-Keeping for Women.

Helpful Advice on How They Should Dress for Bee-Work.

BY EMMA M. WILSON.

THERE is no disputing the fact that in bee-keeping men have a decided advantage over women in the matter of dress. It is so much easier for them to dress cool and comfortable, and also easier to protect themselves from stings, than it is for women. I have felt tempted to envy Dr. Miller more than once, on a sweltering hot day, as he walked around attired in a pair of painter's white overalls, said overalls tucked in his socks to protect himself from stings. He looked so cool and comfortable—perhaps he did not feel as comfortable as he looked, but he looked tantalizingly cool, at any rate.

But women can do much to make their dress comfortable, by a little thought.

Do not wear heavy skirts that take about all your strength to carry around. I have found a light-weight worsted skirt the most satisfactory. Duck skirts are comfortable, but the fact that they soil so easily is a serious objection to wearing them, as they are not very easily laundered. But a worsted skirt and a shirt-waist make a very satisfactory rig.

A large denim apron covering you completely from head to toe is indispensable. Be sure to make it long enough to reach to the very bottom of your dress, so that if a little honey drips on your apron it will not lodge on the bottom of your dress-skirt on its downward course.

Denim is the best material I know of for aprons. I formerly used ticking, but I like denim better, as you can get it in plain colors. The last ones I made were of plain brown denim, and were very satisfactory. Either denim or ticking is good, as far as the wear is concerned, as neither will allow the honey to soak through readily. And when you slip out of your apron, after your day's work is done, you present quite a creditable appearance, which is something dear to the heart of a woman, especially if you are at work in an out-apiary and have a long ride home before you.

My aprons are cut by one of the Butterick patterns, No. 3696, and certainly they are ideal aprons for the apiary. I have worn them for years, and have thoroughly tested them, and I really would feel lost without my big aprons, with their generous pockets. Those pockets are such a comfort (I wish our dressmakers would manage to give some such pockets in our dresses; but no. Dame Fashion has doomed us poor mortals to go pocketless). What do I use those pockets for? Well, I am not going to tell you all I put into them, but one thing I do use them for is to carry my hive-tool. I think it would be lost a good share of the time were it not for those pockets.

One very important item in your outfit is your gloves. I wear a pair of light-weight buckskin at present. I have tried a good many different kinds. For quite a while I wore a white glove, which is quite common. I do not know whether it is sheepskin or hogskin, but I do know that it had a very disagreeable odor. If it was not for that it would be a good glove; as it is, I much prefer the light-weight buckskin.

I sew a pair of white sleeves around the top of the gloves, having the sleeves long enough to come well up on my shoulders. I have a strap sewed from one sleeve to the other across my back. A similiar strap across my chest is

MISS WILSON DRESSED FOR BEE-WORK.

sewed to one sleeve, and buttoned to the other. This is a very convenient arrangement, as it takes very little time to slip my gloves off or on, is perfectly bee-proof, and at the same time keeps the sleeves of my dress clean.

The reason for having the sleeves white is that the bees will rarely sting anything white. I have about half-a-dozen pairs of sleeves, and as fast as one pair becomes soiled I rip them off and sew on a clean pair. The gloves can be washed clean any time. It is a little more convenient to have two pairs, then you are always sure of having one pair ready for service.

A comfortable pair of shoes is an item not to be overlooked. Never get a pair of shoes with high heels; and if you can get a pair with rubber heels you will find them extremely comfortable. If you cannot get the shoes with rubber heels, you can have the rubber heels put on by your shoemaker for 50 cents a pair. If you have never tried them just try a pair and see how you like them.

I am very fond of wearing low shoes and slippers, and many an unnecessary sting I get to pay me for it.

Now we must not forget the bee-hat. I like a broad-brimmed straw-hat with a veil made of net sewed around the brim, and a rubber cord run in the hem around the bottom of the veil; a safety pin caught through the hem passing over the rubber cord in front, ready to pin down securely to my apron, pulling it down tight enough so the rubber cord will be drawn taut, then I feel sure no bee will be able to get under my veil.

One advantage a woman has over a man is that she can use a hat-pin to pin her hat on, and that is a comfort. You are sure your hat is not going to tumble over your eyes at a critical moment when both hands are full. Let us score one for the women on that point.

One trouble I have is to get a hat with a crown small enough so the hat will not rest on my ears. I don't see why some accomodating soul doesn't make a few hats especially for women.

Selling Comb Honey by Weight vs. Case.

BY R. A. BURNETT & CO.

WE have read two articles in the March 13th issue—one by J. A. Green, and the other by R. C. Aikin. They are both excellently written, and the personality of each writer is strongly in evidence. Recently we had the pleasure of meeting Mr. Green (who, by the way, is an old acquaintance), and we have the usual regret that comes to all of us when we lose a neighbor; yet the matter of a thousand miles separation is not as much of a hindrance to intercourse as it was a quarter of a century ago. So rapidly are we progressing in the evolution of the power latent in man that we can even dare look forward to the time when *competition*—which until very recently has been considered the necessary thing to the development of man's power—that it, too, will have served its purpose and no longer be a necessary evil.

and in its place will be co-operation. What a grand transition this would be!

We wondered if all the readers noticed what care Mr. Green has taken to know exactly what he is doing before he sells his honey *by the section*? He will not trust even his own practical eye to detect the difference of weight in the sections, but he puts the case on scales, which are properly balanced and weighted, and then proceeds to put the sections in the cases situated on the other end of the beam until such a time as he has adjusted the sections to get a given quantity of pounds in the case; then he proceeds to sell it by the section! Prudent Mr. Green—he knows exactly what he is doing, and if his customer should question his statement he is ready to verify by placing the contents upon scales, knowing that it will bear him true evidence of good faith and intelligence on his part.

What do you make of this paragraph where he says:

"There are great and undeniable advantages in buying and selling by the case, or by the section, which amounts to the same thing. Grocers almost invariably sell honey by the section if its condition will at all admit of it; and after they have once experienced the advantages of the plan, they generally prefer to buy as well as sell by the piece."

Then he immediately qualifies the proceeding by the following short paragraph:

"To enable them to do this advantageously, there must be a certain uniformity, not only between sections in each case, but between the different cases."

Is this not tantamount to weighing the honey for the grocer. And what overworked tradesman does not want to get as much done for him as it is possible to obtain? In other words, the groceryman trusts Mr. Green, whom he knows to be an intelligent and trustworthy person; therefore, this becomes practically a local matter. Mr. Green sells that which he himself manipulated to a man who has, by prior experience, learned to trust Mr. Green, and he is as safe in doing so as any mortal can be in trafficking one with another.

Notice how fully Mr. Green proves this statement in another paragraph, where he says:

"This year I put up 50 cases for this trade; 40 of them weighed exactly 22 pounds net each, and the remainder 20 pounds net. For another purpose I put up a number of 12-section cases, each of which weighed exactly 9 pounds net."

Then he particularly calls our attention by saying: "Notice, I say, these were exact weights, as exact as your grocer weighs when he weighs out sugar or coffee, and that each section was uniform in appearance, with no extra-light or heavy section in the case," and which he proves by weighing them as they come from the storage-crates.

Now please tell us, did Mr. Green sell his honey by weight, or did he sell it by the section with out knowing what the section weighed? Seems to us this question is not a hard one to answer.

We think it would be only fair to say that at the present time we have on sale a car-load of comb honey from Colorado, that the owners desired to sell by the case, but they would not guarantee that the cases would average any given weight, for they said some were heavier and some lighter; but they wanted to sell it for so much, and the buyer take his chances. They were unable to do so, and now it is being sold by weight.

We find that some producers have been painstaking and their honey runs quite uniform; again, there are others who have put in sections that weigh seven ounces, and some that weigh fifteen, with others ranging between these two extremes.

This is the very thing that is to be feared by adopting the plan of buying and selling honey by the case. The careless and unscrupulous seller will take advantage of the honest and careful ones' reputation, and say, "If Mr. Jones can get \$3.00 for his case, I don't see why I shouldn't get \$3.00 for that is the market price." While competition is the plan upon which society is organized, we must needs have weights and measures to keep the ignorant constantly informed of his duty to his fellows. When the world is run on the much higher plan—that of love, which Mr. Aikin has brought into his article under the term of "co-operation"—then there will not be the necessity for misrepresentation to get a living; for the just will have taken the place of the false, and our evolution to greater and even higher possibilities than the human race has hitherto dreamed of will be dawning. That this panacea for all trouble may be reached it is first necessary to eliminate selfishness. We know that this idea, with perhaps the majority of people, is yet Utopian—in that this world can be run on, "Do for your neighbor rather than for yourself." Cook Co., Ill.

A Beginner's Lesson in Spring Feeding.

WHILE admitting that stimulative feeding is a two-edged sword (as some have called it), liable to cut the wrong way, if carelessly handled, it is exceedingly poor advice to advise beginners to "let it severely alone," as did the American Bee Journal in a recent issue. In localities where the main flow is preceded by a dearth, or a very light, intermittent flow, some sort of stimulative manipulation is absolutely essential in order to have our colonies populous enough to begin storing in supers at or near the beginning of the main flow. Loss of time in having colonies ready for the first alfalfa flow means loss of money, hence one of the most important lessons for beginners to learn is the art of stimulating brood-production at just the proper time to have an immense force of young bees ready to enter the supers with the first opening of the alfalfa blossoms.

To accomplish this requires great tact and some foresight, but the beginner can only acquire this by experience, so my advice to him is to learn from others all that he can upon this subject, and then go at it for himself, with both eyes and ears open. Mistakes will doubtless be made at first, but that is better than never to learn at all.

In Colorado, or any other locality where natural sources of pollen and honey are not sufficient to cause the production of bees enough to take care of the early flow, feeding will undoubtedly pay, and pay big. As soon as the bees begin flying in the spring begin feeding rye or wheat flour or graham. I prefer graham, as they do not get it all over them so badly. This takes the place of pollen, and should be continued until the pollen supply from natural sources is sufficient to satisfy them. The best way to feed graham is to distribute it through the apiary in shallow boxes.

Some warm day in April go through all your colonies and equalize their stores. This is done by taking combs of honey from those that have a plenty and giving it to those that only have a little.

In this climate stimulative operations should not begin before the first of May. It is then 40 or 45 days before alfalfa begins to yield, and that is about the length of time necessary to rear a force of new bees and have them ready when the flow begins. If there is some honey in all the hives, begin operations by uncapping three or four pounds per week. This will cause the bees to move it. In moving it they feed the queen with greater liberality, which stimulates her to laying eggs more rapidly. When the bulk of this left-over honey has been consumed begin to feed. Feed about a quarter of a pound of honey or sugar syrup per colony daily, made almost as thin as water—in fact, have it just sweet enough to induce the bees to work on it.

As a beginner, you will, of course, only have a few colonies, and your best way to feed will be in some kind of shallow receptacle placed on top of the brood-frames in an empty super. Before pouring in the feed throw in a handful of alfalfa hay to prevent the bees from drowning. Continue the feeding until the honey-flow starts, or until the hive is well filled with brood and bees, and when you stop, if honey is not coming in freely enough to supply their daily needs, be sure there is sufficient food in the hives to carry them along until the yield begins. A little stinting or starving at the latter end will result in the undoing of all the good that has been done, and greatly injure the colony.

Put it down as an axiom, that there is no danger in spring feeding provided it is done in the right way and at the right time. To determine the way and the time adapted to the individual needs of the individual colony, the beginner must keep his think-shop in order and use his brains. If you feed too early in the season you will rear a lot of useless bees that will be consumers instead of producers, and, besides, if you begin in cold weather, a cold snap may come on and kill half of your brood and leave the colonies so weak in energy and vitality that spring dwindling will finish them. Learn how, go slow, use your best judgment, and you will come out all right.—X, in the Rocky Mountain Bee Journal. Boulder Co., Colo.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

PICTURES OF APIARIES AND DESCRIPTIONS.

Yes, when you give us that picture of your apiary for publication, "fall to" and tell us the whole thing. Mr. F. W. Hall, pages 161 and 162, sets a most excellent and long-needed example. And the magazines of the outside world need the same sort of teaching worse yet. Who has not felt, on looking through them, sorely tried, and almost insulted? Such numerous, costly, interesting, resplendently beautiful pictures, and not descriptions enough to amount to a hill of beans! It's amazing that publishers, after so much expense and pains, can be willing to throw three-quarters of the value of the illustrations away by leaving the reader with no means of knowing about them. Well, we know that that stack of honey had speaking relations with a remarkable queen. We "allow" that 250 sections and a super of extracted honey and a swarm all in one season is going it gay. Have their tongues surveyed, Mr. Hall. A unique swarm-catcher is a one-legged milking-stool daubed in slum-gum. And four-fifths of the swarms used the stools *when the inventor made a hobby of them*, and only four-twenty-fifths when he got indifferent. And more of us have wondered if sweet-corn tassels didn't yield some honey at times.

KILLING YOUNG QUEENS IN THE FALL.

Mr. T. F. Bingham, you succeeded well in giving us that sense of novelty—killing your young queens if they lay too late in the fall. Why didn't you kill the bees? They are the ones to blame in the case if the colony breeds late. All queens lay till the bees stop them of it (by neglecting to feed them, and by neglecting to hatch the eggs), d'ye hear? And will you kill all the queens now and get along with laying workers? But your idea that a colony breeding in the cellar endangers the colony next to it—it will hardly pay us to throw that idea overboard with a laugh. Guess that's so. Bees sometimes are as bad as their keeper to catch on to a novel but dominant idea—and better posted than Mrs. Grundy about what goes on behind their neighbors' walls. It doesn't very clearly appear what we can do about it, however—but that may be found out later. Page 164.

WINTERING BEES OUTDOORS.

Mr. Dodo, of the Michigans, furnishes a suggestive and somewhat puzzling fact. Three rows of hives were snugged up next to a high fence and packed there. Outside row wintered pretty well, while of the row next the fence one-half died. Premising that deep snow banked up beyond the fence and covered the hives, also it might be guessed that the whole establishment got too warm, and that the outside row naturally suffered much less from that cause—not enough to do much harm. But if the bees had a general flight after they were moved, and before they were shut in, why, then, as Mr. Coveyou suggested, they would largely re-enter in the outside row, and leave the inside row to perish from weakness and lack of young bees. Page 165.

TALL SECTIONS AND TWO COLORS OF HONEY.

Is Mrs. Morrow right, that tall sections are more apt to get two colors of honey in them? Not to any great extent, I think. In a good flow all kinds of sections will be uniform in color; while in a very bad, halting flow all are more or less in danger of being piebald. Page 165.

GLOSSOMETER AND MICROSCOPE—LONG TONGUES.

One phrase I found in Prof. Cook's excellent paper, page 166, which I hardly like. "I found, *as of course I must*, that the glossometer and the microscope told the same story." No "must" about it, quoth the know-it-all fellow. He would call it a triumph instead of a mere rolling off the log. Happy is the man who can reach the same result by two lines of investigation—or make either one of them tally with big, clumsy facts. It is of interest, as well as a little puzzling, that races vary more in tongue-length than do individual colonies inside the race. And the shortest-tongued race (so reported) can beat the longest-tongued race

at putting up section honey—leastwise, the latter has been universally abandoned in America. This is a pretty strong hint that tongues are not all.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Moving Bees in Winter.

I intend to move my bees from Taylor County to Kansas City. I have them still in winter-cases over the supers packed with leaves. Would you to take the winter-cases off? If so, would you take off the supers? I have text-books on the subject but none of them say anything about moving bees in the winter. IOWA.

ANSWER.—It will be better not to take away the winter packing till the warm weather comes. Whether you can handle them in moving without taking away the packing is the question. If convenient to do so, leave the packing. If inconvenient, it must be a question between the inconvenience to you if the packing is left on, and the inconvenience to the bees if it is taken off, and I cannot decide that. Possibly you could take away the packing and then return it after moving.

Bees Coming Out of Hive at Night.

I had one colony of bees that cast 2 swarms last summer, the last one about June 1. I put them into a chaff hive and for a while they seemed to work well, but after a time did not do much, and would come out of the hive at night and hang in a cluster covering the entire end. In the morning they would gradually go in until all disappeared. As I was a beginner in the business I did not know the cause of it. One morning while they were out I opened the hive and found that nearly all the bees inside were drones. Thinking they might be the cause, I killed a large part of them, and I have had no more trouble of the kind. What was the cause of their coming out of the hive in the night? What can I do should I have another case like it? MAINE.

ANSWER.—It looks as if the bees might have been hanging out as a matter of comfort, because it was too warm in the hive, and when you killed off part of them they could all stay in the hive without being to warm. Possibly, however, the bees may have been queenless, the unusually large number of drones pointing that way. So look out for that this spring. Aside from the matter of queenlessness there was no need for you to do anything.

Transferring—Feeding Bees, Etc.

1. I have a colony of bees in a frame hive, but it is not the size I want it. I want to transfer into a Langstroth hive this spring. How shall I do it? and when is the best time?
2. I am afraid my bees will be short of food before summer comes. They are in the cellar. How and what shall I feed them? I have some honey in the comb in sections.
3. Can I feed them without taking off the covers?
4. Can I take off the covers in the cellar and examine them without their flying out all over the cellar?
5. Can bees fly when it is 50 degrees above 0?
6. I intend to clip the wings of my queens this spring. How shall I do it? And when is the best time—before they swarm?
7. Would you advise me to do this? I cannot be near the hives all the time, as I will be out in the fields, etc., but will be around them at meal-time, and at other times when I am at home. MINNESOTA.

ANSWERS.—1. Full directions for transferring hardly belong in this department, but a good text-book will give you fuller instructions than there is any room for here. The

Heddon plan is perhaps as good as any, but nowadays it is thought by many to be a better plan to let the bees swarm, giving the swarm in an improved hive, and then at the end of 21 days drive out the remaining bees and set the old hive off to one side for the bees to rob out. If you prefer not to wait for this, you can transfer in fruit-bloom.

2. Honey in sections will answer nicely. It depends on circumstances how you can feed them. In a frame hive they can be put in frames. But in your box-hive they must either be above or below. If they can be put above and covered up bee-tight, they will be safe from robber-bees. If below, give them in the evening when bees have stopped flying, and be sure the bees make a start on them right away. To do this it may be necessary to pound on the hive to rouse them enough to come down. Sometimes, however, the cluster of bees will be down so near the bottom-board that the bees will readily attack a section lying on the floor, the bottoms of the combs perhaps touching the section. A colony short of stores, however, is not likely to have the cluster down very low.

3. Yes, if there is room to push the sections under, or if the hives can be raised from loose bottoms.

4. Yes, if worked carefully.

5. Yes, if it is bright and still.

6. Catch the queen, being careful not to hold her by the abdomen or hinder part; hold her with the left hand, her stinger pointing to your right, then with a pair of scissors clip off half or more of the two wings on one side. Clip her at any time convenient after warm weather comes.

7. Yes, I should want the queen clipped, even if I were in the apiary every hour of the day.

Transferring from Box-Hives—Yellow-Pine Hives.

Has any one tried to transfer bees from box-hives to movable-frame hives by making a cover to fit the latter hive, and cutting a hole in the top just to fit the box-hive, and set the box-hive on top, stopping all cracks to force the bees out through the new hive, as it is their custom to build below? Would they eventually take up their quarters in the new hive? If so, when is the proper time to take off the old box?

1. I am a beginner. Last summer I bought 6 colonies of bees for \$5.00, 3 hybrids, 1 black, 2 Italians, and want to transfer them this spring into Langstroth hives.

2. Will bees do any good in yellow-pine hives? I use white pine, but yellow is much cheaper. ILLINOIS.

ANSWERS.—1. Yes, that has been done, but it is not always the most satisfactory. You will have the old hive filled with honey that is not in the most satisfactory shape. If you decide to use the plan, cut away all you can from the lower part of the box-hive, cutting away some of the lower edge of the combs—the object is to leave just as little room as possible in the old hive. You could take off the old hive any time after it was so filled with honey that there was no brood in it. Or, you could take it off as soon as the lower hive contained three or four frames of brood, and three weeks later drum the bees out of the old hive.

2. From what I know of yellow pine, I don't believe it would be as cheap as white pine, in the long run. If exposed to the weather it will soak the water when it rains, and soon rot.

Transferring Bees.

A colony of bees was given me for a present last November. The colony was very weak, but had sufficient stores for winter, as my friend asserted. Knowing nothing whatever about bees, I sent for "A B C of Bee-Culture" and studied up "wintering." I then made a good chaff hive. I carefully packed the hive with the super on, and put about 3 inches of chaff on top of the super cover. The whole is at present on a box out in the yard under a tree.

Shortly after I had put the hive on its stand, honey began to flow out of one side of the entrance. The flow is increasing and has spread more than half way across the opening. On looking in, and running a wire in, I found a comb lying on the bottom-board, under the center frames. I suppose that during transportation one of the combs broke loose and fell against the next one, and so on. The evil seems to be increasing, and I do not know what to do.

The hive is a dovetailed 8-frame Langstroth, but in the spring I would like to put the bees into a Danzenbaker hive. Under the circumstances, I cannot transfer by the Heddon method.

1. Do you think the following plan practicable? I would take off the Langstroth super and put a Danz. brood-chamber with frames filled with foundation on top of the old brood-chamber. The Danz. is 3½ inches wider, but I would make that open space bee-tight. I then would drive bees and queen into the Danz. hive by drumming on the sides of the old hive. Would they build comb and bring up the honey and commence rearing brood in the new hive? If they would do that, I would leave them in this position until they had cleaned out the lower hive, then I would remove it and put the Danz. on its own bottom-board in the same place, and give it a super with sections and starters.

2. Would it be advisable for me under the circumstances to change to the Danz. system? IOWA.

ANSWERS.—1. No, your plan would not work. If you should drum the bees up into an empty hive every day, every day they would go back to their combs in the lower hive when you stop drumming. Leave them as they are till fruit-bloom begins, and then drum if you must; but if you drum them out of the old hive you must not leave it below for them to go back into. It may be, however, that the combs are not so badly broken but you can get them cut, and fasten back in the frames those that are broken out.

2. It is not at all certain that you would gain anything by the change.

Requeening—Helping the Bees Get Up.

1. I wish to requeen several colonies this spring, with as little loss as possible. Will this plan work with bees with queen-cells? Place the old queen with some brood above the excluder, give a ripe cell below, and when hatched and mated take the old queen away.

2. Another plan to supersede the old queen, put capped brood and a cell over a wire screen on top of the hive to be requeened with the entrance in front, so that when mating she will return to the lower entrance and take possession below.

3. Sometimes having queenless colonies in the spring, and wishing to introduce fertile queens to them, will this plan work? Take two or more frames of capped brood, place over them a wire screen, give the queen to capped brood immediately, and when hatched unite with the bees below. Which is the best way to unite?

4. How do bees get up among the combs when loaded with honey, when using a deep entrance? Do they have to go up the sides, or rear end? Would it be best to put a narrow plank crosswise, thick enough for them to crawl up on, about the center of the hive?

ANSWERS.—1. Doubtful.

2. Still doubtful.

3. It will probably work all right. Unite by shifting the wire screen so the bees can have a passage at one side. After a few days remove the wire screen.

4. Don't you worry about giving them any help. They can fly right in and alight on the bottom-bars, or they can climb up at the sides. But don't leave a deep space under the bottom-bars in harvest, or the bees will build down into it.

Managing the Increase.

I have 6 colonies of bees and want to get 4 or 5 swarms from them in June. I will be on the road at that time 3 days at a time, as long as a week at a time. I have the 8-frame super with 5⅝-inch frames.

1. Would it be better to have 2 such supers for each hive, as I have not enough to change from one to the other, as the one is nearly filled?

2. The caging of the queen and the bee-entrance guards are a little out of place with me, as I am not advanced enough in the business, so I will ask what I need. If I am at home when they swarm, I can handle them all right; but when I am obliged to be away for 3 or 5 days, and perhaps a week, I am lost, and do not know what to do to save a few swarms. ILLINOIS.

ANSWERS.—1. I am not sure whether I understand you. You should have for each colony as many supers as the bees will fill during the season, and one extra, for you will not know just exactly when the season will close, and the last super given may have little or nothing done with it. If you mean that you intend to take the sections out of the supers as fast as a superful is finished, then you may be able to get along with two for each colony, but you mustn't

think of getting along with less than two, for when a super is nearly finished it would be a waste of honey to have no other super for the bees to be filling while finishing the first.

2. I don't know any way that you can work for comb honey and leave the bees for a week without using an entrance-guard or caging the queen, unless you are much more expert than would be necessary to use a queen-cage or entrance-guard.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nehr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested	1.50	8.00	15.00
Selected Tested	2.00	10.50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

Aikin's Honey and Wax Separator.

About three or four years ago I conceived the idea of an attachment to wax-extractors to separate the honey and wax. The old way of letting the honey and wax run into one common pan or tank had several objections that I longed to get rid of, and, having solved the problem in a very satisfactory way, I now propose to publish the results of my cogitations and experimenting. The device, while having more properly its place with the solar, may be made to answer the same purpose for which it was invented, in connection with wax-extractors of other kinds. I have no extractor but the solar, hence have not used it

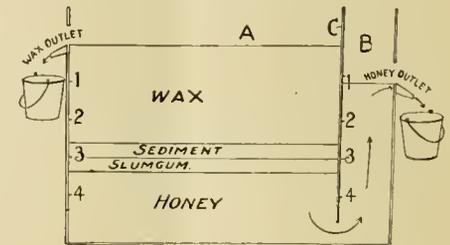

FIG. 1.

with any other kind, but the principle may be applied to others.

The principle upon which this device works is specific gravity. Honey weighs 12 pounds to the gallon, and water about 8 pounds. I do not know what is the weight of beeswax, but I know what every apiarist does—that wax is lighter than water. It is immaterial as to the exact proportion, so we will call it 8 for wax and 12 for honey.

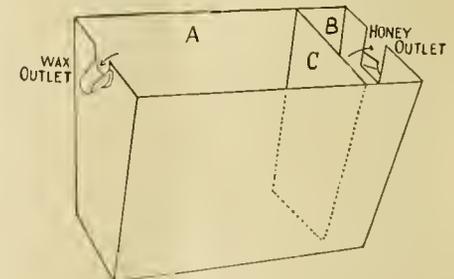

FIG. 2.

Now, suppose you take a cake of wax 3 inches thick and put it into a bucket of honey or into a tank where the wax has plenty of room so it does not touch the bucket or tank in any way that will interfere with its floating, and the wax will stand one inch above the surface of the honey. You see it is just a matter of weight: two parts of the honey are as heavy as three parts of the wax, hence the wax carries its surface clear above the honey, just as a cork floats a considerable part of its bulk above water. It matters not whether the wax is liquid or solid. It is bound to float just the same. A third of its depth will stand above the honey, and the rest will be submerged.

Now look at Fig. 1. This represents the separator as it appears in a general outline view. This is placed under the drip as it runs from the pan supporting the mixture of wax and honey-cappings, broken or any kind of comb. The first to flow from the melting combs will be honey, dropping into the separator at A, the larger of the two compartments. The partition between these compartments does not reach quite to the bottom by about 1/2 inch, hence the honey will pass under and rise in both compartments alike.

Look at the outlet for honey, and you will see that it is deeper from the top than the

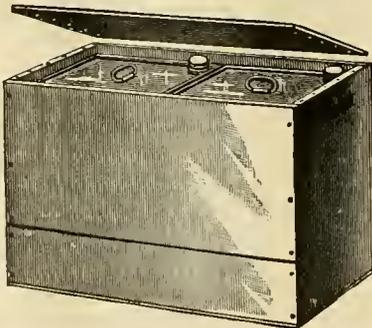

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7 1/2 cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, 1/2 cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

wax-outlet; and so when the honey rises to the opening it flows out, and will continue to flow as long as it pours into the other compartment, passing under the partition. The wax will begin to come shortly, and, being so much lighter than the honey, will begin to rise or pile up in compartment A. No matter what amount of wax falls into the honey, it keeps rising above and settling below the level of the honey-outlet; the depth of the body of wax is above and below; thus it increases until it flows out at its own overflow-outlet, and thereafter maintains its position, becoming neither deeper nor shallower. As long as wax and honey continue to flow in, the wax floats in its own compartment; and the honey, being so much heavier, sinks right through the wax and comes up and out at its own level. If wax stops coming, that body of wax in compartment A just remains as it is, neither less nor more, and honey can pour in all day, but will pass through and out at its own door; and, likewise, should honey stop coming, but wax continue to flow, the honey in the separator remains stationary, and the wax overflows into its own place. There is no limit; the two must separate and flow their own way when they come into the separator, whether it is tons or pounds.

There should be a check or dam to keep back the slumgum that would wash down into the separator. There is always more or less of sediment that will get down; but if the cocoons and more bulky foreign matter are kept back the fine sediment will be found accumulated between the honey and wax; and when the remnant of wax cools and is removed the sediment comes with it.

This little contrivance I count as a valuable adjunct to any solar, and may be used to advantage in many places. I have made my solar with one end for all sorts of trashy combs, and the other end for melting cappings, candied sections, new broken combs, and clean combs that may contain honey suitable for table use that can not well be separated in the extractor. Cappings or broken combs placed in the solar will very soon release the honey and let it run into the separator, and from there it will soon be in a tank or receptacle underneath, and away from the heat and light. I have sold many hundred pounds for table use that has been through the solar and separator. The fact is, the separator is a sort of strainer, acting on the specific-gravity plan, and does its work when the honey is quite warm and thin, so that it separates freely, the impurities floating up next to the wax. This idea of a strainer has been published in this journal, but I do not take the time to hunt up when or by whom.

For cooling and caking the wax I use the Raufuss idea of a series of small pans with an overflow from one to the other. The Root Co. is now putting out the same thing with their solars. The honey, besides being strained by the gravity process in the separa-

tor, passes below into a tank, and there, while still warm and thin, goes through another gravity-straining process; and, if not yet satisfactorily done, can be drawn from there and put through cheese-cloth or other strainer.

My separator, which has handled about a thousand pounds of wax and over a ton of honey this summer, is very well represented in Fig. 2. The bottom is about 2x7 inches, the top about 6x9, and the depth about 7 inches. There should be at the very least an inch from the bottom of the body of the wax to the bottom of the partition C. That will make sure that neither wax nor sediment gets under to float out with the honey. The flaring shape is to make the wax remnant easily removable when cooled, and to get the necessary depth without having an undue amount of honey in the separator, which must be there all the time. Possibly a much smaller arrangement will do as well; and if so, the honey and wax remnants always left over from one day to the next would be very nominal indeed. I think mine carries less than 2 pounds of wax, and it has handled well-nigh 200 pounds in a day—would handle much more if it could be melted and delivered to it. Each morning the wax remnant should be removed and put back to remelt. This keeps the sediment from accumulating. The honey remnant need not be changed for days and weeks.

This is a decided success. I feel that I have at last developed at least one invention that will be useful to apiculture.

[While you do not say anything about it in your article, I should imagine the same outfit would be very handy during extracting time. Suppose, for instance, the honey from the honey-extractors ran direct into compartment A: wax cappings, dead bees, refuse dirt of every description, would remain in A until the surplus would overflow at the wax outlet, while the clear, nice honey would pass under the partition C, and flow out of the honey-outlet as shown in the diagram.—EDITOR]—
 (Gleanings in Bee-Culture.

Temperature for Extracting Honey.

If too hot the combs are tender and easily broken; if too cold the honey will not leave the comb. T. P. Robinson says in the Lone Star Apiarist:

If the operator discovers that they are too warm to extract with practicability, just let him place them in a cool place so that they will cool to a point where the combs will be tougher, and then extract and place in the hive where the bees will clean off all honey and redeposit it. It is not a very desirable job to extract when it is too hot. In the hottest summer days, the best time to gather combs is early in the morning, placed in a cool place, and extracted after the bee-heat has departed.

Did you ever extract honey 20 degrees below freezing, just at Christmas? I have, and it is a job, unless you are prepared and know your business. I do not know that I know so much about it, or know my business so well, but here is the way I proceeded to success:

I gathered my combs when it was so cold that a bee dropped to the ground would be as stiff as a poker in 30 seconds, and placed them separately in a closed room and raised the temperature of the room to 115 degrees. I allowed the combs to remain about seven hours in the hot room, and then proceeded to extract them in the ordinary way.

Cuban Honey.

"Rambler" says in Gleanings in Bee-Culture:

As nearly as I can learn as to the Cuban crop for the past year, it has been equal to if not more than the California yield.

I doubt if California ever produced 10,000,000 pounds; but I am credibly informed that, before the War, when there were more apiaries than at present, the product was over that amount in Cuba.

A marked difference in the yields of California and Cuba is that the former often has

failures, but the latter none. The smaller area, then, of Cuba can be put into the front ranks as a producer.

At present virtually all of the honey produced is liquid, and probably three-fourths of it is handled by one firm in Havana. Price prevailing at present is 34 to 37 cents per gallon. This honey nearly all goes to Europe.

As to the quality of this honey, he says:

I must say that Cuban extracted honey will not find favor in the States as a table honey beside California or New York honey. Comb honey will come to the front, and I am sure the States can absorb large amounts of it at fair prices. Cuban comb honey is thoroughly ripened, and fit for table use.

Hives for Wintering.

Editor Doolittle says in the Progressive Bee-Keeper:

Which is best, single-walled hives, those with double walls, or the cellar, for wintering bees? is something which often puzzles bee-keepers, especially those who have only lately entered the ranks. In giving a decision it is all-important that we take into consideration the part that locality plays in the matter. Those who live in the South would naturally prefer single-walled hives, as they are more cheaply made, take up less room, and are made readily and easily movable, when any manipulation is made which requires a changing of hives. Then those who live in the extreme North will prefer cellar-wintering, generally using the same hives as those preferred in the South, as the double hives hardly give protection enough, where winter holds sway from October till April. But where the winters are moderate, and in some other localities where great quantities of snow fall, the double hives generally give the best results. They are the hives to use in latitude 35 to 40, where they sometimes have a week or more of weather when the thermometer will register zero, or a little below; but the rule is "open weather," with the bees flying occasionally all winter.

Here [New York] the single walls are hardly sufficient for the zero weather, and the temperature of the cellar will run too high for the comfort of bees during the warm spells, they becoming uneasy, and flying out on the floor by thousands to die, while, if in double hives outdoors, they would get beneficial flights. In this matter, as in all others, the ground should be carefully gone over before making a decision. In my locality, 42½ degrees north latitude, the winters, as a rule, are continuously cold, and here the cellar gives the best results, because the cellar can be kept at an even temperature, or very nearly so. This means also light consumption of stores, and comparatively few bees dying during the winter.

A Post Check—Good Idea.

Congress is attempting to perfect a design for currency intended especially for transmission through the mails, and the active people of the country wish it a success. The committees on post-offices and post-roads have before them a measure providing a Post check in denominations of five dollars and under, down to the denominations of fractional currency. It is proposed to retire the five, two, and one dollar bills now issued by the Government, and substitute the Post check, and make the latter the regular paper money for those denominations. The Post check was devised by Mr. C. W. Post, a prominent and public-spirited citizen of Battle Creek, Mich. He was assisted in its perfection by a number of publishers, and the plan has been earnestly endorsed by the American Newspaper Publishers' Association.

The general appearance of the Post check is that of the present one or two dollar bill. On one side are blank lines upon which the holder may write the name and address of any one to whom he desires to make payment by mail. The payee, upon receipt of the money, attaches his signature and collects the money at the office named. To forge the signature of the payee is a penitentiary offense, same as counterfeiting. As rapidly as the

Tennessee Queens

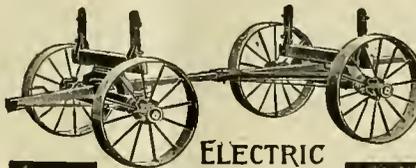

Daughters of Select Imported Italian, Select long-tongued (Moore's), and Select, Straight 5-band Queens, Bred 3/4 miles apart, and mated to select drones. Please mention Bee Journal when writing.

signed bills come into the possession of postmasters they are sent to Washington for redemption. So that by this process, one can carry about his person paper money in various denominations under five dollars, and it passes as good as gold. Should he desire to make remittance by mail, he simply takes out a bill or piece of fractional currency, writes the name of his creditor, affixes and cancels a stamp, and it only requires the signature of the latter to again make the money as good as gold at the office named.

Since the adoption of rural mail delivery, and our farmers are making so many mail orders, our rural friends will be greatly interested in this proposition, and they would do well so to express themselves to their Senators and Representatives in Congress. The design has been dedicated to the Government, so that no individual can selfishly profit by the adoption of the "Post Check."

Hon. Perry S. Heath, now the editor of the Salt Lake Tribune, and writer of the above, was First Assistant Postmaster General under the McKinley administration. The Money Order Service was under his supervision, and he speaks with expert knowledge of all matters pertaining to the transmission of money through the mails. His cordial endorsement of Post Check Currency carries great weight. It is a thing that should be adopted at once by the Government. We hope Congress will soon act favorably upon it.

Difference in Locality.

This was brought out in the discussions at the Ontario convention, as reported in the Canadian Bee Journal. Mr. Chrysler said:

I have managed the Heddon hives for two or three years without a swarm from them, or I might say, even queen-cells. I take probably three brood-chamber sections when fruit-bloom is on, and, when the queen has pretty well filled the two sections, I take the empty brood-chamber and set under the other two, and take one of the upper ones and put a queen-excluder between it and the next one, of course putting the queen below. What honey is gathered as a general rule will be put in the top brood-chamber, and as the bees are being hatched out that will be filled with honey; and by the time that is pretty well filled you can generally put an extra super under of extracting-combs.

Mr. Hall—Mr. Chrysler's plan succeeds with him, but if he comes to Oxford county it won't succeed.

Mr. Gemmill—If he comes to Stratford he won't succeed. I have had them swarm with the queen having the use of five of those half-hives, as you call them; and on a half story of foundation; giving them all the room they wanted. I have had them swarm in eight days from that. Circumstances alter cases.

Mr. Hall—You can give no regular rule for any locality. We have bees in three localities; if the man that ran the east one would run them the same as the other two he would run them into the ground, and they are only nine miles apart. We are all of us confident what we will do with bees, and what they will do with us, but we never take into consideration the locality, and, sometimes, it is the race of bees.

The Ethical Side in Apiculture.

Bessie L. Putnam, speaking of the bond of good-fellowship existing among bee-keepers, says in the American Bee-Keeper:

Old-time contributors have given through the various mediums not only valued experiences but glimpses of their own personality. And it is one in which kindness, gentleness, and patience are dominant characteristics.

So wide-spread are these traits that we feel impelled to seek a more explicit explanation than mere co-incidence. There is a natural sequence in all things; and if we but analyze the qualities which make the good apiarist, contemplate the phases developed by his

thoughtful life, it is not difficult to understand why he is also a good citizen.

Systematic study of his little charges, patience, punctuality, neatness, gentleness, are indispensable. Routine work may apparently succeed for a time; but the perplexities and emergencies sure to come up sooner or later call forth originality of thought and a thorough understanding of the habits of bees.

Did you ever see a really successful bee-keeper who was not something of an enthusiast over his pets? Who did not enjoy working with them? To him their methods of housekeeping, brood-rearing, and the gathering of supplies have an interest higher than that of purely mercenary gain. The construction of the cell, the "bee-line" to and from the distant clover-field, the evident recognition of strangers, these and many other traits point to a higher order of intelligence than is usually accorded to insect life. While much has been written about them, there are volumes yet to be learned. Surprising incidents are of frequent occurrence if we but note them. Those who know the bee understand that it does not go about seeking whom it may sting, but simply attends to its own business, and bravely resents the intrusion of others.

Careful study of the bee increases our interest in it, our respect for it. And the awakening of love and kindness toward the lowest of God's creatures naturally extends to His masterpiece—man.

Wintering Experiment.

I tried an experiment the past winter by putting 8 colonies of bees into my cellar in the same room with the furnace, and took them out March 14, all in good condition.

C. B. HOWARD.

Seneca Co., N. Y., March 20.

Getting Extracting-Combs.

On page 198, C. D., of Michigan, asks: "How do you have your extracting-combs built? In the surplus case or in the brood-chamber?" I wish C. D. to try my plan with at least one colony in a three-story hive.

As soon as his colonies are strong and honey coming in, see that the middle story is the brood-chamber. I use ten-frame three-story Langstroth hives for extracting, nothing less, and am never troubled with swarming. Furnish the upper story with eight combs for extracting, using combs having the most drone-cells. Now see that you have six good worker-combs in the middle story, and in the center insert an empty frame between two frames of brood and sealed honey, and you will be surprised how soon you will have new worker-combs built, and without starters. In the lower story have at least five combs, alternating them with empty frames to secure straight work. As the combs above are filled with honey and brood, the bees will work below. I think Mr. Dadaut might see some advantage if he would give my plan a trial—unless he prefers frames of different sizes.

Lucas Co., Iowa. GEO. W. RIKER.

A Report—Laying Workers.

I started in with 20 colonies of bees in 1901, and increased to 80 colonies, and got 2000 pounds of honey.

1900 was a failure for honey; I had only 20 colonies out of 100 last spring to start with. I have 84 good colonies to start with this spring, and they have plenty of honey. I expect to increase up to 200 colonies this season.

We have had some zero weather in March. I hear a great deal about drone-layers and laying workers, and what to do with them. I have looked and sweated for hours looking for laying workers and drone-layers, and then I would hitch the team and drive seven or eight miles to some bee-keeper and ask him more questions about laying workers than some 10-

Queens you should Have

Does blood tell in other stock? Give your bees a chance. Stock used for breeding the queens offered—not from a sport, but my pick out of an apiary giving last season an average yield as follows:

Honey-Gathering.

102 lbs. extracted and 68 lbs. comb honey per colony besides increase and stores for winter.

Quality of Comb-Honey Produced.

"Man! It would dazzle you."—Wm. Envoy, Ontario Government Inspector of Apiaries.

Wintering Qualities.

Up to the present (January 30), I never found these bees to show the least indication of unrest—always perfectly quiet. They are wintering perfectly.—Frank T. Adams, Brantford, Canada.

General Commendation.

Out of those queens you sent me I have produced the best race or strain of bees I ever owned. Remember that is saying a lot, as I have tried every breed imported in this country. The bees winter better, build up, and stand cold chilly winds in spring better, and are more suitable than any bees I ever owned. For the season they gave me about double the honey the pure Italians did, and more increase. Glad you are going into the queen-business, and are going to join the ranks again. We are much in want of a few men like you. C. W. Post, Ex-president Ontario Bee-keepers' Association (owns 365 colonies).

S. T. Pettit, Canada's most successful comb-honey producer and bee-keeper, says: "The blood in my apiary is largely the progeny of queens sent by you, and they are grand bees."

Prices of Queens.

They are duty free to the United States. Tested, \$2.00 each; \$10.00 for 6; \$18.00 per dozen. Untested until July 1, \$1.25 each; \$7.00 for 6; or \$12.00 per dozen. Same after July 1st, \$1.00 each; \$5.50 for 6; or \$10.00 per dozen. Larger quantities, prices on application. Postage stamps taken for fractions of a dollar. To be fair to every one, no selected tested queens are offered. Every one has the same chance. The above queens are bred from a careful selection of Italian and Carniolans. Pure Italian and Carniolan queens same price. Price of full colonies on application. Orders booked as received, and filled as quickly as possible. Order early.

"Free Trial Proposition."—There is a certain something about the "free trial" proposition that makes it attractive to even the person who is accustomed to buy for cash. Formerly the "free trial" idea was limited entirely to trial by sample, and only such merchandise as could be sampled were subject to "free trial;" matters have been changed quite materially, however, within the past few years, and now many things may be had on "free trial" terms. It remained for the Kalamazoo Carriage and Harness Mfg. Co., Station 33, Kalamazoo, Mich., to introduce the principle of "free trial" in the selling of the output of their large factories. They advertise in our paper to send any buggy, carriage, trap, surrey, harness, etc., which they make, to any purchaser on "30 days free trial," and they lay just claim to being the "Pioneers of the free-trial plan." They not only give that length of time in which to test the vehicle, but they at the same time sell it to the buyer at manufacturers' prices. That they do these two things, and that they give the best of satisfaction is true beyond doubt, as we have never had a single complaint from our readers, many of whom must have embraced their offer.

Those of our readers who have not yet bought a vehicle or harness, will do well to write the Kalamazoo people requesting their 23d annual catalog. It is fully illustrated with each article offered, and is almost sure to contain just what you are looking for. Please mention the American Bee Journal when writing them.

year-old school boy, and I would try to introduce nice queens, and the old bees would kill them as fast as I put them in.

The best way to do with such bees is to carry the hive away from the bee-yard and shake them out of the hive, and let them fly back to the yard and take up with the other bees. Life is too short to fuss with them.

G. W. NANCE.

Woodbury Co., Iowa, March 31.

Basswood and Pine Frames.

Ten years ago I made some brood-frames, using basswood for some and yellow pine for others, of V-shaped top-bars. I can see no evidence of wax-worms on either the poplar or pine, but plenty on the basswood. Why things are so different with me than they are with Mr. Niver I do not know, but I suppose it is caused by the difference in "location." With him they "located" in pine; with me in basswood.

A. ZIEGLER.

Huntington Co., Ind., March 17.

Don't Get Excited Over "Futures."

We have been having some very nice rains, and the present prospect is that we will have some honey, but I do not think any one is justified in getting excited over "futures."

I may give a report later on of my last year's crop, and if you think it would be appreciated, some of my observations, experiences, failures and successes.

J. W. GEORGE.

Riverside Co., Calif., March 15.

[Certainly. Send on your report, etc.—ED.]

Moving Bees—A Hopeful Bee-Keeper

I shipped 31 colonies of bees from Taylor Co., Iowa, to Wyandotte Co., Kans., in March. They came through in good shape. I left the winter-cases on in shipping, and have not removed them yet.

My average yield of honey last year, in Iowa, was 60 pounds per colony, spring count. The prospect does not look very bright for a honey crop at present, as there is very little white clover to be seen coming now, but it may come later. Part of a bee-keeper's living is "hopes," and we are living in hopes of a good season this year.

BERT GARDNER.

Wyandotte Co., Kans., April 1.

Bounteous Returns Expected.

It has been snowing or raining here nearly the whole of this month, and over nearly the whole State. The outlook for a good honey-flow, and for good farm crops, is very encouraging. A plentiful supply of irrigation water is the main thing, and, having secured that, our farmers and bee-keepers are anticipating bounteous returns for their toil this season.

E. S. LOVESY.

Salt Lake Co., Utah, March 27.

Bees in Fine Shape.

Bees are in fine shape this spring, having plenty of honey to carry them through brood-rearing.

J. F. HUNTER.

Morrison Co., Minn., March 26.

Colonies Seem Strong and Active.

I hired a man yesterday to put my bees on the summer stands; they seem very strong and active. They went into the cellar the first of December, and never had a flight until to-day. The temperature of the cellar was from 35 to 40 degrees.

D. C. WILSON.

Liun Co., Iowa, March 28.

Packing Bees for Winter.

One page 164, Ira D. Bartlett is reported as packing his bees for winter by putting on a piece of carpet, kiln-dried planer-shavings, two inches kiln-dried sawdust, then eight inches of planer-shavings. How many inches of planer-shavings does he put next to the carpet? Why does he put in the layer of

sawdust? Why not all planer-shavings or all sawdust?

I note that on page 171, C. J. Oldenburg puts 13 inches of chaff over the frames, thus agreeing in great depth of packing with Mr. Bartlett. **TURNER BUSWELL.**
Somerset Co., Maine.

[Will Mr. Bartlett kindly send answer to the above questions for publication?—ED.]

Worst Storm in Years.

We have been visited in this part of the country with the worst storm in years. It rained havoc with the bees, but we have the scaffold up around here on the river bottom and also on the Tule. One man lost 200 colonies, another 120, another 90. As for myself, I saved the most of 47, but some of them are rather light. You see, the country was flooded with water at the time we had the storm. **N. T. FRANCIS.**

Sutter Co., Calif., March 17.

Loss Due to Honey-Dew.

Our bees came through rather poorly this spring, with a loss of 20 percent, the worst in 10 years, all due to honey-dew and protracted cold weather. **EUGENE HAMBAUGH.**
Brown Co., Ill., March 31.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 234.

200 Nuclei and Full Colonies For Sale.

We have arranged with a good bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei and Full Colonies of Bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing. Full colonies can be shipped now; the Nuclei beginning May 1. We can book your orders for Nuclei now—first come first served.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 at \$2.75 each; 10 or more, \$2.50 each.

Full colonies in 8-frame Langstroth hives (no super.) Prices: 1 for \$6.00; 5 or more at \$5.50 each.

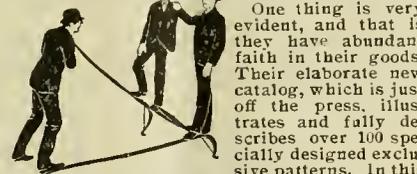

All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

Send all orders to **GEORGE W. YORK & CO.,**

SPLIT HICKORY
YOU CAN BEND IT BUT YOU CAN'T BREAK IT.

This heading is used in one of the advertisements of the Ohio Carriage Manufacturing Co., of Cincinnati, Ohio. They manufacture and sell to the consumer, the now celebrated "Split Hickory" line of vehicles. Unlike any other carriage concern in the country, selling direct to the user, they advertise and sell this special line only. They do not sell to jobbers or dealers; so if you want a "Split Hickory" vehicle the only place where you can buy it is from this concern. They make the bold statement that there is no other line of vehicles sold for anywhere near the money that is as good as "Split Hickory," and they offer as a proof of this assertion what one would consider a most fair proposition, namely, that they will send any of their vehicles anywhere in the United States on 30 days' free trial. If at the end of 30 days the purchaser is not satisfied, he can return the vehicle and will not be out one cent of money, as they pay the freight both ways in case the job comes back.

One thing is very evident, and that is they have abundant faith in their goods. Their elaborate new catalog, which is just off the press, illustrates and fully describes over 100 specially designed exclusive patterns. In this catalog they show several tests to which they have put their vehicles to prove the strength of the material used in their construction. Two of these illustrations we here reproduce. They also reproduce photographs of people who have purchased their vehicles and have given them testimonials. This is a very clever way of proving that the testimonials are genuine. The vehicle illustrated in this article is their top-buggy which has all late improvements, and the price is a genuine surprise. Any of our readers who are thinking of buying a vehicle this season, will do well to write to this concern for their catalog, which is mailed free upon application.

Address, Ohio Carriage Manufacturing Company, Station 6, Cincinnati, Ohio.

NOTE.—This firm offers some fine buggies as prizes to people who send names of persons about to buy a carriage or harness. You should send for plan and list of prizes. You might win one. Please mention the American Bee Journal when writing them.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, March 19.—There is continued depression in the trade owing to light output on the part of retailers and the desire on the part of those having stock on hand to dispose of it. The past two weeks have noted a further decline in price of comb honey, with the exception of basswood, which is scarce and wanted at 2 to 3 cents above any of the other white grades; it now brings 14@15c; alfalfa and other fair white, 10@13c; ambers, 8@10c. White extracted dull at 5 1/2@6 1/4c; ambers, 5 1/4@5 1/2c; Southern and dark, 5@5 1/2c. Beeswax scarce at 30c. **R. A. BURNETT & Co.**

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5 1/4@6 1/2c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c. **THE FRED W. MUTH Co.**

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c. **H. R. WRIGHT.**

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7 1/2c; Florida honey, in barrels, 6@6 1/2c. **BLAKE, SCOTT & LEE.**

BUFFALO, March 28.—Buffalo is very quiet on honey, except very low grades at very low prices. We quote extra fancy, 14c; No. 1, 12@13c; other grades, 8@10c. Extracted, 5@6c. Beeswax scarce; fancy, 28@30c; dark, 22@25c. **BATTERSON & Co.**

DETROIT, Feb. 20.—Fancy white comb honey, 14@15c; No. 1, 13@14c; no dark to quote. Extracted, white, 6@7c. Beeswax, 25@26c. **M. H. HUNT & SON.**

CINCINNATI, March 7.—The general tone of the honey market is lower. Water-white comb honey sells from 14@14 c; it is hard to obtain 15c for extra fancy. Extracted has weakened a little, and sells at 5@5 1/2c; fancy, from 6@6 1/2c. **C. H. W. WEBER.**

NEW YORK, March 8.—Comb honey is now pretty well cleaned up, and what remains on the market is nearly all fancy and No. 1 white honey. The demand is fairly good at following quotations: Fancy white, 14c; No. 1, 13c; No. 2, 12c. Extracted remains dull at unchanged prices with plenty of supply. Beeswax firm, 29c.

We have just received the first large shipment of comb honey from Cuba; some in tall sections, packed 20 combs to the crate and some in square sections packed 32 combs to the crate, glass front on one side, plain, no-bee-way section. The honey was packed in shipping-carriers, containing 8 of the large and 9 of the small crates respectively, and arrived in first-class condition. The flavor of this honey is very fine, and as to the quality—some of it is fancy white, while others is of a yellowish tint. **HILDRETH & SEGELKEN.**

SAN FRANCISCO, March 12.—White comb, 11@12 1/2 cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5 1/2@—; light amber, 4 1/2@5c; amber, 4@—, Beeswax, good to choice, light, 26@28c; dark, 24@25c.

While spot stocks are of rather light volume, holders show more inclination to unload than they did a month ago. Although quotable values are without marked change, concessions are granted to buyers which would not have been thought of at the beginning of the year. A large proportion of the honey now offering is comb of medium grade.

WANTED. EXTRACTED HONEY—either large or small lots; parties having same to offer, send samples, and best prices delivered at Cincinnati, Ohio. We pay cash on delivery. **THE FRED W. MUTH Co.,** 10Atf Front and Walnut Sts., CINCINNATI, O. Please mention Bee Journal when writing.

Standard Belgian Hare Book!

BY M. D. CAPPS.

THIS book of 175 pages presents a clear and concise treatment of the Belgian Hare industry; its growth, origin and kinds; the sanitation and construction of the rabbitry; selection of breeding stock; care of the young, feeding, diseases and their cures, scoring, marketing, shipping, &c. First edition of 50,000 copies was sold in advance of publication.

Price, in handsome paper cover, 25 cents, post-paid; or with the American Bee Journal one year—both for only \$1.10.

Would you increase your profits? Then try the Danz. Hive. It's used from Maine to California. Read the following:

MECHANIC FALLS, MAINE, Feb. 28, 1902.

THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market.

J. B. MASON, Manager North-eastern Branch The A. I. Root Co.

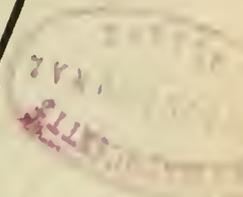

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

THE A. I. ROOT CO., MEDINA, OHIO, U.S.A.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Abbott, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens FOR 1902 FREE!

Long-Tongue Variety—Warranted Purely Mated

We have arranged with the queen-breeder who furnished Long-Tongue Red Clover Queen for us during the season of 1901, to fill our orders this season. Although fully 95 percent of the unmated queens he sent out were purely mated, this season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied last season. And this year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for Sending us only TWO NEW YEARLY SUBSCRIBERS.

In order that every one of our subscribers who wants one of these Warranted Queens this season can easily earn it, we will book your order for one queen for sending us the names and addresses of **two new subscribers** to the American Bee Journal and \$2.00; or for sending us *one new* subscription and 30 cents more (or \$1.30), we will mail you a queen; or send us \$1.60 and we will credit your own subscription for one year, and mail you a warranted queen.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen. We hope that every one of our present readers will decide to have at least one of these Queens. Address,

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a long-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO. Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

ESTABLISHED IN 1861

AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

42d YEAR.

CHICAGO, ILL., APRIL 17, 1902.

No. 16.

* Editorial. *

A New Director of the National Bee-Keepers' Association has just been elected to succeed Mr. Abbott, who resigned as director to take the position of General Manager. The new director is Mr. R. C. Aikin, of Colorado. This is an excellent choice, and should give unanimous satisfaction to all the bee-keepers of the great Middle West.

National Association Notes will be furnished to the various bee-papers by General Manager Abbott from time to time. His first "batch" appears on page 248. This is a good move, and will help the membership to keep in close touch with what is trying to be done by the Association. If you are not now a member, send your dollar at once to Mr. Abbott, and get in line to help the whole bee-keeping industry as well as yourself.

One Colony Continuously Starting Cells.—After a colony has been queenless for a considerable time, it can not be counted on for doing good work at starting queen-cells. But by the right management there need be no difficulty in having good cells continuously started throughout the entire season in the same hive, if not entirely by the same bees. All that is needed is the addition from time to time of frames of brood. This has a two-fold effect: It keeps up the supply of young bees, and also furnishes young brood to be fed, thus keeping up the preparation of a bountiful supply of the right kind of nourishment for the prospective queens.

Next National at Denver.—We have received the following notice from Pres. Hutchinson, announcing that the executive committee have selected Denver:

THE NEXT NATIONAL CONVENTION TO BE HELD IN DENVER.

Denver, Colo., has been selected as the place for holding the next meeting of the National Bee-Keepers' Association. Time—the first week in September. The exact date has not been decided upon, but the first session will probably be held Tuesday evening or Wednesday morning. The West has several times asked for the convention, and been put off with promises—that we must follow the G. A. R., or something of this sort, in order to secure the needed reduction of railroad rates. This year the G. A. R. meets at Washington, away to one side of the country. We met there several years ago, and only about 20 members were present—the most of those from near by. The West has been

going ahead with great leaps and bounds, and can rightfully claim recognition. The Colorado State convention, last fall, was the equal of many meetings of the National Association. And in all probability the Colorado State Bee-Keepers' Association will meet with us in joint convention. If held at Denver, the bee-keepers of Utah, California, Texas, and all of the great West will be able to "get there." I firmly believe that a convention can be held at Denver that will be the equal of any ever held.

Of course, the first question asked will be: "What about rates?" Well, they are all satisfactory, or, of course, we could not go to Denver, as a convention without low rates on the railroads was never a success. The National Letter Carriers' Association holds its annual convention in Denver during the first week in September, and an open rate to everybody will be made at that time. A representative railroad man told Mr. Working (the Secretary of the Colorado State Bee-Keepers' Association) that the regular fare outside of Colorado would be one fare, plus \$2.00, for the round trip, with a regular rate of one fare for a round trip in Colorado; while there have been made some specially low rates from some points in the East. From Chicago the fare will be only \$25 for the round trip. From St. Louis it is \$21. From St. Joseph, Kansas City, and Omaha it will be only \$15. Rates from points still further East have not yet been definitely settled.

Bee-keepers in the West will need no urging to come; to the bee-keepers of the East I will say, take the trip. It will open your eyes, not only in regard to bee-keeping, but to the wonderful possibilities of the great West. Your tickets will give you all of the time you wish to see Colorado's wonderful mountain scenery—"The Switzerland of America." Don't miss this opportunity of seeing its wonders, and mingling with its bee-keepers—the men and women with great, big hearts.

W. Z. HUTCHINSON, Pres.

We are glad that Denver has been selected. This choice will not be regretted, for those hustling Colorado and other Western bee-keepers will simply do their best to have even a bigger and better convention than Chicago ever had; and if they succeed (and we believe they will), none will be more delighted than those who helped to make the last National such a great success in this city, in 1900.

Remember that Denver is the place, and the first week in September the time.

Another thing: Don't fail to plan to go. There is ample time for everybody to get ready to attend the convention. And those Denver bee-keepers will need to make large preparation for the crowd, in addition to furnishing a generous sample of their fine climate.

The Formation of Nuclei seems to be considered by some as a complicated affair only to be undertaken by those of much experience. In reality there is nothing mysterious or difficult about it. Any one can take two or three frames of brood with adhering bees and put them in a hive and set the

hive on a new stand. That makes a nucleus, and the only difficulty in the case is to make sure that the queen is not taken along with the bees, and to make sure that too many bees will not return to the old hive. Some guard against the latter by imprisoning the queen for a certain length of time before putting them on the brood. Some do the imprisoning after forming the nucleus, closing the entrance tightly with green leaves. Within two or three days the leaves will shrivel so as to allow passage for the bees if the bee-keeper himself does not open the entrance.

Some take no precaution except to use for the nuclei bees that have been queenless two or more days. Queenless bees are much better than others as to staying where they are put. Take two or three frames of brood well covered with bees from a queenless colony, and put them in an empty hive, and the work is done. If you want to make more sure, you can brush in some extra bees, or you can fasten the bees in for 24 hours.

Manufactured Comb Honey Again.

—Last month we received the following communication from Rev. A. E. Taylor, of York Co., Pa.:

EDITOR AMERICAN BEE JOURNAL.—

Dear Sir:—I clipped the enclosed from the Philadelphia Record some weeks ago:

"It was recently announced in a Chicago paper that a car-load of manufactured honey, in the comb, had been received in that city from California. In reply to this the publisher of the American Bee Journal has offered \$1,000 for the sight of a single pound of manufactured comb honey. He adds that he has been making this offer for 20 years without finding a taker."

I send it, first, to say that I manufacture comb honey; and, second, to say that you had better call in your offer, if you made such, as some one may claim it. I do not claim any reward.

I manufacture comb honey because—first, I get honey in that way, whereas I would get none otherwise; and, second, I get a better product.

You may, if you wish, inquire of W. H. Huntzinger, principal merchant of our town; Dr. J. C. Channell, Mr. S. C. Kocker, Geo. Weitzel, or H. L. Keller.

Respectfully,

A. E. TAYLOR.

Upon receipt of the above, we wrote Mr. Taylor, telling him he was just the man we were looking for; we also enclosed 40 cents in stamps for two sample pounds of his "manufactured comb honey," and asked him to forward them, securely packed, by express at our expense, or return the stamps. In a few days we received the following:

MESSRS. GEORGE W. YORK & CO.—

Yours of the 6th at hand. I do not pretend to "manufacture comb honey by machinery, without the aid of bees." That would imply that I am a creator or secreter of wax, and I

do neither; that I construct comb; that I make a chemical change in the compound of sugar and fruit, which I give them, into honey. It would be as if a ranchman raised cattle without breeding-stock. Such an effort would result as did Aaron's effort at making a god.

You would be safe in adding six units to your offer, for since the world began man hath created nothing; nor hath he entered into the secret of insect architecture; all the paper-makers together could not make one boruets' nest.

I prepare the material out of which bees give me a product which the best judges of honey pronounce superior to the natural product in both taste and keeping quality.

Enclosed please find stamps returned as per request.

Respectfully,

A. E. TAYLOR.

And so endeth another boaster. In his first letter to us he distinctly said, "I manufacture comb honey." In his reply he says: "I do not pretend to say I manufacture comb honey," etc. We wouldn't care to be compelled to sit under *his* preaching, and help pay for keeping him alive. He belongs in the mistaken crowd instead of the Taylor family. But, thank the Lord, there are few such as he among the preachers.

But we will not "call in" that offer of \$1000 just yet. We prefer to wait and let a few more ignorant ones bite on it. It's pretty good bait—a genuine offer. And we are not afraid of being called on to pay the money, because there is no such thing as manufactured comb honey—made without the aid of bees.

Weekly Budget.

MR. WARD LAMKIN, of Cayuga Co., N. Y., passed through Chicago recently on his way to Colorado, where he contemplates purchasing and keeping bees. He left his 200 colonies in splendid condition at his New York home, and in good hands for the season.

MR. F. K. SCHALOW, of Kern Co., Calif., was in Chicago lately, to dispose of a car-load of extracted honey which his firm (Weems & Schalow) had produced last season. They have about 1000 colonies, and their crop in 1901 was about 70,000 pounds. Mr. Schalow was formerly from Wisconsin, but prefers to live in California now.

AN ARKANSAS APIARY is thus described, as well as its owner, by a friend:

Mr. S. M. Campbell, of Crawford Co., Ark., requested me to write about his success in bee-culture and send it for publication. This will show what can be done if a person just tries.

Mr. C.'s home is high up on the mountain, and a wearisome drive it was to get there. It is only four years since he settled on this place, cleared the land for cultivation, and brought with him 3 colonies of bees and 28 Langstroth hives. His former employer, Mr. Hayworth, from whom he got the bees and hives, saw no profit in them, as he said that one year they are a feast and another a famine; he wanted to go into chicken-raising, and told Mr. Campbell that if he would hew the logs for a chicken-house he could have the bees, hives and all, for the work.

Mr. Campbell had some knowledge of bees in the old-fashioned way, that is, in log-gums, which were always plentiful on his father's

place, and supplied their own table and many of the neighbors with honey; and, of course, he knew that if bees were handled rightly, well taken care of, they would yield a handsome profit, and therefore the bargain was closed.

The logs were hewn in three days; 4 more colonies were added to the lot, making 7 in all to begin with. The first year he took 600 pounds of section honey, and increased to 13 colonies; the honey sold for 10 cents a pound.

The following year was a failure, but the bees stored enough honey to winter them. In the meantime Mr. Campbell had studied up bee-culture. It opened his eyes and gave him new courage not to forsake but stick to the bees, as a good year would surely come again, and would prove that his bees were a profitable investment. Mr. Campbell says the "old reliable" American Bee Journal is surely worth its weight in gold to the bee-man.

The following year the bee-yard was looking fine, with 30 strong, hard-working colonies; the season was good, and an average of

APIARY OF S. M. CAMPBELL, OF CRAWFORD CO., ARK.

72 pounds of section honey per colony, with an increase of 30 colonies, resulted. That was a feast after the famine.

By this time Mr. Campbell began to handle bees in the practical and profitable way; he had studied their ways and doings, and it became a duty performed with pleasure, as he said. Bee-study is the finest study a person can get into.

The year 1900 was a poor one in this part of the country. To begin with, in the spring the bees did well, and the prospects were for a good season, but the dry weather of late summer and fall cut short the honey crop, and therefore they stored only 35 pounds per colony, and increased to 74 colonies.

In the meantime, Mr. Campbell hitched on to chickens, thinking a little side-line would not hurt, and might bring in a few dollars; or, as the good woman said, some pin-money; but the hawks, the owls, and the cholera, came, and got the pin-feathers, and of course forgot to leave the money for the pin-money, consequently the chickens were dropped, except what are needed for home use.

The year 1901 was started with 108 colonies, and over 3500 pounds of honey was taken off, and still they are working hard to close the season with a yield of 5000 pounds, by gathering the honey-dew from the hickory trees, from which it is just dropping to the ground.

This morning (Oct. 27, 1901), at early dawn, as we sat watching them coming in heavily laden with the sweet dew which they had gathered so early, and in fact as busy as little bees, they fairly fell down in clusters at the front of the hive, crowding each other to get in to unload and be off for some more.

Section work in this apiary is done away with, and all the honey is put up in half-depth frames, cut out and sold as bulk comb honey in from 1-pound to 50 pound cans. In this way one can get two supers to one of section honey, and obtain the same price here, with a great deal less work.

Mr. C.'s plan is to tier up as long as they work, by raising the super when two-thirds full, and placing the empty one next to the brood-nest. Sometimes there are as many as six supers on one hive. In hot weather the hives are raised from $\frac{1}{2}$ to 1 inch, according to the strength of the colony, and covered with light boards for shade, as they work much better, and it also keeps the combs from melting down.

Mr. C. gives the bee-papers and books on bee-culture due credit for his success. There are some people not far from this place who also keep bees and give their ideas about bee-papers in this way: "Mr. C. had better save his money that he yearly squanders in books and papers, and invest it in hogs; it would profit him more." Those people did seem to

know all about bees, and perhaps invested their money in hogs, but so far as the writer could see they have neither hogs nor honey, and a mighty sorry looking bee-yard.

Mr. Campbell is also a member of the National Bee-Keepers' Association, and therefore feels safe in regard to spraying, and whatever may come up, and would encourage every bee-keeper to join the Association.

The picture shows Mr. Campbell's home yard. The man with the smoker is Mr. C., the little girl "Fanny" is the keeper of bees in swarming-time; (Gibson, who stands on the hive, takes a great interest for a small lad—he has a colony of his own, and some day may make a bee-man. A FRIEND.

Sweet Clover—(To the Mossback.)

Yes, cut and slash sweet clover down—
Don't stop to ask its name;
Call it a weed and grub it up,
And throw it in the flame.

Let bigotry and ignorance
Have now their fullest sway;
Don't stop to get a new idea,
But mow the plant away.

Let fragrant ragweed, burdock sweet,
And prickly lettuce grow;
It wreathes the mossback's face with smiles
To see such things, you know.

Just find the rut that father trod,
And be content with that;
He always cut sweet clover down,
And that is what we're at.

—Gleanings in Bee-Culture.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 229.)

GROUND CORK FOR WINTER PACKING.

"Is ground cork as good, or better than sawdust for winter packing?"

Mr. Coggshall—Where can ground cork be obtained?

Dr. Miller—Wherever they sell grapes that are imported from California.

Mr. Coggshall—It is safer than sawdust, but it is hard to obtain. I have been inquiring for a year or two.

Mr. Chapman—There is a place here in the city where they manufacture corks. But I get my supplies entirely where Dr. Miller suggests—from the grocer. I get it from the imported grapes that come from Spain—they come in casks. I find it is an excellent material. It is impervious to moisture and allows for considerable circulation of air. I find it an excellent packing material, the best that I have been able to find. I have used excelsior and ground cork-dust, and I consider the latter much the better.

Mr. Coggshall—Sawdust is good enough for me. Of course it is very cheap, but you must have it dry. I have used it for years, and I don't care for anything better. Mice won't work in it, because it will tumble down. It don't give them a chance.

Mr. Dadant—In regard to sawdust, there is a good deal of difference. Sawdust, where they saw logs, is very coarse, pieces of wood, really, but the sawdust of rip-saw is altogether different from the other sawdust. It is in fine, long strings, not exactly excelsior, but something similar. It holds together and will keep out the heat or cold. Sawdust from a fine-cut saw is very good. Has any one ever tried the fine sawdust as compared with the other sawdust for keeping ice? That will tell you as well as anything. If it will keep the ice cold—compare that with the coarse sawdust and you will find how much less quantity will keep your bees warm, or the ice cold.

Dr. Miller—Mr. Coggshall, what kind do you use?

Mr. Coggshall—Hardwood. Set the saw so as not to cut too big a chip, consequently it will be finer than if a larger chip is cut; I endeavor to get the finer sawdust.

Dr. Miller—Do you have any preference for hard or soft wood?

Mr. Coggshall—No, doesn't make any difference. I don't pay any attention to that. We all know that in cutting basswood, pine or hemlock, they set the saw so as to take a chip a little over an eighth of an inch, while in cutting hardwood they can't set the saw so as to take as large a cut, and it makes finer sawdust.

Dr. Miller—How do planer-shavings compare?

Mr. Coggshall—They are too loose.

Mr. Dadant—Too dusty.

Mr. Hintz—How thick a covering do you put on for winter?

Mr. Coggshall—Well, on some I have on three, four, five inches, and with two inches I have wintered them. My packing boxes won't allow more than two inches with a heavy Brussels carpet before the dust is put on. These Brussels carpets—you might think I was extravagant, but I can get them at two cents a pound at any junk-shop, and they are something worth knowing about to bee-keepers. They will last for years. Two cents a pound is nothing, you know.

Mr. Clark—Do you use a Hill's device over the frames?

Mr. Coggshall—No, sir.

Dr. Miller—I think we will be interested if Mr. Coggshall will tell us how he packs his bees for winter.

Mr. Coggshall—There are usually some holes so it gives the bees a chance to go through over the top-bars. Sometimes I pick up a little stick about a quarter of an inch through, and tack that on top, and lay the carpet on that.

Mr. Moore—Mr. Coggshall, how many colonies have you in winter quarters this year?

Mr. Coggshall—1600 or 1700, I think.

Mr. Moore—What is your percent of loss?

Mr. Coggshall—Eight or ten percent, because I don't require young queens are the key to a good record.

Dr. Miller—I would like a word concerning packing over the frames. I never use cork or sawdust, but of later years I use planer-shavings altogether. If I use these shavings five or six inches deep it is too much. If I use about two inches, $1\frac{1}{2}$ to $2\frac{1}{4}$ inches, it is just right, in my locality. If the shavings are too deep they become dampened, get wet on the top, and don't dry out. If I leave only $1\frac{1}{2}$ to 2 inches I have never known them to get damp. They keep dry, and keep the bees dry. I have now 300 colonies wintering in that way. I built a cellar purposely to winter bees, 36×40 feet. I don't use it at all now. I lose from one to three percent of my bees during the winter, and, as Mr. Coggshall says, it is usually from neglect of putting in good queens in the fall. Too much chaff can be put over the bees for winter, and I suppose too much sawdust or too much ground-cork could be put over them.

Mr. Sylvester—Do you use a cushion?

Dr. Miller—Just about three thicknesses of burlap over the combs, and then put the shavings right in. There is one other thing I want to mention—about mice. The man who will let mice get into his hives doesn't look close enough to his work, I think. Some hives, of course, are old, and they have decayed bottoms. Such hives should be set on a good, solid board, and the entrance should be so guarded that mice cannot gnaw it. I tack a piece of tin on the bottom-board and a piece above on the hive so that mice cannot get in—they can't gnaw in. If I don't, they will gnaw in and destroy the bees, and cut the comb down and make bad work every way.

Mr. Whitney—I use planer-shavings for packing my bees. The last two years I haven't lost a colony in wintering. I use a burlap sack with the planer-shavings packed in it about three inches thick. I pack it down solid and then press it down into the upper part of the hives. I have never had any trouble since I commenced using planer-shavings, after packing down solid so they would remain compact. I think, however, if I could get hold of cork-dust I would use it, or that kind of filling.

Mr. Hogge—Do all who have spoken use the chaff hive? It seems to me there is nothing spoken of but top packing. Is there no side-packing?

Mr. Riker—No side-packing in my packing. I have used chaff hives to my detriment. In our locality the weather sets in cold, and cold enough for ice to collect in those chaff hives, and it doesn't melt if the sun should shine for a day or two: but in the thin-wall hives—just the single one-inch lumber or $\frac{3}{8}$, the sun can work on them and melt the ice, so we let the sun get right on it, where in chaff hives my experience is it remains there too long.

Mr. Whitney—Not quite pertinent to the question, perhaps, but I am a little sensitive and I have used two or three kinds, and I don't want anything but the chaff hives.

Mr. Josephson—I have not so many colonies of bees, but three years ago many bees died in the country. In my locality there was one bee-keeper who had 56 colonies in winter quarters and took out 4 in the spring. I had 27 in chaff hives, with about six or seven inches of packing (planer-shavings), and I took out 26 colonies in the spring.

Mr. Whitney—That's my experience. Last year I put in about 58 colonies and took out just as many. I use planer-shavings for packing in the top, in the second story.

Mr. Dadant—We have been wintering our bees for years in hives that have double boards on the north side—which is always the back with us—doubled on one side, division-board side, and we pack the top of the hives full of leaves. When my father began keeping bees here, which is about 58 years ago, he noticed that in a deep gully of the woods where there was six inches of leaves, if the leaves kept dry you could almost dig any time in the hardest winter, and that gave him the idea. We keep our bees under trees, and gather the regular leaves whenever dry, which is very often in the month of November, sometimes December. We have of late years wrapped up the hives with the same material by making slat-work with lath—common plasterer's lath—which we wrap around the hive, and afterwards we rake it full of leaves on all sides but the front; that shelters them on all sides but the sunnyside. Now as to the chaff hives: I agree with Mr. Riker. We had 80, years ago. We sold some of them. We have 20 or 30 of them now. They don't average wintering as well as the others. Not that they are not good in certain sections, but if we have a very cold snap that will last two or three weeks, and the weather gets mild and remains mild, the chaff-hive bees will come out best; but six or seven weeks of cold, and one warm day, during that warm day they are still cold, and they don't know it is a warm day. The others find out as soon as there is one bright day, and they have a flight,

and those in the chaff hive are shut up, and unless we disturb them they will not come out, because the inside of the hive is cold, and everything is cold, and the result is they will very often suffer and die, when bees in some other hives, which are seemingly exposed, come out all right.

No. 2—Improving the Races of Bees.

BY ADRIAN GETAZ.

IN a previous communication (page 55), I insisted on inbreeding, showing that in other kinds of domestic animals inbreeding could be, and had been, practiced successfully, provided all defectuous animals were rejected, otherwise the defects would go on increasing all the time, as well as the good qualities of the stock.

In breeding for improvement it is supposed that the apiarist has selected the best stock obtainable; it may be supposed that he has succeeded in improving it more or less. Then it is evident that any outside stock would be inferior, and, if introduced, would cause deterioration. We may set down as a rule, "No introduction of inferior stock under any condition."

Should we begin with two queens of different stocks—one for the drones and one for the queens, or use the same for queen and drones?

I don't know as it would make much difference, provided both are equally good. In starting with two different stocks, more variations could be expected, but less certain of transmitting the qualities already possessed.

I would choose some of our best breeds of five-banded bees. Some of them are as good and as gentle as any ordinary Italians, and have the advantage of capping their honey whiter. I have tried them.

We must control the drones. That is, arrange so that our queens cannot mate with any other drones than those of the colony we have selected. There is no need of controlling the individual drones except to destroy the undersized or otherwise defectuous ones. There is nothing in the appearance of a drone that can guide us or show us what will be the honey-gathering or other qualities of his daughters; and therefore no choice can be made, except that the only drones flying should be those of the stock selected.

There is only one way to do it, that is, to postpone the rearing of queens (and drones) until the honey-flow is over, and the general destruction of drones has taken place.

There are several advantages in adopting that plan. One is that the young queens have a whole honey season to be tested. Right here, the question might be raised whether a one-year test is enough. I think those decidedly inferior could be removed after the first year test. Those acceptable, especially if they are nearly equal, might have a second year test before the final choice is made. After a decidedly superior queen is obtained, I should use her for queens and drones, until a better one is reared. If the best two queens were nearly equal, I think I would use both. Contingencies will probably occur. For instance, the best honey-gathering stock might be decidedly vicious, and a crossing with a gentler stock might be necessary. In estimating the value of a queen, the strength of the colony and all the circumstances having an influence on the amount of surplus obtained should be taken into consideration.

The rearing of queens will be discussed from a technical standpoint in a future contribution.

INFLUENCE OF THE FEED.

Some writers have insisted that the worker-bees can transmit to the young bees some of their qualities, such as honey-gathering, gentleness, etc., either directly through the feed they prepare for them, or indirectly through the feed they give to the queen.

The question is a very important one. If that opinion is true, then, in order to improve our present races of bees, we will have to select not only the queens and drones, but also the workers. Needless to say that the problem would be considerably complicated.

Fortunately, it is an error. To the uneducated that opinion seems very plausible; to the one possessing even

an elementary knowledge of physiology the error will appear at once.

Only those who have tried it know how difficult it is to explain a scientific subject in a way that even the least educated can understand it. Nevertheless, I will try it.

We have here, say, two plats of land. One is poor clay land, the other is rich loam. In the clay we sow some wheat, and in the loam we plant corn. Would you say that the clay was the cause of the wheat being wheat and the loam was the cause of the corn-plant being corn?

Would you say that if the corn had been planted in the clay, it would have acquired some of the wheat characteristics, and if the wheat had been sown in the loam it would have acquired some of the corn peculiarities?

No, you would not. The land or feed has an influence on the development of the plant, but not on its characteristics. The wheat will be wheat in whatever ground it is sown; but it will be puny and weak on poor land, and tall and thrifty on rich land. So with the corn.

Let us take another example at the other end of the line: Frequently in the Southern States, when a mother cannot nurse her baby, a colored wet-nurse is employed; but it has never been observed that she could transmit any "nigger characteristics" to the baby through her milk.

Sometimes a wet-nurse is not obtainable. Cow or goat milk is resorted to. Would you say that some of the meekness of character of the cow has been transmitted to the child through her milk, or that some of the contrariness of the goat has been acquired in the same way?

No, you would not. And any man who would advocate such a transmission, would not have to go very far before being asked if he had not been raised on ass's milk himself.

Yet some one may insist and ask if there is not some possibility of the worker-bee adding (something) to the feed that might have some effect similar to that of the egg of the female and the sperm of the male. No, there is none. There is nothing in the honey-sac or the stomach of the worker that can produce a living germ similar to the egg of the female or the male germ. There are only glands producing substances similar to the saliva or the stomach-juices of the higher animals. And if there was, these germs would be useless. Put a piece of wood in the fire and burn it. You say it is destroyed. No, it is not; it is only transformed—a part of it is now ashes, and another part smoke and gases.

So it is with the food. You eat meat, fruit, milk, etc. All these substances go through several transformations fully as great as when you burned that piece of wood. Some finally become flesh, some bones, some nerves, etc.; some are actually "burned" in the lungs and produce the heat necessary to the life of the body. So it is with bees. And any living germ that might chance to be among the feed would be transformed (or destroyed as such) as effectively as the rest.

Full details and proofs cannot be given here on account of lack of space. They can be found in the text-books on physiology.

An argument often presented is this: The queen never gathers honey, never stings, never feeds the brood. How can she then transmit to her workers qualities that she never possessed? Is it not reasonable to suppose that "somehow or other" these qualities come from the worker?

The argument at first seems to be pretty strong, yet, after all, there is nothing in it. If you look at it closely; you see that the meaning of it is that the offspring of the queen must necessarily be like her.

But what are the facts? A queen not mated lays eggs as well as one that is mated. According to the above argument such eggs should produce only queens. But, instead of that, they produce only drones, and nothing but drones. This seems to me conclusive, and shows that the progeny of the queen is not necessarily limited to being similar to herself.

EXAMPLES OF THE WORKERS.

Very often we have colonies of bees addicted to robbing, or exceedingly cross. The apiarist changes the queen in hope to correct the evil. To his surprise (if he is a novice) the workers from the new queen are as bad as those of the old one.

Yet nothing else could be expected. Bees follow each other's example almost invariably. Let a bee, in a time of scarcity of nectar, find some honey. She sips a load, hurries home and starts back for more. The other bees of the same colony, noticing her movements, follow her. By and by the other colonies also notice the proceedings and take part in the operations, until the whole apiary is in an up-

roar. The bees from the new queen simply follow the example and action of those of the old queen.

SURVIVAL OF THE FITTEST.

In a measure, the workers do influence the future generations, but it is in a very indirect way. If the workers of a colony are defectuous in honey-gathering or some other essential qualification, that colony will probably die during the following winter, queen and all. That race of bees will disappear.

On the other hand, a race of bees better than the average will prosper, send out swarms, and eventually predominate, while less gifted ones will stay behind or even disappear.

INFLUENCE OF THE MALE.

It is often said—and it is the opinion generally admitted—that the male has a greater influence on the offspring than the female. The question is almost impossible to settle.

When breeding from parents possessing the same qualities, it is impossible to tell from which the offspring inherited its characteristics. For instance, let us choose the case of a calf descendant of a bull and a cow both of pure Jersey stock. That calf probably will possess all the traits of the Jersey stock. Did he inherit it from the cow or the bull, or equally from both? We cannot tell.

Let us try it another way. Let us cross two very different stocks; for instance, a Shorthorn bull with a Jersey cow. Now, if the male has more influence than the female, the calf should be more like a Shorthorn than a Jersey. Yes, it should be, but it is not. In crossing very different stock, the offspring is sometimes like the mother, sometimes like the father, sometimes takes equally from both, and sometimes exhibits particularities (or variations) that neither parent possessed.

We see such a case when crossing black with Italian bees. Some colonies are uniformly two-banded, some nearly black, and some have bees of all shades and colors from the three-banded to the full-black. Nevertheless, all or nearly all the stock-breeders will tell you that the male has the greatest influence.

Before proceeding any further it may be well to mention that in crossing different stocks, the qualities that are the best "fixed" are those which are transmitted, rather than the others.

What do you mean by "fixed"? In breeding Jersey stock the originators have chosen a certain well-known color; they have raised exclusively from cows and bulls possessing that color. Their successors have followed the same rule, and that color has become "fixed", that is, invariably possessed by Jersey animals.

Now to return to our subject: The cows or mares owned by the majority of farmers and breeders are of no particular stock at all—common, scrub, hydrids, and nondescripts of all sorts, sizes and colors, and nothing "fixed".

When needed, the services of some high-grade hybrid or pure-stock bull or stallion are secured; then the calf or colt inherits chiefly the qualities of his father. Why? Chiefly, and possibly altogether, because the father is of a better stock and possessed of stronger and better "fixed" characteristics. Perhaps to some extent to his sex, but certainly not much, if at all.

For full information on this subject, see the text-books on breeding stock; in preference the German writers. Their works are far in advance of ours. Also Darwin, Wallace, Huxley, etc., on the origin and variations of species.

The conclusion drawn from the study of the higher animals cannot be strictly applied to the bees. In the higher animals, the concurrence of both sexes is necessary to the reproduction, whether the offspring is male or female. With bees the case is different. The drone has no father and is exclusively the son of his mother. The female (worker or queen, for both come from the same kind of egg) is born exclusively from impregnated eggs. More than that, the impregnated egg produces females and never males. This seems to show that the female element comes rather from the drone; and, it is very possible—even probable—that the workers and queens inherit their qualities chiefly from the drone. We cannot, however, reach a final decision until careful and extensive experiments are made. On this subject see the text-books, especially Dzierzon and Cheshire.

(Concluded next week.)

Spreading Brood in the Hive in Spring.

BY G. M. DOOLITTLE.

SEVERAL subscribers to the American Bee Journal wish me to give an article on spreading the brood in the bee-hive in spring, and what is to be the object to be obtained. To this I will say that it is a common trait in our American people—that of desiring to get all that is possible into the "now" of life—they are not being willing to wait till another year for what, with a little extra exertion, can be gotten this year; and so it comes to pass that in almost every pursuit in life we see a reaching forth for the fruits of *to-day*, and the bending of every energy and nerve to accomplish great results during the present season. And bee-keepers are no exception to this rule.

The old and natural way was to allow the queen-bee from four or five years in which to lay her 700,000 to 800,000 eggs Nature had provided her with, but the Yankee push says she must lay all of these eggs in from one to three years, if the thing is possible, and if the science of apiculture is to demand our attention. Hence many plans have been devised to stimulate the bees in spring, so that they in turn would feed and coax the queen to lay the greatest possible number of eggs, said eggs really meaning the laborers in the harvest-field.

Without going over the many plans devised to accomplish the object sought, I will simply say that after trying nearly all, I consider the mode of stimulating known as the "spreading of brood" the best of any, for by it the queen can be coaxed to lay to a greater extent than by any other which I have tried.

Before describing the plan I wish to say that it requires great care and considerable experience to be successful with it, for an injudicious move will often make the colony worse off than it would have been had it been let alone.

As soon as we can reasonably expect warm weather has come to stay, which in this locality is at about the time the cherry and plum trees bloom, we go to a colony of bees and lift out the combs to see the shape the brood is in. If it proves to be a good colony we will find brood in five or six combs, the two central ones being well filled, while the outside ones have little more than half a frame full. Finding a colony in this condition at this time of the year, we do what is called "reversing the brood-nest," that is, we put the two central combs, or those having the most brood, at the outside, and those having the least brood in, in the center between the full ones. Now the six combs of brood occupy the same place in the hive that they did before, except that those having the least are in the center of the brood-nest. This places the most advanced brood near the outside of the cluster of bees and the youngest in the center, and allows the queen to lay her eggs in the warmest part of the nest, instead of the coldest part, as she was doing before. The bees are also averse to an empty comb-space in the center of their nest, so see that it is filled in the shortest time possible, thus coaxing the queen to fill those empty cells with eggs in less than one-half the time she naturally would.

If the weather keeps favorable, in about a week we go to this hive again and take one of the combs from the next outside of the hive, one having considerable honey in it, and after moving the combs along till we come to the center of the brood-nest, we insert this comb, after having broken the sealing to the cells containing honey, by passing a knife over them flatwise. The bees go at once to removing this honey, and in doing so are stimulated to feed the queen to a greater amount, and the heat of the colony is increased so that the queen fills the cells with eggs almost as fast as the bees remove the honey, through this still greater incited activity.

In this way we keep on inserting combs till all in the hive are filled with brood. Should it so happen, before we secure brood in all the combs, that the queen does not keep up her egg-laying in the outside combs as the brood hatches, this can be remedied by again reversing the brood-nest.

As the season advances, so there is no danger from chilling, through a greater number of bees and warmer and more settled weather, two frames can be inserted in the center at a time, every week, if need be.

If all has worked well the hive should be filled with brood in a little over one-half the time it would have taken if let alone, so that double the number of workers will be ready for the harvest, if we have planned our time of commencement wisely, than otherwise would have been.

If the honey harvest comes very early in your locality you will want to commence to spread the brood five or six

17 The Premiums offered this week are well worth working for. Look at them.

weeks before this harvest, in order to meet the harvest with the maximum number of bees. If you have a late harvest, then govern yourself accordingly; but remember that the earlier you commence, the more care is needed.

To show the harm that may arise, let us suppose that you have a moderate sized colony which is carrying all the brood it can keep warm in moderate weather. We go and insert a comb in this nest, and by so doing cause the colony to spread out so as to keep just so much more comb-space warm. Now it turns cold, and after a little the bees are obliged to contract the cluster to keep from being chilled, in doing which they leave the two outside combs of well-developed brood to perish, in order to protect themselves and the center combs containing eggs and the youngest brood. Without explaining further, all will see that much harm, instead of good, would result. Therefore I said at the outset, "care and experience" are necessary. With these great gain can be made by spreading the brood. Without them, the colony is much better off undisturbed.

Onondago Co., N. Y.

Association Notes

By EMERSON T. ABBOTT, St. Joseph, Missouri,
Gen. Mgr. of the National Bee-Keepers' Association.

The New General Manager has not gotten things entirely in hand yet, but desires to say to the bee-keepers of the country that there is a great deal demanding the immediate attention of the Association. The question of spraying fruit-trees in bloom has come up, and a member has appealed to the General Manager for aid. This will receive his attention at once.

A Bill Against Sweet Clover.—As has been announced in the bee-papers, an attempt has been made to pass a law in Ohio with a view of exterminating sweet clover. The General Manager has written a vigorous protest, in the name of the Association, to the chairman of the committee which has the bill in charge. Secretary Mason and Acting Chairman Root have seconded the efforts of the General Manager, and it is hoped the bill will be killed in the committee.

Director Miller has suggested that an attempt be made to get the Department of Agriculture to issue a bulletin on sweet clover. The General Manager will take this up at once with the Secretary of Agriculture, and see what can be done.

The Lie About Manufactured Comb Honey.—The question of manufacturing comb honey still continues to disturb the minds of city reporters, and the General Manager has also found it necessary to write vigorous protests in the name of the Association, to the New York Tribune, and to the Medical Brief, of St. Louis, on this subject. It remains to be seen what will be the responses of these publications.

The General Manager has also addressed a letter to the Chairman of the California State Board of Health on the subject of honey-adulteration.

Bee-Keepers Invited to Co-operate.—It is the earnest request of the General Manager that bee-keepers all over the United States and Canada be on the alert, and inform him at once if anything comes under their notice which tends to the injury of our industry. In the meantime it is hoped that old members will send in their dues promptly, and that bee-keepers everywhere will see the importance of sending in their dollar for membership fee. The new General Manager desires to say that all moneys received by him will be acknowledged at once, and those who send in membership fees and do not hear from them promptly should write and make inquiry about them.

The Change of General Managers.—The retiring General Manager has been absent from home, attending to his duties as a member of the legislature of Iowa, and for this reason there has been some delay in making the change, but if our friends will be a little patient, all will be in working order in a short time, and we will make a long pull, and a strong pull, and a pull all together, for victory.

St. Joseph, Mo. EMERSON T. ABBOTT, Gen. Mgr.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

DIFFERENCE IN LONGEVITY IN BEES.

That was a shrewd experiment of Mr. Olmstead's, on page 149. As it is very suggestive, and very easy, it should be repeated by many observers until we can have a settled knowledge of what it amounts to, and what it teaches. Among your dark-colored bees choose the colony that puts the most white food around the hatching eggs; also choose the one that does the least in that line. Give each a frame of eggs from very yellow stock (both from the same queen if possible), and then observe how long the yellow bees live in the two respective colonies. Mr. Olmstead's observation that the ones extra-well fed in early babyhood live two weeks the longest is almost beyond belief.

Yes, Mr. Olmstead, those bees that forget all about putting any honey below in their zeal for filling sections are very valuable bees; and there is serious danger that Nature will weed them out by starvation unless man interposes.

WAX-WORMS IN PINE AND BASSWOOD.

As to the preference of wax-worms, my memory is that they eat the pine and the basswood about equally when they burrow between a section and the adjacent wall. But my memory sometimes plays me tricks. Some pine is very soft while some is quite hard—and basswood is usually pretty tough. Page 147.

THAT SEVEN-YEAR-OLD QUEEN.

Hello! Mr. Riker gets himself into good and ancient company. Virgil gives seven years as the extreme age of the bee—and Mr. Riker claims a seven-year-old queen. Probably the ancients, most of them, didn't know that workers lived to a less age than the queens. And Mr. Riker will encounter lots of Thomases who will tell him that anything beyond five years must be a mistake. Page 150.

HONEY CROP VS. YELLOW BANDS.

Queen tested for honey crop worth three times as much as the one tested for yellow bands. Right—and might have said more and still be right—Miss Emma Wilson. Even when you studied the harness of the horse you intended to drive you were not any "right-er." But the provoking mischief of it is that it *costs* much more than three times as much. And when the testing is fairly complete the queen is not as young as once she was. Page 151.

OILED MUSLIN HIVE-COVERS—YELLOW SWEET CLOVER.

Is the hive-garment projected by R. McCradie, page 154, a practical thing? (Oiled muslin to cover all the hive except the entrance.) The object sought is valuable. A dry wall is warm when the sun shines even a little; but a soaked wall uses up more of the heat evaporating its surplus water. If the device can be kept from *clinging*—as wet garments are inclined to do, and thus imparting lots of moisture to the wood—I think it would be worth while in any cold climate prone to frequent rains and drizzle driven by winds. Possibly one might profitably and as well go further and fare better with regular outside packing and a big piece of corrugated iron for top.

And so there is one yellow sweet clover that blooms three or four weeks earlier than the white. Page 172.

DON'T BE A PROPOLIS-RUBBER.

If dirt or propolis are *rubbed on* to sections to make the Thomas family believe in them, and the ingenious rubber gets found out, the family aforesaid will have "confirmation strong, etc.," and the honey-man will find his mouth awkwardly stopped. Guess it would be safer, as well as more strictly moral, to let alone. Page 154.

SHADE FOR BEES.

My opinion of the shade proposed by Albert Wiltz, is that it is a wonder that some one has not proposed it before. Artichokes are a vegetable I am unfamiliar with. There'll be some hot days before they are big enough to suffice, will there not? With artichokes, sunflowers, asparagus and grapes on trial,

which would furnish a sufficient shade first? On rich ground, and for small hives set low, I suspect rhubarb could be made to beat either one—but that would die down and leave us just when we wanted it most. On the whole, artichokes look very promising for an aprary that is to be moved every year. As to a settled location, I might go hunting for a weak point and say that perhaps spreading around in the ground might bother some in years after the first. Page 154.

THE JOUNCER THAT RAMBLER BOTH JOUNCE.

I like patient persistence, and Rambler seems to have it when his jouncer is involved. I guess we will have to confess that some people find it useful, and succeed in using it without doing serious mischief. The pointing of the corner-posts is a good idea. They penetrate the soil a little and favorably reduce the all-fracturing emphasis of the jouncer. Honest in him to confess that thin honey gets badly jounced out sometimes. Page 158.

SETTING THE PRICE OF HONEY.

I fear, Comrade Akin, that the price of honey is sometimes set not by "the best and up-to-date methods," as you put it, but by the cheapest—and also decidedly reprehensible methods—which ought not to be allowed at all. Some time we'll set the pure-food commissioners after the offenders—so we will. Page 158.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Swarming with No Increase.

I am desirous of having my colonies swarm without increasing their number, and want to know a good way to unite the swarm and old colony. Last year I placed the old colony over the swarm, a few days after the swarming, but the plan was not satisfactory. My honey-flow is light and continuous during the summer, the only surplus coming after the middle of August. NEW JERSEY.

ANSWER.—I'm not sure I can tell you any way that will be entirely satisfactory. Here is one way you might try, which would have the advantage of leaving you a young and vigorous queen: When the colony swarms, kill or remove the old queen—an easy thing to do if your queens are clipped. A week later destroy all queen-cells but one. Or, wait till you hear the young queen piping, then destroy *all* queen-cells remaining.

Flavoring Bogus Honey—Bee-Bread Flavor—Drones.

1. What is the name of the stuff the manufacturers of bogus honey use to flavor the product? I think I knew the name when I was a child, and saw my father put a few drops of it on a tray of rye-flour which he placed in the open air in early spring, to encourage the bees to begin brood-rearing, I suppose.

2. Is there anything used to put in extracted honey to imitate the flavor of bee-bread? I bought a small jar of honey in a Chicago store last September, and there was no particles in it to indicate bee-bread, but there was such a decided flavor of bee-bread that the honey was quite spoiled for me. And I wondered if it could be imitated, and was as a supposed guarantee of genuineness, for I never knew that the flavor would so permeate the honey that it would remain when not a particle was visible in the jar. I thought to take it to Mr. York and ask him about it but I never got to go. The flavors of different kinds of honey interest me very much, and when I taste a new kind of honey I wonder from what it was gathered. The most finely and deliciously flavored honey I ever tasted was a box of comb honey I bought in Chicago, last fall, and I imagined it came from apple or peach blossoms.

3. My other question was about drones. I may be displaying unpardonable ignorance, but I want to know your idea. I have understood that drones are always hatched from unfertilized eggs. Lately I was reading a manuscript in

which the writer—an old, experienced bee-keeper whom I had known, personally, from childhood—said that he had watched the queen laying eggs in drone-cells, worker-cells and queen-cells, on the same comb, while he held the comb in his hands, and those eggs hatched out drones, workers and queens, according to the cells. ILLINOIS.

ANSWERS.—1. I do not know that anything but honey is used as a flavor. I have had no personal experience in that line, but I have sampled honey that was adulterated, and the only flavor I could detect was that of honey and glucose. Still, it may be that other flavors are used. I suspect that the flavor you have in mind that your father used is anise, for that is used sometimes. I believe, to bait bees.

2. I never heard of anything being used to imitate the flavor of bee-bread. There are so many different flavors in pure honey that it is possible there may have been nothing wrong except that the bees got the honey from flowers that yielded the disagreeable flavor. It may also be that the honey was adulterated. I doubt that the honey you liked so well was from apple or peach bloom. At the time of fruit-bloom bees are not generally in sufficient force to store surplus, and all the honey then gathered is used in brood-rearing.

3. There is no conflict between your understanding and the statement of your friend. All the eggs of the queen are unimpregnated as they leave the ovaries. In its outward passage the egg is impregnated as it passes the seminal sac or spermatheca *if* the egg is destined for a worker-cell or a queen-cell. But if the egg is destined for a drone-cell it is not impregnated. In the absence of a queen, workers sometimes undertake the business of egg-laying, but their eggs, being unimpregnated, produce only drones, even if laid in worker-cells.

Now it would be just like you to ask whether the queen voluntarily decides what eggs shall or shall not be impregnated, or whether there be something in the nature of the case by which she is mechanically compelled to lay the right sort of egg in the cell. To that question I refuse to give any answer. I must draw the line somewhere. But if in place of that question you will ask one to which I know the answer, I will cheerfully make reply.

Management for the Most Honey.

By which of the following plans do you think the most honey can be obtained in a case where bees in an 8-frame hive swarm about May 30, and the surplus honey commences to come in about June 15, and lasts until about July 15, and then a fall flow from buckwheat commencing about Aug. 1?

1. By allowing them to swarm May 30 and getting a little of the white surplus from both parent colony and the swarm, and building them both up for the fall flow?

2. Or, by not allowing them to swarm, by giving them more room, until June 15, and then practice the Heddon method to get most of the bees with the swarm? With this plan the parent colony does not get strong enough to do much surplus work on the fall flow. NEW YORK.

ANSWER.—The answer to your question depends upon the *proportion* the buckwheat harvest bears to your early harvest, and also upon the number of colonies you have. If you have enough colonies to stock the field, then your better plan is to keep down increase as much as possible. If there is no danger of overstocking, your first will be better if the buckwheat crop is large compared with the earlier crop. The second plan will be better if you expect only half as much from buckwheat as from the early flow. This is only a guess and I will be glad if those who have had experience will set me right if I am wrong.

Getting Increase and Honey.

1. What method would you advise in making nuclei? I want to increase, and I also want honey.

2. Or, would you divide and give an untested queen?

3. Would you divide the strongest colonies or the weakest ones? IOWA.

ANSWERS.—1. The question is just a little like asking how to build a house. Much depends upon circumstances as to the kind of house, etc. So it is with nuclei. It is an easy thing to tell how to start a nucleus, but just the best way depends on circumstances. You say you want to increase and also have honey, which is more of a help than many questioners give. In the first place, you should inform yourself thoroughly by the study of your text-book as to general principles, and then you are less likely to make mistakes. Making the

guess that you do not care for nuclei except to build up into full colonies, you can wait till a colony swarms, then about a week after hiving the swarm divide the old colony into as many nuclei as you can by taking two frames of brood and bees for each, making sure that each nucleus has a good queen-cell in the center of the bees so it will not be chilled. It will be well for you to fasten the bees of each nucleus in its hive for 24 hours by plugging the entrance with green leaves. If you have one or more choice colonies, build them up in advance of others, so that they will first swarm. Draw brood from other colonies to build them up.

2. You can make faster work by buying untested queens, but of course it will cost more. If your untested queens make an improvement in stock, they may be the cheapest in the long run.

3. It will perhaps be best to leave the strong colonies for

honey. So many things have a bearing, however, that it is hard to say just what will be best without knowing all about what you will do.

Spring Dwindling in California.

Did you ever hear of bees having spring dwindling in this part of the country? From what I can learn from the "A B C of Bee-Culture," that is what our bees have. The hives are full of honey and the bees all gone, or nearly. We have had plenty of rain so far this season for this section, but we are overstocked with bees at present. If you know of any remedy, please let me know.

CALIFORNIA.

ANSWER.—There seems to be no remedy except the coming of good weather to allow daily flight.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nehr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, before July 1st:

	1	6	12
Selected, Warranted.....	\$1.00	\$5.00	\$ 9.50
Tested.....	1.50	8.00	15.00
Selected Tested.....	2.00	10 50	
Extra Selected Tested, the best that money can buy..	4.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

A Beginner's Report.

I bought one colony a year ago this winter, and when the time came to put on the super, I put on one with 28 sections, and in June they swarmed and I put on a super and had to take them off and put on more supers. In the fall I took off the honey and sold it for \$19.18, and that gave me the bee-fever, so my wife says, and I bought 22 colonies more, and caught 2 swarms, so that made 26 colonies. The 22 colonies that I bought cost me \$25.15 besides my work, but 7 of them I killed, as I thought they were too light in stores for winter. The 19 I have left are in good shape, I think; I put 7 into the cellar and 12 out-of-doors, with protection on the north and west. The ones in the cellar are in the best shape, hardly any dead; the ones that are out have from half to one pint of dead bees per colony.

My bees are almost all in Langstroth-Simplicity hives, but they are not on straight combs so I can handle them with pleasure. I have bought 10 Danz. hives, and expect to start right if I can learn the trick. I have chosen the Danz. hives to start with for comb honey, and if I have made a mistake I wish some of the veterans would straighten me out on that line. But there is one thing I do not understand about the hive, and that is, Mr. Danz. says if the bees do not build to the bottom-bars to reverse them. I should think if that were done the honey would run out, and the rest of the cells would be upside down.

E. B. PRICHETT.

Warren Co., Iowa, March 19.

Counteracting Honey-Lies.

After reading several items about "Lies About Honey," I began thinking, Is there no remedy? Yes, I think that there is one remedy, and the sooner it is applied the better for all producers of pure honey. It is organization. For the coming season ask the officers of the National Association to act as officers. Make it independent of the present organization for now, at least; if they wish to unite later, all well.

Each member pay his dues according to the number of colonies of bees, spring count. As soon as the season ends, each member should send a report of his crop. This would give each a good estimate of the crop all over the United States, and from each section, and be governed by the same in selling.

The officers should appoint a committee of investigation to look after the welfare of its members.

Each member should put his honey on the market under the seal of the organization, with his own name and address attached. This could be easily done with small stickers on each package.

If any adulterated honey be found on the market under the seal of the organization, the committee will look after the matter. If a member put it on the market, black-list him and expel him from the organization. If not

Tennessee Queens

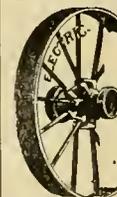

Daughters of Select Imported (Italian, Select long-tongued (Moore's), and Select, Straight 5-band Queens. Bred 3 1/4 miles apart, and mated to select drones. No bees owned within 3, and but few within 5 miles. No disease. 29 years' experience. WARRANTED QUEENS, 75 cents each; TESTED, \$1.50 each. Discount on large orders. 200 tested reared last season ready to-day. Contracts with dealers a specialty. Discount after July 1st. Send for circular.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

a member, deal with the forgery according to law.

Let the business of this organization be known to all dealers and consumers as far as possible, and that they will not let any but pure honey pass under their name without punishment if the guilty can be caught. If need be, a reward could be offered for any adulteration passing under their name, if evidence could be had to convict the guilty.

I think that this would guarantee a pure article to dealer and consumer, and would increase both demand and price, and bring money to the pockets of the producers.

Washington Co., Pa. WM. R. MARTIN.

A Skunk in a Bee-Cellar.

I will tell how I got a skunk out of my beecellar, and I wish to know whether I did right. My cellar is under the dining-room, is 8x10 feet, with one window and a door on the outside on the south. I have 63 colonies—40 colonies on one side (8 hives long and 5 high), and the other 23 colonies across one end.

Well, Sunday morning I went down to sweep the dead bees from the cellar-bottom; it has a cement floor, and I noticed the bees were all stirred up. I thought mice had gotten in. I commenced to sweep the bees up. There was a barrel in one corner; I took hold of it and moved it, and there was Mr. Skunk. I started for the door, but he caught me. My, what a smell! My wife smelled it as soon as I did. I said, "Martha, there is a skunk in the cellar!" and she said, "Yes, and you got it!"

The next thing was to get him out. I could open the door and let him go out, but he would come in again. I could poison him, but he would likely go behind the hives, and I could not get him out without overhauling them. He had made the cellar smell, and I did not want to let him go. I set a steel-trap at the foot of the stairs, and put on some honey for bait, but he was too smart. About 4 o'clock I opened the cellar-door and he came out from behind the hives, but before I could shoot him he went behind the hives again. At 6 o'clock I tried it again, and got him. Do bees hear? I do not know. It did not seem to disturb them. I open the door at night to cool the cellar, and that is how he got in. Now I put on a screen-door also. Did I do right? L. C. GREEN.

St. Francis Co., Ark., March 15.

[Yes, sir, you did just right. The proof of the pudding was in the eating—or the smelling. You got Mr. Skunk, and deserve to be congratulated upon your success. Perhaps the noise of the gun was so much less a disturbance to them than the "loud" perfume of Mr. Skunk, that the bees didn't notice the sound of the shot. Not every bee-keeper can go a-hunting in his cellar.—EDITOR.]

A Home Partnership Bee-Keeping.

My wife and I have kept a few colonies of bees for the last six years with different results—some years we would get little honey, other years a little more, and sometimes we had to feed; but last year being a very hot, dry season here, we were surprised by the quality and quantity of the honey gathered by the bees.

We keep only 5 colonies, and are trying to keep the number down to that, so we go through the hives once a week during the spring-time and cut out queen-cells, besides giving the queen plenty of room to deposit her eggs, by putting a second brood-chamber on top, and by transferring full brood-combs from the lower to the upper chamber, and filling in again with empty combs; we keep this up until the main honey-flow (sweet clover) starts in, then condense again by shaking all bees from upper chamber in front of hive, and put on two supers. Of course we get a good many brood-combs in the upper chamber filled with honey, but it makes fine winter stores. By thus handling them in the spring we get large colonies ready for the main honey-flow, and have very little swarming.

Last year the different flower-blooms and

The Family Friend

An old and true friend that will help you in times of distress. When racked with pain you would give anything for relief. In the hour when the little child, too young to make its wants known, lies suffering, its little face drawn with agony; in the hour when the good wife, worn and tired, needs an arm to lean on; at all such times, when the calling of a doctor means a dangerous delay, besides great suffering and a heavy bill, there is nothing else so good as a bottle of

WATKINS' Vegetable Anodyne Liniment.

We receive numberless letters like these: **SAVED THE CHILDREN.**

CLARA CITY, Minn., June 14, 1901. We had five children sick with diphtheria last winter and carried them all through in one week without any doctor. Watkins' Vegetable Anodyne Liniment should be used at once as soon as any symptoms appear. We mixed two teaspoonfuls of Watkins' Liniment with two of vinegar and one of salt. Gave some of the mixture once an hour, also rubbed the Liniment on outside of neck. OTTO PETER.

HORSES WOULD HAVE DIED.

SHIPSHEWANA, Ind., June 18, 1901. I have used Watkins' Vegetable Anodyne Liniment for nine years and find it the best remedy for colic in horses I ever knew. I saved two horses with it that would have died. Cannot speak highly enough of it. HENRY CATTON.

The best thing made for Cholera Morbus, diarrhea, flux, rheumatism, cuts, cramps, strains, hurns, colic, mumps, sore throat, diphtheria, frosted limbs, etc. For horses and cattle it cures sprains, cuts, scratches, bruises, sweeny, colic, etc. Of course when you read this advertisement you may not feel the need, but the need of it may arise at any moment of the day or night, and then its worth can not be counted in dollars and cents. Order it the next time our agent calls, or if we have no agent in your county, send us your name and address at once, and we will see that you are supplied.

FREE! FREE! FREE!

We send out a beautiful 100 page illustrated Home Doctor and Cook Book absolutely free, and want to place your name on our mailing list. It is the cleverest and most complete thing of its kind ever issued. Write for one to-day.

J.R. Watkins

Wanted a Man. We want one good, open-eyed, young man in each neighborhood who has a little ambition, and an inclination to get on in the world, to write to us. We are in a position to start him in a good paying business of his own. We have lots of young fellows, "hoys" you might call them, who are making a nice thing selling Watkins' Remedies.

The J. R. Watkins Medical Co.
10 Liberty Street,
Winona, Minnesota, U. S. A.

honey-flows succeeded each other almost every 10 days, commencing in March with maple and following with elm, willow, cherry, plum, apple, dandelion, black and honey locust, catalpa, white clover, mother-wort and sweet clover, the bees working all the time.

With all precaution we had 2 colonies swarn, but we put each of them back in their old hive; they stayed and were contented. These 2 colonies must have had poor queens, as they gave us the least honey, so we killed the queens the middle of August and introduced 2 new ones a few days later. We hope they will do well this season.

On May 28 we put two supers on each hive to give them plenty of room, and the bees went right to work in them. By the end of June sweet clover commenced to bloom, hot winds commenced to blow, and we thought that would end the flow, but just the reverse, for on July 22 we took off 184 filled sections; Aug. 21, 186 sections; Sept. 16, 183 sections; and by the end of the season we had taken from hive No. 1 (an 8-frame) 138 sections; Hive No. 2 (an 8-frame), 124 sections; Hive No. 3 (an 8-frame), 70 sections; Hive No. 4 (10-frame Danz.), 192 sections; and Hive No. 5 (10-frame Danz.), 77 sections, making a total of 601 sections. It was as fine white capped honey as was ever produced by bees, and all in 4 by 5 inch sections, divided by fences. Besides, we had about 30 unfinished sections, which we fed back to the bees for winter stores.

As we sell 6 pounds for \$1.00, it was quite an income from 5 colonies. We all like honey, so we have sold a little over half and kept the rest for ourselves and the children.

Hall Co., Nebr., March 12. GUS KOLLS.

Hiving Bees—Swarm-Catcher.

On page 206 is an item by Sarah Griffith on "Hiving Bees." For ten years I have not cut off a limb on which a swarm clustered. I never think of carrying the hive to where the bees have clustered—I always take the bees to the hive. I never try to put my bees on top of the hive; I have a better way. I have my hives all ready on the stand, and when a swarm comes out I lift the hive off and set it on the ground by the stand. I have a nice platform about 3 feet square that I lay down in front of the hive, that is just even with the entrance, so the bees can crawl right in when they are shaken out of the catcher. I always have a pail of water with a little salt dropped in and a dust-brush which I dip in the water and sprinkle the bees slightly in the catcher, then shake some of the bees out on the platform, but not too close to the entrance; sprinkle them a little, and with a stick tap on the side of the hive, and it would surprise you to see them rush for the entrance. When they get well started I can shake the others out of the catcher (not too close), or I can lay the catcher down and the bees will all leave and go to the hive, and the job is done.

I will now give a description of my swarm-catcher, which, I think, is a good one for many reasons.

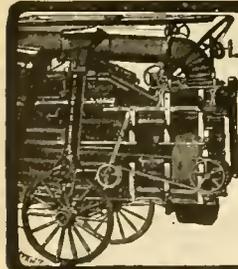

It is 12x16 inches. Take thin boards, four of them. Take the short end of an iron square, which is 1 1/2 inches wide, with this make lines 1 1/2 inches apart each way on all four of the boards. Then with a 1/2-inch bit bore a hole just where each of the lines cross, except the center of two of the boards, there bore a 3/4 inch hole, and make one hole square, leaving the other round. Then take another board 3/4 or 3/8 inch thick, big enough for a bottom (no holes in this). Now you are ready to nail the box; be sure to get the 3/4 holes opposite each other; these are for the pole or handle, which is made square to fit the square hole and go through the box, the end made round to fit the round hole on the opposite side from the square. There must be a shoulder on the pole where made square. When the pole is nicely fitted mark it at the round end close to the box, then pull it out. Bore a gimlet hole through the pole for a pin to hold the box in place, and the catcher is complete. I have four of these, with handles of different lengths. I also have a number of light poles of different lengths, with hooks on the end to shake the bees from the limbs. I have set this box up where the swarm had

Please Mention the Bee Journal when writing Advertisers *****

just begun to cluster, and every one of the bees would go into it. I have held it up where the bees were thick and ready to cluster (on a limb), and taken in the box. When I go to take down a cluster I shake them gently until the most of them are off the limb on and in the box, then I hold the box out and clear from the place of clustering, and with a pole and hook shake the limb to keep the bees from settling. In a few minutes the bees are all in the box, then I can carry them anywhere or set them down, if another swarm comes out before this one is hived. I have had all my catchers full more than once. I have found bees and carried them $\frac{1}{4}$ of a mile on my shoulder, all snug in this catcher. It is the best catcher I have ever tried, the bees take to it kindly, and are easily carried to where you want them. A slight jar on the handle, or pole, and the bees are on the platform ready for the hive.
Platt Co., Ill. J. W. C. GRAY.

Foul Brood—Bacteria and Their Relation to Diseases.

We speak of bacteria as causing diseases, then, again, as preventing diseases, and sometimes as curing diseases. These opposite and apparently irreconcilable properties in objects that can only be seen in a microscope, have caused the bacteria to be looked upon as mythical bodies by many intelligent persons who have not made them a special study. In explanation of the ways in which bacteria act, I propose adopting a method frequently used by lawyers in court, *i. e.*, of stating a case, and I present the case of the boy learning to smoke. If a boy takes five or six whiffs of smoke from a tobacco-pipe, he will in three or four minutes turn pale and have to lie down. He will be a very sick boy for half an hour, when he will begin to recover, and in an hour he will be nearly well again. The nicotine poison in the tobacco acts quickly, and only for a short time. If the boy had taken one whiff the first day, two the second, and three the third, he could have gone on for a month, and, without being sick, have made himself an educated smoker—likely enough proud of his accomplishment. Men and women have educated themselves to take with impunity a dose of opium or morphine sufficient to kill a dozen persons, and men have been known to take, without any immediate ill effects, a quantity of arsenic sufficient to kill a score of men. They commenced by taking small quantities.

We will now suppose that there are bacteria which secrete nicotine poison as their weapon in the battle of life. The poisons secreted by the bacteria are very similar to the poisons formed in the leaves and flowers of plants, and the bark of trees, to protect them from their enemies, so that the nicotine bacteria are not impossible bacteria—they may exist. If the smoking boy, and another boy not educated to smoke, should be infected with these bacteria at the same time, no effects would be noticeable for several days, the period of incubation—say ten days—when the bacteria would begin producing nicotine. The smoking boy would not be affected by it, while the other boy would be killed very quickly—probably in an hour. Now, if we had taken this boy before he died, taken him on the day he was infected, or the day after, and had given him a whiff of tobacco-smoke, the next day two, and so on, until the bacteria commenced secreting nicotine, he might have been sick from the larger dose, but he would have recovered to find himself as accomplished a smoker as the other boy, the bacteria having completed his education.

We would have saved the boy precisely in the same way as a person bitten by a rabid dog is saved in the Pasteur Institution, and the smoking boy's protection from the nicotine bacteria shows how immunity from small-pox, by vaccination, may be produced at will.

The Carrier Says So....
Purchasers of our Rural Mail Box often write that they are "more than satisfied;" many say "it is a dandy;" others "a beauty;" and more than one has called it "a dream." Some say "it will last as long as I will want a box," or "will last 50 years," etc., but nearly all wind up with, "Our carrier says it is the best on the route."

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get grand bee-book for a very little money or work.

"What Happened to Ted"

BY ISABELLE HORTON.
This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 $\frac{3}{4}$ inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,
227 EAST OHIO STREET, CHICAGO, ILL.

200 Nuclei and Full Colonies For Sale.

We have arranged with a good bee-keeper located in Kankakee Co., Ill., (within 12 miles of Kankakee), to fill orders for Nuclei and Full Colonies of Bees. All are to be first-class, and most of the bees show Italian markings. The queens in the Nuclei will be Italian, of this year's rearing. Full colonies can be shipped now; the Nuclei beginning May 1. We can book your orders for Nuclei now—first come first served.

The Nuclei are 3-frame Langstroth, in light shipping-boxes. Prices: 1 for \$3.00; 5 at \$2.75 each.

Full colonies in 8-frame Langstroth hives (no super.) Prices: 1 for \$6.00; 5 or more at \$5.50 each.

All are f.o.b. shipping-point, and will be sent by express, a postal card notice being mailed to each purchaser a day or two before shipping the bees.

Send all orders to **GEORGE W. YORK & CO.,**
144 & 146 Erie Street, CHICAGO, ILL.

It should be observed that it makes no difference whether we use the poisons of the bacteria or the bacteria themselves, weakened by growing in a cow or by overheating, or by merely drying—as Pasteur did the rabid dogs' virus to protect against the disease—the result is the same. It is the poisons of the bacteria that cause and protect against the disease.

Our control over diseases, however, is very much limited by the great, and, I might say, insurmountable difficulties that have to be overcome in isolating the bacteria, and cultivating them so as to obtain their poison. The poisons can, as we have seen, protect against the acute infectious diseases caused by the bacteria, but when the disease has set in, the poison can not be used as a remedial agent in the disease. Anti-toxins are then used in a few diseases with some advantage.

Bacteria, although vegetable organisms, live like bees in colonies, and the individuals act in the interest of the colony. It is numbers that make them formidable. If a bee stings it dies, and if a bacterium secretes poison it dies in secreting it. Both lose their lives in defense of the colony. A bacterium can multiply, and a bee sometimes tries to multiply, but fails. The bacteria grow and multiply for some time before they commence secreting poison, and this explains the nearly uniform periods of incubation connected with most infectious diseases. The incubation period of hydrophobia varies to a great extent.

The nicotine bacteria did not grow in the smoking boy. Bacteria will not grow unless the surroundings are favorable. Parasitic fungi will not grow in strong and healthy plants, but will readily in weak plants, and the tubercle bacilli will not grow in strong animals, but will readily in the weak. When the bacteria are unable to poison and paralyze

the animal cells, the white blood-corpuscles and tissue-cells (Metschnikoff's Phagocytes) eat them, and when the tissue-cells become resistant to the bacteria-poison they quickly dispose of the bacteria. We find, therefore, that the attendants of the sick in small-pox, consumption, and fever hospitals, are more secure from the diseases than if less exposed to them. The exposure strengthens the resistance and preserves the immunity of the disease.

The animal cells know on the first touch of the bacteria whether they are dangerous or not, as one bee knows on the touch of another whether it is from a queenless colony or not. The dangerous bacteria are of small size, and may be known to some extent in that way. If we inoculate a person with small-pox virus, and at the same time vaccinate with vaccine virus, the vaccine virus will commence growing four or five days sooner than the small-pox virus, and will protect wholly or partially from the small-pox virus. This is the same kind of protection by which we proposed to save the boy, and the same that Pasteur used in hydrophobia. It is simply inducing a mild form of the disease during the incubation period to protect against the fatal form at the end of it. The animal cells offer less resistance to the growth of the bacteria producing the milder poison.

I have stated as briefly as possible the action of bacteria in causing and protecting against diseases, to show that we can not make use of the bacteria or their poison in curing or preventing foul brood. That all parasitic bacteria, however, are continually increasing the resistance of animals to bacterial diseases, is evident—the acquired resistance is transmitted and becomes hereditary. Also, to show that germicide remedies in the treatment of foul brood endeavor to

Watkins Remedies—Our columns contain the advertisement of the J. R. Watkins Medical Company, a long established and favorably-known medical house of Winona, Minn. This institution takes its name from its President, J. R. Watkins, who established the business in a small way about 35 years ago. It was incorporated in 1894. It has therefore had a long and prosperous career under the same management, who was the discoverer and compounder of all its remedies. The Watkins group of remedies have become household words in many parts of the country. In some sections the Watkins wagons have been traversing the country year after year, calling upon regular patrons who would not think of being without the Watkins remedies and extracts. People have no hesitancy in patronizing the Watkins wagons. The drivers are specially commissioned hounded rep-

J.R. Watkins.

representatives of the Watkins house. Elsewhere the mail order, selling direct from the laboratories to the consumer, has been employed. By these means an immense business has been built up, and this "old reliable" boasts the largest and best equipped house of its kind in the world.

The 1902 Watkins Almanac, Home Doctor and Cook-Book combined into one, is a most valuable book for preservation in any home. It is replete in discussions of ailments, remedies, recipes, etc. It is much larger for this year than ever before, and embraces many new and valuable features. Nothing untried or illy considered finds a place in it. Many of our readers are long-time patrons of the house. Such as are not should at least write for the above book, which is sent free, and correspond freely for anything desired in its line. Correspondence should be addressed to The J. R. Watkins Medical Co., 10 Liberty St., Winona, Minn. Please mention the American Bee Journal when writing.

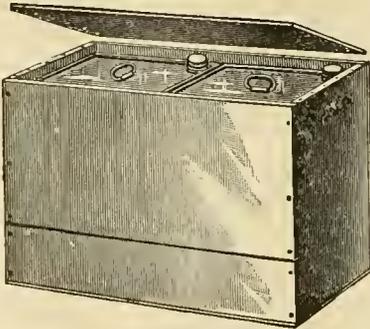

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 7½ cents per pound; 4 cans or more, 7 cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

make the surrounding conditions as unfavorable to the growth of bacteria as possible; and if this principle is kept in view the details in carrying it out will be easily understood as we proceed with the subject.

The condition must be exceedingly favorable to the growth of bacteria to enable them to destroy a colony of bees. The bees can protect their colony against bacteria to a greater extent than is generally supposed. No one has found foul brood in bees located in chimneys or garrets, or, in fact, in any home not purposely made for them. If we continue to favor the growth of bacteria in the hive so as to give the bacteria an advantage over the bees in the "struggle of life," and persist in cultivating the bacteria, and not the bees, we will, most assuredly, never succeed with disinfectants and germicides in getting rid of the disease caused by the favored bacteria.—A. W. SMYTH, in the Irish Bee Journal.

The foregoing interesting article will, no doubt, help to clear up matters for many readers. The implied statement, however, that foul brood is never found except in man-made hives, will hardly be accepted by many who think that one great difficulty in the way of getting rid of foul brood lies in the fact that it is impossible to control it in wild colonies in trees.

THE SPRAYING SEASON.—Time moves so rapidly that trees and vines will be in blossom and setting their fruit again almost before we are aware of it. This means that the spraying season will be upon us shortly and that now is the best time to decide what means shall be employed to save the berries, fruit, etc., the coming season. Nobody stops to consider the advisability of spraying in these times. It is not only now thought to be advisable but absolutely necessary to successful fruit-culture. This, then, leaves the small fruit-grower, orchardist and others merely to the selection of the particular spraying outfit which he shall use. In this connection we wish to direct the attention of our readers to the line of spraying goods manufactured and regularly advertised in these columns by the Deming Co., of Salem, Ohio. In their bucket, knapsack, barrel and power sprayers they cover completely the entire line, and the Deming goods leave nothing to be desired as to quality, general utility, convenience and thorough and effective work. Their "Simplex," "Century" and "Peerless" barrel sprayers with special mechanical agitators and all brass working parts, are ideal general-purpose outfits. The Deming nozzles and spraying fixtures are of equal superiority. Write them for their illustrated catalog and Spraying Calendar, free. Send 10 cents in postage stamps for a copy of their valuable and comprehensive little book, "Spraying for a Profit." Please mention the American Bee Journal when writing them.

Went Like Hotcakes

A Nebraska customer when ordering a new supply of our fine Alfalfa honey in 60-pound cans, said: "The last I got went like hotcakes." So it does.

More people might do well they would order this honey, or basswood, and sell it. It not only goes off "like hotcakes," but it is mighty good on hot cakes.

See honey-offers on page 234.

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

THE SURE HATCH INCUBATOR.—While hot-water incubators are very generally admitted to be superior to the hot-air kind, a number of manufacturers, with a desire to cater to every opinion and catch their trade either "coming or going," continue to make both kinds. Usually they claim that in the hot-water make they have something superior to anything on the market, and in the same breath weakly insist that their hot air machines are "just as good." There is no such equivocation about our advertising patron, the Sure Hatch Incubator Co., of Clay Center, Neb. They direct their energies toward making the best incubator possible and always on the hot-water principle. Their straightforward course seems to have brought most gratifying results. Their good name has spread to all parts of the country. Wherever one of their incubators or brooders is introduced and put to the test, multiplied sales follow in a reasonable time. It is the proud boast of the Company that their most effective advertising has always been the work of their machines. The latest catalog of the Sure Hatch Incubator Co. is a valuable work on poultry-raising. Any of our readers interested should write for it, whether they contemplate buying an incubator or not. Look up their advertisement elsewhere in our columns and direct to Clay Center, Neb., mentioning the American Bee Journal.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Apr. 7.—Choice white comb honey produced from basswood and white clover is scarce, and brings 15c; all other kinds of white is in over supply, and the market is weak at 12@13c; light amber grades, 10@11c; dark, 8@9c; candied and mixed lots, 7@8c. Extracted weak, with white ranging from 5½@6¼c; amber and dark, 5@5½c. Beeswax selling at 32 cents, and in good demand. **R. A. BURNETT & Co.**

CINCINNATI, March 6.—The market in extracted honey is good with prices lower. Amber, for manufacturing purposes, brings from 5½@6¼c; better grades from 7@8c. Fancy comb honey sells at 16c; lower grades hard to sell at any price. Beeswax strong at 27@30c. **THE FRED W. MUTH Co.**

ALBANY, N. Y., Feb. 21.—Our market has not been so empty of comb honey in a long time. Fancy white comb, 15@16c; No. 1, 15c; dark and buckwheat, 13@14c. Extracted, buckwheat, 6c. Beeswax, 30c. **H. R. WRIGHT.**

BOSTON, March 20.—The demand for comb honey remains good. Market ranges as follows: Fancy white, in cartons, 15@16c; A No. 1, 14@15c; No. 1, 13@14c; honey in glass-front cases about one cent less. Extracted, California light amber, 7@7½c; Florida honey, in barrels, 6@6½c. **BLAKE, SCOTT & LEE.**

Detroit, Apr. 8.—Fancy white comb honey, 15c; No. 1, 13@14c; dark and amber, 11@12c. Extracted, white, 6½@7c; dark and amber, 5@6c. Beeswax, 29@30c. **M. H. HUNT & Son.**

CINCINNATI, Apr. 11.—Stock of comb honey here is larger than it ought to be at this time of the year, and this is why it is offered for very low figures. Water-white is sold at 14@14½c and hard to obtain; for extra fancy, 15c.

Extracted finds a steady sale, and amber is sold in barrel lots for 5@5½c; water-white alfalfa sells from 6@6½c, and white clover brings from 6½@7c. Beeswax scarce at 30c. **C. H. W. WEBER.**

NEW YORK, Apr. 7.—Comb honey, last year's crop, practically cleaned up, but as we wrote a little while ago we had received new crop from Cuba, and are now receiving new crop from the South. Demand is fair at 14c for fancy white, 13c for No. 1, 12c for No. 2, and 10@11c for amber.

Extracted: The market is decidedly dull. Very little demand, with large stocks on hand, some of which no doubt will have to be carried over, and indications point to a further decline in prices. We quote: White, 6c; light amber, 5½c; amber, 5c; Southern, 5½@5¾c per gallon, according to quality. Even these prices are shaded in car lots. Beeswax, scarce and firm at 29@30c. **HILDRETH & SEGLKEN.**

BUFFALO, March 23.—Buffalo is very quiet on honey, except very low grades at very low prices. We quote extra fancy, 4c; No. 1, 12@13c; other grades, 8@10c. Extracted, 5@6c. Beeswax scarce; fancy, 28@30c; dark, 22@25c. **BARTER & Co.**

SAN FRANCISCO, March 12.—White comb, 11@12½ cents; amber, 8@10c; dark, 6@7 cents. Extracted, white, 5½@—; light amber, 4½@5c; amber, 4@—; Beeswax, good to choice, light, 26@28c; dark, 24@25c.

While spot stocks are of rather light volume, holders show more inclination to unload than they did a month ago. Although quotable values are without marked change, concessions are granted to buyers which would not have been thought of at the beginning of the year. A large proportion of the honey now offering is comb of medium grade.

WANTED. EXTRACTED HONEY—either large or small lots; parties having same to offer, send samples, and best prices delivered at Cincinnati, Ohio. We pay cash on delivery. **THE FRED W. MUTH Co.,** 1041½ Front and Walnut Sts., CINCINNATI, O. Please mention Bee Journal when writing

MEDICAN FALLS, MAINE, Feb. 28, 1902.

THE A. I. ROOT COMPANY, Medina, Ohio.

GENTLEMEN:—I am VERY, VERY pleased that you are willing I should recommend the Danz. hive. I have had a great many inquiries regarding it, and have not felt at liberty to recommend it over our regular hives. At first I was prejudiced against it, but the sales have increased without recommendations, and wherever I have sold they have bought again and praised the hive with extravagant claims, and I am forced to the conclusion that it is the BEST COMB-HONEY HIVE on the market. J. B. MASON, Manager North-eastern Branch The A. I. Root Co.

The above unsolicited testimonial speaks for itself.

M. H. Mendleson, of California, has just ordered 700 Danzenbaker supers. Sales are doubling every year. Still the demand for honey in Danz. sections is greater than the supply. If you are wise you will raise comb honey in Danz. hives.

Know What Your Dealer Pays

THIS BOOK CONTAINS
70,000 PRICES
17,000 PICTURES
1,000 PAGES

This book tells pretty nearly what your dealer pays for everything. It quotes wholesale prices on 70,000 articles, and shows pictures of 17,000 of them. It includes practically everything that anybody uses, wears or eats; and its prices are the lowest ever quoted. It will save the average family at least \$100 per year--some \$500. Two million people send for this book yearly as a buying guide, and we want you to have one too.

For 30 Years we have been selling merchandise by mail at about what dealers pay. Ours is the original catalogue business, and the greatest mail order house in the world. This enormous business has been gained and held by underselling everybody, treating customers fairly, and doing as we agree.

Two Million People are now numbered among our customers. We carry for them a stock valued at \$2,500,000. We employ 2,000 clerks to fill their orders. It requires 100 typewriters to write our letters to them.

You Need This Book because you can rely on it. Other catalogues are offered you, but this one is best. Our house is the oldest and largest, and our prices are always the lowest. Our guarantee is the fairest, and our record of a quarter century assures you of fair dealing. We keep our customers.

We Guarantee satisfaction and safe delivery. Every article in our catalogue is described exactly as it is. Not the slightest exaggeration is ever permitted. But if anything you get doesn't suit you in quality, or price, or fit, send it back and we will replace it. Or we will send your money back, and pay transportation both ways. We consider no expense or effort too great to avoid having one dissatisfied customer.

Two Thousand Stores in One

Two thousand average dealers together will not buy so much in a year as we. The makers who sell to us have no traveling expense, no credit risk, no losses, no salesmen to pay. They save the whole cost of selling the same goods to 2,000 separate stores, scattered everywhere. The fiercest competition in America centers in the effort to get our trade. The prices we pay are never

much above cost; and goods that we cannot buy low enough are made in factories of our own. Is it any wonder that we can sell for about what common dealers pay?

We get along with a fraction of the profit charged by stores. We have no salesmen--no selling expense save our catalogue. A dealer must make several times as much on each article to pay his expenses and live. Our expense is but a small percentage when spread over sales that amount to millions of dollars annually.

We simply combine the buying and selling of two thousand average stores. We save the wasteful methods that cost more than the merchandise, and we give the saving to you. This is the modern method of business, and the buying of the 20th century will be done more and more by mail. In this way we are now saving our customers from four to five million dollars annually. You will become one of those customers when you see this book.

Send Only 15 Cents If you want our catalogue, fill out carefully the slip to the left of this, and mail it to us today, enclosing 15 cents. This catalogue which we offer you costs us about 70 cents to print, even in million lots. The postage on it costs us 22 cents more. We ask you to send us but 15 cents (less than half the postage alone) just to show that you do not send from mere curiosity.

This book will save any average family at least \$100 per year. If you don't find that it will save you at least a hundred times what it costs you, simply write us, and we will cheerfully send you 15 cents back.

Please send today, before you forget it.

Cut this slip out and send it with 15 cents in stamps *Today*.

* Editorial. *

Quoting the Honey Market.—An editorial on page 195 has called forth the following:

EDITOR AMERICAN BEE JOURNAL.—

Dear Sir:—Referring to "Quoting the Honey Market"—editorial page, 27th inst.—"It is better to quote a cent lower rather than a cent above," etc. Our Great Teacher said that our conversation should be yea, yea, and nay, nay. "The truth is mighty, and will prevail," although all the commission men come to your rescue. Don't make a fight on that.

Yours truly,

C. C. PARSONS.

The fact that a lower quotation than the market leads to less trouble than a higher quotation is by no means an argument that either one is as good as a correct quotation; and at this end of the line there is implicit confidence that it is the wise thing to obey the precepts of the Great Teacher. So it has constantly been the effort to tell "the truth, the whole truth, and nothing but the truth."

One of those things that no one with an editorial experience will be likely to label as belonging in the list of things so easy to be done that they do themselves, is the matter of pleasing everybody, and especially is this true with regard to the matter of market quotations. There are those that believe it would be better to have no market quotations whatever; but it is not likely that this number is very large; and a conviction that by far the greater number of bee-keepers desire to have such quotations continued has been the warrant for their continuance.

Again, the opinion has been expressed that it would be better to give the price of comb honey and omit that of extracted; and it is possible that the exact opposite of this opinion may be entertained.

Neither does the foregoing complete the list of dissenting views, as witness the following:

MR. EDITOR:—Why do you print in the honey and beeswax market quotations the name of one firm in each city? If it is meant as an advertisement of that firm, and you get pay for that advertising, I have nothing to say. But I do not see the sense in taking up room with the names otherwise. It hardly seems the fair thing to others in the same place equally trustworthy, even if they do not do so large a business; and if it is a matter of free favor, should you not favor the weak rather than the strong? I have looked through my daily, which has one page pretty well filled with market quotations of nearly every commodity under the sun, and I do not find the name given of the man who sells hides, or of the one who sells butter, or onions, or anything else. Of course, you

ought to know your own business, but I thought it would do no harm to tell you how things look to others. HONEY-PRODUCER.

Not entirely in agreement with this is the view that a full list of dealers or commission men should be given.

Does it not appear pretty clear that these diverging views can not easily be all carried out at the same time? There is a large capacity for the reception of advice at this office, and further installments of that article will be cheerfully received. But please don't insist on it that we must follow all that is supplied.

A little later we expect to publish the views of the commission men on the subject of quoting the honey market. Then there'll be some interesting reading for "Rip Van Winkle," as well as others.

Traite Pratique Pour L'Elevage De Reines (Practical Treatise on Queen-Rearing), is the title of a little work of 90 pages just issued by Giraud-Pabou & Fils, in France. It gives the latest methods in use in this country, for which it seems desirous to give full credit (unless it be in the case of Pridgen's nursery and West's cell-protector), and gives especial credit to "Doolittle's magnificent work"—"Scientific Queen-Rearing."

Tarred Paper as a Winter Covering.—After another winter's trial of black tarred paper tacked or tied about hives. Arthur C. Miller says in the American Bee-Keeper:

In the matter of warmth I find that the wrapping of tarred paper about single-walled hives continues to work most satisfactorily. During the past winter I have had seven colonies so protected, and they are now in prime condition. The black surface of the paper absorbs the sun's rays, and the hives are warmed through and through, and yet the bees do not seem to fly abnormally or in unseasonable weather.

The Proper Naming of Swarms is a matter not without its difficulties. Take just the three terms—prime swarm, first swarm, and second swarm. Very likely nine out of ten will say, "A prime swarm is just the same as a first swarm—the swarm that issues first in the season from any given colony; and a second swarm is the next one that issues after the prime or first swarm."

That looks simple and easy enough, and it would be so if nothing but the time of issuing were ever taken into consideration. But the same man who gave the foregoing answer will say, "A first swarm has a laying queen, and a second swarm has a virgin." Then comes a colony which by some means has lost its laying queen, and the first time it sends out a

swarm there is a virgin queen with the swarm. According to the first statement it is a first swarm, according to the second statement it is a second swarm. Dadant's "Langstroth" speaks of a prime or primary swarm with a young or virgin queen. Root's "A B C of Bee-Culture" says that a swarm with a virgin queen is an after-swarm.

The only object of the present paragraphs is to call attention to the confusion of terms, in the hope that in some way the matter may be straightened out.

Black and White Hives.—At the Chicago convention Secretary Moore said that to satisfy his desires a hive should be painted at least twice a year—white at the coming of hot weather in summer, so as to keep the hive cool, and black when cold weather comes in the fall so as to attract the rays of the sun. He has held that opinion for some time, and no one has objected to the desirability of such a thing, but it did not seem an easy thing to accomplish. Now that Arthur C. Miller seems to have made a success of using black tarred paper as a winter wrapping for hives, there seems nothing in the way of his at least trying the plan of white and black.

Sugar for Bees.—An interesting discussion as to the right kind of sugar for bees is published in Gleanings in Bee-Culture, in which W. K. Morrison contends that beet-sugar is unsuitable for bees, and Melvin R. Gilmore contends that there is no difference whatever between refined cane-sugar and refined beet-sugar. It is somewhat hard to decide which has the better of the argument. So long as all agree that cane is at least as good as beet-sugar, it might seem the part of wisdom to prefer the cane. Unfortunately for the possibility of carrying that out, we are told that by far the larger portion of sugar on the market is beet, and no one can tell one kind from the other.

Excluders Under Section-Supers.—Some say they are not needed, while others say that without them the queen will go up and lay in the sections. This difference of opinion may result from difference in conditions. With plenty of room below there is little inducement for the queen to go above to lay. Yet with plenty of room below, if there is no drone-comb in the lower story, and room for it above, the workers will be likely to build drone-comb above, and the queen will be likely to use it. If the sections are filled with foundation, so that no drone-comb can be built above, the cases will probably be rare in which the queen will go above. If small starters are used in sections, with no drone-comb below, it will be a safe thing to use a queen-excluder.

Convention Proceedings.

The Chicago Convention.

Report of the Semi-Annual Convention of the Chicago Bee-Keepers' Association, Held Dec. 5, 1901.

BY A SHORTHAND REPORTER.

(Continued from page 246.)

DEPTH OF FRAMES FOR WINTERING.

"Do bees winter better on frames deeper than the Langstroth frames?"

Pres. York—How many think that bees winter better on frames deeper than the Langstroth? Five think so, and I suppose the rest don't think so, or perhaps don't think at all.

Dr. Miller—I haven't a preference.

Mr. Dadant—I prefer deeper frames than the Langstroth because there is more honey over the cluster. They tell us that the bees can work as well back as up. They can't have it warm enough. I have seen bees starved to death many a time with honey on the side. I don't think anybody ever saw bees starve to death, or freeze to death, with honey above them. I suppose others, as well as I, have seen the bees starve to death with honey just a little over on the side.

Pres. York—It often is too cold for bees to move sidewise in the hive, but the heat going up, they can go up.

Mr. Baldrige—If you have two sets of six-inch or shallow frames, you have the same as a top hive with twelve-inch frames. In fact, you have a better hive for wintering, because there is a space between the two sets that will enable them to pass; but if in the cellar, it makes no difference how shallow, they will reach the honey if it is in the hive, if you keep it as warm as I keep mine, 40 or 50 degrees.

Mr. Riker—My experience is that the best wintering is in the Langstroth frame. I suppose Mr. Dadant's frames are a little deeper than the Langstroth.

Mr. Dadant—A little over two inches deeper.

Mr. Riker—But with the Langstroth frame properly filled with honey, it will take any colony of bees through the winter, properly protected. I put 100 colonies in proper condition, and all will come out unless they become queenless, not on account of the frames not being right depth.

RACE OF BEES FOR COMB HONEY.

"What race of bees would you recommend for comb-honey producers?"

Pres. York—How many would recommend the Italian bees? Fourteen.

Pres. York—How many would recommend Carniolan bees?

A Member—I don't know anything about them.

Pres. York—How many would recommend black bees for comb honey? One.

LONGEVITY OF BEES.

"What is the cause of longer or shorter lives of worker-bees?"

Dr. Miller—Work.

Mr. Dadant—Outdoor work.

Mr. Riker—I would think it was the proper manner that the queen was reared. I have had a little experience in that line. Some queens are reared according to Nature. I never have known queens reared that way but what would produce good, long-lived bees. I have known queens reared otherwise than in accordance with Nature that would live 20, 30, 60 days; the result was, it took the queen all her time, that is, the colony wouldn't increase. The bees would die as fast as she would lay eggs to produce bees, where, on the other hand, bees would be three or four generations in one hive.

Mr. Dadant—What do you mean by three or four generations?

Mr. Riker—Three or four sets of bees—three or four months. The queen will lay eggs for three or four months and all those bees would be retained in the hive. I have had queens that would produce bees that would live from the first of September until the first of June—good, strong colonies without the queen in that hive.

Mr. Dadant—Suppose you took those first bees on the first

of May instead of September, how long would they live? Suppose you introduced a queen of another color, how long would those bees live?

Mr. Riker—The first of April I have taken queens from bees, and the first of December I had good colonies yet, almost as strong. Same color. Remove the queen.

Mr. Dadant—Those bees didn't go out to the field. If you put another queen in, that's the way to test that. Take black bees.

Mr. Riker—The best way to test them is to remove them entirely.

Mr. Dadant—Those bees will not go out, because they are discouraged, and they will sit in the hive. Those same bees, if they have a live queen, in less than three months will all disappear. Has any one else ever tried changing from blacks to Italians, and from Italians to blacks?

Three voted.

Mr. Dadant—How long was it before all the bees had disappeared?

Mr. Riker—Well, with me, I have tested it that way. I have tested it by taking the queen from the colony. I have tested it by taking in the fall and putting in again in the spring. That seems to me to be about the fairest way to test the life of the worker-bee. I have taken other queens and in three months from the time I have removed the queen from the hive the old bees would be gone. Those are queens that would rear bees that are short-lived. Take a long-lived queen, and she rears long-lived bees. They always have a good, strong colony. I have never known it to miss. But take the other queens, that rear bees that are short-lived, and you always get a weak lot—invariably they will be weak. One queen need not be any more prolific than the other, but the long-lived bees will be the stronger.

COMB HONEY BY THE CASE OR POUND—WHICH?

"Should comb honey be sold wholesale by the case or by the pound?"

Mr. Burnett—I would like to have an expression from some one else first, but I certainly have bought and sold some honey in the last 25 years, and I have yet to buy the first package by the case; so that answers a multitude of questions, perhaps, on that side. I never could understand how, where I had to dispose of these goods again in ordinary methods that are now in vogue, of exchanging merchandise for money, the question of both being altogether obsolete with us; but I can understand that where a party has produced some honey, and for so many pieces of honey can exchange it for what he wants in some other merchandise—and perhaps in that case, where both parties know exactly what they are doing, every piece of comb being visible to the purchaser, that a fair understanding can be had; but where honey is to be handled in any quantity, and where we must send to buyers who cannot examine the goods until it reaches them, we must know, it seems to me, what the weight of the merchandise is. There is no way of satisfying all parties concerned like records, and if we have those records—the weights—the number of sections in a package—it is difficult for a misunderstanding to arise from that standpoint. But, if we send a package of honey of so many cases, we don't know the weight of that package, either gross, tare or net, it is liable to disappoint the buyer. For instance, it contains 24 sections, his understanding having been that 24 sections meant 24 pounds. As a matter of fact, it may weigh 15, 16 or 20 pounds, or it may weigh 25 or 28. I am at a loss to understand, really, why there should have been as much business done as there seems to have been done in the last two or three years in selling honey by the case, unweighed. Of course, we have found that parties have bought it that way and have been satisfied, and others have bought it that way and are not satisfied.

Mr. Dunn—Isn't it optional with the merchants of South Water street to sell by the case if they want to sell by the case? There is no question that honey has been sold by the case there; that can't be denied.

Mr. Burnett—We never have sold it.

Mr. Dunn—Then you haven't been using the same concessions other men have been using.

Dr. Miller—I know that Mr. Burnett has sold hundreds and hundreds of cases by the case. Of course he took the weight of it!

Mr. Dunn—Is there one house that controls this market, that can make or break it? I have sold honey two cents a pound higher than I could find anywhere on the market, and I want to say that the quotations in the bee-papers are not always correct. They are behind the times generally two or three weeks, and that's not right to the men that deal in honey.

Mr. Horstmann—I believe honey should be sold by the pound. I don't believe there is any fair way except by the pound. There are a great many different sizes of sections. As to the commission man, I don't care how he disposes of it—by the case or pound—but I think in order to be fair all around, we must sell by the pound when we sell it wholesale.

Pres. York—That's the question.

Mr. Moore—In my experience I have seen sections weighing 10 ounces, and some weighing 20 ounces. As long as the variation is a possible one ounce, which means considerable on a case of 24 sections, it is too far off to sell honey by the case in a general way.

Pres. York—How many are there who sell comb honey through the dealers? Nine. Referring to the market quotations, I rely upon Mr. Burnett to keep me posted for the Chicago market. Mr. Dunn has criticised the quotations published in the American Bee Journal. I want to refer the matter to Mr. Burnett to explain to us whether it is necessary to correct the quotations every day or two, and whether we can rely upon his quotations.

Mr. Dunn—I notice that those quotations are generally two, three and four weeks behind. That's not a fair quotation.

Pres. York—What do you mean by "behind"?

Mr. Dunn—In date. The market 20 days ago is no criterion today. I claim that reports ought to be prompt and up to the publication. We should not have the reports late. Now, then, those reports are what govern the whole country. We find reports from New York three weeks late, and four weeks late, and from Cincinnati. I claim they should as nearly as possible be up to date of the publication.

Pres. York—Do you mean we ought to change the date of them, or change the figures?

Mr. Dunn—No, sir, I want a correct report, actual, as it is. I don't think, sir, with all due respect, that Mr. Burnett should have the say to fix the market, or any other commission merchant. I think it the duty of the editor to go along the street and find out what honey is selling for. He should not depend on one man; there are other men selling just as well as Mr. Burnett. I told you I am selling two cents higher than others.

Pres. York—Now, Mr. Burnett, it is "up to you," as they say.

Mr. Burnett—I wish Mr. Dunn would tell us to whom he sells honey so we can get advantage of the two cents. I didn't know that Mr. York relied solely upon me as to the quotations. I think in a sense he meant to say that he has quotations from me, and expects to get them whenever there is a change in the market, and that is our purpose. As soon as there is any change in price we send in a quotation, and, as a matter of fact, honey has not changed in price here in the last 60 days, and there is practically no necessity for a repetition of those figures. So far as the question of controlling the market is concerned, I don't think many people here, who have any experience, have the idea that I, or any two or three, control the market price of honey. Of course, I have had beekeepers come in here who sell their honey in Chicago, or as much of it as they can, and sometimes leave the balance with me or somebody else to sell, and they say, "Here, now; why don't you put up that price two cents a pound? You can do it; and if you can do it that helps all of us; we can all get a higher price. If you put it up then we can sell." Now, I took a little pains to find out what the producers of honey in Cook County, who asked me to do that thing, did with their honey. Of course, we know that the majority of the trade of this city, that buy in any of the honey, before they buy they find out what can be done on the general market. I asked many if they knew so and so? "Yes." Have you ever bought any honey of him? "Yes, a little; I bought some a while ago, and he came in the other day and wanted to sell some more." What price did he ask? "He offered to sell a cent less than your price." Of course, I am willing to do my share, as I see it, for a community as a whole, but I don't want to be deluded to putting up a price that is really a fictitious price, and have them go around and say, "You can't buy it on South Water Street. Here is the quotation of Burnett & Co. I will sell it a cent less than they do." That isn't the market. Is what he sells at going to be considered a market? If we put it a cent higher than he is selling it at, that isn't a market. A market is made by two people—the buyer and seller. The buyer says, "I will give so much." The seller says, "I want so much." Now, then, if they cannot come together there, it is no trade. There is no market. If they come together there is a trade, there is a market.

Mr. Dunn—I take it that it is a very large market, and I claim that the price of honey can be advanced to a price so that honey from outside cannot come in and undersell us,

when you ask more than quotations in other cities, and what they can bring it here for from other points; but you can afford to hold the honey high enough, and I claim it is the duty of the gentlemen handling honey in this country to make a price. If they are not getting commission enough let them say so; they ought to get a reasonable commission. The commission merchants can't afford to do business unless they get a good commission. It is a small business and they must get a good, round commission, and then hold the price up. I have been told by men among the merchants along the line that there are two houses here that control this honey market. Mr. Burnett is one, and I can't find out who the other is; and these two houses fix the price. I don't know what he thinks; if honey outside is quoted at a certain rate he can afford to quote the Chicago price with added transportation here, and sell at that price, because there is a big market here.

Mr. Burnett—It seems to me it will increase the importation of honey if we quote a very high price, or the highest possible price. If we quote very high prices people will say, "They are getting big prices in Chicago." If we quote lower prices, they will say, "We can get more here." It seems to me it is advisable to quote rather a little lower than the highest price. Another thing, if the bee-keeper in disposing of his honey comes to the market and can't get that price, he will say, "Gentlemen, here are your quotations; now you don't sell for that price. Why don't you?"

Pres. York—It is a big question.

Mr. Dunn—Hogs and cattle are quoted daily, and why should not honey follow the same course?

(Voice from the audience)—Is honey quoted on the exchange?

Mr. Dunn—Certainly, it ought to be. We have a right to see it daily quoted.

Dr. Miller—I noticed today for the first time the quotation of honey in the daily paper—in the Record-Herald. It is the first time I have seen it quoted for years. There is, however, this difference between the market price of honey and that of other articles. For instance, in beef, cattle come in every day and the papers report the ruling prices at which they were sold. Now if those prices did not change daily there would not be the necessity for the daily report of them. If the price of honey changes every day then there is the necessity for a daily report, and I suppose that it doesn't matter, either, how we get these reports, provided we get them correct, and as often as a change is made we should be informed of it. If the American Bee Journal does not report the changes from time to time they are failing of their duty, but I don't know that there would be any necessity for their getting a fresh report so long as there is no change in it, but I believe this: We should know the truth.

Mr. Dunn—That's it.

Dr. Miller—The truth never hurts anybody. We should have the whole of it, whether up or down. We should know as nearly as we can the amount of honey in the country, and that helps to fix the prices. I believe that one man might do something towards fixing the price. I can do a great deal towards fixing the price in Marengo. I defy Mr. Burnett to hurt my market; but if I come to fixing the price in Chicago it is only a drop in the bucket, and I suppose that Mr. Burnett or any other man must be guided by the law of supply and demand. If he gives a false report of the market he is very much to blame for it. It is his business to tell Mr. York what the transactions are, and not what he wants, or anybody else wants. That's what we ought to have—the market for honey. Here is a question that one time came up for me: I see they report so and so in Chicago; then I see at another place it is two cents higher, and as nearly as I understand the matter of freight it will not be two cents from one place to the other; then I say, Why not ship all the honey from Chicago and get that higher market; but this comes in: Any of you who have done very much in shipping honey know that it is not simply the question of amount of freight, but loss and breakage, so that I would rather take a good deal less for my honey in Marengo than have it shipped off. Those things must be considered. I will tell you one of the things that you can do: Whenever you find that the reports are not all right—I said I couldn't do anything towards changing prices in Chicago, but I did once. At one time, a good many years ago, when the daily papers were reporting the market, and anything but correct, I went to the editor's room and laid before him a bill of sale, and showed him just what the prices were, and the commission was just about the average, and I changed the prices then two cents a pound, and any of you can do that. If you have sales, report the sales to the paper, and they may help.

Mr. Chapman—The Daily Trade Bulletin has all of the prices on South Water Street and stock-yards, and also a

separate sheet with the Chicago Board of Trade prices on, and they follow largely the same method that is followed by the American Bee Journal that is quoted for honey, because the price of honey does not fluctuate up or down frequently; that is to say, it is frequently stationary at a certain price, or just about a certain price, for sometimes several weeks at a time, then they don't change the quotations, they don't even change the print of it. It stands sometimes several weeks; but let there be a little difference in price, sufficient to affect more than one house, and they are quick to take note of it in that Trade Bulletin, but with hardly any more change than occurs in the American Bee Journal.

Dr. Miller—The amount of transactions in any one article makes a great deal of difference with the papers and with the market as to the reports. In the daily papers you will find the market for green goods and picked turkeys, but you will not find that they give you the report of market prices of honey, because they say there is so much less, not even enough honey to warrant any quotation at all. You and I think there is a big lot of honey sold, but compared with cheese it is a small matter. They will only report things in which there are large transactions. I doubt very much whether there are more than two or three men here who can give me the fair market price of turkey-feathers just now. I can't straighten you out if you don't know anything about it. That's just what applies to this honey-business. If we can produce enough of it and get more on the market we will have more exact prices. So long as there isn't enough of it so that the daily papers feel warranted in giving any quotations at all, you can't have the thing figured down.

Mr. Dunn—Where the bulk of the product is in the hands of two houses they can protect the market. Take the outside markets and compare them and the cost of transportation here. They can get that price. They have to make the money on it. They have the right to a liberal commission, but I want Chicago to stand as high as it can stand, and it can afford to stand transportation added as well as any one in the market.

Dr. Miller—There is no law that I know of against allowing Mr. Dunn, when the market is two cents higher elsewhere, and one cent for transportation—no law against Mr. Dunn buying out these two houses and transporting it. [Applause.]

Pres. York—I rely upon Mr. Burnett to give the proper quotations. I believe he can tell the truth; I have felt pretty sure in the quotations. I would like to have him raise the market two cents, if he can.

Dr. Miller—If he can raise the market two cents we ought to raise his wages.

Mr. Dunn—Yes, sir.

A Discussion of Selling by Weight or Case—Which?—The Cause of Light Weights—Colorado Grading Rules All Right—Two Sides to the Question.

BY R. C. AIRIN.

[NOTE.—Since the following article was written there have been several articles and editorials on the subject. But, as the ground has not been fully covered by any, and this article touches a number of points not at all considered by other writers, I think it best to let it go without re-writing. I recommend particularly that the reader note the abuse that may be made by the middlemen of buying by weight and selling by the case. Also, do a little figuring on the cost of cases and sections, and you will see that there is nothing gained by producing light-weight honey. Three pounds more honey in the case pays for the case and sections, approximately.]

IN No. 6 [page 167] I dealt somewhat with the questions of separators to obtain even-weight sections, and of selling "by the piece." While the thought is before us, I may as well pay my respects to the Editor, and to Mr. Burnett.

I think I see Messrs. York and Burnett doing a retail business, each handing out 14-ounce pounds to customers who pay for 16 ounces. They sell also maple syrup at \$1.50 a gallon, and give me 11 pounds, *can and all*; canned fruits at so much for so many—1, 2 or 3 pound cans, "shorts"; 48 pounds of flour when I ask for and pay for 50 pounds; and on and on through a long list of articles.

I hear my friends in Chicago laughing when they have read thus far, and, between their fits of laughter, saying to me, "Everybody does so; it's the custom, and the can, bag, box, etc., are worth, or cost, something." Then they turn to the wholesale-house man who has just come in, take him into the private office and "raise Ned" with him because he insists on selling flour by the hundred-weight, that is, four pounds short; and all other goods in like manner. Excuse me, I mean they treat the "traveling man" like a king, and do the "Ned" act with honey-producers who sell honey at so much a case, guaranteed so much per case average, with a minimum below which no single case may go.

York and Burnett, stand up. Now, sirs, tell me how we came to produce short-weight sections. Tell me if it was the bee-keeper, or the wholesale buyer, or the retailer, or who it was that wanted 14-ounce sections, or originated them. Do you say none of them? Possibly you are right. I do not think that any one specially devised or brought out a 14-ounce section with a view to selling a "short" pound. I suspect so good, fair and honest a man as A. I. Root, and possibly some other good men, had something to do with it. The plan was to have a $4\frac{1}{4} \times 4\frac{1}{4}$ pound section that would fit a certain place. This same section was originally very largely used two inches thick, and was intended to hold a full pound.

Later it was found that a two-inch-thick section was too thick to be quickly and neatly finished by the bees; then came the idea of reducing the thickness to get a nicer and better-finished one. The prime object sought was the quality of the goods, and when bee-men found that the thinner section was in fact a nicer one, they consoled themselves with the thought that, if they could not supply a full pound in the thin section they could make it up in quality, thus no one was harmed. Possibly some have been guilty of selling the short-weight section with the hope to increase profits thereby; but, sirs, that thought did not originate the short-weight; but will you deny that the 48-pound 50-pound sacks of flour, etc., had not so good an excuse back of them?

The bee-man can produce a neater and more salable article in a section thinner than two inches; and, knowing this, we use a thinner one. We would use a thinner still if it were not that the weight would be altogether too much reduced. You see we can not change the other dimensions of our sections without a great expense in changing hives and such, hence we are trying to do the very best we can under the circumstances.

Then, too, conditions of the colony, strength of the honey-flow, and a great many things conspire to make a variation in the weights of sections of honey, but the fraternity, as a whole, are striving to obtain the most even results. If we were to-day—knowing what we do of the science of the business and needs of the trade—to be placed in a position in which we were to start all anew—hive-making machinery, size, shape and proportion of hives—in short, with present knowledge but everything to build anew, I would make some changes that would be for the better in obtaining an honest and best pound of honey. I believe thousands of others feel just the same way.

So the light-weight section came, and came not simply of choice, or premeditated for fraudulent ends. Once here, no doubt some bee-keepers who retailed honey thought to increase profits. And, some retailers not bee-keepers, saw that to buy 22-pound cases of honey at 10 cents a pound, and retail at $12\frac{1}{2}$ cents a piece, meant 80 cents profit, where a 24-pound case bought and sold in the same way would only give a 60-cent profit. This made an inducement to demand a 14-ounce section, and that it be sold to the wholesale and retail merchants by the pound.

Now, sirs, Messrs. York, *et al.*, can not you see that when I produce light-weight sections to sell by the pound that it is to your interests, and yours only? One thousand sections for light-weight use cost me almost, if not quite, as much as for heavy-weight use. Cases ditto. And, when you make me sell to you by weight it is plainly your advantage and my loss. If I am to sell by weight I want 18-ounce sections, for then I have the pay for four ounces more honey, and the sections and cases cost me no more than for light-weight goods. A case of 14 ounce sections at 10 cents a pound brings \$2.10, while a case of 18-ounce ones at the same price brings \$2.70—enough to pay for the case and sections, and approximately a good, big 25 cents a case net profit besides.

But something is wrong. I should not sell 14 ounces of honey for a pound, nor should you. You should not want to buy my honey by weight and sell by the piece, nor any

such thing. The bee-keeper who produces light-weight honey and sells it by the case without specification or limit is decidedly wrong—just as wrong as the wholesaler and retailer who wants him to produce light-weight sections to be bought by the pound and sold by the piece—the whole thing is of the same rotten piece of cloth. This everlasting shifting and changing to gain a temporary advantage over somebody is a sad thing in our commercial life, I care not who does it.

I have told you somewhat of how and why we have a light-weight section, and that which follows—light-weight cases. Not every middle man has been guilty of taking advantage of it as herein indicated, but such things have been done. Having studied out all these things, threshed over and over the straw to get every grain of truth in it, Colorado bee-keepers have adopted a fair and honest method of grading and selling. The proof of my statement is in our Grading Rules, which specifically state that certain minimum weights shall obtain in every case. Any buyer who buys under these rules, so far as weights go, is *protected*, and so is the producer. I defy any man, whoever he may be, to prove to the intelligent reader and business man, that there is any more fair and honorable plan than that adopted by the Colorado State Association. It shows in itself that it has honesty as its basis—the greatest amount of protection to all concerned.

Again, I wish to call the attention of producers to the idea of profit or loss as between light and heavy weight sections. On the basis of general averages, prices of commodities will adjust themselves sooner or later, and any gain you can hope to make by light-weight sections is only temporary, soon discovered, then a readjustment comes. If you do have less than a pound in a section, when you sell by the pound you are the loser, because your cases and sections cost you just as much for light as heavy weight. If you sell by the case and have not the weight therein—if the shortage is known it only creates suspicion, prejudice, and a disposition to hold you down to a lower price. The honest pound gives confidence, and should be striven after. But, as every bee-keeper knows, it is impossible to have absolute uniformity of weight, but you can hold confidence and present a fair basis by guaranteeing and selling a minimum weight per case—it is fair to all, and should be done by all. Colorado Grading Rules are a protection to buyers, and the buyer purchasing under these rules gets all or more than he pays for, because every case is to weigh so much, a minimum limit placed on each individual case, and a general average on the whole lot, so there can not be any "pig in the bag" about it.

If honey must sell at wholesale by the pound, it must also sell at retail by the pound, but it *does not*. The "pig in the bag" does not apply to Colorado, but the "nigger in the wood-pile" has been made to serve to the hurt of some Colorado honey-producers. Our rules are all right, and every buyer should insist on their observance when he buys; their enforcement protects the wholesale buyer, and limits the producer, preventing fraud. The very purpose of the adoption of our rules was to *avoid sharp dealings*. It is the common understanding that 24 pounds is a case of honey, and buyers knowing this will buy a car of honey to be delivered in Chicago, or other market, at say 10 cents a pound, or \$2.40 a case. When the honey arrives, and the buyer weighs it—which he will do—and finds only 21 pounds to the case instead of 24, he kicks, and having everything his own way because the honey is in his possession, he refuses to pay \$2.40 a case; he will pay but \$2.10, because he bought at \$2.40 a case, and the case is three pounds short.

We have, therefore, adopted a standard of weights, so that while it is impossible to have absolutely even weights, we can have a rule that protects each way—both seller and buyer.

But the Editor will *again* ask, "Why not sell simply by weight?" Well, if we sell *simply by weight*, why, sir, I will put into first grade honey every very nice 10, 12 or 13 ounce section—its *only* fault being light weight, and thus there may be sold as No. 1 honey many cases as light as 15 to 20 pounds. But our rules will compel the producer to put in a minimum weight in every No. 1 case, and, no matter how fancy his honey may be otherwise, he must have *weight*, too.

The Premiums offered this week are well worth working for. Look at them.

No. 3.—Improving the Races of Bees.

BY ADRIAN GETAZ.

(Continued from page 247.)

INFLUENCE OF PREVIOUS MATING.

The opinion has often been expressed that while the egg producing a drone is not impregnated, it may nevertheless be influenced by the drone which mated with the queen. In support of this the assertion has been made that a young animal sometimes resembles not only his father and mother, but also the male which had mated with the mother at some previous time.

We will discuss the second question first. Such an influence in an impossibility. When the female germ (the scientists call it the egg) is ripe, it cuts itself completely loose from the organ that produced it and descends in the womb; there it meets the male germs. These are extremely minute, being possessed of a distinct and independent life. The majority of them soon die and are thrown out. Some meet the egg and enter into it. When the egg is thus impregnated, a sac is formed around it. The egg develops itself from within—inside of that sac. The only communication that the new being has with the mother is an opening in that sac, through which the blood of the mother brings nutriment to the offspring, and carries out the rejected matters.

How could the male germs have an influence later on, when they were never a part of the mother's body, when they were completely loose, as foreign bodies would be, and soon die or become a part of the young offspring?

Now I will answer some of the arguments in favor of this doctrine. In the first place, the fact that a calf or colt sometimes resemble the male used in a previous mating has hardly any value as an argument. A number of calves and colts are neither exactly like their mother nor exactly like their father, especially in regard to color. That occasionally some would resemble a male previously used is no more than should be expected.

The case of fowls is altogether different. The fact is, that one mating is sufficient to impregnate the eggs for several days, from 5 to 8 or even 10 days. That is, the male germs live in the hen's body that length of time, ready to impregnate the eggs as they come to maturity.

Suppose that before the 5 or 10 days are over, another mating takes place; then for a few days that hen will carry the male germs from both roosters, and whatever eggs mature during that time may just as well happen to be impregnated by the germs of the first mating as by those of the second. The chicks resulting will actually be offspring of the first mating. In this case, like in the preceding, there is no back influence from a previous mating. For full information on this subject, see the scientific works on physiology. The elementary books found in the schools and ordinary bookstores are not sufficient. Munn & Co., of New York, N. Y., can furnish any scientific book published anywhere, and give the information necessary to make the right kind of purchase.

Concerning bees, the assertion is that the drones, though born of unimpregnated eggs, are, nevertheless, influenced by the drone which mated with the queen.

In the first place, this alleged influence is an impossibility, as far as we can ascertain. When a queen mates, the drone-germs enter in a sac situated near the end of her body. The pressure of the mating operation opens the sac and puts the germs in. Then the sac closes and they remain therein, entirely cut off and without any communication with any other part of the queen's body.

The eggs are formed in what are called the ovaries, situated farther up in the queen's body. As they mature, they separate and come down through what might be called a tube, and pass before the sac containing the drone-germs and are discharged. The sac has a small aperture which the queen can open for an instant, when an egg passes. If she opens it one male germ slips out and enters into the egg through an opening that exists there. The egg is then impregnated and becomes a female egg possessing the rudiments of the organs of both queen and worker. The amount and quality of feed given during its development determines which set of organs will develop. If the egg is not impregnated, it will produce a drone, no matter whether the queen has mated or not.

The proof advanced in favor of the above assertion is something like this: An Italian queen mates with a black drone. Her workers are of course hybrids. According to the principles generally accepted her drones ought to be pure Italians, but they are darker than the apiarist expected.

How is it? Well, in first place, as we have no control of the mating, we can never be sure that a queen is absolutely pure Italian, but even if she was it would be no proof. The Italian queens and drones vary greatly in color, some are quite dark. The fact that the drones were darker than the apiarist expected does not prove that they were impure or were influenced by the drone that mated with their mother.

WHAT SHALL WE BREED FOR?

Honey-gathering qualities, of course. Gentleness, capping the honey white, etc., will be considered to some extent, but the honey is what we are after. And the queens whose colonies give the largest surplus will be the ones to breed from.

I mentioned once the fact that in breeding for honey we are working in the same line as Nature does, and, therefore, we could not expect such results as have been attained with other kinds of domestic animals. For instance, the faculty of producing milk has been left almost completely undeveloped in the wild animals. We take the same animal and develop that quality away beyond what Nature does in the wild state. But suppose that we were to work in the same line as Nature; suppose, for instance, that we would try to prove the hardiness of the Texas cattle, we would then make but little progress, because that quality has already reached the limit, or nearly so.

This is very nearly the case with the bees. The qualities tending to honey-gathering—such as activity, hardiness, etc.—are already well developed, so there is not room for very much improvement, as the limit attainable cannot be very far.

That is not very encouraging. To offset it we must remember that a very little improvement might increase the surplus considerably.

In feeding back extracted honey to complete the partially filled sections it has been found that a good colony of bees consume $1\frac{1}{2}$ pounds of honey per day. That honey goes to sustain the life of the bees, keeps the necessary heat, feeds the brood and produces the wax; it cannot be doubted that the same amount is required during the honey-flow. Through the winter something like 25 pounds is used. After the honey-flow, perhaps half a pound a day. Half a pound of honey for perhaps 20,000 bees is a mighty small daily ration for each one, considering that there is always a little brood reared, and perhaps some wax secreted.

Upon the whole, a colony of bees of normal size consumes something like 200 pounds of honey every year, at least, and probably more.

We have a colony that gives us 40 pounds of surplus; that means that 240 pounds have been gathered in all. Now we improve the stock, and the colony becomes able to gather $\frac{1}{6}$ more, only $\frac{1}{6}$. The total gathered will be 280 pounds instead of 240. Deducting the 200 pounds consumed, we have now a surplus of 80 pounds—double what we had before.

SIZE OF BEES.

Would we gain by breeding a large-sized kind of bees? Notwithstanding the contrary opinion of some high authorities, I say, unhesitatingly, Yes. Granting that a large bee would not fly faster than a small one, and granting, also, that she could not suck the nectar out of the flowers faster than the small one, there would yet be a saving of time going and coming. For the large bee would bring in the same quantity of nectar in a less number of trips to the field and back. But it is probable that the large bee would fly somewhat faster, and it is almost certain that she could suck the nectar from the flowers faster, on account of a larger tongue.

In order to breed larger bees it will be necessary to use foundation with larger cells, for a bee cannot be larger than the cell in which she has been reared. If any one doubts the correctness of this last statement, let him look at the drones reared in worker-cells. That will settle it.

The increase of the size of the cells should be gradual, otherwise it would be difficult to avoid and overproduction of drones.

There is a limit to the size of the cells that can be used. Too large cell would not hold the honey; that is, the honey would run out of it. It is probable that cells of drone-size, or perhaps a fraction larger, are all that can be used. This might give us bees the size of the famous "Apis dorsata".

In India and other parts of South Asia are found several kinds of wild bees, some of them the size of our bees, some much smaller—and finally the *Apis dorsata*, much larger. While this last gathers a considerable amount of honey, the small kinds do not gather enough to speak of, and never more than they can use.

LONG TONGUES.

I am not going to rehash the subject. I want only to bring out one point that has been neglected.

With the increase of population and improvements of farming, the forests, pastures, and other present sources of nectar, will decrease and disappear; red clover will be more and more cultivated as being the chief crop of a good system of farming. And the time comes when it will be almost the only honey-plant available. Other things being equal, the largest bees will evidently have the longest tongues.

INFLUENCE OF LOCALITY.

Yes, locality and also management. Let me give some examples: John Smith lives in a good-locality; plenty of flowers and to spare. Bees with short tongues will find all they can gather, as well as those with long tongues. Then the colonies giving the largest surplus may just as well be among those with short tongues.

Jim Jones lives in a poorer or overstocked locality. There are not enough flowers accessible to short-tongued bees to enable them to furnish a good surplus. After that they will be idle, while the long-tongued bees will continue to gather from deep-corolla flowers. Result: The long-tongued bees will give the most surplus. Jim Jones will breed from their queens and eventually create a race of long-tongued bees.

Gilbert M. D. uses a small hive, or, rather, brood-nest. The colonies with very prolific queens fill it early, and then swarm for lack of space, and just as often as not keep on swarming during the honey season. No surplus, or very little.

Those with queens not very prolific do not get crowded, and refrain from swarming. Colonies that do not swarm are those which give the largest surplus. These Gilbert will choose for breeding purposes, and eventually create a strain of moderately prolific bees.

Camille P. D. uses Dadant hives. Queens not very prolific do not fill the brood-nest in time for harvest. They keep at it during the honey-flow, and when the colony is ready to go "up-stairs" it is too late to do much good. Those very prolific fill that big brood-nest with a whole army of workers in time for the harvest, and when the flow comes a big surplus is stored. Result is, Camille selects these prolific queens as breeders, and creates a strain or prolific queens.

A contribution of mine on the same subject (August, 1901, page 646) was bitterly, and I think unjustly, criticised in the *Bee-Keepers' Review* (for November, 1901.) To those who might think the above is not exactly what it ought to be, I will say this: Instead of indulging in cheap criticism, write a better article on the same subject, if you can; and if you succeed I will be glad of it, for I will get the benefit of it.

Knox Co., Tenn.

Value of Good Queens, and Methods of Queen-Introduction.

Read at the Wisconsin Convention in February, 1902.

BY ADA L. PICKARD.

IT is not that I choose to come before this assemblage, nor is the subject before us one of my own choice; but since a number of the members of this Association asked that the secretary contribute a paper, and suggested the present topic, I was willing to do what I could to help the convention along, and so it may be said of me as it was of the widow who gave her mite, "She hath done what she could."

No adage is more true than, "What is home without a mother?" and just so true is the statement, What is a colony of bees without a good queen? By a good queen I do not mean a beautiful queen to look at, but one that is prolific.

Upon no other one thing does the success of the apiarist depend as it does upon the queen. Give me a good queen—one that can be brought up to the highest production of eggs just at the time they are wanted—and I will promise you a honey crop, if the flowers do not fail to secrete nectar; but with a poor queen—one that may not even be coaxed to lay to little or no purpose at the proper time—the flowers may bloom and secrete large quantities of nectar in vain.

I must confess that we have had queens at different times in our apiaries that, with all the coaxing we could bring to bear upon them, would not lay any more eggs pre-

THE HOME APIARY OF MRS. W. J. PICKARD, RICHLAND CO., WIS.

vious to the honey harvest than would keep up the spring strength of the colony; and when the flow was at its best, there would not be $\frac{1}{4}$ of the number of workers there should be. No doubt these were good, prolific queens one day, but at this time they were old, worn-out queens, proving themselves worthless. Those colonies made a failure for that season, all on account of the queens. The more queens of this kind the apiarist has the worse he is off.
